  At this point, ESP Timer will attempt to dispatch all unhandled callbacks if there are any. It can potentially lead to the overflow of ESP Timer callback execution queue. This behavior may be undesirable for certain applications, and the ways to avoid it are covered in *Handling Callbacks in Light-sleep Mode*.

FreeRTOS Timers Although FreeRTOS provides software timers, they have limitations:

- FreeRTOS timer resolution is bound by the tick frequency, which is typically in the range of 100 to 1000 Hz.
- Timer callbacks are dispatched from a low-priority timer task that can be preempted by other tasks, leading to decreased timer precision and accuracy.

However, FreeRTOS timers are portable (non-dependent on ESP-IDF) and are written to be deterministic as they do not dispatch callbacks from ISRs.

Usage

While setting up your ESP-IDF project, make sure to:

- Add required component dependencies to your `CMakeLists.txt`.
- Include required header files in your `.c` files.
- (Optional) Set Kconfig options. For this, see *Kconfig Options* > *ESP Timer (High Resolution Timer)*

General Procedure The general procedure to create, start, stop, and delete a timer is as follows:

1. Create a timer
   - Define a timer handle using the type `esp_timer_handle_t`
   - Set the timer configuration parameters by defining the structure `esp_timer_create_args_t` which also includes the callback function

     Note: It is recommended to keep callbacks as short as possible to avoid delaying other callbacks.

   - To create a timer, call the function `esp_timer_create()`
2. Start the timer in one-shot mode or periodic mode depending on your requirements
   - To start the timer in one-shot mode, call `esp_timer_start_once()`

- To start the timer in periodic mode, call `esp_timer_start_periodic()`; the timer will continue running until you explicitly stop it using `esp_timer_stop()`

Note: When executing a start function, ensure that the timer is not running. If a timer is running, either call `esp_timer_restart()` or stop it first using `esp_timer_stop()` and then call one of the start functions.

3. Stop the timer
   - To stop the running timer, call the function `esp_timer_stop()`
4. Delete the timer
   - When the timer is no longer needed, delete it to free up memory using the function `esp_timer_delete()`

Using the Interrupt Dispatch Method Out of the available *callback methods*, if you choose the Interrupt Dispatch method, follow these steps:

1. Set Kconfig options
   - Enable *CONFIG_ESP_TIMER_SUPPORTS_ISR_DISPATCH_METHOD*
2. Create a timer
   - Set the timer configuration parameters by defining the structure `esp_timer_create_args_t`

```
const esp_timer_create_args_t timer = {
  ... ,
  .dispatch_method = ESP_TIMER_ISR,
  ...
};
```

   - To create a timer, call the function `esp_timer_create()`

For further steps, refer to *General Procedure*.

Handling Callbacks in Light-sleep Mode Light sleep allows you to save power while maintaining the ability to quickly wake up for specific actions. To use ESP Timer in conjunction with Light-sleep mode, see *Sleep Mode APIs*.

During light sleep, to keep unhandled callbacks under control and avoid potential overflow of ESP Timer callback execution queue on wakeup, do one of the following:

- Prevent the invocation of callbacks in the first place: stop the timer before entering light sleep by using `esp_timer_stop()`.
- If calling the stop function is not desirable for any reason, use the option `esp_timer_create_args_t::skip_unhandled_events`. In this case, if a periodic timer expires one or more times during light sleep, then only one callback is executed on wakeup.

Debugging Timers The function `esp_timer_dump()` allows dumping information about either all or only running timers: the parameters for timers, the number of times the timers were started, triggered, skipped, and time taken by timer callbacks to execute. This information can be helpful in debugging.

To debug timers, use the following procedure:

1. Set Kconfig options for more detailed output:
   - Enable *CONFIG_ESP_TIMER_PROFILING*

   Note that enabling this option increases code size and heap memory usage.
2. Wherever required in your code, call the function `esp_timer_dump()` to print the information and use it to debug your timers.
3. Once debugging is complete, consider disabling *CONFIG_ESP_TIMER_PROFILING*.

Troubleshooting

Unstable Callback Dispatch Time While dispatching the same callback function repeatedly, if the response time varies considerably, try to stabilize it by doing the following:

- Use the *ESP_TIMER_ISR callback method*

Significant Delays Dispatching Callbacks If dispatching a callback function takes a considerable amount of time, the problem can lie in the callback function itself. More precisely, as all callback functions are processed one by one in a single esp_timer task, the delays might be caused by other callback functions earlier in the queue.

For this reason, make sure that all callback functions in your application can execute on their own quickly and without any blocking operations.

Repeated Callback Dispatches After Sleep If the callback functions are executed repeatedly upon wakeup from sleep, see *Handling Callbacks in Light-sleep Mode*.

Stack Overflow While Dispatching Callbacks If you see a stack overflow error when executing a callback function, consider reducing the stack usage within your callback function. Alternatively, try increasing the size of the ESP Timer task stack by adjusting *CONFIG_ESP_TIMER_TASK_STACK_SIZE*.

Application Examples

- system/esp_timer creates and starts one-shot and periodic software timers, shows how they work with Light-sleep mode, and then stops and deletes the timers

API Reference

Header File

- components/esp_timer/include/esp_timer.h
- This header file can be included with:

```
#include "esp_timer.h"
```

- This header file is a part of the API provided by the `esp_timer` component. To declare that your component depends on `esp_timer`, add the following to your CMakeLists.txt:

```
REQUIRES esp_timer
```

or

```
PRIV_REQUIRES esp_timer
```

Functions

esp_err_t **esp_timer_early_init** (void)

Minimal initialization of esp_timer.

This function can be called very early in startup process, after this call only *esp_timer_get_time()* function can be used.

Note: This function is called from startup code. Applications do not need to call this function before using other esp_timer APIs.

Returns

- ESP_OK on success

esp_err_t **esp_timer_init** (void)

Initialize esp_timer library.

This function will be called from startup code on every core. If Kconfig option `CONFIG_ESP_TIMER_ISR_AFFINITY` is set to `NO_AFFINITY`, it allocates the timer ISR on MULTIPLE cores and creates the timer task which can be run on any core.

Note: This function is called from startup code. Applications do not need to call this function before using other esp_timer APIs. Before calling this function, *esp_timer_early_init()* must be called by the startup code.

Returns
- ESP_OK on success
- ESP_ERR_NO_MEM if allocation has failed
- ESP_ERR_INVALID_STATE if already initialized
- other errors from interrupt allocator

esp_err_t **esp_timer_deinit** (void)

De-initialize esp_timer library.

Note: Normally this function should not be called from applications

Returns
- ESP_OK on success
- ESP_ERR_INVALID_STATE if not yet initialized

esp_err_t **esp_timer_create** (const *esp_timer_create_args_t* *create_args, *esp_timer_handle_t* *out_handle)

Create an esp_timer instance.

Note: When timer no longer needed, delete it using *esp_timer_delete()*.

Parameters
- **create_args** -- Pointer to a structure with timer creation arguments. Not saved by the library, can be allocated on the stack.
- **out_handle** -- **[out]** Output, pointer to esp_timer_handle_t variable that holds the created timer handle.

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if some of the create_args are not valid
- ESP_ERR_INVALID_STATE if esp_timer library is not initialized yet
- ESP_ERR_NO_MEM if memory allocation fails

esp_err_t **esp_timer_start_once** (*esp_timer_handle_t* timer, uint64_t timeout_us)

Start a one-shot timer.

Timer represented by `timer` should not be running when this function is called.

Parameters
- **timer** -- timer handle created using *esp_timer_create()*
- **timeout_us** -- timer timeout, in microseconds relative to the current moment

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is already running

esp_err_t **esp_timer_start_periodic**(*esp_timer_handle_t* timer, uint64_t period)

Start a periodic timer.

Timer represented by `timer` should not be running when this function is called. This function starts the timer which will trigger every `period` microseconds.

Parameters
- **timer** -- timer handle created using *esp_timer_create()*
- **period** -- timer period, in microseconds

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is already running

esp_err_t **esp_timer_restart**(*esp_timer_handle_t* timer, uint64_t timeout_us)

Restart a currently running timer.

Type of `timer`	Action
One-shot timer	Restarted immediately and times out once in `timeout_us` microseconds
Periodic timer	Restarted immediately with a new period of `timeout_us` microseconds

Parameters
- **timer** -- timer handle created using *esp_timer_create()*
- **timeout_us** -- Timeout in microseconds relative to the current time. In case of a periodic timer, also represents the new period.

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is not running

esp_err_t **esp_timer_stop**(*esp_timer_handle_t* timer)

Stop a running timer.

This function stops the timer previously started using *esp_timer_start_once()* or *esp_timer_start_periodic()*.

Parameters **timer** -- timer handle created using *esp_timer_create()*

Returns
- ESP_OK on success
- ESP_ERR_INVALID_STATE if the timer is not running

esp_err_t **esp_timer_delete**(*esp_timer_handle_t* timer)

Delete an esp_timer instance.

The timer must be stopped before deleting. A one-shot timer which has expired does not need to be stopped.

Parameters **timer** -- timer handle created using *esp_timer_create()*

Returns
- ESP_OK on success
- ESP_ERR_INVALID_STATE if the timer is running

int64_t **esp_timer_get_time**(void)

Get time in microseconds since boot.

Returns Number of microseconds since the initialization of ESP Timer

int64_t **esp_timer_get_next_alarm**(void)

Get the timestamp of the next expected timeout.

Returns Timestamp of the nearest timer event, in microseconds. The timebase is the same as for the values returned by *esp_timer_get_time()*.

int64_t **esp_timer_get_next_alarm_for_wake_up**(void)

Get the timestamp of the next expected timeout excluding those timers that should not interrupt light sleep (such timers have *esp_timer_create_args_t::skip_unhandled_events* enabled)

Returns Timestamp of the nearest timer event, in microseconds. The timebase is the same as for the values returned by *esp_timer_get_time()*.

esp_err_t **esp_timer_get_period**(*esp_timer_handle_t* timer, uint64_t *period)

Get the period of a timer.

This function fetches the timeout period of a timer. For a one-shot timer, the timeout period will be 0.

Parameters
- **timer** -- timer handle created using *esp_timer_create()*
- **period** -- memory to store the timer period value in microseconds

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the arguments are invalid

esp_err_t **esp_timer_get_expiry_time**(*esp_timer_handle_t* timer, uint64_t *expiry)

Get the expiry time of a one-shot timer.

This function fetches the expiry time of a one-shot timer.

Note: Passing the timer handle of a periodic timer will result in an error.

Parameters
- **timer** -- timer handle created using *esp_timer_create()*
- **expiry** -- memory to store the timeout value in microseconds

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the arguments are invalid
- ESP_ERR_NOT_SUPPORTED if the timer type is periodic

esp_err_t **esp_timer_dump**(FILE *stream)

Dump the list of timers to a stream.

By default, this function prints the list of active (running) timers. The output format is:

| Name | Period | Alarm |

- Name —timer pointer
- Period —period of timer in microseconds, or 0 for one-shot timer
- Alarm - time of the next alarm in microseconds since boot, or 0 if the timer is not started

To print the list of all created timers, enable Kconfig option `CONFIG_ESP_TIMER_PROFILING`. In this case, the output format is:

| Name | Period | Alarm | Times_armed | Times_trigg | Times_skip | Cb_exec_time |

- Name —timer name
- Period —same as above
- Alarm —same as above
- Times_armed —number of times the timer was armed via esp_timer_start_X
- Times_triggered - number of times the callback was triggered
- Times_skipped - number of times the callback was skipped
- Callback_exec_time - total time taken by callback to execute, across all calls

Parameters **stream** -- stream (such as stdout) to which to dump the information

Returns
- ESP_OK on success
- ESP_ERR_NO_MEM if can not allocate temporary buffer for the output

void **esp_timer_isr_dispatch_need_yield**(void)

Requests a context switch from a timer callback function.

This only works for a timer that has an ISR dispatch method. The context switch will be called after all ISR dispatch timers have been processed.

bool **esp_timer_is_active**(*esp_timer_handle_t* timer)

Returns status of a timer, active or not.

This function is used to identify if the timer is still active (running) or not.

Parameters **timer** -- timer handle created using *esp_timer_create()*

Returns
- 1 if timer is still active (running)
- 0 if timer is not active

esp_err_t **esp_timer_new_etm_alarm_event**(esp_etm_event_handle_t *out_event)

Get the ETM event handle of esp_timer underlying alarm event.

Note: The created ETM event object can be deleted later using esp_etm_del_event()

Note: The ETM event is generated by the underlying hardware - systimer; therefore, if the esp_timer is not clocked by systimer, then no ETM event will be generated.

Parameters **out_event** -- **[out]** Returned ETM event handle

Returns
- ESP_OK Success
- ESP_ERR_INVALID_ARG Parameter error

Structures

struct **esp_timer_create_args_t**

Timer configuration passed to *esp_timer_create()*

Public Members

esp_timer_cb_t **callback**

Callback function to execute when timer expires.

void ***arg**

Argument to pass to callback.

esp_timer_dispatch_t **dispatch_method**

Dispatch callback from task or ISR; if not specified, esp_timer task.

const char ***name**

Timer name, used in *esp_timer_dump()* function.

bool **skip_unhandled_events**

Setting to skip unhandled events in light sleep for periodic timers.

Type Definitions

typedef struct esp_timer ***esp_timer_handle_t**

Opaque type representing a single timer handle.

typedef void (***esp_timer_cb_t**)(void *arg)

Timer callback function type.

Param arg pointer to opaque user-specific data

Enumerations

enum **esp_timer_dispatch_t**

Method to dispatch timer callback.

Values:

enumerator **ESP_TIMER_TASK**

Callback is dispatched from esp_timer task.

enumerator **ESP_TIMER_ISR**

Callback is dispatched from interrupt handler.

enumerator **ESP_TIMER_MAX**

Sentinel value for the number of callback dispatch methods.

2.10.18 Internal and Unstable APIs

This section is listing some APIs that are internal or likely to be changed or removed in the next releases of ESP-IDF.

API Reference

Header File

- components/esp_rom/include/esp_rom_sys.h
- This header file can be included with:

```
#include "esp_rom_sys.h"
```

Functions

void **esp_rom_software_reset_system**(void)

Software Reset digital core include RTC.

It is not recommended to use this function in esp-idf, use esp_restart() instead.

void **esp_rom_software_reset_cpu**(int cpu_no)

Software Reset cpu core.

It is not recommended to use this function in esp-idf, use esp_restart() instead.

Parameters **cpu_no** -- : The CPU to reset, 0 for PRO CPU, 1 for APP CPU.

int **esp_rom_printf**(const char *fmt, ...)

Print formatted string to console device.

Note: float and long long data are not supported!

Parameters
- **fmt** -- Format string
- **...** -- Additional arguments, depending on the format string

Returns int: Total number of characters written on success; A negative number on failure.

int **esp_rom_vprintf**(const char *fmt, va_list ap)

Print formatted string to console device.

Note: float and long long data are not supported!

Parameters
- **fmt** -- Format string
- **ap** -- List of arguments.

Returns int: Total number of characters written on success; A negative number on failure.

void **esp_rom_delay_us**(uint32_t us)

Pauses execution for us microseconds.

Parameters **us** -- Number of microseconds to pause

void **esp_rom_install_channel_putc**(int channel, void (*putc)(char c))

esp_rom_printf can print message to different channels simultaneously. This function can help install the low level putc function for esp_rom_printf.

Parameters
- **channel** -- Channel number (starting from 1)
- **putc** -- Function pointer to the putc implementation. Set NULL can disconnect esp_rom_printf with putc.

void **esp_rom_output_to_channels**(char c)

It outputs a character to different channels simultaneously. This function is used by esp_rom_printf/esp_rom_vprintf.

Parameters **c** -- Char to output.

void **esp_rom_install_uart_printf**(void)

Install UART1 as the default console channel, equivalent to `esp_rom_install_channel_putc(1, esp_rom_output_putc)`

soc_reset_reason_t **esp_rom_get_reset_reason**(int cpu_no)

Get reset reason of CPU.

Parameters **cpu_no** -- CPU number

Returns Reset reason code (see in soc/reset_reasons.h)

void **esp_rom_route_intr_matrix**(int cpu_core, uint32_t periph_intr_id, uint32_t cpu_intr_num)

Route peripheral interrupt sources to CPU's interrupt port by matrix.

Usually there're 4 steps to use an interrupt:

a. Route peripheral interrupt source to CPU. e.g. esp_rom_route_intr_matrix(0, ETS_WIFI_MAC_INTR_SOURCE, ETS_WMAC_INUM)

b. Set interrupt handler for CPU
c. Enable CPU interrupt
d. Enable peripheral interrupt

Parameters

- **cpu_core** -- The CPU number, which the peripheral interrupt will inform to
- **periph_intr_id** -- The peripheral interrupt source number
- **cpu_intr_num** -- The CPU (external) interrupt number. On targets that use CLIC as their interrupt controller, this number represents the external interrupt number. For example, passing `cpu_intr_num = i` to this function would in fact bind peripheral source to CPU interrupt `CLIC_EXT_INTR_NUM_OFFSET + i`.

uint32_t **esp_rom_get_cpu_ticks_per_us** (void)

Get the real CPU ticks per us.

Returns CPU ticks per us

void **esp_rom_set_cpu_ticks_per_us** (uint32_t ticks_per_us)

Set the real CPU tick rate.

Note: Call this function when CPU frequency is changed, otherwise the `esp_rom_delay_us` can be inaccurate.

Parameters **ticks_per_us** -- CPU ticks per us

2.10.19 Interrupt Allocation

Overview

The ESP32-C3 has one core, with 31 interrupts. Each interrupt's priority is independently programmable.

Because there are more interrupt sources than interrupts, sometimes it makes sense to share an interrupt in multiple drivers. The *esp_intr_alloc()* abstraction exists to hide all these implementation details.

A driver can allocate an interrupt for a certain peripheral by calling *esp_intr_alloc()* (or *esp_intr_alloc_intrstatus()*). It can use the flags passed to this function to specify the type, priority, and trigger method of the interrupt to allocate. The interrupt allocation code will then find an applicable interrupt, use the interrupt matrix to hook it up to the peripheral, and install the given interrupt handler and ISR to it.

The interrupt allocator presents two different types of interrupts, namely shared interrupts and non-shared interrupts, both of which require different handling. Non-shared interrupts will allocate a separate interrupt for every *esp_intr_alloc()* call, and this interrupt is use solely for the peripheral attached to it, with only one ISR that will get called. Shared interrupts can have multiple peripherals triggering them, with multiple ISRs being called when one of the peripherals attached signals an interrupt. Thus, ISRs that are intended for shared interrupts should check the interrupt status of the peripheral they service in order to check if any action is required.

Non-shared interrupts can be either level- or edge-triggered. Shared interrupts can only be level interrupts due to the chance of missed interrupts when edge interrupts are used.

To illustrate why shard interrupts can only be level-triggered, take the scenario where peripheral A and peripheral B share the same edge-triggered interrupt. Peripheral B triggers an interrupt and sets its interrupt signal high, causing a low-to-high edge, which in turn latches the CPU's interrupt bit and triggers the ISR. The ISR executes, checks that peripheral A did not trigger an interrupt, and proceeds to handle and clear peripheral B's interrupt signal. Before the ISR returns, the CPU clears its interrupt bit latch. Thus, during the entire interrupt handling process, if peripheral A triggers an interrupt, it will be missed due the CPU clearing the interrupt bit latch.

IRAM-Safe Interrupt Handlers

The `ESP_INTR_FLAG_IRAM` flag registers an interrupt handler that always runs from IRAM (and reads all its data from DRAM), and therefore does not need to be disabled during flash erase and write operations.

This is useful for interrupts which need a guaranteed minimum execution latency, as flash write and erase operations can be slow (erases can take tens or hundreds of milliseconds to complete).

It can also be useful to keep an interrupt handler in IRAM if it is called very frequently, to avoid flash cache misses.

Refer to the *SPI flash API documentation* for more details.

Multiple Handlers Sharing A Source

Several handlers can be assigned to a same source, given that all handlers are allocated using the `ESP_INTR_FLAG_SHARED` flag. They will all be allocated to the interrupt, which the source is attached to, and called sequentially when the source is active. The handlers can be disabled and freed individually. The source is attached to the interrupt (enabled), if one or more handlers are enabled, otherwise detached. A handler will never be called when disabled, while **its source may still be triggered** if any one of its handler enabled.

Sources attached to non-shared interrupt do not support this feature.

Though the framework supports this feature, you have to use it **very carefully**. There usually exist two ways to stop an interrupt from being triggered: **disable the source** or **mask peripheral interrupt status**. ESP-IDF only handles enabling and disabling of the source itself, leaving status and mask bits to be handled by users.

Status bits shall either be masked before the handler responsible for it is disabled, or be masked and then properly handled in another enabled interrupt.

Note: Leaving some status bits unhandled without masking them, while disabling the handlers for them, will cause the interrupt(s) to be triggered indefinitely, resulting therefore in a system crash.

Troubleshooting Interrupt Allocation

On most Espressif SoCs, CPU interrupts are a limited resource. Therefore it is possible for a program to run out of CPU interrupts, for example by initializing several peripheral drivers. Typically, this will result in the driver initialization function returning `ESP_ERR_NOT_FOUND` error code.

If this happens, you can use `esp_intr_dump()` function to print the list of interrupts along with their status. The output of this function typically looks like this:

```
CPU 0 interrupt status:
Int  Level  Type   Status
0     1    Level  Reserved
1     1    Level  Reserved
2     1    Level  Used: RTC_CORE
3     1    Level  Used: TG0_LACT_LEVEL
...
```

The columns of the output have the following meaning:

- `Int`: CPU interrupt input number. This is typically not used in software directly, and is provided for reference only.
- `Level`: For interrupts which have been allocated, the priority of the interrupt. For free interrupts `*` is printed.
- `Type`: For interrupts which have been allocated, the type (Level or Edge) of the interrupt. For free interrupts `*` is printed.
- **`Status`: One of the possible statuses of the interrupt:**

- `Reserved`: The interrupt is reserved either at hardware level, or by one of the parts of ESP-IDF. It can not be allocated using `esp_intr_alloc()`.
- `Used: <source>`: The interrupt is allocated and connected to a single peripheral.
- `Shared: <source1> <source2> ...`: The interrupt is allocated and connected to multiple peripherals. See *Multiple Handlers Sharing A Source* above.
- `Free`: The interrupt is not allocated and can be used by `esp_intr_alloc()`.

If you have confirmed that the application is indeed running out of interrupts, a combination of the following suggestions can help resolve the issue:

- Determine the interrupts which can tolerate higher latency, and allocate them using `ESP_INTR_FLAG_SHARED` flag (optionally ORed with `ESP_INTR_FLAG_LOWMED`). Using this flag for two or more peripherals will let them use a single interrupt input, and therefore save interrupt inputs for other peripherals. See *Multiple Handlers Sharing A Source* above.
- Check if some of the peripheral drivers do not need to be used all the time, and initialize or deinitialize them on demand. This can reduce the number of simultaneously allocated interrupts.

API Reference

Header File

- components/esp_hw_support/include/esp_intr_types.h
- This header file can be included with:

```
#include "esp_intr_types.h"
```

Macros

ESP_INTR_CPU_AFFINITY_TO_CORE_ID (cpu_affinity)

Convert esp_intr_cpu_affinity_t to CPU core ID.

Type Definitions

typedef void (***intr_handler_t**)(void *arg)

Function prototype for interrupt handler function

typedef struct intr_handle_data_t ***intr_handle_t**

Handle to an interrupt handler

Enumerations

enum **esp_intr_cpu_affinity_t**

Interrupt CPU core affinity.

This type specify the CPU core that the peripheral interrupt is connected to.

Values:

enumerator **ESP_INTR_CPU_AFFINITY_AUTO**

Install the peripheral interrupt to ANY CPU core, decided by on which CPU the interrupt allocator is running.

enumerator **ESP_INTR_CPU_AFFINITY_0**

Install the peripheral interrupt to CPU core 0.

enumerator **ESP_INTR_CPU_AFFINITY_1**

Install the peripheral interrupt to CPU core 1.

Header File

- components/esp_hw_support/include/esp_intr_alloc.h
- This header file can be included with:

```
#include "esp_intr_alloc.h"
```

Functions

esp_err_t **esp_intr_mark_shared**(int intno, int cpu, bool is_in_iram)

Mark an interrupt as a shared interrupt.

This will mark a certain interrupt on the specified CPU as an interrupt that can be used to hook shared interrupt handlers to.

Parameters
- **intno** -- The number of the interrupt (0-31)
- **cpu** -- CPU on which the interrupt should be marked as shared (0 or 1)
- **is_in_iram** -- Shared interrupt is for handlers that reside in IRAM and the int can be left enabled while the flash cache is disabled.

Returns ESP_ERR_INVALID_ARG if cpu or intno is invalid ESP_OK otherwise

esp_err_t **esp_intr_reserve**(int intno, int cpu)

Reserve an interrupt to be used outside of this framework.

This will mark a certain interrupt on the specified CPU as reserved, not to be allocated for any reason.

Parameters
- **intno** -- The number of the interrupt (0-31)
- **cpu** -- CPU on which the interrupt should be marked as shared (0 or 1)

Returns ESP_ERR_INVALID_ARG if cpu or intno is invalid ESP_OK otherwise

esp_err_t **esp_intr_alloc**(int source, int flags, *intr_handler_t* handler, void *arg, *intr_handle_t* *ret_handle)

Allocate an interrupt with the given parameters.

This finds an interrupt that matches the restrictions as given in the flags parameter, maps the given interrupt source to it and hooks up the given interrupt handler (with optional argument) as well. If needed, it can return a handle for the interrupt as well.

The interrupt will always be allocated on the core that runs this function.

If ESP_INTR_FLAG_IRAM flag is used, and handler address is not in IRAM or RTC_FAST_MEM, then ESP_ERR_INVALID_ARG is returned.

Parameters
- **source** -- The interrupt source. One of the ETS_*_INTR_SOURCE interrupt mux sources, as defined in soc/soc.h, or one of the internal ETS_INTERNAL_*_INTR_SOURCE sources as defined in this header.
- **flags** -- An ORred mask of the ESP_INTR_FLAG_* defines. These restrict the choice of interrupts that this routine can choose from. If this value is 0, it will default to allocating a non-shared interrupt of level 1, 2 or 3. If this is ESP_INTR_FLAG_SHARED, it will allocate a shared interrupt of level 1. Setting ESP_INTR_FLAG_INTRDISABLED will return from this function with the interrupt disabled.
- **handler** -- The interrupt handler. Must be NULL when an interrupt of level >3 is requested, because these types of interrupts aren't C-callable.
- **arg** -- Optional argument for passed to the interrupt handler
- **ret_handle** -- Pointer to an intr_handle_t to store a handle that can later be used to request details or free the interrupt. Can be NULL if no handle is required.

Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid. ESP_ERR_NOT_FOUND No free interrupt found with the specified flags ESP_OK otherwise

esp_err_t **esp_intr_alloc_intrstatus**(int source, int flags, uint32_t intrstatusreg, uint32_t intrstatusmask, *intr_handler_t* handler, void *arg, *intr_handle_t* *ret_handle)

Allocate an interrupt with the given parameters.

This essentially does the same as esp_intr_alloc, but allows specifying a register and mask combo. For shared interrupts, the handler is only called if a read from the specified register, ANDed with the mask, returns non-zero. By passing an interrupt status register address and a fitting mask, this can be used to accelerate interrupt handling in the case a shared interrupt is triggered; by checking the interrupt statuses first, the code can decide which ISRs can be skipped

Parameters

- **source** -- The interrupt source. One of the ETS_*_INTR_SOURCE interrupt mux sources, as defined in soc/soc.h, or one of the internal ETS_INTERNAL_*_INTR_SOURCE sources as defined in this header.
- **flags** -- An ORred mask of the ESP_INTR_FLAG_* defines. These restrict the choice of interrupts that this routine can choose from. If this value is 0, it will default to allocating a non-shared interrupt of level 1, 2 or 3. If this is ESP_INTR_FLAG_SHARED, it will allocate a shared interrupt of level 1. Setting ESP_INTR_FLAG_INTRDISABLED will return from this function with the interrupt disabled.
- **intrstatusreg** -- The address of an interrupt status register
- **intrstatusmask** -- A mask. If a read of address intrstatusreg has any of the bits that are 1 in the mask set, the ISR will be called. If not, it will be skipped.
- **handler** -- The interrupt handler. Must be NULL when an interrupt of level >3 is requested, because these types of interrupts aren't C-callable.
- **arg** -- Optional argument for passed to the interrupt handler
- **ret_handle** -- Pointer to an intr_handle_t to store a handle that can later be used to request details or free the interrupt. Can be NULL if no handle is required.

Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid. ESP_ERR_NOT_FOUND No free interrupt found with the specified flags ESP_OK otherwise

esp_err_t **esp_intr_free**(*intr_handle_t* handle)

Disable and free an interrupt.

Use an interrupt handle to disable the interrupt and release the resources associated with it. If the current core is not the core that registered this interrupt, this routine will be assigned to the core that allocated this interrupt, blocking and waiting until the resource is successfully released.

Note: When the handler shares its source with other handlers, the interrupt status bits it's responsible for should be managed properly before freeing it. see `esp_intr_disable` for more details. Please do not call this function in `esp_ipc_call_blocking`.

Parameters **handle** -- The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

Returns ESP_ERR_INVALID_ARG the handle is NULL ESP_FAIL failed to release this handle ESP_OK otherwise

int **esp_intr_get_cpu**(*intr_handle_t* handle)

Get CPU number an interrupt is tied to.

Parameters **handle** -- The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

Returns The core number where the interrupt is allocated

int **esp_intr_get_intno**(*intr_handle_t* handle)

Get the allocated interrupt for a certain handle.

Parameters **handle** -- The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus
Returns The interrupt number

esp_err_t **esp_intr_disable**(*intr_handle_t* handle)

Disable the interrupt associated with the handle.

Note:

a. For local interrupts (ESP_INTERNAL_* sources), this function has to be called on the CPU the interrupt is allocated on. Other interrupts have no such restriction.
b. When several handlers sharing a same interrupt source, interrupt status bits, which are handled in the handler to be disabled, should be masked before the disabling, or handled in other enabled interrupts properly. Miss of interrupt status handling will cause infinite interrupt calls and finally system crash.

Parameters **handle** -- The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus
Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid. ESP_OK otherwise

esp_err_t **esp_intr_enable**(*intr_handle_t* handle)

Enable the interrupt associated with the handle.

Note: For local interrupts (ESP_INTERNAL_* sources), this function has to be called on the CPU the interrupt is allocated on. Other interrupts have no such restriction.

Parameters **handle** -- The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus
Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid. ESP_OK otherwise

esp_err_t **esp_intr_set_in_iram**(*intr_handle_t* handle, bool is_in_iram)

Set the "in IRAM" status of the handler.

Note: Does not work on shared interrupts.

Parameters
- **handle** -- The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus
- **is_in_iram** -- Whether the handler associated with this handle resides in IRAM. Handlers residing in IRAM can be called when cache is disabled.

Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid. ESP_OK otherwise

void **esp_intr_noniram_disable**(void)

Disable interrupts that aren't specifically marked as running from IRAM.

void **esp_intr_noniram_enable**(void)

Re-enable interrupts disabled by esp_intr_noniram_disable.

void **esp_intr_enable_source**(int inum)

enable the interrupt source based on its number

Parameters **inum** -- interrupt number from 0 to 31

void **esp_intr_disable_source**(int inum)

disable the interrupt source based on its number

Parameters **inum** -- interrupt number from 0 to 31

static inline int **esp_intr_flags_to_level** (int flags)

Get the lowest interrupt level from the flags.

Parameters **flags** -- The same flags that pass to `esp_intr_alloc_intrstatus` API

static inline int **esp_intr_level_to_flags** (int level)

Get the interrupt flags from the supplied level (priority)

Parameters **level** -- The interrupt priority level

esp_err_t **esp_intr_dump** (FILE *stream)

Dump the status of allocated interrupts.

Parameters **stream** -- The stream to dump to, if NULL then stdout is used
Returns ESP_OK on success

Macros

ESP_INTR_FLAG_LEVEL1

Interrupt allocation flags.

These flags can be used to specify which interrupt qualities the code calling esp_intr_alloc* needs. Accept a Level 1 interrupt vector (lowest priority)

ESP_INTR_FLAG_LEVEL2

Accept a Level 2 interrupt vector.

ESP_INTR_FLAG_LEVEL3

Accept a Level 3 interrupt vector.

ESP_INTR_FLAG_LEVEL4

Accept a Level 4 interrupt vector.

ESP_INTR_FLAG_LEVEL5

Accept a Level 5 interrupt vector.

ESP_INTR_FLAG_LEVEL6

Accept a Level 6 interrupt vector.

ESP_INTR_FLAG_NMI

Accept a Level 7 interrupt vector (highest priority)

ESP_INTR_FLAG_SHARED

Interrupt can be shared between ISRs.

ESP_INTR_FLAG_EDGE

Edge-triggered interrupt.

ESP_INTR_FLAG_IRAM

ISR can be called if cache is disabled.

ESP_INTR_FLAG_INTRDISABLED

Return with this interrupt disabled.

ESP_INTR_FLAG_LOWMED

Low and medium prio interrupts. These can be handled in C.

ESP_INTR_FLAG_HIGH

High level interrupts. Need to be handled in assembly.

ESP_INTR_FLAG_LEVELMASK

Mask for all level flags

ETS_INTERNAL_TIMER0_INTR_SOURCE

Platform timer 0 interrupt source.

The esp_intr_alloc* functions can allocate an int for all ETS_*_INTR_SOURCE interrupt sources that are routed through the interrupt mux. Apart from these sources, each core also has some internal sources that do not pass through the interrupt mux. To allocate an interrupt for these sources, pass these pseudo-sources to the functions.

ETS_INTERNAL_TIMER1_INTR_SOURCE

Platform timer 1 interrupt source.

ETS_INTERNAL_TIMER2_INTR_SOURCE

Platform timer 2 interrupt source.

ETS_INTERNAL_SW0_INTR_SOURCE

Software int source 1.

ETS_INTERNAL_SW1_INTR_SOURCE

Software int source 2.

ETS_INTERNAL_PROFILING_INTR_SOURCE

Int source for profiling.

ETS_INTERNAL_UNUSED_INTR_SOURCE

Interrupt is not assigned to any source.

ETS_INTERNAL_INTR_SOURCE_OFF

Provides SystemView with positive IRQ IDs, otherwise scheduler events are not shown properly

ESP_INTR_ENABLE(inum)

Enable interrupt by interrupt number

ESP_INTR_DISABLE(inum)

Disable interrupt by interrupt number

2.10.20 Logging library

Overview

The logging library provides three ways for setting log verbosity:

- **At compile time**: in menuconfig, set the verbosity level using the option *CONFIG_LOG_DEFAULT_LEVEL*.
- Optionally, also in menuconfig, set the maximum verbosity level using the option *CONFIG_LOG_MAXIMUM_LEVEL*. By default, this is the same as the default level, but it can be set higher in order to compile more optional logs into the firmware.
- **At runtime**: all logs for verbosity levels lower than *CONFIG_LOG_DEFAULT_LEVEL* are enabled by default. The function `esp_log_level_set()` can be used to set a logging level on a per-module basis. Modules are identified by their tags, which are human-readable ASCII zero-terminated strings. Note that the ability to change the log level at runtime depends on *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL*.
- **At runtime**: if *CONFIG_LOG_MASTER_LEVEL* is enabled then a `Master logging level` can be set using `esp_log_set_level_master()`. This option adds an additional logging level check for all compiled logs. Note that this will increase application size. This feature is useful if you want to compile a lot of logs that are selectable at runtime, but also want to avoid the performance hit from looking up the tags and their log level when you don't want log output.

There are the following verbosity levels:

- Error (lowest)
- Warning
- Info
- Debug
- Verbose (highest)

Note: The function `esp_log_level_set()` cannot set logging levels higher than specified by *CONFIG_LOG_MAXIMUM_LEVEL*. To increase log level for a specific file above this maximum at compile time, use the macro *LOG_LOCAL_LEVEL* (see the details below).

How to Use Logging Library

In each C file that uses logging functionality, define the TAG variable as shown below:

```
static const char* TAG = "MyModule";
```

Then use one of logging macros to produce output, e.g:

```
ESP_LOGW(TAG, "Baud rate error %.1f%%. Requested: %d baud, actual: %d baud", error
↪* 100, baud_req, baud_real);
```

Several macros are available for different verbosity levels:

- `ESP_LOGE` - Error (lowest)
- `ESP_LOGW` - Warning
- `ESP_LOGI` - Info
- `ESP_LOGD` - Debug
- `ESP_LOGV` - Verbose (highest)

Additionally, there are `ESP_EARLY_LOGx` versions for each of these macros, e.g. `ESP_EARLY_LOGE`. These versions have to be used explicitly in the early startup code only, before heap allocator and syscalls have been initialized. Normal `ESP_LOGx` macros can also be used while compiling the bootloader, but they will fall back to the same implementation as `ESP_EARLY_LOGx` macros.

There are also `ESP_DRAM_LOGx` versions for each of these macros, e.g. `ESP_DRAM_LOGE`. These versions are used in some places where logging may occur with interrupts disabled or with flash cache inaccessible. Use of this macros should be as sparse as possible, as logging in these types of code should be avoided for performance reasons.

Note: Inside critical sections interrupts are disabled so it's only possible to use `ESP_DRAM_LOGx` (preferred) or `ESP_EARLY_LOGx`. Even though it's possible to log in these situations, it's better if your program can be structured not to require it.

To override default verbosity level at file or component scope, define the `LOG_LOCAL_LEVEL` macro.

At file scope, define it before including `esp_log.h`, e.g.:

```
#define LOG_LOCAL_LEVEL ESP_LOG_VERBOSE
#include "esp_log.h"
```

At component scope, define it in the component CMakeLists:

```
target_compile_definitions(${COMPONENT_LIB} PUBLIC "-DLOG_LOCAL_LEVEL=ESP_LOG_
↪VERBOSE")
```

Dynamic Log Level Control

To configure logging output per module at runtime, add calls to the function `esp_log_level_set()` as follows:

```
esp_log_level_set("*", ESP_LOG_ERROR);        // set all components to ERROR level
esp_log_level_set("wifi", ESP_LOG_WARN);      // enable WARN logs from WiFi stack
esp_log_level_set("dhcpc", ESP_LOG_INFO);     // enable INFO logs from DHCP client
```

Note: The "DRAM" and "EARLY" log macro variants documented above do not support per module setting of log verbosity. These macros will always log at the "default" verbosity level, which can only be changed at runtime by calling `esp_log_level("*", level)`.

Even when logs are disabled by using a tag name, they will still require a processing time of around 10.9 microseconds per entry.

The log component provides several options to better adjust the system to your needs, reducing memory usage and speeding up operations. The *CONFIG_LOG_TAG_LEVEL_IMPL* option sets the method of tag level checks:

- "None". This option disables the ability to set the log level per tag. The ability to change the log level at runtime depends on *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL*. If disabled, changing the log level at runtime using `esp_log_level_set()` is not possible. This implementation is suitable for highly constrained environments.
- "Linked list" (no cache). This option enables the ability to set the log level per tag. This approach searches the linked list of all tags for the log level, which may be slower for a large number of tags but may have lower memory requirements than the cache approach.
- (Default) "Cache + Linked List". This option enables the ability to set the log level per tag. This hybrid approach offers a balance between speed and memory usage. The cache stores recently accessed log tags and their corresponding log levels, providing faster lookups for frequently used tags.

When the *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL* option is enabled, log levels to be changed at runtime via `esp_log_level_set()`. Dynamic log levels increase flexibility but also incurs additional code size. If your application does not require dynamic log level changes and you do not need to control logs per module using tags, consider disabling *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL*. It reduces IRAM usage by approximately 260 bytes, DRAM usage by approximately 264 bytes, and flash usage by approximately 1 KB compared to the default option. It is not only streamlines logs for memory efficiency but also contributes to speeding up log operations in your application about 10 times.

Note: The "Linked list" and "Cache + Linked List" options will automatically enable *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL*.

Master Logging Level To enable the Master logging level feature, the *CONFIG_LOG_MASTER_LEVEL* option must be enabled. It adds an additional level check for `ESP_LOGx` macros before calling `esp_log_write()`. This allows to set a higher *CONFIG_LOG_MAXIMUM_LEVEL*, but not inflict a performance hit during normal operation (only when directed). An application may set the master logging level (`esp_log_set_level_master()`) globally to enforce a maximum log level. `ESP_LOGx` macros above this level will be skipped immediately, rather than calling `esp_log_write()` and doing a tag lookup. It is recommended to only use this in an top-level application and not in shared components as this would override the global log level for any user using the component. By default, at startup, the Master logging level is *CONFIG_LOG_DEFAULT_LEVEL*.

Note that this feature increases application size because the additional check is added into all `ESP_LOGx` macros.

The snippet below shows how it works. Setting the Master logging level to `ESP_LOG_NONE` disables all logging globally. `esp_log_level_set()` does not currently affect logging. But after the Master logging level is released, the logs will be printed as set by `esp_log_level_set()`.

```
// Master logging level is CONFIG_LOG_DEFAULT_LEVEL at start up and = ESP_LOG_INFO
ESP_LOGI("lib_name", "Message for print");          // prints a INFO message
esp_log_level_set("lib_name", ESP_LOG_WARN);        // enables WARN logs from lib_
↪name

esp_log_set_level_master(ESP_LOG_NONE);             // disables all logs globally.␣
↪esp_log_level_set has no effect at the moment

ESP_LOGW("lib_name", "Message for print");          // no print, Master logging␣
↪level blocks it
esp_log_level_set("lib_name", ESP_LOG_INFO);        // enable INFO logs from lib_
↪name
ESP_LOGI("lib_name", "Message for print");          // no print, Master logging␣
↪level blocks it

esp_log_set_level_master(ESP_LOG_INFO);             // enables all INFO logs␣
↪globally

ESP_LOGI("lib_name", "Message for print");          // prints a INFO message
```

Logging to Host via JTAG By default, the logging library uses the vprintf-like function to write formatted output to the dedicated UART. By calling a simple API, all log output may be routed to JTAG instead, making logging several times faster. For details, please refer to Section *Logging to Host*.

Thread Safety The log string is first written into a memory buffer and then sent to the UART for printing. Log calls are thread-safe, i.e., logs of different threads do not conflict with each other.

Application Example

The logging library is commonly used by most ESP-IDF components and examples. For demonstration of log functionality, check ESP-IDF's examples directory. The most relevant examples that deal with logging are the following:

- system/ota
- storage/sd_card
- protocols/https_request

API Reference

Header File

- components/log/include/esp_log.h
- This header file can be included with:

```
#include "esp_log.h"
```

Functions

vprintf_like_t **esp_log_set_vprintf** (*vprintf_like_t* func)

Set function used to output log entries.

By default, log output goes to UART0. This function can be used to redirect log output to some other destination, such as file or network. Returns the original log handler, which may be necessary to return output to the previous destination.

Note: Please note that function callback here must be re-entrant as it can be invoked in parallel from multiple thread context.

Parameters **func** -- new Function used for output. Must have same signature as vprintf.
Returns func old Function used for output.

void **esp_log_write** (*esp_log_level_t* level, const char *tag, const char *format, ...)

Write message into the log.

This function is not intended to be used directly. Instead, use one of ESP_LOGE, ESP_LOGW, ESP_LOGI, ESP_LOGD, ESP_LOGV macros.

This function or these macros should not be used from an interrupt.

void **esp_log_writev** (*esp_log_level_t* level, const char *tag, const char *format, va_list args)

Write message into the log, va_list variant.

This function is provided to ease integration toward other logging framework, so that esp_log can be used as a log sink.

See also:

esp_log_write()

Macros

ESP_EARLY_LOGE (tag, format, ...)

macro to output logs in startup code, before heap allocator and syscalls have been initialized. Log at `ESP_LOG_ERROR` level.

See also:

`printf`,`ESP_LOGE`,`ESP_DRAM_LOGE` In the future, we want to become compatible with clang. Hence, we provide two versions of the following macros which are using variadic arguments. The first one is using the GNU extension ##__VA_ARGS__. The second one is using the C++20 feature **VA_OPT**(,). This allows users to compile their code with standard C++20 enabled instead of the GNU extension. Below C++20, we haven't found any good alternative to using ##__VA_ARGS__.

ESP_EARLY_LOGW (tag, format, ...)

macro to output logs in startup code at `ESP_LOG_WARN` level.

See also:

`ESP_EARLY_LOGE`,`ESP_LOGE`, `printf`

ESP_EARLY_LOGI (tag, format, ...)

macro to output logs in startup code at `ESP_LOG_INFO` level.

See also:

`ESP_EARLY_LOGE`,`ESP_LOGE`, `printf`

ESP_EARLY_LOGD (tag, format, ...)

macro to output logs in startup code at `ESP_LOG_DEBUG` level.

See also:

`ESP_EARLY_LOGE`,`ESP_LOGE`, `printf`

ESP_EARLY_LOGV (tag, format, ...)

macro to output logs in startup code at `ESP_LOG_VERBOSE` level.

See also:

`ESP_EARLY_LOGE`,`ESP_LOGE`, `printf`

ESP_LOG_EARLY_IMPL (tag, format, log_level, log_tag_letter, ...)

ESP_LOGE (tag, format, ...)

ESP_LOGW (tag, format, ...)

ESP_LOGI (tag, format, ...)

ESP_LOGD (tag, format, ...)

ESP_LOGV (tag, format, ...)

ESP_LOG_LEVEL (level, tag, format, ...)

runtime macro to output logs at a specified level.

See also:

`printf`

Parameters

- **tag** -- tag of the log, which can be used to change the log level by `esp_log_level_set` at runtime.
- **level** -- level of the output log.
- **format** -- format of the output log. See `printf`
- **...** -- variables to be replaced into the log. See `printf`

ESP_LOG_LEVEL_LOCAL (level, tag, format, ...)

runtime macro to output logs at a specified level. Also check the level with `LOG_LOCAL_LEVEL`. If `CONFIG_LOG_MASTER_LEVEL` set, also check first against `esp_log_get_level_master()`.

See also:

`printf`, `ESP_LOG_LEVEL`

ESP_DRAM_LOGE (tag, format, ...)

Macro to output logs when the cache is disabled. Log at `ESP_LOG_ERROR` level.

Similar to

Usage: `ESP_DRAM_LOGE(DRAM_STR("my_tag"), "format",` `or`ESP_DRAM_LOGE(TAG, "format", ...)`, where TAG is a char* that points to a str in the DRAM.

See also:

`ESP_EARLY_LOGE`, the log level cannot be changed per-tag, however esp_log_level_set("*", level) will set the default level which controls these log lines also.

See also:

`esp_rom_printf`,`ESP_LOGE`

Note: Unlike normal logging macros, it's possible to use this macro when interrupts are disabled or inside an ISR.

Note: Placing log strings in DRAM reduces available DRAM, so only use when absolutely essential.

ESP_DRAM_LOGW (tag, format, ...)

macro to output logs when the cache is disabled at `ESP_LOG_WARN` level.

See also:

`ESP_DRAM_LOGW`,`ESP_LOGW`, `esp_rom_printf`

ESP_DRAM_LOGI (tag, format, ...)

macro to output logs when the cache is disabled at `ESP_LOG_INFO` level.

See also:

`ESP_DRAM_LOGI`,`ESP_LOGI`, `esp_rom_printf`

ESP_DRAM_LOGD (tag, format, ...)

macro to output logs when the cache is disabled at `ESP_LOG_DEBUG` level.

See also:

`ESP_DRAM_LOGD`,`ESP_LOGD`, `esp_rom_printf`

ESP_DRAM_LOGV (tag, format, ...)

macro to output logs when the cache is disabled at `ESP_LOG_VERBOSE` level.

See also:

`ESP_DRAM_LOGV`,`ESP_LOGV`, `esp_rom_printf`

Type Definitions

typedef int (***vprintf_like_t**)(const char*, va_list)

Header File

- components/log/include/esp_log_level.h
- This header file can be included with:

```
#include "esp_log_level.h"
```

Functions

static inline *esp_log_level_t* **esp_log_get_default_level** (void)

Get the default log level.

This function returns the default log level. The default log level is used by the definition of ESP_LOGx macros and can be overridden for specific tags using `esp_log_level_set("*", level)`. If CONFIG_LOG_DYNAMIC_LEVEL_CONTROL=n, changing the default log level is not possible.

Returns The default log level.

void **esp_log_set_level_master** (*esp_log_level_t* level)

Master log level.

Optional master log level to check against for ESP_LOGx macros before calling esp_log_write. Allows one to set a higher CONFIG_LOG_MAXIMUM_LEVEL but not impose a performance hit during normal operation (only when instructed). An application may set esp_log_set_level_master(level) to globally enforce a maximum log level. ESP_LOGx macros above this level will be skipped immediately, rather than calling esp_log or esp_log_write and doing a cache hit.

Note: The tradeoff is increased application size.

Parameters **level** -- Master log level

esp_log_level_t **esp_log_get_level_master** (void)

Returns master log level.

Returns Master log level

void **esp_log_level_set** (const char *tag, *esp_log_level_t* level)

Set log level for given tag.

If logging for given component has already been enabled, changes previous setting.

To raise log level above the default one for a given file, define LOG_LOCAL_LEVEL to one of the ESP_LOG_* values, before including esp_log.h in this file.

If CONFIG_LOG_DYNAMIC_LEVEL_CONTROL is not selected the static (no-op) implementation of log level is used. Changing the log level is not possible, esp_log_level_set does not work.

Note: Note that this function can not raise log level above the level set using CONFIG_LOG_MAXIMUM_LEVEL setting in menuconfig.

Parameters

- **tag** -- Tag of the log entries to enable. Must be a non-NULL zero terminated string. Value "*" resets log level for all tags to the given value. If the tag is NULL then a silent return happens.
- **level** -- Selects log level to enable. Only logs at this and lower verbosity levels will be shown.

esp_log_level_t **esp_log_level_get** (const char *tag)

Get log level for a given tag, can be used to avoid expensive log statements.

If CONFIG_LOG_DYNAMIC_LEVEL_CONTROL is not selected the static (no-op) implementation of log level is used. Changing the log level is not possible, esp_log_level_set does not work. This function returns the default log level.

Parameters **tag** -- Tag of the log to query current level. Must be a zero terminated string. If tag is NULL then the default log level is returned (see esp_log_get_default_level()).

Returns The current log level for the given tag.

Enumerations

enum **esp_log_level_t**

Log level.

Values:

enumerator **ESP_LOG_NONE**

No log output

enumerator **ESP_LOG_ERROR**

Critical errors, software module can not recover on its own

enumerator **ESP_LOG_WARN**

Error conditions from which recovery measures have been taken

enumerator **ESP_LOG_INFO**

Information messages which describe normal flow of events

enumerator **ESP_LOG_DEBUG**

Extra information which is not necessary for normal use (values, pointers, sizes, etc).

enumerator **ESP_LOG_VERBOSE**

Bigger chunks of debugging information, or frequent messages which can potentially flood the output.

enumerator **ESP_LOG_MAX**

Number of levels supported

Header File

- components/log/include/esp_log_buffer.h
- This header file can be included with:

```
#include "esp_log_buffer.h"
```

Functions

void **esp_log_buffer_hex_internal** (const char *tag, const void *buffer, uint16_t buff_len, *esp_log_level_t* level)

Logs a buffer of hexadecimal bytes at the specified log level.

This function logs a buffer of hexadecimal bytes with 16 bytes per line. The log level determines the severity of the log message.

Note: This function does not check the log level against the ESP_LOCAL_LEVEL. The log level comparison should be done in esp_log.h.

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.
- **level** -- Log level indicating the severity of the log message.

void **esp_log_buffer_char_internal**(const char *tag, const void *buffer, uint16_t buff_len, *esp_log_level_t* level)

This function logs a buffer of characters with 16 characters per line. The buffer should contain only printable characters. The log level determines the severity of the log message.

Note: This function does not check the log level against the ESP_LOCAL_LEVEL. The log level comparison should be done in esp_log.h.

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.
- **level** -- Log level indicating the severity of the log message.

void **esp_log_buffer_hexdump_internal**(const char *tag, const void *buffer, uint16_t buff_len, *esp_log_level_t* log_level)

This function dumps a buffer to the log in a formatted hex dump style, displaying both the memory address and the corresponding hex and ASCII values of the bytes. The log level determines the severity of the log message.

Note: This function does not check the log level against the ESP_LOCAL_LEVEL. The log level comparison should be done in esp_log.h.

Note: It is recommended to use terminals with a width of at least 102 characters to display the log dump properly.

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.
- **log_level** -- Log level indicating the severity of the log message.

Macros

ESP_LOG_BUFFER_HEX_LEVEL(tag, buffer, buff_len, level)

Log a buffer of hex bytes at specified level, separated into 16 bytes each line.

The hex log shows just like the one below:

```
I (954) log_example: 54 68 65 20 77 61 79 20 74 6f 20 67 65 74 20 73
I (962) log_example: 74 61 72 74 65 64 20 69 73 20 74 6f 20 71 75 69
I (969) log_example: 74 20 74 61 6c 6b 69 6e 67 20 61 6e 64 20 62 65
I (977) log_example: 67 69 6e 20 64 6f 69 6e 67 2e 20 2d 20 57 61 6c
I (984) log_example: 74 20 44 69 73 6e 65 79 00
```

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.
- **level** -- Log level

ESP_LOG_BUFFER_CHAR_LEVEL(tag, buffer, buff_len, level)

Log a buffer of characters at specified level, separated into 16 bytes each line. Buffer should contain only printable characters.

The char log shows just like the one below:

```
I (980) log_example: The way to get s
I (985) log_example: tarted is to qui
I (989) log_example: t talking and be
I (994) log_example: gin doing. - Wal
I (999) log_example: t Disney
```

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.
- **level** -- Log level.

ESP_LOG_BUFFER_HEXDUMP(tag, buffer, buff_len, level)

Dump a buffer to the log at specified level.

The dump log shows just like the one below:

```
I (1013) log_example: 0x3ffb5bc0   54 68 65 20 77 61 79 20  74 6f 20 67 65 74␣
↪20 73  |The way to get s|
I (1024) log_example: 0x3ffb5bd0   74 61 72 74 65 64 20 69  73 20 74 6f 20 71␣
↪75 69  |tarted is to qui|
I (1034) log_example: 0x3ffb5be0   74 20 74 61 6c 6b 69 6e  67 20 61 6e 64 20␣
↪62 65  |t talking and be|
I (1044) log_example: 0x3ffb5bf0   67 69 6e 20 64 6f 69 6e  67 2e 20 2d 20 57␣
↪61 6c  |gin doing. - Wal|
I (1054) log_example: 0x3ffb5c00   74 20 44 69 73 6e 65 79  00              ␣
↪       |t Disney.|
```

Note: It is highly recommended to use terminals with over 102 text width.

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.
- **level** -- Log level.

ESP_LOG_BUFFER_HEX(tag, buffer, buff_len)

Log a buffer of hex bytes at Info level.

See also:

`ESP_LOG_BUFFER_HEX_LEVEL`

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.

- **buff_len** -- Length of the buffer in bytes.

ESP_LOG_BUFFER_CHAR(tag, buffer, buff_len)

Log a buffer of characters at Info level. Buffer should contain only printable characters.

See also:

ESP_LOG_BUFFER_CHAR_LEVEL

Parameters

- **tag** -- Description tag to identify the log.
- **buffer** -- Pointer to the buffer array containing the data to be logged.
- **buff_len** -- Length of the buffer in bytes.

Header File

- components/log/include/esp_log_timestamp.h
- This header file can be included with:

```
#include "esp_log_timestamp.h"
```

Functions

uint32_t **esp_log_timestamp**(void)

Function which returns timestamp to be used in log output.

This function is used in expansion of ESP_LOGx macros. In the 2nd stage bootloader, and at early application startup stage this function uses CPU cycle counter as time source. Later when FreeRTOS scheduler start running, it switches to FreeRTOS tick count.

For now, we ignore millisecond counter overflow.

Returns timestamp, in milliseconds

char ***esp_log_system_timestamp**(void)

Function which returns system timestamp to be used in log output.

This function is used in expansion of ESP_LOGx macros to print the system time as "HH:MM:SS.sss". The system time is initialized to 0 on startup, this can be set to the correct time with an SNTP sync, or manually with standard POSIX time functions.

Currently, this will not get used in logging from binary blobs (i.e. Wi-Fi & Bluetooth libraries), these will still print the RTOS tick time.

Returns timestamp, in "HH:MM:SS.sss"

uint32_t **esp_log_early_timestamp**(void)

Function which returns timestamp to be used in log output.

This function uses HW cycle counter and does not depend on OS, so it can be safely used after application crash.

Returns timestamp, in milliseconds

Header File

- components/log/include/esp_log_color.h
- This header file can be included with:

```
#include "esp_log_color.h"
```

2.10.21 Miscellaneous System APIs

Software Reset

To perform software reset of the chip, the `esp_restart()` function is provided. When the function is called, execution of the program stops, the CPU is reset, the application is loaded by the bootloader and starts execution again.

Additionally, the `esp_register_shutdown_handler()` function can register a routine that will be automatically called before a restart (that is triggered by `esp_restart()`) occurs. This is similar to the functionality of `atexit` POSIX function.

Reset Reason

ESP-IDF applications can be started or restarted due to a variety of reasons. To get the last reset reason, call `esp_reset_reason()` function. See description of `esp_reset_reason_t` for the list of possible reset reasons.

Heap Memory

Two heap-memory-related functions are provided:

- `esp_get_free_heap_size()` returns the current size of free heap memory.
- `esp_get_minimum_free_heap_size()` returns the minimum size of free heap memory that has ever been available (i.e., the smallest size of free heap memory in the application's lifetime).

Note that ESP-IDF supports multiple heaps with different capabilities. The functions mentioned in this section return the size of heap memory that can be allocated using the `malloc` family of functions. For further information about heap memory, see *Heap Memory Allocation*.

MAC Address

These APIs allow querying and customizing MAC addresses for different supported network interfaces (e.g., Wi-Fi, Bluetooth, Ethernet).

To fetch the MAC address for a specific network interface (e.g., Wi-Fi, Bluetooth, Ethernet), call the function `esp_read_mac()`.

In ESP-IDF, the MAC addresses for the various network interfaces are calculated from a single **base MAC address**. By default, the Espressif base MAC address is used. This base MAC address is pre-programmed into the ESP32-C3 eFuse in the factory during production.

Interface	MAC Address (4 universally administered, default)	MAC Address (2 universally administered)
Wi-Fi Station	base_mac	base_mac
Wi-Fi SoftAP	base_mac, +1 to the last octet	*Local MAC* (derived from Wi-Fi Station MAC)
Bluetooth	base_mac, +2 to the last octet	base_mac, +1 to the last octet
Ethernet	base_mac, +3 to the last octet	*Local MAC* (derived from Bluetooth MAC)

Note: The *configuration* configures the number of universally administered MAC addresses that are provided by Espressif.

Note: Although ESP32-C3 has no integrated Ethernet MAC, it is still possible to calculate an Ethernet MAC address. However, this MAC address can only be used with an external ethernet interface such as an SPI-Ethernet device. See *Ethernet*.

Custom Interface MAC Sometimes you may need to define custom MAC addresses that are not generated from the base MAC address. To set a custom interface MAC address, use the `esp_iface_mac_addr_set()` function. This function allows you to overwrite the MAC addresses of interfaces set (or not yet set) by the base MAC address. Once a MAC address has been set for a particular interface, it will not be affected when the base MAC address is changed.

Custom Base MAC The default base MAC is pre-programmed by Espressif in eFuse BLK1. To set a custom base MAC instead, call the function `esp_iface_mac_addr_set()` with the `ESP_MAC_BASE` argument (or `esp_base_mac_addr_set()`) before initializing any network interfaces or calling the `esp_read_mac()` function. The custom MAC address can be stored in any supported storage device (e.g., flash, NVS).

The custom base MAC addresses should be allocated such that derived MAC addresses will not overlap. Based on the table above, users can configure the option *CONFIG_ESP32C3_UNIVERSAL_MAC_ADDRESSES* to set the number of valid universal MAC addresses that can be derived from the custom base MAC.

Note: It is also possible to call the function `esp_netif_set_mac()` to set the specific MAC used by a network interface after network initialization. But it is recommended to use the base MAC approach documented here to avoid the possibility of the original MAC address briefly appearing on the network before being changed.

Custom MAC Address in eFuse When reading custom MAC addresses from eFuse, ESP-IDF provides a helper function `esp_efuse_mac_get_custom()`. Users can also use `esp_read_mac()` with the `ESP_MAC_EFUSE_CUSTOM` argument. This loads the MAC address from eFuse BLK3. The `esp_efuse_mac_get_custom()` function assumes that the custom base MAC address is stored in the following format:

Field	# of bits	Range of bits
MAC address	48	200:248

Note: The eFuse BLK3 uses RS-coding during burning, which means that all eFuse fields in this block must be burnt at the same time.

Once custom eFuse MAC address has been obtained (using `esp_efuse_mac_get_custom()` or `esp_read_mac()`), you need to set it as the base MAC address. There are two ways to do it:

1. Use an old API: call `esp_base_mac_addr_set()`.
2. Use a new API: call `esp_iface_mac_addr_set()` with the `ESP_MAC_BASE` argument.

Local Versus Universal MAC Addresses ESP32-C3 comes pre-programmed with enough valid Espressif universally administered MAC addresses for all internal interfaces. The table above shows how to calculate and derive the MAC address for a specific interface according to the base MAC address.

When using a custom MAC address scheme, it is possible that not all interfaces can be assigned with a universally administered MAC address. In these cases, a locally administered MAC address is assigned. Note that these addresses are intended for use on a single local network only.

See this article for the definition of locally and universally administered MAC addresses.

Function `esp_derive_local_mac()` is called internally to derive a local MAC address from a universal MAC address. The process is as follows:

1. The U/L bit (bit value 0x2) is set in the first octet of the universal MAC address, creating a local MAC address.
2. If this bit is already set in the supplied universal MAC address (i.e., the supplied "universal" MAC address was in fact already a local MAC address), then the first octet of the local MAC address is XORed with 0x4.

Chip Version

esp_chip_info() function fills *esp_chip_info_t* structure with information about the chip. This includes the chip revision, number of CPU cores, and a bit mask of features enabled in the chip.

SDK Version

esp_get_idf_version() returns a string describing the ESP-IDF version which is used to compile the application. This is the same value as the one available through `IDF_VER` variable of the build system. The version string generally has the format of `git describe` output.

To get the version at build time, additional version macros are provided. They can be used to enable or disable parts of the program depending on the ESP-IDF version.

- *ESP_IDF_VERSION_MAJOR*, *ESP_IDF_VERSION_MINOR*, *ESP_IDF_VERSION_PATCH* are defined to integers representing major, minor, and patch version.
- *ESP_IDF_VERSION_VAL* and *ESP_IDF_VERSION* can be used when implementing version checks:

```
#include "esp_idf_version.h"

#if ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)
    // enable functionality present in ESP-IDF v4.0
#endif
```

App Version

The application version is stored in *esp_app_desc_t* structure. It is located in DROM sector and has a fixed offset from the beginning of the binary file. The structure is located after *esp_image_header_t* and *esp_image_segment_header_t* structures. The type of the field version is string and it has a maximum length of 32 chars.

To set the version in your project manually, you need to set the `PROJECT_VER` variable in the `CMakeLists.txt` of your project. In application `CMakeLists.txt`, put `set(PROJECT_VER "0.1.0.1")` before including `project.cmake`.

If the *CONFIG_APP_PROJECT_VER_FROM_CONFIG* option is set, the value of *CONFIG_APP_PROJECT_VER* will be used. Otherwise, if the `PROJECT_VER` variable is not set in the project, it will be retrieved either from the `$(PROJECT_PATH)/version.txt` file (if present) or using git command `git describe`. If neither is available, `PROJECT_VER` will be set to "1". Application can make use of this by calling *esp_app_get_description()* or *esp_ota_get_partition_description()* functions.

API Reference

Header File

- components/esp_system/include/esp_system.h
- This header file can be included with:

```
#include "esp_system.h"
```

Functions

esp_err_t **esp_register_shutdown_handler** (*shutdown_handler_t* handle)

Register shutdown handler.

This function allows you to register a handler that gets invoked before the application is restarted using esp_restart function.

Parameters **handle** -- function to execute on restart

Returns

- ESP_OK on success
- ESP_ERR_INVALID_STATE if the handler has already been registered
- ESP_ERR_NO_MEM if no more shutdown handler slots are available

esp_err_t **esp_unregister_shutdown_handler** (*shutdown_handler_t* handle)

Unregister shutdown handler.

This function allows you to unregister a handler which was previously registered using esp_register_shutdown_handler function.

- ESP_OK on success
- ESP_ERR_INVALID_STATE if the given handler hasn't been registered before

void **esp_restart** (void)

Restart PRO and APP CPUs.

This function can be called both from PRO and APP CPUs. After successful restart, CPU reset reason will be SW_CPU_RESET. Peripherals (except for Wi-Fi, BT, UART0, SPI1, and legacy timers) are not reset. This function does not return.

esp_reset_reason_t **esp_reset_reason** (void)

Get reason of last reset.

Returns See description of esp_reset_reason_t for explanation of each value.

uint32_t **esp_get_free_heap_size** (void)

Get the size of available heap.

Note: Note that the returned value may be larger than the maximum contiguous block which can be allocated.

Returns Available heap size, in bytes.

uint32_t **esp_get_free_internal_heap_size** (void)

Get the size of available internal heap.

Note: Note that the returned value may be larger than the maximum contiguous block which can be allocated.

Returns Available internal heap size, in bytes.

uint32_t **esp_get_minimum_free_heap_size** (void)

Get the minimum heap that has ever been available.

Returns Minimum free heap ever available

void **esp_system_abort** (const char *details)

Trigger a software abort.

Parameters **details** -- Details that will be displayed during panic handling.

Type Definitions

typedef void (*`shutdown_handler_t`)(void)

Shutdown handler type

Enumerations

enum `esp_reset_reason_t`

Reset reasons.

Values:

enumerator `ESP_RST_UNKNOWN`

Reset reason can not be determined.

enumerator `ESP_RST_POWERON`

Reset due to power-on event.

enumerator `ESP_RST_EXT`

Reset by external pin (not applicable for ESP32)

enumerator `ESP_RST_SW`

Software reset via esp_restart.

enumerator `ESP_RST_PANIC`

Software reset due to exception/panic.

enumerator `ESP_RST_INT_WDT`

Reset (software or hardware) due to interrupt watchdog.

enumerator `ESP_RST_TASK_WDT`

Reset due to task watchdog.

enumerator `ESP_RST_WDT`

Reset due to other watchdogs.

enumerator `ESP_RST_DEEPSLEEP`

Reset after exiting deep sleep mode.

enumerator `ESP_RST_BROWNOUT`

Brownout reset (software or hardware)

enumerator `ESP_RST_SDIO`

Reset over SDIO.

enumerator `ESP_RST_USB`

Reset by USB peripheral.

enumerator `ESP_RST_JTAG`

Reset by JTAG.

enumerator **ESP_RST_EFUSE**

Reset due to efuse error.

enumerator **ESP_RST_PWR_GLITCH**

Reset due to power glitch detected.

enumerator **ESP_RST_CPU_LOCKUP**

Reset due to CPU lock up.

Header File

- components/esp_common/include/esp_idf_version.h
- This header file can be included with:

```
#include "esp_idf_version.h"
```

Functions

const char ***esp_get_idf_version**(void)

Return full IDF version string, same as 'git describe' output.

Note: If you are printing the ESP-IDF version in a log file or other information, this function provides more information than using the numerical version macros. For example, numerical version macros don't differentiate between development, pre-release and release versions, but the output of this function does.

Returns constant string from IDF_VER

Macros

ESP_IDF_VERSION_MAJOR

Major version number (X.x.x)

ESP_IDF_VERSION_MINOR

Minor version number (x.X.x)

ESP_IDF_VERSION_PATCH

Patch version number (x.x.X)

ESP_IDF_VERSION_VAL(major, minor, patch)

Macro to convert IDF version number into an integer

To be used in comparisons, such as ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)

ESP_IDF_VERSION

Current IDF version, as an integer

To be used in comparisons, such as ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)

Header File

- components/esp_hw_support/include/esp_mac.h
- This header file can be included with:

```
#include "esp_mac.h"
```

Functions

esp_err_t **esp_base_mac_addr_set** (const uint8_t *mac)

Set base MAC address with the MAC address which is stored in BLK3 of EFUSE or external storage e.g. flash and EEPROM.

Base MAC address is used to generate the MAC addresses used by network interfaces.

If using a custom base MAC address, call this API before initializing any network interfaces. Refer to the ESP-IDF Programming Guide for details about how the Base MAC is used.

Note: Base MAC must be a unicast MAC (least significant bit of first byte must be zero).

Note: If not using a valid OUI, set the "locally administered" bit (bit value 0x02 in the first byte) to avoid collisions.

Parameters **mac** -- base MAC address, length: 6 bytes. length: 6 bytes for MAC-48

Returns ESP_OK on success ESP_ERR_INVALID_ARG If mac is NULL or is not a unicast MAC

esp_err_t **esp_base_mac_addr_get** (uint8_t *mac)

Return base MAC address which is set using esp_base_mac_addr_set.

Note: If no custom Base MAC has been set, this returns the pre-programmed Espressif base MAC address.

Parameters **mac** -- base MAC address, length: 6 bytes. length: 6 bytes for MAC-48

Returns ESP_OK on success ESP_ERR_INVALID_ARG mac is NULL ESP_ERR_INVALID_MAC base MAC address has not been set

esp_err_t **esp_efuse_mac_get_custom** (uint8_t *mac)

Return base MAC address which was previously written to BLK3 of EFUSE.

Base MAC address is used to generate the MAC addresses used by the networking interfaces. This API returns the custom base MAC address which was previously written to EFUSE BLK3 in a specified format.

Writing this EFUSE allows setting of a different (non-Espressif) base MAC address. It is also possible to store a custom base MAC address elsewhere, see esp_base_mac_addr_set() for details.

Note: This function is currently only supported on ESP32.

Parameters **mac** -- base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64(used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)

Returns ESP_OK on success ESP_ERR_INVALID_ARG mac is NULL ESP_ERR_INVALID_MAC CUSTOM_MAC address has not been set, all zeros (for esp32-xx) ESP_ERR_INVALID_VERSION An invalid MAC version field was read from BLK3 of EFUSE (for esp32) ESP_ERR_INVALID_CRC An invalid MAC CRC was read from BLK3 of EFUSE (for esp32)

esp_err_t **esp_efuse_mac_get_default** (uint8_t *mac)

Return base MAC address which is factory-programmed by Espressif in EFUSE.

Parameters **mac** -- base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64(used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)

Returns ESP_OK on success ESP_ERR_INVALID_ARG mac is NULL

esp_err_t **esp_read_mac** (uint8_t *mac, *esp_mac_type_t* type)

Read base MAC address and set MAC address of the interface.

This function first get base MAC address using esp_base_mac_addr_get(). Then calculates the MAC address of the specific interface requested, refer to ESP-IDF Programming Guide for the algorithm.

The MAC address set by the esp_iface_mac_addr_set() function will not depend on the base MAC address.

Parameters

- **mac** -- base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64(used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)
- **type** -- Type of MAC address to return

Returns ESP_OK on success

esp_err_t **esp_derive_local_mac** (uint8_t *local_mac, const uint8_t *universal_mac)

Derive local MAC address from universal MAC address.

This function copies a universal MAC address and then sets the "locally

administered" bit (bit 0x2) in the first octet, creating a locally administered MAC address.

If the universal MAC address argument is already a locally administered MAC address, then the first octet is XORed with 0x4 in order to create a different locally administered MAC address.

Parameters

- **local_mac** -- base MAC address, length: 6 bytes. length: 6 bytes for MAC-48
- **universal_mac** -- Source universal MAC address, length: 6 bytes.

Returns ESP_OK on success

esp_err_t **esp_iface_mac_addr_set** (const uint8_t *mac, *esp_mac_type_t* type)

Set custom MAC address of the interface. This function allows you to overwrite the MAC addresses of the interfaces set by the base MAC address.

Parameters

- **mac** -- MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64(used for ESP_MAC_IEEE802154 type, if CONFIG_SOC_IEEE802154_SUPPORTED=y)
- **type** -- Type of MAC address

Returns ESP_OK on success

size_t **esp_mac_addr_len_get** (*esp_mac_type_t* type)

Return the size of the MAC type in bytes.

If CONFIG_SOC_IEEE802154_SUPPORTED is set then for these types:

- ESP_MAC_IEEE802154 is 8 bytes.
- ESP_MAC_BASE, ESP_MAC_EFUSE_FACTORY and ESP_MAC_EFUSE_CUSTOM the MAC size is 6 bytes.
- ESP_MAC_EFUSE_EXT is 2 bytes. If CONFIG_SOC_IEEE802154_SUPPORTED is not set then for all types it returns 6 bytes.

Parameters **type** -- Type of MAC address

Returns 0 MAC type not found (not supported) 6 bytes for MAC-48. 8 bytes for EUI-64.

Macros

MAC2STR(a)

MACSTR

Enumerations

enum **esp_mac_type_t**

Values:

enumerator **ESP_MAC_WIFI_STA**

MAC for WiFi Station (6 bytes)

enumerator **ESP_MAC_WIFI_SOFTAP**

MAC for WiFi Soft-AP (6 bytes)

enumerator **ESP_MAC_BT**

MAC for Bluetooth (6 bytes)

enumerator **ESP_MAC_ETH**

MAC for Ethernet (6 bytes)

enumerator **ESP_MAC_IEEE802154**

if CONFIG_SOC_IEEE802154_SUPPORTED=y, MAC for IEEE802154 (8 bytes)

enumerator **ESP_MAC_BASE**

Base MAC for that used for other MAC types (6 bytes)

enumerator **ESP_MAC_EFUSE_FACTORY**

MAC_FACTORY eFuse which was burned by Espressif in production (6 bytes)

enumerator **ESP_MAC_EFUSE_CUSTOM**

MAC_CUSTOM eFuse which was can be burned by customer (6 bytes)

enumerator **ESP_MAC_EFUSE_EXT**

if CONFIG_SOC_IEEE802154_SUPPORTED=y, MAC_EXT eFuse which is used as an extender for IEEE802154 MAC (2 bytes)

Header File

- components/esp_hw_support/include/esp_chip_info.h
- This header file can be included with:

```
#include "esp_chip_info.h"
```

Functions

void **esp_chip_info**(*esp_chip_info_t* *out_info)

Fill an *esp_chip_info_t* structure with information about the chip.

Parameters **out_info** -- **[out]** structure to be filled

Structures

struct **esp_chip_info_t**

The structure represents information about the chip.

Public Members

esp_chip_model_t **model**

chip model, one of esp_chip_model_t

uint32_t **features**

bit mask of CHIP_FEATURE_x feature flags

uint16_t **revision**

chip revision number (in format MXX; where M - wafer major version, XX - wafer minor version)

uint8_t **cores**

number of CPU cores

Macros

CHIP_FEATURE_EMB_FLASH

Chip has embedded flash memory.

CHIP_FEATURE_WIFI_BGN

Chip has 2.4GHz WiFi.

CHIP_FEATURE_BLE

Chip has Bluetooth LE.

CHIP_FEATURE_BT

Chip has Bluetooth Classic.

CHIP_FEATURE_IEEE802154

Chip has IEEE 802.15.4.

CHIP_FEATURE_EMB_PSRAM

Chip has embedded psram.

Enumerations

enum **esp_chip_model_t**

Chip models.

Values:

enumerator **CHIP_ESP32**

ESP32.

enumerator **CHIP_ESP32S2**

ESP32-S2.

enumerator **CHIP_ESP32S3**

ESP32-S3.

enumerator **CHIP_ESP32C3**

ESP32-C3.

enumerator **CHIP_ESP32C2**

ESP32-C2.

enumerator **CHIP_ESP32C6**

ESP32-C6.

enumerator **CHIP_ESP32H2**

ESP32-H2.

enumerator **CHIP_ESP32P4**

ESP32-P4.

enumerator **CHIP_ESP32C61**

ESP32-C61.

enumerator **CHIP_ESP32C5**

ESP32-C5.

enumerator **CHIP_POSIX_LINUX**

The code is running on POSIX/Linux simulator.

Header File

- components/esp_hw_support/include/esp_cpu.h
- This header file can be included with:

```
#include "esp_cpu.h"
```

Functions

void **esp_cpu_stall** (int core_id)

Stall a CPU core.

Parameters **core_id** -- The core's ID

void **esp_cpu_unstall** (int core_id)

Resume a previously stalled CPU core.

Parameters **core_id** -- The core's ID

void **esp_cpu_reset** (int core_id)

Reset a CPU core.

Parameters **core_id** -- The core's ID

void **esp_cpu_wait_for_intr** (void)

Wait for Interrupt.

This function causes the current CPU core to execute its Wait For Interrupt (WFI or equivalent) instruction. After executing this function, the CPU core will stop execution until an interrupt occurs.

int **esp_cpu_get_core_id** (void)

Get the current core's ID.

This function will return the ID of the current CPU (i.e., the CPU that calls this function).

Returns The current core's ID [0..SOC_CPU_CORES_NUM - 1]

void ***esp_cpu_get_sp** (void)

Read the current stack pointer address.

Returns Stack pointer address

esp_cpu_cycle_count_t **esp_cpu_get_cycle_count** (void)

Get the current CPU core's cycle count.

Each CPU core maintains an internal counter (i.e., cycle count) that increments every CPU clock cycle.

Returns Current CPU's cycle count, 0 if not supported.

void **esp_cpu_set_cycle_count** (*esp_cpu_cycle_count_t* cycle_count)

Set the current CPU core's cycle count.

Set the given value into the internal counter that increments every CPU clock cycle.

Parameters **cycle_count** -- CPU cycle count

void ***esp_cpu_pc_to_addr** (uint32_t pc)

Convert a program counter (PC) value to address.

If the architecture does not store the true virtual address in the CPU's PC or return addresses, this function will convert the PC value to a virtual address. Otherwise, the PC is just returned

Parameters **pc** -- PC value
Returns Virtual address

void **esp_cpu_intr_get_desc** (int core_id, int intr_num, *esp_cpu_intr_desc_t* *intr_desc_ret)

Get a CPU interrupt's descriptor.

Each CPU interrupt has a descriptor describing the interrupt's capabilities and restrictions. This function gets the descriptor of a particular interrupt on a particular CPU.

Parameters
- **core_id** -- **[in]** The core's ID
- **intr_num** -- **[in]** Interrupt number
- **intr_desc_ret** -- **[out]** The interrupt's descriptor

void **esp_cpu_intr_set_ivt_addr** (const void *ivt_addr)

Set the base address of the current CPU's Interrupt Vector Table (IVT)

Parameters **ivt_addr** -- Interrupt Vector Table's base address

void **esp_cpu_intr_set_type** (int intr_num, *esp_cpu_intr_type_t* intr_type)

Set the interrupt type of a particular interrupt.

Set the interrupt type (Level or Edge) of a particular interrupt on the current CPU.

Parameters
- **intr_num** -- Interrupt number (from 0 to 31)
- **intr_type** -- The interrupt's type

esp_cpu_intr_type_t **esp_cpu_intr_get_type** (int intr_num)

Get the current configured type of a particular interrupt.

Get the currently configured type (i.e., level or edge) of a particular interrupt on the current CPU.

Parameters **intr_num** -- Interrupt number (from 0 to 31)
Returns Interrupt type

void **esp_cpu_intr_set_priority** (int intr_num, int intr_priority)

Set the priority of a particular interrupt.

Set the priority of a particular interrupt on the current CPU.

Parameters
- **intr_num** -- Interrupt number (from 0 to 31)
- **intr_priority** -- The interrupt's priority

int **esp_cpu_intr_get_priority** (int intr_num)

Get the current configured priority of a particular interrupt.

Get the currently configured priority of a particular interrupt on the current CPU.

Parameters **intr_num** -- Interrupt number (from 0 to 31)
Returns Interrupt's priority

bool **esp_cpu_intr_has_handler** (int intr_num)

Check if a particular interrupt already has a handler function.

Check if a particular interrupt on the current CPU already has a handler function assigned.

Note: This function simply checks if the IVT of the current CPU already has a handler assigned.

Parameters **intr_num** -- Interrupt number (from 0 to 31)
Returns True if the interrupt has a handler function, false otherwise.

void **esp_cpu_intr_set_handler** (int intr_num, *esp_cpu_intr_handler_t* handler, void *handler_arg)

Set the handler function of a particular interrupt.

Assign a handler function (i.e., ISR) to a particular interrupt on the current CPU.

Note: This function simply sets the handler function (in the IVT) and does not actually enable the interrupt.

Parameters
- **intr_num** -- Interrupt number (from 0 to 31)
- **handler** -- Handler function
- **handler_arg** -- Argument passed to the handler function

void ***esp_cpu_intr_get_handler_arg** (int intr_num)

Get a handler function's argument of.

Get the argument of a previously assigned handler function on the current CPU.

Parameters **intr_num** -- Interrupt number (from 0 to 31)
Returns The the argument passed to the handler function

void **esp_cpu_intr_enable** (uint32_t intr_mask)

Enable particular interrupts on the current CPU.

Parameters **intr_mask** -- Bit mask of the interrupts to enable

void **esp_cpu_intr_disable** (uint32_t intr_mask)

Disable particular interrupts on the current CPU.

Parameters **intr_mask** -- Bit mask of the interrupts to disable

uint32_t **esp_cpu_intr_get_enabled_mask** (void)

Get the enabled interrupts on the current CPU.

Returns Bit mask of the enabled interrupts

void **esp_cpu_intr_edge_ack**(int intr_num)

Acknowledge an edge interrupt.

Parameters **intr_num** -- Interrupt number (from 0 to 31)

void **esp_cpu_configure_region_protection**(void)

Configure the CPU to disable access to invalid memory regions.

esp_err_t **esp_cpu_set_breakpoint**(int bp_num, const void *bp_addr)

Set and enable a hardware breakpoint on the current CPU.

Note: This function is meant to be called by the panic handler to set a breakpoint for an attached debugger during a panic.

Note: Overwrites previously set breakpoint with same breakpoint number.

Parameters
- **bp_num** -- Hardware breakpoint number [0..SOC_CPU_BREAKPOINTS_NUM - 1]
- **bp_addr** -- Address to set a breakpoint on

Returns ESP_OK if breakpoint is set. Failure otherwise

esp_err_t **esp_cpu_clear_breakpoint**(int bp_num)

Clear a hardware breakpoint on the current CPU.

Note: Clears a breakpoint regardless of whether it was previously set

Parameters **bp_num** -- Hardware breakpoint number [0..SOC_CPU_BREAKPOINTS_NUM - 1]

Returns ESP_OK if breakpoint is cleared. Failure otherwise

esp_err_t **esp_cpu_set_watchpoint**(int wp_num, const void *wp_addr, size_t size, *esp_cpu_watchpoint_trigger_t* trigger)

Set and enable a hardware watchpoint on the current CPU.

Set and enable a hardware watchpoint on the current CPU, specifying the memory range and trigger operation. Watchpoints will break/panic the CPU when the CPU accesses (according to the trigger type) on a certain memory range.

Note: Overwrites previously set watchpoint with same watchpoint number. On RISC-V chips, this API uses method0(Exact matching) and method1(NAPOT matching) according to the riscv-debug-spec-0.13 specification for address matching. If the watch region size is 1byte, it uses exact matching (method 0). If the watch region size is larger than 1byte, it uses NAPOT matching (method 1). This mode requires the watching region start address to be aligned to the watching region size.

Parameters
- **wp_num** -- Hardware watchpoint number [0..SOC_CPU_WATCHPOINTS_NUM - 1]
- **wp_addr** -- Watchpoint's base address, must be naturally aligned to the size of the region
- **size** -- Size of the region to watch. Must be one of 2^n and in the range of [1 ... SOC_CPU_WATCHPOINT_MAX_REGION_SIZE]
- **trigger** -- Trigger type

Returns ESP_ERR_INVALID_ARG on invalid arg, ESP_OK otherwise

esp_err_t **esp_cpu_clear_watchpoint** (int wp_num)

Clear a hardware watchpoint on the current CPU.

Note: Clears a watchpoint regardless of whether it was previously set

Parameters **wp_num** -- Hardware watchpoint number [0..SOC_CPU_WATCHPOINTS_NUM - 1]

Returns ESP_OK if watchpoint was cleared. Failure otherwise.

bool **esp_cpu_dbgr_is_attached** (void)

Check if the current CPU has a debugger attached.

Returns True if debugger is attached, false otherwise

void **esp_cpu_dbgr_break** (void)

Trigger a call to the current CPU's attached debugger.

intptr_t **esp_cpu_get_call_addr** (intptr_t return_address)

Given the return address, calculate the address of the preceding call instruction This is typically used to answer the question "where was the function called from?".

Parameters **return_address** -- The value of the return address register. Typically set to the value of __builtin_return_address(0).

Returns Address of the call instruction preceding the return address.

bool **esp_cpu_compare_and_set** (volatile uint32_t *addr, uint32_t compare_value, uint32_t new_value)

Atomic compare-and-set operation.

Parameters

- **addr** -- Address of atomic variable
- **compare_value** -- Value to compare the atomic variable to
- **new_value** -- New value to set the atomic variable to

Returns Whether the atomic variable was set or not

Structures

struct **esp_cpu_intr_desc_t**

CPU interrupt descriptor.

Each particular CPU interrupt has an associated descriptor describing that particular interrupt's characteristics. Call esp_cpu_intr_get_desc() to get the descriptors of a particular interrupt.

Public Members

int **priority**

Priority of the interrupt if it has a fixed priority, (-1) if the priority is configurable.

esp_cpu_intr_type_t **type**

Whether the interrupt is an edge or level type interrupt, ESP_CPU_INTR_TYPE_NA if the type is configurable.

uint32_t **flags**

Flags indicating extra details.

Macros

ESP_CPU_INTR_DESC_FLAG_SPECIAL

Interrupt descriptor flags of *esp_cpu_intr_desc_t*.

The interrupt is a special interrupt (e.g., a CPU timer interrupt)

ESP_CPU_INTR_DESC_FLAG_RESVD

The interrupt is reserved for internal use

Type Definitions

typedef uint32_t **esp_cpu_cycle_count_t**

CPU cycle count type.

This data type represents the CPU's clock cycle count

typedef void (*__esp_cpu_intr_handler_t__)(void *arg)

CPU interrupt handler type.

Enumerations

enum **esp_cpu_intr_type_t**

CPU interrupt type.

Values:

enumerator **ESP_CPU_INTR_TYPE_LEVEL**

enumerator **ESP_CPU_INTR_TYPE_EDGE**

enumerator **ESP_CPU_INTR_TYPE_NA**

enum **esp_cpu_watchpoint_trigger_t**

CPU watchpoint trigger type.

Values:

enumerator **ESP_CPU_WATCHPOINT_LOAD**

enumerator **ESP_CPU_WATCHPOINT_STORE**

enumerator **ESP_CPU_WATCHPOINT_ACCESS**

Header File

- components/esp_app_format/include/esp_app_desc.h
- This header file can be included with:

```
#include "esp_app_desc.h"
```

- This header file is a part of the API provided by the `esp_app_format` component. To declare that your component depends on `esp_app_format`, add the following to your CMakeLists.txt:

```
REQUIRES esp_app_format
```

or

```
PRIV_REQUIRES esp_app_format
```

Functions

const *esp_app_desc_t* ***esp_app_get_description*** (void)

Return esp_app_desc structure. This structure includes app version.

Return description for running app.

Returns Pointer to esp_app_desc structure.

int ***esp_app_get_elf_sha256*** (char *dst, size_t size)

Fill the provided buffer with SHA256 of the ELF file, formatted as hexadecimal, null-terminated. If the buffer size is not sufficient to fit the entire SHA256 in hex plus a null terminator, the largest possible number of bytes will be written followed by a null.

Parameters

- **dst** -- Destination buffer
- **size** -- Size of the buffer

Returns Number of bytes written to dst (including null terminator)

char ***esp_app_get_elf_sha256_str*** (void)

Return SHA256 of the ELF file which is already formatted as hexadecimal, null-terminated included. Can be used in panic handler or core dump during when cache is disabled. The length is defined by CONFIG_APP_RETRIEVE_LEN_ELF_SHA option.

Returns Hexadecimal SHA256 string

Structures

struct ***esp_app_desc_t***

Description about application.

Public Members

uint32_t ***magic_word***

Magic word ESP_APP_DESC_MAGIC_WORD

uint32_t ***secure_version***

Secure version

uint32_t ***reserv1***[2]

reserv1

char ***version***[32]

Application version

char ***project_name***[32]

Project name

char ***time***[16]

Compile time

char **date**[16]

Compile date

char **idf_ver**[32]

Version IDF

uint8_t **app_elf_sha256**[32]

sha256 of elf file

uint32_t **reserv2**[20]

reserv2

Macros

ESP_APP_DESC_MAGIC_WORD

The magic word for the esp_app_desc structure that is in DROM.

2.10.22 Over The Air Updates (OTA)

OTA Process Overview

The OTA update mechanism allows a device to update itself based on data received while the normal firmware is running (for example, over Wi-Fi, Bluetooth or Ethernet).

OTA requires configuring the *Partition Tables* of the device with at least two OTA app slot partitions (i.e., `ota_0` and `ota_1`) and an OTA Data Partition.

The OTA operation functions write a new app firmware image to whichever OTA app slot that is currently not selected for booting. Once the image is verified, the OTA Data partition is updated to specify that this image should be used for the next boot.

OTA Data Partition

An OTA data partition (type `data`, subtype `ota`) must be included in the *Partition Tables* of any project which uses the OTA functions.

For factory boot settings, the OTA data partition should contain no data (all bytes erased to 0xFF). In this case, the ESP-IDF software bootloader will boot the factory app if it is present in the partition table. If no factory app is included in the partition table, the first available OTA slot (usually `ota_0`) is booted.

After the first OTA update, the OTA data partition is updated to specify which OTA app slot partition should be booted next.

The OTA data partition is two flash sectors (0x2000 bytes) in size, to prevent problems if there is a power failure while it is being written. Sectors are independently erased and written with matching data, and if they disagree a counter field is used to determine which sector was written more recently.

App Rollback

The main purpose of the application rollback is to keep the device working after the update. This feature allows you to roll back to the previous working application in case a new application has critical errors. When the rollback process is enabled and an OTA update provides a new version of the app, one of three things can happen:

- The application works fine, *esp_ota_mark_app_valid_cancel_rollback()* marks the running application with the state ESP_OTA_IMG_VALID. There are no restrictions on booting this application.
- The application has critical errors and further work is not possible, a rollback to the previous application is required, *esp_ota_mark_app_invalid_rollback_and_reboot()* marks the running application with the state ESP_OTA_IMG_INVALID and reset. This application will not be selected by the bootloader for boot and will boot the previously working application.
- If the *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is set, and a reset occurs without calling either function then the application is rolled back.

The following code serves detect the initial boot for an application after the OTA update. Upon the first boot, the application checks its state and performs diagnostics. If the diagnostics are successful, the application should call *esp_ota_mark_app_valid_cancel_rollback()* to confirm the operability of the application. If the diagnostics fail, the application should call *esp_ota_mark_app_invalid_rollback_and_reboot()* to roll back to the previous working application.

If the application is not able to boot or execute this code due to an abort/reboot/power loss error, the bootloader marks this application as ESP_OTA_IMG_INVALID in the next booting attempt and rolls back to the previous working application.

```
const esp_partition_t *running = esp_ota_get_running_partition();
esp_ota_img_states_t ota_state;
if (esp_ota_get_state_partition(running, &ota_state) == ESP_OK) {
    if (ota_state == ESP_OTA_IMG_PENDING_VERIFY) {
        // run diagnostic function ...
        bool diagnostic_is_ok = diagnostic();
        if (diagnostic_is_ok) {
            ESP_LOGI(TAG, "Diagnostics completed successfully! Continuing␣
↪execution ...");
            esp_ota_mark_app_valid_cancel_rollback();
        } else {
            ESP_LOGE(TAG, "Diagnostics failed! Start rollback to the previous␣
↪version ...");
            esp_ota_mark_app_invalid_rollback_and_reboot();
        }
    }
}
```

For the example incorporating the above code snippet, see the system/ota/native_ota_example example.

Note: The state is not written to the binary image of the application but rather to the otadata partition. The partition contains a ota_seq counter, which is a pointer to the slot (ota_0, ota_1, ...) from which the application will be selected for boot.

App OTA State States control the process of selecting a boot app:

States	Restriction of selecting a boot app in bootloader
ESP_OTA_IMG_VALID	None restriction. Will be selected.
ESP_OTA_IMG_UNDEFINED	None restriction. Will be selected.
ESP_OTA_IMG_INVALID	Will not be selected.
ESP_OTA_IMG_ABORTED	Will not be selected.
ESP_OTA_IMG_NEW	If *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is set it will be selected only once. In bootloader the state immediately changes to ESP_OTA_IMG_PENDING_VERIFY.
ESP_OTA_IMG_PENDING_VERIFY	If *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is set it will not be selected, and the state will change to ESP_OTA_IMG_ABORTED.

If *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is not enabled (by default), then the use of the following functions *esp_ota_mark_app_valid_cancel_rollback()* and

esp_ota_mark_app_invalid_rollback_and_reboot() are optional, and ESP_OTA_IMG_NEW and ESP_OTA_IMG_PENDING_VERIFY states are not used.

An option in Kconfig *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* allows you to track the first boot of a new application. In this case, the application must confirm its operability by calling *esp_ota_mark_app_valid_cancel_rollback()* function, otherwise the application will be rolled back upon reboot. It allows you to control the operability of the application during the boot phase. Thus, a new application has only one attempt to boot successfully.

Rollback Process The description of the rollback process when *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is enabled:

- The new application is successfully downloaded and *esp_ota_set_boot_partition()* function makes this partition bootable and sets the state ESP_OTA_IMG_NEW. This state means that the application is new and should be monitored for its first boot.
- Reboot *esp_restart()*.
- The bootloader checks for the ESP_OTA_IMG_PENDING_VERIFY state if it is set, then it will be written to ESP_OTA_IMG_ABORTED.
- The bootloader selects a new application to boot so that the state is not set as ESP_OTA_IMG_INVALID or ESP_OTA_IMG_ABORTED.
- The bootloader checks the selected application for ESP_OTA_IMG_NEW state if it is set, then it will be written to ESP_OTA_IMG_PENDING_VERIFY. This state means that the application requires confirmation of its operability, if this does not happen and a reboot occurs, this state will be overwritten to ESP_OTA_IMG_ABORTED (see above) and this application will no longer be able to start, i.e., there will be a rollback to the previous working application.
- A new application has started and should make a self-test.
- If the self-test has completed successfully, then you must call the function *esp_ota_mark_app_valid_cancel_rollback()* because the application is awaiting confirmation of operability (ESP_OTA_IMG_PENDING_VERIFY state).
- If the self-test fails, then call *esp_ota_mark_app_invalid_rollback_and_reboot()* function to roll back to the previous working application, while the invalid application is set ESP_OTA_IMG_INVALID state.
- If the application has not been confirmed, the state remains ESP_OTA_IMG_PENDING_VERIFY, and the next boot it will be changed to ESP_OTA_IMG_ABORTED, which prevents re-boot of this application. There will be a rollback to the previous working application.

Unexpected Reset If a power loss or an unexpected crash occurs at the time of the first boot of a new application, it will roll back the application.

Recommendation: Perform the self-test procedure as quickly as possible, to prevent rollback due to power loss.

Only OTA partitions can be rolled back. Factory partition is not rolled back.

Booting Invalid/aborted Apps Booting an application which was previously set to ESP_OTA_IMG_INVALID or ESP_OTA_IMG_ABORTED is possible:

- Get the last invalid application partition *esp_ota_get_last_invalid_partition()*.
- Pass the received partition to *esp_ota_set_boot_partition()*, this will update the otadata.
- Restart *esp_restart()*. The bootloader will boot the specified application.

To determine if self-tests should be run during startup of an application, call the *esp_ota_get_state_partition()* function. If result is ESP_OTA_IMG_PENDING_VERIFY then self-testing and subsequent confirmation of operability is required.

Where the States Are Set A brief description of where the states are set:

- ESP_OTA_IMG_VALID state is set by *esp_ota_mark_app_valid_cancel_rollback()* function.

- ESP_OTA_IMG_UNDEFINED state is set by *esp_ota_set_boot_partition()* function if *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is not enabled.
- ESP_OTA_IMG_NEW state is set by *esp_ota_set_boot_partition()* function if *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is enabled.
- ESP_OTA_IMG_INVALID state is set by *esp_ota_mark_app_invalid_rollback_and_reboot()* function.
- ESP_OTA_IMG_ABORTED state is set if there was no confirmation of the application operability and occurs reboots (if *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is enabled).
- ESP_OTA_IMG_PENDING_VERIFY state is set in a bootloader if *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* option is enabled and selected app has ESP_OTA_IMG_NEW state.

Anti-rollback

Anti-rollback prevents rollback to application with security version lower than one programmed in eFuse of chip.

This function works if set *CONFIG_BOOTLOADER_APP_ANTI_ROLLBACK* option. In the bootloader, when selecting a bootable application, an additional security version check is added which is on the chip and in the application image. The version in the bootable firmware must be greater than or equal to the version in the chip.

CONFIG_BOOTLOADER_APP_ANTI_ROLLBACK and *CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE* options are used together. In this case, rollback is possible only on the security version which is equal or higher than the version in the chip.

A Typical Anti-rollback Scheme Is

- New firmware released with the elimination of vulnerabilities with the previous version of security.
- After the developer makes sure that this firmware is working. He can increase the security version and release a new firmware.
- Download new application.
- To make it bootable, run the function *esp_ota_set_boot_partition()*. If the security version of the new application is smaller than the version in the chip, the new application will be erased. Update to new firmware is not possible.
- Reboot.
- In the bootloader, an application with a security version greater than or equal to the version in the chip will be selected. If otadata is in the initial state, and one firmware was loaded via a serial channel, whose secure version is higher than the chip, then the secure version of efuse will be immediately updated in the bootloader.
- New application booted. Then the application should perform diagnostics of the operation and if it is completed successfully, you should call *esp_ota_mark_app_valid_cancel_rollback()* function to mark the running application with the ESP_OTA_IMG_VALID state and update the secure version on chip. Note that if was called *esp_ota_mark_app_invalid_rollback_and_reboot()* function a rollback may not happen as the device may not have any bootable apps. It will then return ESP_ERR_OTA_ROLLBACK_FAILED error and stay in the ESP_OTA_IMG_PENDING_VERIFY state.
- The next update of app is possible if a running app is in the ESP_OTA_IMG_VALID state.

Recommendation:

If you want to avoid the download/erase overhead in case of the app from the server has security version lower than the running app, you have to get `new_app_info.secure_version` from the first package of an image and compare it with the secure version of efuse. Use `esp_efuse_check_secure_version(new_app_info.secure_version)` function if it is true then continue downloading otherwise abort.

```
....
bool image_header_was_checked = false;
while (1) {
    int data_read = esp_http_client_read(client, ota_write_data, BUFFSIZE);
    ...
    if (data_read > 0) {
        if (image_header_was_checked == false) {
```

(continues on next page)

(continued from previous page)

```
            esp_app_desc_t new_app_info;
            if (data_read > sizeof(esp_image_header_t) + sizeof(esp_image_segment_
↪header_t) + sizeof(esp_app_desc_t)) {
                // check current version with downloading
                if (esp_efuse_check_secure_version(new_app_info.secure_version) ==␣
↪false) {
                  ESP_LOGE(TAG, "This a new app can not be downloaded due to a␣
↪secure version is lower than stored in efuse.");
                  http_cleanup(client);
                  task_fatal_error();
                }

                image_header_was_checked = true;

                esp_ota_begin(update_partition, OTA_SIZE_UNKNOWN, &update_handle);
            }
        }
        esp_ota_write( update_handle, (const void *)ota_write_data, data_read);
    }
}
...
```

Restrictions:

- The number of bits in the `secure_version` field is limited to 16 bits. This means that only 16 times you can do an anti-rollback. You can reduce the length of this efuse field using *CONFIG_BOOTLOADER_APP_SEC_VER_SIZE_EFUSE_FIELD* option.
- Factory and Test partitions are not supported in anti rollback scheme and hence partition table should not have partition with SubType set to `factory` or `test`.

`security_version`:

- In application image it is stored in `esp_app_desc` structure. The number is set *CONFIG_BOOTLOADER_APP_SECURE_VERSION*.

Secure OTA Updates Without Secure Boot

The verification of signed OTA updates can be performed even without enabling hardware secure boot. This can be achieved by setting *CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT* and *CONFIG_SECURE_SIGNED_ON_UPDATE_NO_SECURE_BOOT*

Tuning OTA Performance

- Erasing the update partition at once instead of sequential erasing (default mechanism) while write operation might help in reducing the overall time taken for firmware upgrade. To enable this, set *esp_https_ota_config_t::bulk_flash_erase* to true in *esp_https_ota_config_t* structure. If the partition to be erased is too large, task watchdog could be triggered. It is advised to increase the watchdog timeout in such cases.

```
esp_https_ota_config_t ota_config = {
    .bulk_flash_erase = true,
}
```

- Tuning the `esp_https_ota_config_t::http_config::buffer_size` can also help in improving the OTA performance.
- *esp_https_ota_config_t* has a member *esp_https_ota_config_t::buffer_caps* which can be used to specify the memory type to use when allocating memory to the OTA buffer. Configuring

this value to MALLOC_CAP_INTERNAL might help in improving the OTA performance when SPIRAM is enabled.
- For optimizing network performance, please refer to **Improving Network Speed** section in the *Speed Optimization* for more details.

OTA Tool `otatool.py`

The component `app_update` provides a tool app_update/otatool.py for performing OTA partition-related operations on a target device. The following operations can be performed using the tool:

- read contents of otadata partition (read_otadata)
- erase otadata partition, effectively resetting device to factory app (erase_otadata)
- switch OTA partitions (switch_ota_partition)
- erasing OTA partition (erase_ota_partition)
- write to OTA partition (write_ota_partition)
- read contents of OTA partition (read_ota_partition)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool's Python API and command-line interface, respectively.

Python API Before anything else, make sure that the `otatool` module is imported.

```
import sys
import os

idf_path = os.environ["IDF_PATH"]  # get value of IDF_PATH from environment
otatool_dir = os.path.join(idf_path, "components", "app_update")  # otatool.py␣
↪lives in $IDF_PATH/components/app_update

sys.path.append(otatool_dir)  # this enables Python to find otatool module
from otatool import *  # import all names inside otatool module
```

The starting point for using the tool's Python API to do is create a `OtatoolTarget` object:

```
# Create a parttool.py target device connected on serial port /dev/ttyUSB1
target = OtatoolTarget("/dev/ttyUSB1")
```

The created object can now be used to perform operations on the target device:

```
# Erase otadata, resetting the device to factory app
target.erase_otadata()

# Erase contents of OTA app slot 0
target.erase_ota_partition(0)

# Switch boot partition to that of app slot 1
target.switch_ota_partition(1)

# Read OTA partition 'ota_3' and save contents to a file named 'ota_3.bin'
target.read_ota_partition("ota_3", "ota_3.bin")
```

The OTA partition to operate on is specified using either the app slot number or the partition name.

More information on the Python API is available in the docstrings for the tool.

Command-line Interface The command-line interface of `otatool.py` has the following structure:

```
otatool.py [command-args] [subcommand] [subcommand-args]

- command-args - these are arguments that are needed for executing the main␣
↪command (parttool.py), mostly pertaining to the target device
- subcommand - this is the operation to be performed
- subcommand-args - these are arguments that are specific to the chosen operation
```

```
# Erase otadata, resetting the device to factory app
otatool.py --port "/dev/ttyUSB1" erase_otadata

# Erase contents of OTA app slot 0
otatool.py --port "/dev/ttyUSB1" erase_ota_partition --slot 0

# Switch boot partition to that of app slot 1
otatool.py --port "/dev/ttyUSB1" switch_ota_partition --slot 1

# Read OTA partition 'ota_3' and save contents to a file named 'ota_3.bin'
otatool.py --port "/dev/ttyUSB1" read_ota_partition --name=ota_3 --output=ota_3.bin
```

More information can be obtained by specifying `--help` as argument:

```
# Display possible subcommands and show main command argument descriptions
otatool.py --help

# Show descriptions for specific subcommand arguments
otatool.py [subcommand] --help
```

Application Example

End-to-end example of OTA firmware update workflow: system/ota.

API Reference

Header File

- components/app_update/include/esp_ota_ops.h
- This header file can be included with:

```
#include "esp_ota_ops.h"
```

- This header file is a part of the API provided by the `app_update` component. To declare that your component depends on `app_update`, add the following to your CMakeLists.txt:

```
REQUIRES app_update
```

or

```
PRIV_REQUIRES app_update
```

Functions

const *esp_app_desc_t* ***esp_ota_get_app_description*** (void)

Return esp_app_desc structure. This structure includes app version.

Return description for running app.

Note: This API is present for backward compatibility reasons. Alternative function with the same functionality is `esp_app_get_description`

Returns Pointer to esp_app_desc structure.

int ***esp_ota_get_app_elf_sha256*** (char *dst, size_t size)

Fill the provided buffer with SHA256 of the ELF file, formatted as hexadecimal, null-terminated. If the buffer size is not sufficient to fit the entire SHA256 in hex plus a null terminator, the largest possible number of bytes will be written followed by a null.

Note: This API is present for backward compatibility reasons. Alternative function with the same functionality is `esp_app_get_elf_sha256`

Parameters
- **dst** -- Destination buffer
- **size** -- Size of the buffer

Returns Number of bytes written to dst (including null terminator)

esp_err_t ***esp_ota_begin*** (const *esp_partition_t* *partition, size_t image_size, *esp_ota_handle_t* *out_handle)

Commence an OTA update writing to the specified partition.

The specified partition is erased to the specified image size.

If image size is not yet known, pass OTA_SIZE_UNKNOWN which will cause the entire partition to be erased.

On success, this function allocates memory that remains in use until esp_ota_end() is called with the returned handle.

Note: If the rollback option is enabled and the running application has the ESP_OTA_IMG_PENDING_VERIFY state then it will lead to the ESP_ERR_OTA_ROLLBACK_INVALID_STATE error. Confirm the running app before to run download a new app, use esp_ota_mark_app_valid_cancel_rollback() function for it (this should be done as early as possible when you first download a new application).

Parameters
- **partition** -- Pointer to info for partition which will receive the OTA update. Required.
- **image_size** -- Size of new OTA app image. Partition will be erased in order to receive this size of image. If 0 or OTA_SIZE_UNKNOWN, the entire partition is erased.
- **out_handle** -- On success, returns a handle which should be used for subsequent esp_ota_write() and esp_ota_end() calls.

Returns
- ESP_OK: OTA operation commenced successfully.
- ESP_ERR_INVALID_ARG: partition or out_handle arguments were NULL, or partition doesn't point to an OTA app partition.
- ESP_ERR_NO_MEM: Cannot allocate memory for OTA operation.
- ESP_ERR_OTA_PARTITION_CONFLICT: Partition holds the currently running firmware, cannot update in place.
- ESP_ERR_NOT_FOUND: Partition argument not found in partition table.
- ESP_ERR_OTA_SELECT_INFO_INVALID: The OTA data partition contains invalid data.

- ESP_ERR_INVALID_SIZE: Partition doesn't fit in configured flash size.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_ROLLBACK_INVALID_STATE: If the running app has not confirmed state. Before performing an update, the application must be valid.

esp_err_t **esp_ota_write**(*esp_ota_handle_t* handle, const void *data, size_t size)

Write OTA update data to partition.

This function can be called multiple times as data is received during the OTA operation. Data is written sequentially to the partition.

Parameters
- **handle** -- Handle obtained from esp_ota_begin
- **data** -- Data buffer to write
- **size** -- Size of data buffer in bytes.

Returns
- ESP_OK: Data was written to flash successfully, or size = 0
- ESP_ERR_INVALID_ARG: handle is invalid.
- ESP_ERR_OTA_VALIDATE_FAILED: First byte of image contains invalid app image magic byte.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_SELECT_INFO_INVALID: OTA data partition has invalid contents
- ESP_ERR_INVALID_SIZE: if write would go out of bounds of the partition
- or one of error codes from lower-level flash driver.

esp_err_t **esp_ota_write_with_offset**(*esp_ota_handle_t* handle, const void *data, size_t size, uint32_t offset)

Write OTA update data to partition at an offset.

This function can write data in non-contiguous manner. If flash encryption is enabled, data should be 16 bytes aligned.

Note: While performing OTA, if the packets arrive out of order, esp_ota_write_with_offset() can be used to write data in non-contiguous manner. Use of esp_ota_write_with_offset() in combination with esp_ota_write() is not recommended.

Parameters
- **handle** -- Handle obtained from esp_ota_begin
- **data** -- Data buffer to write
- **size** -- Size of data buffer in bytes
- **offset** -- Offset in flash partition

Returns
- ESP_OK: Data was written to flash successfully.
- ESP_ERR_INVALID_ARG: handle is invalid.
- ESP_ERR_OTA_VALIDATE_FAILED: First byte of image contains invalid app image magic byte.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_SELECT_INFO_INVALID: OTA data partition has invalid contents

esp_err_t **esp_ota_end**(*esp_ota_handle_t* handle)

Finish OTA update and validate newly written app image.

Note: After calling esp_ota_end(), the handle is no longer valid and any memory associated with it is freed (regardless of result).

Parameters **handle** -- Handle obtained from esp_ota_begin().

Returns

- ESP_OK: Newly written OTA app image is valid.
- ESP_ERR_NOT_FOUND: OTA handle was not found.
- ESP_ERR_INVALID_ARG: Handle was never written to.
- ESP_ERR_OTA_VALIDATE_FAILED: OTA image is invalid (either not a valid app image, or - if secure boot is enabled - signature failed to verify.)
- ESP_ERR_INVALID_STATE: If flash encryption is enabled, this result indicates an internal error writing the final encrypted bytes to flash.

esp_err_t **esp_ota_abort** (*esp_ota_handle_t* handle)

Abort OTA update, free the handle and memory associated with it.

Parameters **handle** -- obtained from esp_ota_begin().

Returns

- ESP_OK: Handle and its associated memory is freed successfully.
- ESP_ERR_NOT_FOUND: OTA handle was not found.

esp_err_t **esp_ota_set_boot_partition** (const *esp_partition_t* *partition)

Configure OTA data for a new boot partition.

Note: If this function returns ESP_OK, calling esp_restart() will boot the newly configured app partition.

Parameters **partition** -- Pointer to info for partition containing app image to boot.

Returns

- ESP_OK: OTA data updated, next reboot will use specified partition.
- ESP_ERR_INVALID_ARG: partition argument was NULL or didn't point to a valid OTA partition of type "app".
- ESP_ERR_OTA_VALIDATE_FAILED: Partition contained invalid app image. Also returned if secure boot is enabled and signature validation failed.
- ESP_ERR_NOT_FOUND: OTA data partition not found.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash erase or write failed.

const *esp_partition_t* ***esp_ota_get_boot_partition** (void)

Get partition info of currently configured boot app.

If esp_ota_set_boot_partition() has been called, the partition which was set by that function will be returned.

If esp_ota_set_boot_partition() has not been called, the result is usually the same as esp_ota_get_running_partition(). The two results are not equal if the configured boot partition does not contain a valid app (meaning that the running partition will be an app that the bootloader chose via fallback).

If the OTA data partition is not present or not valid then the result is the first app partition found in the partition table. In priority order, this means: the factory app, the first OTA app slot, or the test app partition.

Note that there is no guarantee the returned partition is a valid app. Use esp_image_verify(ESP_IMAGE_VERIFY, ...) to verify if the returned partition contains a bootable image.

Returns Pointer to info for partition structure, or NULL if partition table is invalid or a flash read operation failed. Any returned pointer is valid for the lifetime of the application.

const *esp_partition_t* ***esp_ota_get_running_partition** (void)

Get partition info of currently running app.

This function is different to esp_ota_get_boot_partition() in that it ignores any change of selected boot partition caused by esp_ota_set_boot_partition(). Only the app whose code is currently running will have its partition information returned.

The partition returned by this function may also differ from esp_ota_get_boot_partition() if the configured boot partition is somehow invalid, and the bootloader fell back to a different app partition at boot.

Returns Pointer to info for partition structure, or NULL if no partition is found or flash read operation failed. Returned pointer is valid for the lifetime of the application.

const *esp_partition_t* ***esp_ota_get_next_update_partition*** (const *esp_partition_t* *start_from)

Return the next OTA app partition which should be written with a new firmware.

Call this function to find an OTA app partition which can be passed to esp_ota_begin().

Finds next partition round-robin, starting from the current running partition.

Parameters **start_from** -- If set, treat this partition info as describing the current running partition. Can be NULL, in which case esp_ota_get_running_partition() is used to find the currently running partition. The result of this function is never the same as this argument.

Returns Pointer to info for partition which should be updated next. NULL result indicates invalid OTA data partition, or that no eligible OTA app slot partition was found.

esp_err_t ***esp_ota_get_partition_description*** (const *esp_partition_t* *partition, *esp_app_desc_t* *app_desc)

Returns esp_app_desc structure for app partition. This structure includes app version.

Returns a description for the requested app partition.

Parameters

- **partition** -- **[in]** Pointer to app partition. (only app partition)
- **app_desc** -- **[out]** Structure of info about app.

Returns

- ESP_OK Successful.
- ESP_ERR_NOT_FOUND app_desc structure is not found. Magic word is incorrect.
- ESP_ERR_NOT_SUPPORTED Partition is not application.
- ESP_ERR_INVALID_ARG Arguments is NULL or if partition's offset exceeds partition size.
- ESP_ERR_INVALID_SIZE Read would go out of bounds of the partition.
- or one of error codes from lower-level flash driver.

esp_err_t ***esp_ota_get_bootloader_description*** (const *esp_partition_t* *bootloader_partition, *esp_bootloader_desc_t* *desc)

Returns the description structure of the bootloader.

Parameters

- **bootloader_partition** -- **[in]** Pointer to bootloader partition. If NULL, then the current bootloader is used (the default location). offset = CONFIG_BOOTLOADER_OFFSET_IN_FLASH, size = CONFIG_PARTITION_TABLE_OFFSET - CONFIG_BOOTLOADER_OFFSET_IN_FLASH,
- **desc** -- **[out]** Structure of info about bootloader.

Returns

- ESP_OK Successful.
- ESP_ERR_NOT_FOUND Description structure is not found in the bootloader image. Magic byte is incorrect.
- ESP_ERR_INVALID_ARG Arguments is NULL.
- ESP_ERR_INVALID_SIZE Read would go out of bounds of the partition.
- or one of error codes from lower-level flash driver.

uint8_t ***esp_ota_get_app_partition_count*** (void)

Returns number of ota partitions provided in partition table.

Returns

- Number of OTA partitions

esp_err_t **esp_ota_mark_app_valid_cancel_rollback**(void)

This function is called to indicate that the running app is working well.

Returns
- ESP_OK: if successful.

esp_err_t **esp_ota_mark_app_invalid_rollback_and_reboot**(void)

This function is called to roll back to the previously workable app with reboot.

If rollback is successful then device will reset else API will return with error code. Checks applications on a flash drive that can be booted in case of rollback. If the flash does not have at least one app (except the running app) then rollback is not possible.

Returns
- ESP_FAIL: if not successful.
- ESP_ERR_OTA_ROLLBACK_FAILED: The rollback is not possible due to flash does not have any apps.

const *esp_partition_t* ***esp_ota_get_last_invalid_partition**(void)

Returns last partition with invalid state (ESP_OTA_IMG_INVALID or ESP_OTA_IMG_ABORTED).

Returns partition.

esp_err_t **esp_ota_get_state_partition**(const *esp_partition_t* *partition, esp_ota_img_states_t *ota_state)

Returns state for given partition.

Parameters
- **partition** -- **[in]** Pointer to partition.
- **ota_state** -- **[out]** state of partition (if this partition has a record in otadata).

Returns
- ESP_OK: Successful.
- ESP_ERR_INVALID_ARG: partition or ota_state arguments were NULL.
- ESP_ERR_NOT_SUPPORTED: partition is not ota.
- ESP_ERR_NOT_FOUND: Partition table does not have otadata or state was not found for given partition.

esp_err_t **esp_ota_erase_last_boot_app_partition**(void)

Erase previous boot app partition and corresponding otadata select for this partition.

When current app is marked to as valid then you can erase previous app partition.

Returns
- ESP_OK: Successful, otherwise ESP_ERR.

bool **esp_ota_check_rollback_is_possible**(void)

Checks applications on the slots which can be booted in case of rollback.

These applications should be valid (marked in otadata as not UNDEFINED, INVALID or ABORTED and crc is good) and be able booted, and secure_version of app >= secure_version of efuse (if anti-rollback is enabled).

Returns
- True: Returns true if the slots have at least one app (except the running app).
- False: The rollback is not possible.

esp_err_t **esp_ota_revoke_secure_boot_public_key**(*esp_ota_secure_boot_public_key_index_t* index)

Revokes the signature digest denoted by the given index. This should be called in the application only after the rollback logic otherwise the device may end up in unrecoverable state.

Relevant for Secure boot v2 on ESP32-S2, ESP32-S3, ESP32-C3, ESP32-C6, ESP32-H2 where up to 3 key digests can be stored (Key #N-1, Key #N, Key #N+1). When a key used to sign an app is invalidated, an OTA update is to be sent with an app signed with at least one of the other two keys which has not been revoked already. After successfully booting the OTA app should call this function to revoke Key #N-1.

Parameters `index` -- - The index of the signature block to be revoked

Returns

- ESP_OK: If revocation is successful.
- ESP_ERR_INVALID_ARG: If the index of the public key to be revoked is incorrect.
- ESP_FAIL: If secure boot v2 has not been enabled.

Macros

`OTA_SIZE_UNKNOWN`

Used for esp_ota_begin() if new image size is unknown

`OTA_WITH_SEQUENTIAL_WRITES`

Used for esp_ota_begin() if new image size is unknown and erase can be done in incremental manner (assuming write operation is in continuous sequence)

`ESP_ERR_OTA_BASE`

Base error code for ota_ops api

`ESP_ERR_OTA_PARTITION_CONFLICT`

Error if request was to write or erase the current running partition

`ESP_ERR_OTA_SELECT_INFO_INVALID`

Error if OTA data partition contains invalid content

`ESP_ERR_OTA_VALIDATE_FAILED`

Error if OTA app image is invalid

`ESP_ERR_OTA_SMALL_SEC_VER`

Error if the firmware has a secure version less than the running firmware.

`ESP_ERR_OTA_ROLLBACK_FAILED`

Error if flash does not have valid firmware in passive partition and hence rollback is not possible

`ESP_ERR_OTA_ROLLBACK_INVALID_STATE`

Error if current active firmware is still marked in pending validation state (ESP_OTA_IMG_PENDING_VERIFY), essentially first boot of firmware image post upgrade and hence firmware upgrade is not possible

Type Definitions

typedef uint32_t **`esp_ota_handle_t`**

Opaque handle for an application OTA update.

esp_ota_begin() returns a handle which is then used for subsequent calls to esp_ota_write() and esp_ota_end().

Enumerations

enum **`esp_ota_secure_boot_public_key_index_t`**

Secure Boot V2 public key indexes.

Values:

enumerator **SECURE_BOOT_PUBLIC_KEY_INDEX_0**

Points to the 0th index of the Secure Boot v2 public key

enumerator **SECURE_BOOT_PUBLIC_KEY_INDEX_1**

Points to the 1st index of the Secure Boot v2 public key

enumerator **SECURE_BOOT_PUBLIC_KEY_INDEX_2**

Points to the 2nd index of the Secure Boot v2 public key

Debugging OTA Failure

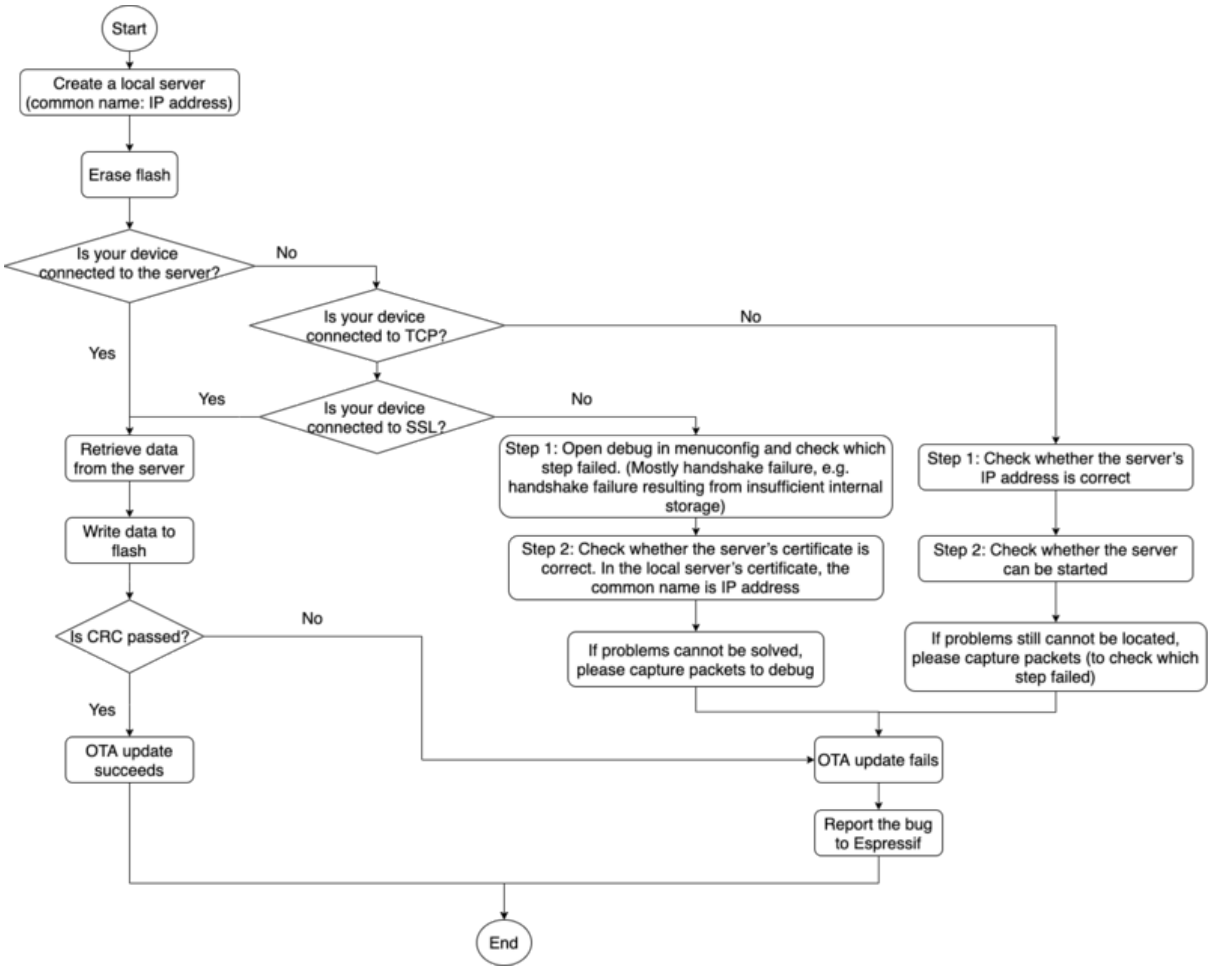

Fig. 42: How to Debug When OTA Fails (click to enlarge)

2.10.23 Power Management

Overview

Power management algorithm included in ESP-IDF can adjust the advanced peripheral bus (APB) frequency, CPU frequency, and put the chip into Light-sleep mode to run an application at smallest possible power consumption, given the requirements of application components.

Application components can express their requirements by creating and acquiring power management locks.

For example:

- Driver for a peripheral clocked from APB can request the APB frequency to be set to 80 MHz while the peripheral is used.
- RTOS can request the CPU to run at the highest configured frequency while there are tasks ready to run.
- A peripheral driver may need interrupts to be enabled, which means it has to request disabling Light-sleep.

Since requesting higher APB or CPU frequencies or disabling Light-sleep causes higher current consumption, please keep the usage of power management locks by components to a minimum.

Configuration

Power management can be enabled at compile time, using the option *CONFIG_PM_ENABLE*.

Enabling power management features comes at the cost of increased interrupt latency. Extra latency depends on a number of factors, such as the CPU frequency, single/dual core mode, whether or not frequency switch needs to be done. Minimum extra latency is 0.2 us (when the CPU frequency is 240 MHz and frequency scaling is not enabled). Maximum extra latency is 40 us (when frequency scaling is enabled, and a switch from 40 MHz to 80 MHz is performed on interrupt entry).

Dynamic frequency scaling (DFS) and automatic Light-sleep can be enabled in an application by calling the function `esp_pm_configure()`. Its argument is a structure defining the frequency scaling settings, `esp_pm_config_t`. In this structure, three fields need to be initialized:

- `max_freq_mhz`: Maximum CPU frequency in MHz, i.e., the frequency used when the `ESP_PM_CPU_FREQ_MAX` lock is acquired. This field is usually set to the default CPU frequency.
- `min_freq_mhz`: Minimum CPU frequency in MHz, indicating the frequency used when not holding the power management lock.
  - `light_sleep_enable`: Whether the system should automatically enter Light-sleep when no locks are acquired (`true`/`false`).

Alternatively, if you enable the option *CONFIG_PM_DFS_INIT_AUTO* in menuconfig, the maximum CPU frequency will be determined by the *CONFIG_ESP_DEFAULT_CPU_FREQ_MHZ* setting, and the minimum CPU frequency will be locked to the XTAL frequency.

Note: Automatic Light-sleep is based on FreeRTOS Tickless Idle functionality. If automatic Light-sleep is requested while the option *CONFIG_FREERTOS_USE_TICKLESS_IDLE* is not enabled in menuconfig, `esp_pm_configure()` will return the error *ESP_ERR_NOT_SUPPORTED*.

Note: In Light-sleep, peripherals are clock gated, and interrupts (from GPIOs and internal peripherals) will not be generated. A wakeup source described in the *Sleep Modes* documentation can be used to trigger wakeup from the Light-sleep state.

Power Management Locks

Applications have the ability to acquire/release locks in order to control the power management algorithm. When an application acquires a lock, the power management algorithm operation is restricted in a way described below. When the lock is released, such restrictions are removed.

Power management locks have acquire/release counters. If the lock has been acquired a number of times, it needs to be released the same number of times to remove associated restrictions.

ESP32-C3 supports three types of locks described in the table below.

Lock	Description
ESP_PM_CPU_FREQ_MAX	Requests CPU frequency to be at the maximum value set with *esp_pm_configure()*. For ESP32-C3, this value can be set to 80 MHz or 160 MHz.
ESP_PM_APB_FREQ_MAX	Requests the APB frequency to be at the maximum supported value. For ESP32-C3, this is 80 MHz.
ESP_PM_NO_LIGHT_SLEEP	Disables automatic switching to Light-sleep.

ESP32-C3 Power Management Algorithm

The table below shows how CPU and APB frequencies will be switched if dynamic frequency scaling is enabled. You can specify the maximum CPU frequency with either *esp_pm_configure()* or *CONFIG_ESP_DEFAULT_CPU_FREQ_MHZ*.

Max CPU Frequency Set	Lock Acquisition	CPU and APB Frequencies
160	ESP_PM_CPU_FREQ_MAX acquired	CPU: 160 MHz APB: 80 MHz
	ESP_PM_APB_FREQ_MAX acquired, ESP_PM_CPU_FREQ_MAX not acquired	CPU: 80 MHz APB: 80 MHz
	None	Min values for both frequencies set with *esp_pm_configure()*
80	Any of ESP_PM_CPU_FREQ_MAX or ESP_PM_APB_FREQ_MAX acquired	CPU: 80 MHz APB: 80 MHz
	None	Min values for both frequencies set with *esp_pm_configure()*

If none of the locks are acquired, and Light-sleep is enabled in a call to *esp_pm_configure()*, the system will go into Light-sleep mode. The duration of Light-sleep will be determined by:

- FreeRTOS tasks blocked with finite timeouts
- Timers registered with *High resolution timer* APIs

Light-sleep duration is chosen to wake up the chip before the nearest event (task being unblocked, or timer elapses).

To skip unnecessary wake-up, you can consider initializing an `esp_timer` with the `skip_unhandled_events` option as `true`. Timers with this flag will not wake up the system and it helps to reduce consumption.

Dynamic Frequency Scaling and Peripheral Drivers

When DFS is enabled, the APB frequency can be changed multiple times within a single RTOS tick. The APB frequency change does not affect the operation of some peripherals, while other peripherals may have issues. For example, Timer Group peripheral timers keeps counting, however, the speed at which they count changes proportionally to the APB frequency.

Peripheral clock sources such as `REF_TICK`, `XTAL`, `RC_FAST` (i.e., `RTC_8M`), their frequencies will not be inflenced by APB frequency. And therefore, to ensure the peripheral behaves consistently during DFS, it is recom-

mended to select one of these clocks as the peripheral clock source. For more specific guidelines, please refer to the "Power Management" section of each peripheral's "API Reference > Peripherals API" page.

Currently, the following peripheral drivers are aware of DFS and use the `ESP_PM_APB_FREQ_MAX` lock for the duration of the transaction:

- SPI master
- I2C
- I2S (If the APLL clock is used, then it will use the `ESP_PM_NO_LIGHT_SLEEP` lock)
- SDMMC

The following drivers hold the `ESP_PM_APB_FREQ_MAX` lock while the driver is enabled:

- **SPI slave**: between calls to *`spi_slave_initialize()`* and *`spi_slave_free()`*.
- **GPTimer**: between calls to *`gptimer_enable()`* and *`gptimer_disable()`*.
- **Ethernet**: between calls to *`esp_eth_driver_install()`* and *`esp_eth_driver_uninstall()`*.
- **WiFi**: between calls to *`esp_wifi_start()`* and *`esp_wifi_stop()`*. If modem sleep is enabled, the lock will be released for the periods of time when radio is disabled.
- **TWAI**: between calls to *`twai_driver_install()`* and *`twai_driver_uninstall()`* (only when the clock source is set to *`TWAI_CLK_SRC_APB`*).
- **Bluetooth**: between calls to *`esp_bt_controller_enable()`* and *`esp_bt_controller_disable()`*. If Bluetooth Modem-sleep is enabled, the `ESP_PM_APB_FREQ_MAX` lock will be released for the periods of time when radio is disabled. However the `ESP_PM_NO_LIGHT_SLEEP` lock will still be held.

The following peripheral drivers are not aware of DFS yet. Applications need to acquire/release locks themselves, when necessary:

- PCNT
- Sigma-delta
- The legacy timer group driver

Light-sleep Peripheral Power Down

API Reference

Header File

- components/esp_pm/include/esp_pm.h
- This header file can be included with:

```
#include "esp_pm.h"
```

- This header file is a part of the API provided by the `esp_pm` component. To declare that your component depends on `esp_pm`, add the following to your CMakeLists.txt:

```
REQUIRES esp_pm
```

or

```
PRIV_REQUIRES esp_pm
```

Functions

esp_err_t **`esp_pm_configure`** (const void *config)

Set implementation-specific power management configuration.

Parameters **`config`** -- pointer to implementation-specific configuration structure (e.g. esp_pm_config_esp32)

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the configuration values are not correct
- ESP_ERR_NOT_SUPPORTED if certain combination of values is not supported, or if CONFIG_PM_ENABLE is not enabled in sdkconfig

esp_err_t **esp_pm_get_configuration**(void *config)

Get implementation-specific power management configuration.

Parameters **config** -- pointer to implementation-specific configuration structure (e.g. esp_pm_config_esp32)

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the pointer is null

esp_err_t **esp_pm_lock_create**(*esp_pm_lock_type_t* lock_type, int arg, const char *name, *esp_pm_lock_handle_t* *out_handle)

Initialize a lock handle for certain power management parameter.

When lock is created, initially it is not taken. Call esp_pm_lock_acquire to take the lock.

This function must not be called from an ISR.

Note: If the lock_type argument is not valid, it will cause an abort.

Parameters

- **lock_type** -- Power management constraint which the lock should control
- **arg** -- argument, value depends on lock_type, see esp_pm_lock_type_t
- **name** -- arbitrary string identifying the lock (e.g. "wifi" or "spi"). Used by the esp_pm_dump_locks function to list existing locks. May be set to NULL. If not set to NULL, must point to a string which is valid for the lifetime of the lock.
- **out_handle** -- **[out]** handle returned from this function. Use this handle when calling esp_pm_lock_delete, esp_pm_lock_acquire, esp_pm_lock_release. Must not be NULL.

Returns

- ESP_OK on success
- ESP_ERR_NO_MEM if the lock structure can not be allocated
- ESP_ERR_INVALID_ARG if out_handle is NULL
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

esp_err_t **esp_pm_lock_acquire**(*esp_pm_lock_handle_t* handle)

Take a power management lock.

Once the lock is taken, power management algorithm will not switch to the mode specified in a call to esp_pm_lock_create, or any of the lower power modes (higher numeric values of 'mode').

The lock is recursive, in the sense that if esp_pm_lock_acquire is called a number of times, esp_pm_lock_release has to be called the same number of times in order to release the lock.

This function may be called from an ISR.

This function is not thread-safe w.r.t. calls to other esp_pm_lock_* functions for the same handle.

Parameters **handle** -- handle obtained from esp_pm_lock_create function

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

esp_err_t **esp_pm_lock_release**(*esp_pm_lock_handle_t* handle)

Release the lock taken using esp_pm_lock_acquire.

Call to this functions removes power management restrictions placed when taking the lock.

Locks are recursive, so if esp_pm_lock_acquire is called a number of times, esp_pm_lock_release has to be called the same number of times in order to actually release the lock.

This function may be called from an ISR.

This function is not thread-safe w.r.t. calls to other esp_pm_lock_* functions for the same handle.

Parameters **`handle`** -- handle obtained from esp_pm_lock_create function

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if lock is not acquired
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

esp_err_t **`esp_pm_lock_delete`**(*esp_pm_lock_handle_t* handle)

Delete a lock created using esp_pm_lock.

The lock must be released before calling this function.

This function must not be called from an ISR.

Parameters **`handle`** -- handle obtained from esp_pm_lock_create function

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle argument is NULL
- ESP_ERR_INVALID_STATE if the lock is still acquired
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

esp_err_t **`esp_pm_dump_locks`**(FILE *stream)

Dump the list of all locks to stderr

This function dumps debugging information about locks created using esp_pm_lock_create to an output stream.

This function must not be called from an ISR. If esp_pm_lock_acquire/release are called while this function is running, inconsistent results may be reported.

Parameters **`stream`** -- stream to print information to; use stdout or stderr to print to the console; use fmemopen/open_memstream to print to a string buffer.

Returns

- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

Structures

struct **`esp_pm_config_t`**

Power management config.

Pass a pointer to this structure as an argument to esp_pm_configure function.

Public Members

int **`max_freq_mhz`**

Maximum CPU frequency, in MHz

int **`min_freq_mhz`**

Minimum CPU frequency to use when no locks are taken, in MHz

bool **`light_sleep_enable`**

Enter light sleep when no locks are taken

Type Definitions

typedef *esp_pm_config_t* **esp_pm_config_esp32_t**

backward compatibility newer chips no longer require this typedef

typedef *esp_pm_config_t* **esp_pm_config_esp32s2_t**

typedef *esp_pm_config_t* **esp_pm_config_esp32s3_t**

typedef *esp_pm_config_t* **esp_pm_config_esp32c3_t**

typedef *esp_pm_config_t* **esp_pm_config_esp32c2_t**

typedef *esp_pm_config_t* **esp_pm_config_esp32c6_t**

typedef struct esp_pm_lock ***esp_pm_lock_handle_t**

Opaque handle to the power management lock.

Enumerations

enum **esp_pm_lock_type_t**

Power management constraints.

Values:

enumerator **ESP_PM_CPU_FREQ_MAX**

Require CPU frequency to be at the maximum value set via esp_pm_configure. Argument is unused and should be set to 0.

enumerator **ESP_PM_APB_FREQ_MAX**

Require APB frequency to be at the maximum value supported by the chip. Argument is unused and should be set to 0.

enumerator **ESP_PM_NO_LIGHT_SLEEP**

Prevent the system from going into light sleep. Argument is unused and should be set to 0.

enumerator **ESP_PM_LOCK_MAX**

2.10.24 POSIX Support (Including POSIX Threads Support)

Overview

ESP-IDF is based on FreeRTOS but offers a range of POSIX-compatible APIs that allow easy porting of third-party code. This includes support for common parts of the POSIX Threads `pthread` API.

POSIX Threads are implemented in ESP-IDF as wrappers around equivalent FreeRTOS features. The runtime memory or performance overhead of using the pthreads API is quite low, but not every feature available in either pthreads or FreeRTOS is available via the ESP-IDF pthreads support.

Pthreads can be used in ESP-IDF by including standard `pthread.h` header, which is included in the toolchain libc. An additional ESP-IDF specific header, `esp_pthread.h`, provides additional non-POSIX APIs for using some ESP-IDF features with pthreads.

Besides POSIX Threads, ESP-IDF also supports *POSIX message queues*.

C++ Standard Library implementations for `std::thread`, `std::mutex`, `std::condition_variable`, etc., are realized using pthreads and other POSIX APIs (via GCC libstdc++). Therefore, restrictions mentioned here also apply to the equivalent C++ standard library functionality.

If you identify a useful API that you would like to see implemented in ESP-IDF, please open a feature request on GitHub with the details.

RTOS Integration

Unlike many operating systems using POSIX Threads, ESP-IDF is a real-time operating system with a real-time scheduler. This means that a thread will only stop running if a higher priority task is ready to run, the thread blocks on an OS synchronization structure like a mutex, or the thread calls any of the functions `sleep`, `vTaskDelay()`, or `usleep`.

Note: When calling a standard libc or C++ sleep function, such as `usleep` defined in `unistd.h`, the task will only block and yield the core if the sleep time is longer than *one FreeRTOS tick period*. If the time is shorter, the thread will busy-wait instead of yielding to another RTOS task.

Note: The POSIX `errno` is provided by newlib in ESP-IDF. Thus the configuration `configUSE_POSIX_ERRNO` is not used and should stay disabled.

By default, all POSIX Threads have the same RTOS priority, but it is possible to change this by calling a *custom API*.

Standard Features

The following standard APIs are implemented in ESP-IDF.

Refer to standard POSIX Threads documentation, or `pthread.h`, for details about the standard arguments and behaviour of each function. Differences or limitations compared to the standard APIs are noted below.

Thread APIs

- **`pthread_create()`**
  - The `attr` argument is supported for setting stack size and detach state only. Other attribute fields are ignored.
  - Unlike FreeRTOS task functions, the `start_routine` function is allowed to return. A detached type thread is automatically deleted if the function returns. The default joinable type thread will be suspended until `pthread_join()` is called on it.
- `pthread_join()`
- `pthread_detach()`
- `pthread_exit()`
- `sched_yield()`
- **`pthread_self()`**
  - An assert will fail if this function is called from a FreeRTOS task which is not a pthread.
- `pthread_equal()`

Thread Attributes

- `pthread_attr_init()`
- **`pthread_attr_destroy()`**

  - This function does not need to free any resources and instead resets the `attr` structure to defaults. The implementation is the same as `pthread_attr_init()`.
- `pthread_attr_getstacksize()` / `pthread_attr_setstacksize()`
- `pthread_attr_getdetachstate()` / `pthread_attr_setdetachstate()`

Once

- `pthread_once()`

Static initializer constant `PTHREAD_ONCE_INIT` is supported.

Note: This function can be called from tasks created using either pthread or FreeRTOS APIs.

Mutexes POSIX Mutexes are implemented as FreeRTOS Mutex Semaphores (normal type for "fast" or "error check" mutexes, and Recursive type for "recursive" mutexes). This means that they have the same priority inheritance behavior as mutexes created with `xSemaphoreCreateMutex()`.

- `pthread_mutex_init()`
- `pthread_mutex_destroy()`
- `pthread_mutex_lock()`
- `pthread_mutex_timedlock()`
- `pthread_mutex_trylock()`
- `pthread_mutex_unlock()`
- `pthread_mutexattr_init()`
- `pthread_mutexattr_destroy()`
- `pthread_mutexattr_gettype()` / `pthread_mutexattr_settype()`

Static initializer constant `PTHREAD_MUTEX_INITIALIZER` is supported, but the non-standard static initializer constants for other mutex types are not supported.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs.

Condition Variables

- **`pthread_cond_init()`**
  - The `attr` argument is not implemented and is ignored.
- `pthread_cond_destroy()`
- `pthread_cond_signal()`
- `pthread_cond_broadcast()`
- `pthread_cond_wait()`
- `pthread_cond_timedwait()`

Static initializer constant `PTHREAD_COND_INITIALIZER` is supported.

- The resolution of `pthread_cond_timedwait()` timeouts is the RTOS tick period (see *CONFIG_FREERTOS_HZ*). Timeouts may be delayed up to one tick period after the requested timeout.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs.

Semaphores In ESP-IDF, POSIX **unnamed** semaphores are implemented. The accessible API is described below. It implements semaphores as specified in the POSIX standard, unless specified otherwise.

- sem_init()
- sem_destroy()
  - `pshared` is ignored. Semaphores can always be shared between FreeRTOS tasks.

- sem_post()
  - If the semaphore has a value of `SEM_VALUE_MAX` already, `-1` is returned and `errno` is set to `EAGAIN`.
- sem_wait()
- sem_trywait()
- sem_timedwait()
  - The time value passed by abstime will be rounded up to the next FreeRTOS tick.
  - The actual timeout happens after the tick that the time was rounded to and before the following tick.
  - It is possible, though unlikely, that the task is preempted directly after the timeout calculation, delaying the timeout of the following blocking operating system call by the duration of the preemption.
- sem_getvalue()

Read/Write Locks The following API functions of the POSIX reader-writer locks specification are implemented:

- pthread_rwlock_init()
  - The `attr` argument is not implemented and is ignored.
- pthread_rwlock_destroy()
- pthread_rwlock_rdlock()
- pthread_rwlock_tryrdlock()
- pthread_rwlock_wrlock()
- pthread_rwlock_trywrlock()
- pthread_rwlock_unlock()

The static initializer constant `PTHREAD_RWLOCK_INITIALIZER` is supported.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs.

Thread-Specific Data

- **`pthread_key_create()`**
  - The `destr_function` argument is supported and will be called if a thread function exits normally, calls `pthread_exit()`, or if the underlying task is deleted directly using the FreeRTOS function *`vTaskDelete()`*.
- `pthread_key_delete()`
- `pthread_setspecific()` / `pthread_getspecific()`

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs. When calling these functions from tasks created using FreeRTOS APIs, *CONFIG_FREERTOS_TLSP_DELETION_CALLBACKS* config option must be enabled to ensure the thread-specific data is cleaned up before the task is deleted.

Note: There are other options for thread local storage in ESP-IDF, including options with higher performance. See *Thread Local Storage*.

Message Queues The message queue implementation is based on the FreeRTOS-Plus-POSIX project. Message queues are not made available in any filesystem on ESP-IDF. Message priorities are not supported. The following API functions of the POSIX message queue specification are implemented:

- mq_open()
  - **The `name` argument has, besides the POSIX specification, the following additional restrictions:**
    - It has to begin with a leading slash.
    - It has to be no more than 255 + 2 characters long (including the leading slash, excluding the terminating null byte). However, memory for `name` is dynamically allocated internally, so the shorter it is, the fewer memory it will consume.

  - The `mode` argument is not implemented and is ignored.
  - Supported `oflags`: `O_RDWR`, `O_CREAT`, `O_EXCL`, and `O_NONBLOCK`
- mq_close()
- mq_unlink()
- mq_receive()
  - Since message priorities are not supported, `msg_prio` is unused.
- mq_timedreceive()
  - Since message priorities are not supported, `msg_prio` is unused.
- mq_send()
  - Since message priorities are not supported, `msg_prio` has no effect.
- mq_timedsend()
  - Since message priorities are not supported, `msg_prio` has no effect.
- mq_getattr()

mq_notify() and mq_setattr() are not implemented.

Building To use the POSIX message queue API, please add `rt` as a requirement in your component's `CMakeLists.txt`

Note: If you have used FreeRTOS-Plus-POSIX in another FreeRTOS project before, please note that the include paths in IDF are POSIX-like. Hence, applications include `mqueue.h` directly instead of using the subdirectory include `FreeRTOS_POSIX/mqueue.h`.

Not Implemented

The `pthread.h` header is a standard header and includes additional APIs and features which are not implemented in ESP-IDF. These include:

- `pthread_cancel()` returns `ENOSYS` if called.
- `pthread_condattr_init()` returns `ENOSYS` if called.
- mq_notify() returns `ENOSYS` if called.
- mq_setattr() returns `ENOSYS` if called.

Other POSIX Threads functions (not listed here) are not implemented and will produce either a compiler or a linker error if referenced from an ESP-IDF application.

ESP-IDF Extensions

The API *`esp_pthread_set_cfg()`* defined in the `esp_pthreads.h` header offers custom extensions to control how subsequent calls to `pthread_create()` behaves. Currently, the following configuration can be set:

- Default stack size of new threads, if not specified when calling `pthread_create()` (overrides *CONFIG_PTHREAD_TASK_STACK_SIZE_DEFAULT*).
- Stack memory capabilities determine which kind of memory is used for allocating pthread stacks. The field takes ESP-IDF heap capability flags, as defined in heap/include/esp_heap_caps.h. The memory must be 8-bit accessible (MALLOC_CAP_8BIT), besides other custom flags the user can choose from. The user is responsible for ensuring the correctness of the stack memory capabilities. For more information about memory locations, refer to the documentation of *Memory Capabilities*.
- RTOS priority of new threads (overrides *CONFIG_PTHREAD_TASK_PRIO_DEFAULT*).
- FreeRTOS task name for new threads (overrides *CONFIG_PTHREAD_TASK_NAME_DEFAULT*)

This configuration is scoped to the calling thread (or FreeRTOS task), meaning that *`esp_pthread_set_cfg()`* can be called independently in different threads or tasks. If the `inherit_cfg` flag is set in the current configuration then any new thread created will inherit the creator's configuration (if that thread calls `pthread_create()` recursively), otherwise the new thread will have the default configuration.

Examples

- system/pthread demonstrates using the pthreads API to create threads.
- cxx/pthread demonstrates using C++ Standard Library functions with threads.

API Reference

Header File

- components/pthread/include/esp_pthread.h
- This header file can be included with:

```
#include "esp_pthread.h"
```

- This header file is a part of the API provided by the `pthread` component. To declare that your component depends on `pthread`, add the following to your CMakeLists.txt:

```
REQUIRES pthread
```

or

```
PRIV_REQUIRES pthread
```

Functions

esp_pthread_cfg_t **esp_pthread_get_default_config** (void)

Creates a default pthread configuration based on the values set via menuconfig.

Returns A default configuration structure.

esp_err_t **esp_pthread_set_cfg** (const *esp_pthread_cfg_t* *cfg)

Configure parameters for creating pthread.

This API allows you to configure how the subsequent pthread_create() call will behave. This call can be used to setup configuration parameters like stack size, priority, configuration inheritance etc.

If the 'inherit' flag in the configuration structure is enabled, then the same configuration is also inherited in the thread subtree.

Note: If cfg->stack_alloc_caps is 0, it is automatically set to valid default stack memory capabilities. If cfg->stack_alloc_caps is non-zero, the developer is responsible for its correctenss. This function only checks that the capabilities are MALLOC_CAP_8BIT, the rest is unchecked.

Note: Passing non-NULL attributes to pthread_create() will override the stack_size parameter set using this API

Parameters **cfg** -- The pthread config parameters

Returns

- ESP_OK if configuration was successfully set
- ESP_ERR_NO_MEM if out of memory
- ESP_ERR_INVALID_ARG if stack_size is less than PTHREAD_STACK_MIN
- ESP_ERR_INVALID_ARG if stack_alloc_caps does not include MALLOC_CAP_8BIT

esp_err_t **esp_pthread_get_cfg** (*esp_pthread_cfg_t* *p)

Get current pthread creation configuration.

This will retrieve the current configuration that will be used for creating threads.

Parameters **p** -- Pointer to the pthread config structure that will be updated with the currently configured parameters

Returns

- ESP_OK if the configuration was available
- ESP_ERR_NOT_FOUND if a configuration wasn't previously set

esp_err_t **esp_pthread_init** (void)

Initialize pthread library.

Structures

struct **esp_pthread_cfg_t**

pthread configuration structure that influences pthread creation

Public Members

size_t **stack_size**

The stack size of the pthread

size_t **prio**

The thread's priority

bool **inherit_cfg**

Inherit this configuration further

const char ***thread_name**

The thread name.

int **pin_to_core**

The core id to pin the thread to. Has the same value range as xCoreId argument of xTaskCreatePinnedToCore.

uint32_t **stack_alloc_caps**

A bit mask of memory capabilities (MALLOC_CAPS*) to use when allocating the stack. The memory must be 8 bit accessible (MALLOC_CAP_8BIT). The developer is responsible for the correctenss of `stack_alloc_caps`.

Macros

PTHREAD_STACK_MIN

2.10.25 Random Number Generation

ESP32-C3 contains a hardware random number generator (RNG). You can use the APIs `esp_random()` and `esp_fill_random()` to obtained random values from it.

The hardware RNG produces true random numbers so long as one or more of the following conditions are met:

- RF subsystem is enabled. i.e., Wi-Fi or Bluetooth are enabled.

- The internal entropy source (SAR ADC) has been enabled by calling `bootloader_random_enable()` and not yet disabled by calling `bootloader_random_disable()`.
- While the ESP-IDF *Second Stage Bootloader* is running. This is because the default ESP-IDF bootloader implementation calls `bootloader_random_enable()` when the bootloader starts, and `bootloader_random_disable()` before executing the application.

When any of these conditions are true, samples of physical noise are continuously mixed into the internal hardware RNG state to provide entropy. Consult the **ESP32-C3 Technical Reference Manual > Random Number Generator (RNG)** [PDF] chapter for more details.

If none of the above conditions are true, the output of the RNG should be considered as pseudo-random only.

Startup

During startup, the ESP-IDF bootloader temporarily enables the non-RF internal entropy source (SAR ADC using internal reference voltage noise) that provides entropy for any first boot key generation.

However, after the application starts executing, then normally only pseudo-random numbers are available until Wi-Fi or Bluetooth are initialized or until the internal entropy source has been enabled again.

To re-enable the entropy source temporarily during application startup, or for an application that does not use Wi-Fi or Bluetooth, call the function `bootloader_random_enable()` to re-enable the internal entropy source. The function `bootloader_random_disable()` must be called to disable the entropy source again before using any of the following features:

- ADC
- Wi-Fi or Bluetooth

Note: The entropy source enabled during the boot process by the ESP-IDF Second Stage Bootloader seeds the internal RNG state with some entropy. However, the internal hardware RNG state is not large enough to provide a continuous stream of true random numbers. This is why a continuous entropy source must be enabled whenever true random numbers are required.

Note: If an application requires a source of true random numbers but cannot permanently enable a hardware entropy source, consider using a strong software DRBG implementation such as the mbedTLS CTR-DRBG or HMAC-DRBG, with an initial seed of entropy from hardware RNG true random numbers.

Secondary Entropy

ESP32-C3 RNG contains a secondary entropy source, based on sampling an asynchronous 8 MHz internal oscillator (see the Technical Reference Manual for details). This entropy source is always enabled in ESP-IDF and is continuously mixed into the RNG state by hardware. In testing, this secondary entropy source was sufficient to pass the Dieharder random number test suite without the main entropy source enabled (test input was created by concatenating short samples from continuously resetting ESP32-C3). However, it is currently only guaranteed that true random numbers are produced when the main entropy source is also enabled as described above.

API Reference

Header File

- components/esp_hw_support/include/esp_random.h
- This header file can be included with:

```
#include "esp_random.h"
```

Functions

uint32_t **esp_random**(void)

Get one random 32-bit word from hardware RNG.

If Wi-Fi or Bluetooth are enabled, this function returns true random numbers. In other situations, if true random numbers are required then consult the ESP-IDF Programming Guide "Random Number Generation" section for necessary prerequisites.

This function automatically busy-waits to ensure enough external entropy has been introduced into the hardware RNG state, before returning a new random number. This delay is very short (always less than 100 CPU cycles).

Returns Random value between 0 and UINT32_MAX

void **esp_fill_random**(void *buf, size_t len)

Fill a buffer with random bytes from hardware RNG.

Note: This function is implemented via calls to esp_random(), so the same constraints apply.

Parameters

- **buf** -- Pointer to buffer to fill with random numbers.
- **len** -- Length of buffer in bytes

Header File

- components/bootloader_support/include/bootloader_random.h
- This header file can be included with:

```
#include "bootloader_random.h"
```

- This header file is a part of the API provided by the `bootloader_support` component. To declare that your component depends on `bootloader_support`, add the following to your CMakeLists.txt:

```
REQUIRES bootloader_support
```

or

```
PRIV_REQUIRES bootloader_support
```

Functions

void **bootloader_random_enable**(void)

Enable an entropy source for RNG if RF subsystem is disabled.

The exact internal entropy source mechanism depends on the chip in use but all SoCs use the SAR ADC to continuously mix random bits (an internal noise reading) into the HWRNG. Consult the SoC Technical Reference Manual for more information.

Can also be called from app code, if true random numbers are required without initialized RF subsystem. This might be the case in early startup code of the application when the RF subsystem has not started yet or if the RF subsystem should not be enabled for power saving.

Consult ESP-IDF Programming Guide "Random Number Generation" section for details.

Warning: This function is not safe to use if any other subsystem is accessing the RF subsystem or the ADC at the same time!

void **bootloader_random_disable**(void)

Disable entropy source for RNG.

Disables internal entropy source. Must be called after bootloader_random_enable() and before RF subsystem features, ADC, or I2S (ESP32 only) are initialized.

Consult the ESP-IDF Programming Guide "Random Number Generation" section for details.

void **bootloader_fill_random**(void *buffer, size_t length)

Fill buffer with 'length' random bytes.

Note: If this function is being called from app code only, and never from the bootloader, then it's better to call esp_fill_random().

Parameters

- **buffer** -- Pointer to buffer
- **length** -- This many bytes of random data will be copied to buffer

getrandom()

A compatible version of the Linux `getrandom()` function is also provided for ease of porting:

```
#include <sys/random.h>

ssize_t getrandom(void *buf, size_t buflen, unsigned int flags);
```

This function is implemented by calling *esp_fill_random()* internally.

The `flags` argument is ignored. This function is always non-blocking but the strength of any random numbers is dependent on the same conditions described above.

Return value is -1 (with `errno` set to `EFAULT`) if the `buf` argument is NULL, and equal to `buflen` otherwise.

getentropy()

A compatible version of the Linux `getentropy()` function is also provided for easy porting:

```
#include <unistd.h>

int getentropy(void *buffer, size_t length);
```

This function is implemented by calling `getrandom()` internally.

The strength of any random numbers is dependent on the same conditions described above.

Return value is 0 on success and -1 otherwise with `errno` set to:

- `EFAULT` if the `buffer` argument is NULL.
- `EIO` if the `length` is more then 256.

2.10.26 Sleep Modes

Overview

ESP32-C3 supports two major power saving modes: Light-sleep and Deep-sleep. According to the features used by an application, there are some sub sleep modes. See *Sleep Modes* for these sleep modes and sub sleep modes. Additionally, there are some power-down options that can be configured to further reduce the power consumption. See *Power-down Options* for more details.

There are several wakeup sources in the sleep modes. These sources can also be combined so that the chip will wake up when any of the sources are triggered. *Wakeup Sources* describes these wakeup sources and configuration APIs in detail.

The configuration of power-down options and wakeup sources are optional. They can be configured at any moment before entering the sleep modes.

Then the application can call sleep start APIs to enter one of the sleep modes. See *Entering Sleep* for more details. When the wakeup condition is met, the application is awoken from sleep. See *Checking Sleep Wakeup Cause* on how to get the wakeup cause, and *Disable Sleep Wakeup Source* on how to handle the wakeup sources after wakeup.

Sleep Modes

In Light-sleep mode, the digital peripherals, most of the RAM, and CPUs are clock-gated and their supply voltage is reduced. Upon exit from Light-sleep, the digital peripherals, RAM, and CPUs resume operation and their internal states are preserved.

In Deep-sleep mode, the CPUs, most of the RAM, and all digital peripherals that are clocked from APB_CLK are powered off. The only parts of the chip that remain powered on are:

- RTC controller
- RTC FAST memory

Wi-Fi/Bluetooth and Sleep Modes In Deep-sleep and Light-sleep modes, the wireless peripherals are powered down. Before entering Deep-sleep or Light-sleep modes, the application must disable Wi-Fi and Bluetooth using the appropriate calls (i.e., `nimble_port_stop()`, `nimble_port_deinit()`, `esp_bluedroid_disable()`, `esp_bluedroid_deinit()`, `esp_bt_controller_disable()`, `esp_bt_controller_deinit()`, `esp_wifi_stop()`). Wi-Fi and Bluetooth connections are not maintained in Deep-sleep or Light-sleep mode, even if these functions are not called.

If Wi-Fi/Bluetooth connections need to be maintained, enable Wi-Fi/Bluetooth Modem-sleep mode and automatic Light-sleep feature (see *Power Management APIs*). This allows the system to wake up from sleep automatically when required by the Wi-Fi/Bluetooth driver, thereby maintaining the connection.

Sub Sleep Modes Tables below list the sub sleep modes in the first row and the features they support in the first column. Modes that support more features may consume more power during sleep mode. The sleep system automatically selects the mode that satisfies all the features required by the user while consuming least power.

Deep-sleep:

	DSLP_ULTRA_LOW	DSLP_DEFAULT	DSLP_8MD256/ DSLP_ADC_TSENS
ULP/Touch sensor (ESP32-S2 and ESP32-S3 only)	Y	Y	Y
RTC IO input/RTC memory at high temperature		Y	Y
ADC_TSEN_MONITOR			Y
8MD256 as the clock source for RTC_SLOW_CLK			Y

Features:

1. RTC IO input/RTC memory at high temperature (experimental): Use RTC IO as input pins, or use RTC memory at high temperature. The chip can go into ultra low power mode when these features are disabled. Controlled by API `rtc_sleep_enable_ultra_low()`.
2. ADC_TSEN_MONITOR: Use ADC/Temperature Sensor in monitor mode (controlled by ULP). Enabled by API `ulp_adc_init()` or its higher level APIs. Only available for ESP32-S2 and ESP32-S3 chips with monitor mode.
3. 8MD256 as the clock source for RTC_SLOW_CLK: When 8MD256 is selected as the clock source for RTC_SLOW_CLK using the Kconfig option `CONFIG_RTC_CLK_SRC_INT_8MD256`, the chip will automatically enter this sub sleep mode during Deep-sleep mode.

Light-sleep:

	LSLP_DEFAULT	LSLP_ADC_TSENS	LSLP_8MD256	LSLP_LEDC8M/ LSLP_XTAL_FPU
ULP/Touch sensor (ESP32-S2 and ESP32-S3 only)	Y	Y	Y	Y
RTC IO input/RTC memory at high temperature	Y	Y	Y	Y
ADC_TSEN_MONITOR		Y	Y	Y
8MD256 as the clock source for RTC_SLOW_CLK			Y	Y
8 MHz RC clock source used by digital peripherals				Y
Keep the XTAL clock on				Y

Features: (Also see 8MD256 and ADC_TSEN_MONITOR features for Deep-sleep mode above)

1. 8 MHz RC clock source used by digital peripherals: Currently, only LEDC uses this clock source during Light-sleep mode. When LEDC selects this clock source, this feature is automatically enabled.
2. Keep the XTAL clock on: Keep the XTAL clock on during Light-sleep mode. Controlled by `ESP_PD_DOMAIN_XTAL` power domain.

ESP32-C3 does not have ADC_TSEN_MONITOR or LSLP_ADC_TSENS feature.

Wakeup Sources

Wakeup sources can be enabled using `esp_sleep_enable_X_wakeup` APIs. Wakeup sources are not disabled after wakeup, you can disable them using *`esp_sleep_disable_wakeup_source()`* API if you do not need them any more. See *Disable Sleep Wakeup Source*.

Following are the wakeup sources supported on ESP32-C3.

Timer The RTC controller has a built-in timer which can be used to wake up the chip after a predefined amount of time. Time is specified at microsecond precision, but the actual resolution depends on the clock source selected for RTC_SLOW_CLK.

RTC peripherals or RTC memories do not need to be powered on during sleep in this wakeup mode.

`esp_sleep_enable_timer_wakeup()` function can be used to enable sleep wakeup using a timer.

GPIO Wakeup Any IO can be used as the external input to wake up the chip from Light-sleep. Each pin can be individually configured to trigger wakeup on high or low level using the *`gpio_wakeup_enable()`* function. Then the *`esp_sleep_enable_gpio_wakeup()`* function should be called to enable this wakeup source.

Additionally, IOs that are powered by the VDD3P3_RTC power domain can be used to wake up the chip from Deep-sleep. The wakeup pin and wakeup trigger level can be configured by calling

esp_deep_sleep_enable_gpio_wakeup(). The function will enable the Deep-sleep wakeup for the selected pin.

UART Wakeup (Light-sleep Only) When ESP32-C3 receives UART input from external devices, it is often necessary to wake up the chip when input data is available. The UART peripheral contains a feature which allows waking up the chip from Light-sleep when a certain number of positive edges on RX pin are seen. This number of positive edges can be set using *uart_set_wakeup_threshold()* function. Note that the character which triggers wakeup (and any characters before it) will not be received by the UART after wakeup. This means that the external device typically needs to send an extra character to the ESP32-C3 to trigger wakeup before sending the data.

esp_sleep_enable_uart_wakeup() function can be used to enable this wakeup source.

After waking-up from UART, you should send some extra data through the UART port in Active mode, so that the internal wakeup indication signal can be cleared. Otherwises, the next UART wake-up would trigger with two less rising edges than the configured threshold value.

Disable Sleep Wakeup Source Previously configured wakeup sources can be disabled later using *esp_sleep_disable_wakeup_source()* API. This function deactivates trigger for the given wakeup source. Additionally, it can disable all triggers if the argument is `ESP_SLEEP_WAKEUP_ALL`.

Power-down Options

The application can force specific powerdown modes for RTC peripherals and RTC memories. In Deep-sleep mode, we can also isolate some IOs to further reduce current consumption.

Power-down of RTC Peripherals and Memories By default, *esp_deep_sleep_start()* and *esp_light_sleep_start()* functions power down all RTC power domains which are not needed by the enabled wakeup sources. To override this behaviour, *esp_sleep_pd_config()* function is provided.

In ESP32-C3, there is only RTC FAST memory, so if some variables in the program are marked by `RTC_DATA_ATTR`, `RTC_SLOW_ATTR` or `RTC_FAST_ATTR` attributes, all of them go to RTC FAST memory. It will be kept powered on by default. This can be overridden using *esp_sleep_pd_config()* function, if desired.

Power-down of Flash By default, to avoid potential issues, *esp_light_sleep_start()* function does **not** power down flash. To be more specific, it takes time to power down the flash and during this period the system may be woken up, which then actually powers up the flash before this flash could be powered down completely. As a result, there is a chance that the flash may not work properly.

So, in theory, it is ok if you only wake up the system after the flash is completely powered down. However, in reality, the flash power-down period can be hard to predict (for example, this period can be much longer when you add filter capacitors to the flash's power supply circuit) and uncontrollable (for example, the asynchronous wake-up signals make the actual sleep time uncontrollable).

> **Warning:** If a filter capacitor is added to your flash power supply circuit, please do everything possible to avoid powering down flash.

Therefore, it is recommended not to power down flash when using ESP-IDF. For power-sensitive applications, it is recommended to use Kconfig option *CONFIG_ESP_SLEEP_FLASH_LEAKAGE_WORKAROUND* to reduce the power consumption of the flash during Light-sleep, instead of powering down the flash.

However, for those who have fully understood the risk and are still willing to power down the flash to further reduce the power consumption, please check the following mechanisms:

- Setting Kconfig option *CONFIG_ESP_SLEEP_POWER_DOWN_FLASH* only powers down the flash when the RTC timer is the only wake-up source **and** the sleep time is longer than the flash power-down period.
- Calling `esp_sleep_pd_config(ESP_PD_DOMAIN_VDDSDIO, ESP_PD_OPTION_OFF)` powers down flash when the RTC timer is not enabled as a wakeup source **or** the sleep time is longer than the flash power-down period.

Note:

- ESP-IDF does not provide any mechanism that can power down the flash in all conditions when Light-sleep.
- `esp_deep_sleep_start()` function forces power down flash regardless of user configuration.

Configuring IOs (Deep-sleep Only) Some ESP32-C3 IOs have internal pullups or pulldowns, which are enabled by default. If an external circuit drives this pin in Deep-sleep mode, current consumption may increase due to current flowing through these pullups and pulldowns.

In Deep-sleep mode:

- digital GPIOs (GPIO6 ~ 21) are in a high impedance state.
- **RTC GPIOs (GPIO0 ~ 5) can be in the following states, depending on their hold function enabled or not:**
  - if the hold function is not enabled, RTC GPIOs will be in a high impedance state.
  - if the hold function is enabled, RTC GPIOs will retain the pin state latched at that hold moment.

Entering Sleep

`esp_light_sleep_start()` or `esp_deep_sleep_start()` functions can be used to enter Light-sleep or Deep-sleep modes correspondingly. After that, the system configures the parameters of RTC controller according to the requested wakeup sources and power-down options.

It is also possible to enter sleep modes with no wakeup sources configured. In this case, the chip will be in sleep modes indefinitely until external reset is applied.

UART Output Handling Before entering sleep mode, `esp_deep_sleep_start()` will flush the contents of UART FIFOs.

When entering Light-sleep mode using `esp_light_sleep_start()`, UART FIFOs will not be flushed. Instead, UART output will be suspended, and remaining characters in the FIFO will be sent out after wakeup from Light-sleep.

Checking Sleep Wakeup Cause

`esp_sleep_get_wakeup_cause()` function can be used to check which wakeup source has triggered wakeup from sleep mode.

Application Example

- protocols/sntp: the implementation of basic functionality of Deep-sleep, where ESP module is periodically waken up to retrieve time from NTP server.
- wifi/power_save: the usage of Wi-Fi Modem-sleep mode and automatic Light-sleep feature to maintain Wi-Fi connections.
- bluetooth/nimble/power_save: the usage of Bluetooth Modem-sleep mode and automatic Light-sleep feature to maintain Bluetooth connections.

- system/deep_sleep: the usage of Deep-sleep wakeup triggered by various sources supported by the chip (RTC Timer, GPIO, EXT0, EXT1, Touch Sensor, etc.).
- system/light_sleep: the usage of Light-sleep wakeup triggered by various sources supported by the chip (Timer, GPIO, Touch Sensor, etc.).

- This header file can be included with:

```
#include "esp_sleep.h"
```

Functions

esp_err_t **esp_sleep_disable_wakeup_source**(*esp_sleep_source_t* source)

Disable wakeup source.

This function is used to deactivate wake up trigger for source defined as parameter of the function.

See docs/sleep-modes.rst for details.

Note: This function does not modify wake up configuration in RTC. It will be performed in esp_deep_sleep_start/esp_light_sleep_start function.

Parameters **source** -- - number of source to disable of type esp_sleep_source_t

Returns
- ESP_OK on success
- ESP_ERR_INVALID_STATE if trigger was not active

esp_err_t **esp_sleep_enable_timer_wakeup**(uint64_t time_in_us)

Enable wakeup by timer.

Parameters **time_in_us** -- time before wakeup, in microseconds

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if value is out of range (TBD)

bool **esp_sleep_is_valid_wakeup_gpio**(gpio_num_t gpio_num)

Returns true if a GPIO number is valid for use as wakeup source.

Note: For SoCs with RTC IO capability, this can be any valid RTC IO input pin.

Parameters **gpio_num** -- Number of the GPIO to test for wakeup source capability

Returns True if this GPIO number will be accepted as a sleep wakeup source.

esp_err_t **esp_deep_sleep_enable_gpio_wakeup**(uint64_t gpio_pin_mask, *esp_deepsleep_gpio_wake_up_mode_t* mode)

Enable wakeup using specific gpio pins.

This function enables an IO pin to wake up the chip from deep sleep.

Note: This function does not modify pin configuration. The pins are configured inside esp_deep_sleep_start, immediately before entering sleep mode.

Note: You don't need to worry about pull-up or pull-down resistors before using this function because the ESP_SLEEP_GPIO_ENABLE_INTERNAL_RESISTORS option is enabled by default. It will automatically set pull-up or pull-down resistors internally in esp_deep_sleep_start based on the wakeup mode. However, when using external pull-up or pull-down resistors, please be sure to disable the ESP_SLEEP_GPIO_ENABLE_INTERNAL_RESISTORS option, as the combination of internal and external resistors may cause interference. BTW, when you use low level to wake up the chip, we strongly recommend you to add external resistors (pull-up).

Parameters
- **gpio_pin_mask** -- Bit mask of GPIO numbers which will cause wakeup. Only GPIOs which have RTC functionality (pads that powered by VDD3P3_RTC) can be used in this bit map.
- **mode** -- Select logic function used to determine wakeup condition:
  - ESP_GPIO_WAKEUP_GPIO_LOW: wake up when the gpio turn to low.
  - ESP_GPIO_WAKEUP_GPIO_HIGH: wake up when the gpio turn to high.

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the mask contains any invalid deep sleep wakeup pin or wakeup mode is invalid

esp_err_t **esp_sleep_enable_gpio_wakeup**(void)

Enable wakeup from light sleep using GPIOs.

Each GPIO supports wakeup function, which can be triggered on either low level or high level. Unlike EXT0 and EXT1 wakeup sources, this method can be used both for all IOs: RTC IOs and digital IOs. It can only be used to wakeup from light sleep though.

To enable wakeup, first call gpio_wakeup_enable, specifying gpio number and wakeup level, for each GPIO which is used for wakeup. Then call this function to enable wakeup feature.

Note: On ESP32, GPIO wakeup source can not be used together with touch or ULP wakeup sources.

Returns
- ESP_OK on success
- ESP_ERR_INVALID_STATE if wakeup triggers conflict

esp_err_t **esp_sleep_enable_uart_wakeup**(int uart_num)

Enable wakeup from light sleep using UART.

Use uart_set_wakeup_threshold function to configure UART wakeup threshold.

Wakeup from light sleep takes some time, so not every character sent to the UART can be received by the application.

Note: ESP32 does not support wakeup from UART2.

Parameters **uart_num** -- UART port to wake up from

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if wakeup from given UART is not supported

esp_err_t **esp_sleep_enable_bt_wakeup** (void)

Enable wakeup by bluetooth.

Returns
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if wakeup from bluetooth is not supported

esp_err_t **esp_sleep_disable_bt_wakeup** (void)

Disable wakeup by bluetooth.

Returns
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if wakeup from bluetooth is not supported

esp_err_t **esp_sleep_enable_wifi_wakeup** (void)

Enable wakeup by WiFi MAC.

Returns
- ESP_OK on success

esp_err_t **esp_sleep_disable_wifi_wakeup** (void)

Disable wakeup by WiFi MAC.

Returns
- ESP_OK on success

esp_err_t **esp_sleep_enable_wifi_beacon_wakeup** (void)

Enable beacon wakeup by WiFi MAC, it will wake up the system into modem state.

Returns
- ESP_OK on success

esp_err_t **esp_sleep_disable_wifi_beacon_wakeup** (void)

Disable beacon wakeup by WiFi MAC.

Returns
- ESP_OK on success

uint64_t **esp_sleep_get_ext1_wakeup_status** (void)

Get the bit mask of GPIOs which caused wakeup (ext1)

If wakeup was caused by another source, this function will return 0.

Returns bit mask, if GPIOn caused wakeup, BIT(n) will be set

uint64_t **esp_sleep_get_gpio_wakeup_status** (void)

Get the bit mask of GPIOs which caused wakeup (gpio)

If wakeup was caused by another source, this function will return 0.

Returns bit mask, if GPIOn caused wakeup, BIT(n) will be set

esp_err_t **esp_sleep_pd_config** (*esp_sleep_pd_domain_t* domain, *esp_sleep_pd_option_t* option)

Set power down mode for an RTC power domain in sleep mode.

If not set set using this API, all power domains default to ESP_PD_OPTION_AUTO.

Parameters
- **domain** -- power domain to configure
- **option** -- power down option (ESP_PD_OPTION_OFF, ESP_PD_OPTION_ON, or ESP_PD_OPTION_AUTO)

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if either of the arguments is out of range

esp_err_t **esp_deep_sleep_try_to_start** (void)

Enter deep sleep with the configured wakeup options.

The reason for the rejection can be such as a short sleep time.

Note: In general, the function does not return, but if the sleep is rejected, then it returns from it.

Returns

- No return - If the sleep is not rejected.
- ESP_ERR_SLEEP_REJECT sleep request is rejected(wakeup source set before the sleep request)

void **esp_deep_sleep_start** (void)

Enter deep sleep with the configured wakeup options.

Note: The function does not do a return (no rejection). Even if wakeup source set before the sleep request it goes to deep sleep anyway.

esp_err_t **esp_light_sleep_start** (void)

Enter light sleep with the configured wakeup options.

Returns

- ESP_OK on success (returned after wakeup)
- ESP_ERR_SLEEP_REJECT sleep request is rejected(wakeup source set before the sleep request)
- ESP_ERR_SLEEP_TOO_SHORT_SLEEP_DURATION after deducting the sleep flow overhead, the final sleep duration is too short to cover the minimum sleep duration of the chip, when rtc timer wakeup source enabled

esp_err_t **esp_deep_sleep_try** (uint64_t time_in_us)

Enter deep-sleep mode.

The device will automatically wake up after the deep-sleep time Upon waking up, the device calls deep sleep wake stub, and then proceeds to load application.

Call to this function is equivalent to a call to esp_deep_sleep_enable_timer_wakeup followed by a call to esp_deep_sleep_start.

The reason for the rejection can be such as a short sleep time.

Note: In general, the function does not return, but if the sleep is rejected, then it returns from it.

Parameters **time_in_us** -- deep-sleep time, unit: microsecond

Returns

- No return - If the sleep is not rejected.
- ESP_ERR_SLEEP_REJECT sleep request is rejected(wakeup source set before the sleep request)

void **esp_deep_sleep** (uint64_t time_in_us)

Enter deep-sleep mode.

The device will automatically wake up after the deep-sleep time Upon waking up, the device calls deep sleep wake stub, and then proceeds to load application.

Call to this function is equivalent to a call to esp_deep_sleep_enable_timer_wakeup followed by a call to esp_deep_sleep_start.

Note: The function does not do a return (no rejection).. Even if wakeup source set before the sleep request it goes to deep sleep anyway.

Parameters **time_in_us** -- deep-sleep time, unit: microsecond

esp_err_t **esp_deep_sleep_register_hook**(*esp_deep_sleep_cb_t* new_dslp_cb)

Register a callback to be called from the deep sleep prepare.

Warning: deepsleep callbacks should without parameters, and MUST NOT, UNDER ANY CIRCUMSTANCES, CALL A FUNCTION THAT MIGHT BLOCK.

Parameters **new_dslp_cb** -- Callback to be called

Returns

- ESP_OK: Callback registered to the deepsleep misc_modules_sleep_prepare
- ESP_ERR_NO_MEM: No more hook space for register the callback

void **esp_deep_sleep_deregister_hook**(*esp_deep_sleep_cb_t* old_dslp_cb)

Unregister an deepsleep callback.

Parameters **old_dslp_cb** -- Callback to be unregistered

esp_sleep_wakeup_cause_t **esp_sleep_get_wakeup_cause**(void)

Get the wakeup source which caused wakeup from sleep.

Returns cause of wake up from last sleep (deep sleep or light sleep)

void **esp_wake_deep_sleep**(void)

Default stub to run on wake from deep sleep.

Allows for executing code immediately on wake from sleep, before the software bootloader or ESP-IDF app has started up.

This function is weak-linked, so you can implement your own version to run code immediately when the chip wakes from sleep.

See docs/deep-sleep-stub.rst for details.

void **esp_set_deep_sleep_wake_stub**(*esp_deep_sleep_wake_stub_fn_t* new_stub)

Install a new stub at runtime to run on wake from deep sleep.

If implementing esp_wake_deep_sleep() then it is not necessary to call this function.

However, it is possible to call this function to substitute a different deep sleep stub. Any function used as a deep sleep stub must be marked RTC_IRAM_ATTR, and must obey the same rules given for esp_wake_deep_sleep().

void **esp_set_deep_sleep_wake_stub_default_entry**(void)

Set wake stub entry to default `esp_wake_stub_entry`

esp_deep_sleep_wake_stub_fn_t **esp_get_deep_sleep_wake_stub**(void)

Get current wake from deep sleep stub.

Returns Return current wake from deep sleep stub, or NULL if no stub is installed.

void **esp_default_wake_deep_sleep**(void)

The default esp-idf-provided esp_wake_deep_sleep() stub.

See docs/deep-sleep-stub.rst for details.

void **esp_deep_sleep_disable_rom_logging**(void)

Disable logging from the ROM code after deep sleep.

Using LSB of RTC_STORE4.

esp_err_t **esp_sleep_cpu_pd_low_init**(void)

CPU Power down low-level initialize, enable CPU power down during light sleep.

Returns
- ESP_OK on success
- ESP_ERR_NO_MEM not enough retention memory

esp_err_t **esp_sleep_cpu_pd_low_deinit**(void)

CPU Power down low-level deinitialize, disable CPU power down during light sleep.

Returns
- ESP_OK on success
- ESP_ERR_NO_MEM not enough retention memory

esp_err_t **esp_sleep_cpu_retention_init**(void)

CPU Power down initialize.

Returns
- ESP_OK on success
- ESP_ERR_NO_MEM not enough retention memory

esp_err_t **esp_sleep_cpu_retention_deinit**(void)

CPU Power down de-initialize.

Release system retention memory.

Returns
- ESP_OK on success

void **esp_sleep_config_gpio_isolate**(void)

Configure to isolate all GPIO pins in sleep state.

void **esp_sleep_enable_gpio_switch**(bool enable)

Enable or disable GPIO pins status switching between slept status and waked status.

Parameters **enable** -- decide whether to switch status or not

Macros

ESP_PD_DOMAIN_RTC8M

ESP_SLEEP_POWER_DOWN_CPU

Type Definitions

typedef void (*__esp_deep_sleep_cb_t__)(void)

typedef *esp_sleep_source_t* **esp_sleep_wakeup_cause_t**

typedef void (*__esp_deep_sleep_wake_stub_fn_t__)(void)

Function type for stub to run on wake from sleep.

Enumerations

enum **esp_deepsleep_gpio_wake_up_mode_t**

Logic function used for EXT1 wakeup mode.

Values:

enumerator **ESP_GPIO_WAKEUP_GPIO_LOW**

enumerator **ESP_GPIO_WAKEUP_GPIO_HIGH**

enum **esp_sleep_pd_domain_t**

Power domains which can be powered down in sleep mode.

Values:

enumerator **ESP_PD_DOMAIN_XTAL**

XTAL oscillator.

enumerator **ESP_PD_DOMAIN_RC_FAST**

Internal Fast oscillator.

enumerator **ESP_PD_DOMAIN_CPU**

CPU core.

enumerator **ESP_PD_DOMAIN_VDDSDIO**

VDD_SDIO.

enumerator **ESP_PD_DOMAIN_MAX**

Number of domains.

enum **esp_sleep_pd_option_t**

Power down options.

Values:

enumerator **ESP_PD_OPTION_OFF**

Power down the power domain in sleep mode.

enumerator **ESP_PD_OPTION_ON**

Keep power domain enabled during sleep mode.

enumerator **ESP_PD_OPTION_AUTO**

Keep power domain enabled in sleep mode, if it is needed by one of the wakeup options. Otherwise power it down.

enum **esp_sleep_source_t**

Sleep wakeup cause.

Values:

enumerator **ESP_SLEEP_WAKEUP_UNDEFINED**

In case of deep sleep, reset was not caused by exit from deep sleep.

enumerator **ESP_SLEEP_WAKEUP_ALL**

Not a wakeup cause, used to disable all wakeup sources with esp_sleep_disable_wakeup_source.

enumerator **ESP_SLEEP_WAKEUP_EXT0**

Wakeup caused by external signal using RTC_IO.

enumerator **ESP_SLEEP_WAKEUP_EXT1**

Wakeup caused by external signal using RTC_CNTL.

enumerator **ESP_SLEEP_WAKEUP_TIMER**

Wakeup caused by timer.

enumerator **ESP_SLEEP_WAKEUP_TOUCHPAD**

Wakeup caused by touchpad.

enumerator **ESP_SLEEP_WAKEUP_ULP**

Wakeup caused by ULP program.

enumerator **ESP_SLEEP_WAKEUP_GPIO**

Wakeup caused by GPIO (light sleep only on ESP32, S2 and S3)

enumerator **ESP_SLEEP_WAKEUP_UART**

Wakeup caused by UART (light sleep only)

enumerator **ESP_SLEEP_WAKEUP_WIFI**

Wakeup caused by WIFI (light sleep only)

enumerator **ESP_SLEEP_WAKEUP_COCPU**

Wakeup caused by COCPU int.

enumerator **ESP_SLEEP_WAKEUP_COCPU_TRAP_TRIG**

Wakeup caused by COCPU crash.

enumerator **ESP_SLEEP_WAKEUP_BT**

Wakeup caused by BT (light sleep only)

enum **esp_sleep_mode_t**

Sleep mode.

Values:

enumerator **ESP_SLEEP_MODE_LIGHT_SLEEP**

light sleep mode

enumerator **ESP_SLEEP_MODE_DEEP_SLEEP**

deep sleep mode

enum **[anonymous]**

Values:

enumerator **ESP_ERR_SLEEP_REJECT**

enumerator **ESP_ERR_SLEEP_TOO_SHORT_SLEEP_DURATION**

2.10.27 SoC Capabilities

This section lists the macro definitions of the ESP32-C3's SoC hardware capabilities. These macros are commonly used by conditional-compilation directives (e.g., `#if`) in ESP-IDF to determine which hardware-dependent features are supported, thus control what portions of code are compiled.

Warning: These macro definitions are currently not considered to be part of the public API, and may be changed in a breaking manner (see *ESP-IDF Versions* for more details).

Support Bluetooth 5.0

SOC_BLE_DEVICE_PRIVACY_SUPPORTED

Support BLE device privacy mode

SOC_BLUFI_SUPPORTED

Support BLUFI

SOC_PHY_COMBO_MODULE

Support Wi-Fi and BLE

2.10.28 System Time

Overview

ESP32-C3 uses two hardware timers for the purpose of keeping system time. System time can be kept by using either one or both of the hardware timers depending on the application's purpose and accuracy requirements for system time. The two hardware timers are:

- **RTC timer**: This timer allows time keeping in various sleep modes, and can also persist time keeping across any resets (with the exception of power-on resets which reset the RTC timer). The frequency deviation depends on the *RTC Timer Clock Sources* and affects the accuracy only in sleep modes, in which case the time will be measured at 6.6667 µs resolution.
- **High-resolution timer**: This timer is not available in sleep modes and will not persist over a reset, but has greater accuracy. The timer uses the APB_CLK clock source (typically 80 MHz), which has a frequency deviation of less than ±10 ppm. Time will be measured at 1 µs resolution.

The possible combinations of hardware timers used to keep system time are listed below:

- RTC and high-resolution timer (default)
- RTC
- High-resolution timer
- None

It is recommended that users stick to the default option as it provides the highest accuracy. However, users can also select a different setting via the *CONFIG_NEWLIB_TIME_SYSCALL* configuration option.

RTC Timer Clock Sources

The RTC timer has the following clock sources:

- `Internal 136 kHz RC oscillator` (default): Features the lowest Deep-sleep current consumption and no dependence on any external components. However, the frequency stability of this clock source is affected by temperature fluctuations, so time may drift in both Deep-sleep and Light-sleep modes.
- `External 32 kHz crystal`: Requires a 32 kHz crystal to be connected to the XTAL_32K_P and XTAL_32K_N pins. This source provides a better frequency stability at the expense of a slightly higher (by 1 µA) Deep-sleep current consumption.
- `External 32 kHz oscillator at XTAL_32K_P pin`: Allows using 32 kHz clock generated by an external circuit. The external clock signal must be connected to the XTAL_32K_P pin. The amplitude should be less than 1.2 V for sine wave signal and less than 1 V for square wave signal. Common mode voltage

should be in the range of 0.1 < Vcm < 0.5xVamp, where Vamp stands for signal amplitude. In this case, the XTAL_32K_P pin cannot be used as a GPIO pin.

- `Internal 17.5 MHz oscillator, divided by 256 (about 68 kHz)`: Provides better frequency stability than the `Internal 136 kHz RC oscillator` at the expense of a higher (by 5 µA) Deep-sleep current consumption. It also does not require external components.

The choice depends on your requirements for system time accuracy and power consumption in sleep modes. To modify the RTC clock source, set *CONFIG_RTC_CLK_SRC* in project configuration.

More details about the wiring requirements for the external crystal or external oscillator, please refer to the Hardware Design Guidelines.

Get Current Time

To get the current time, use the POSIX function `gettimeofday()`. Additionally, you can use the following standard C library functions to obtain time and manipulate it:

```
gettimeofday
time
asctime
clock
ctime
difftime
gmtime
localtime
mktime
strftime
adjtime*
```

To stop smooth time adjustment and update the current time immediately, use the POSIX function `settimeofday()`.

If you need to obtain time with one second resolution, use the following code snippet:

```
time_t now;
char strftime_buf[64];
struct tm timeinfo;

time(&now);
// Set timezone to China Standard Time
setenv("TZ", "CST-8", 1);
tzset();

localtime_r(&now, &timeinfo);
strftime(strftime_buf, sizeof(strftime_buf), "%c", &timeinfo);
ESP_LOGI(TAG, "The current date/time in Shanghai is: %s", strftime_buf);
```

If you need to obtain time with one microsecond resolution, use the code snippet below:

```
struct timeval tv_now;
gettimeofday(&tv_now, NULL);
int64_t time_us = (int64_t)tv_now.tv_sec * 1000000L + (int64_t)tv_now.tv_usec;
```

SNTP Time Synchronization

To set the current time, you can use the POSIX functions `settimeofday()` and `adjtime()`. They are used internally in the lwIP SNTP library to set current time when a response from the NTP server is received. These functions can also be used separately from the lwIP SNTP library.

Some lwIP APIs, including SNTP functions, are not thread safe, so it is recommended to use *esp_netif component* when interacting with SNTP module.

To initialize a particular SNTP server and also start the SNTP service, simply create a default SNTP server configuration with a particular server name, then call *esp_netif_sntp_init()* to register that server and start the SNTP service.

```
esp_sntp_config_t config = ESP_NETIF_SNTP_DEFAULT_CONFIG("pool.ntp.org");
esp_netif_sntp_init(&config);
```

This code automatically performs time synchronization once a reply from the SNTP server is received. Sometimes it is useful to wait until the time gets synchronized, *esp_netif_sntp_sync_wait()* can be used for this purpose:

```
if (esp_netif_sntp_sync_wait(pdMS_TO_TICKS(10000)) != ESP_OK) {
    printf("Failed to update system time within 10s timeout");
}
```

To configure multiple NTP servers (or use more advanced settings, such as DHCP provided NTP servers), please refer to the detailed description of *SNTP API* in *esp_netif* documentation.

The lwIP SNTP library could work in one of the following sync modes:

- *SNTP_SYNC_MODE_IMMED* (default): Updates system time immediately upon receiving a response from the SNTP server after using `settimeofday()`.
- *SNTP_SYNC_MODE_SMOOTH*: Updates time smoothly by gradually reducing time error using the function `adjtime()`. If the difference between the SNTP response time and system time is more than 35 minutes, update system time immediately by using `settimeofday()`.

If you want to choose the *SNTP_SYNC_MODE_SMOOTH* mode, please set the `esp_sntp_config::smooth` to `true` in the SNTP configuration struct. Otherwise (and by default) the *SNTP_SYNC_MODE_IMMED* mode will be used.

For setting a callback function that is called when time gets synchronized, use the *esp_sntp_config::sync_cb* field in the configuration struct.

An application with this initialization code periodically synchronizes the time. The time synchronization period is determined by *CONFIG_LWIP_SNTP_UPDATE_DELAY* (the default value is one hour). To modify the variable, set *CONFIG_LWIP_SNTP_UPDATE_DELAY* in project configuration.

A code example that demonstrates the implementation of time synchronization based on the lwIP SNTP library is provided in the protocols/sntp directory.

Note that it is also possible to use lwIP API directly, but care must be taken to thread safety. Here we list the thread-safe APIs:

- *sntp_set_time_sync_notification_cb()* can be used to set a callback function that notifies of the time synchronization process.
- *sntp_get_sync_status()* and *sntp_set_sync_status()* can be used to get/set time synchronization status.
- *sntp_set_sync_mode()* can be used to set the synchronization mode.
- *esp_sntp_setoperatingmode()* sets the preferred operating mode.:cpp:enumerator:*ESP_SNTP_OPMODE_POLL* and *esp_sntp_init()* initializes SNTP module.
- *esp_sntp_setservername()* configures one SNTP server.

Timezones

To set the local timezone, use the following POSIX functions:

1. Call `setenv()` to set the `TZ` environment variable to the correct value based on the device location. The format of the time string is the same as described in the GNU libc documentation (although the implementation is different).
2. Call `tzset()` to update C library runtime data for the new timezone.

Once these steps are completed, call the standard C library function `localtime()`, and it returns the correct local time taking into account the timezone offset and daylight saving time.

Year 2036 and 2038 Overflow Issues

SNTP/NTP 2036 Overflow SNTP/NTP timestamps are represented as 64-bit unsigned fixed point numbers, where the first 32 bits represent the integer part, and the last 32 bits represent the fractional part. The 64-bit unsigned fixed point number represents the number of seconds since 00:00 on 1st of January 1900, thus SNTP/NTP times will overflow in the year 2036.

To address this issue, lifetime of the SNTP/NTP timestamps has been extended by convention by using the MSB (bit 0 by convention) of the integer part to indicate time ranges between years 1968 to 2104 (see RFC2030 for more details). This convention is implemented in lwIP library SNTP module. Therefore SNTP-related functions in ESP-IDF are future-proof until year 2104.

Unix Time 2038 Overflow Unix time (type `time_t`) was previously represented as a 32-bit signed integer, leading to an overflow in year 2038 (i.e., Y2K38 issue). To address the Y2K38 issue, ESP-IDF uses a 64-bit signed integer to represent `time_t` starting from release v5.0, thus deferring `time_t` overflow for another 292 billion years.

API Reference

Header File

- components/lwip/include/apps/esp_sntp.h
- This header file can be included with:

```
#include "esp_sntp.h"
```

- This header file is a part of the API provided by the `lwip` component. To declare that your component depends on `lwip`, add the following to your CMakeLists.txt:

```
REQUIRES lwip
```

or

```
PRIV_REQUIRES lwip
```

Functions

void **sntp_sync_time** (struct timeval *tv)

This function updates the system time.

This is a weak-linked function. It is possible to replace all SNTP update functionality by placing a sntp_sync_time() function in the app firmware source. If the default implementation is used, calling sntp_set_sync_mode() allows the time synchronization mode to be changed to instant or smooth. If a callback function is registered via sntp_set_time_sync_notification_cb(), it will be called following time synchronization.

Parameters **tv** -- Time received from SNTP server.

void **sntp_set_sync_mode** (*sntp_sync_mode_t* sync_mode)

Set the sync mode.

Modes allowed: SNTP_SYNC_MODE_IMMED and SNTP_SYNC_MODE_SMOOTH.

Parameters **sync_mode** -- Sync mode.

sntp_sync_mode_t **sntp_get_sync_mode** (void)

Get set sync mode.

Returns SNTP_SYNC_MODE_IMMED: Update time immediately. SNTP_SYNC_MODE_SMOOTH: Smooth time updating.

sntp_sync_status_t **sntp_get_sync_status** (void)

Get status of time sync.

After the update is completed, the status will be returned as SNTP_SYNC_STATUS_COMPLETED. After that, the status will be reset to SNTP_SYNC_STATUS_RESET. If the update operation is not completed yet, the status will be SNTP_SYNC_STATUS_RESET. If a smooth mode was chosen and the synchronization is still continuing (adjtime works), then it will be SNTP_SYNC_STATUS_IN_PROGRESS.

Returns SNTP_SYNC_STATUS_RESET: Reset status. SNTP_SYNC_STATUS_COMPLETED: Time is synchronized. SNTP_SYNC_STATUS_IN_PROGRESS: Smooth time sync in progress.

void **sntp_set_sync_status** (*sntp_sync_status_t* sync_status)

Set status of time sync.

Parameters **sync_status** -- status of time sync (see sntp_sync_status_t)

void **sntp_set_time_sync_notification_cb** (*sntp_sync_time_cb_t* callback)

Set a callback function for time synchronization notification.

Parameters **callback** -- a callback function

void **sntp_set_sync_interval** (uint32_t interval_ms)

Set the sync interval of SNTP operation.

Note: SNTPv4 RFC 4330 enforces a minimum sync interval of 15 seconds. This sync interval will be used in the next attempt update time throught SNTP. To apply the new sync interval call the sntp_restart() function, otherwise, it will be applied after the last interval expired.

Parameters **interval_ms** -- The sync interval in ms. It cannot be lower than 15 seconds, otherwise 15 seconds will be set.

uint32_t **sntp_get_sync_interval** (void)

Get the sync interval of SNTP operation.

Returns the sync interval

bool **sntp_restart** (void)

Restart SNTP.

Returns True - Restart False - SNTP was not initialized yet

void **esp_sntp_setoperatingmode** (*esp_sntp_operatingmode_t* operating_mode)

Sets SNTP operating mode. The mode has to be set before init.

Parameters **operating_mode** -- Desired operating mode

void **esp_sntp_init** (void)

Init and start SNTP service.

void **esp_sntp_stop** (void)

Stops SNTP service.

void **esp_sntp_setserver** (u8_t idx, const ip_addr_t *addr)

Sets SNTP server address.

Parameters

- **idx** -- Index of the server
- **addr** -- IP address of the server

void **esp_sntp_setservername** (u8_t idx, const char *server)

Sets SNTP hostname.

Parameters

- **idx** -- Index of the server
- **server** -- Name of the server

const char ***esp_sntp_getservername**(u8_t idx)

Gets SNTP server name.

Parameters **idx** -- Index of the server
Returns Name of the server

const ip_addr_t ***esp_sntp_getserver**(u8_t idx)

Get SNTP server IP.

Parameters **idx** -- Index of the server
Returns IP address of the server

bool **esp_sntp_enabled**(void)

Checks if sntp is enabled.

Returns true if sntp module is enabled

uint8_t **esp_sntp_getreachability**(uint8_t idx)

Gets the server reachability shift register as described in RFC 5905.

Parameters **idx** -- Index of the SNTP server
Returns reachability shift register

esp_sntp_operatingmode_t **esp_sntp_getoperatingmode**(void)

Get the configured operating mode.

Returns operating mode enum

static inline void **sntp_setoperatingmode**(u8_t operating_mode)

if not build within lwip, provide translating inlines, that will warn about thread safety

static inline void **sntp_servermode_dhcp**(int set_servers_from_dhcp)

static inline void **sntp_setservername**(u8_t idx, const char *server)

static inline void **sntp_init**(void)

static inline const char ***sntp_getservername**(u8_t idx)

static inline const ip_addr_t ***sntp_getserver**(u8_t idx)

static inline uint8_t **sntp_getreachability**(uint8_t idx)

static inline *esp_sntp_operatingmode_t* **sntp_getoperatingmode**(void)

Macros

esp_sntp_sync_time

Aliases for esp_sntp prefixed API (inherently thread safe)

esp_sntp_set_sync_mode

esp_sntp_get_sync_mode

esp_sntp_get_sync_status

esp_sntp_set_sync_status

esp_sntp_set_time_sync_notification_cb

esp_sntp_set_sync_interval

esp_sntp_get_sync_interval

esp_sntp_restart

SNTP_OPMODE_POLL

Type Definitions

typedef void (*`sntp_sync_time_cb_t`)(struct timeval *tv)

SNTP callback function for notifying about time sync event.

Param tv Time received from SNTP server.

Enumerations

enum `sntp_sync_mode_t`

SNTP time update mode.

Values:

enumerator `SNTP_SYNC_MODE_IMMED`

Update system time immediately when receiving a response from the SNTP server.

enumerator `SNTP_SYNC_MODE_SMOOTH`

Smooth time updating. Time error is gradually reduced using adjtime function. If the difference between SNTP response time and system time is large (more than 35 minutes) then update immediately.

enum `sntp_sync_status_t`

SNTP sync status.

Values:

enumerator `SNTP_SYNC_STATUS_RESET`

enumerator `SNTP_SYNC_STATUS_COMPLETED`

enumerator `SNTP_SYNC_STATUS_IN_PROGRESS`

enum `esp_sntp_operatingmode_t`

SNTP operating modes per lwip SNTP module.

Values:

enumerator `ESP_SNTP_OPMODE_POLL`

enumerator `ESP_SNTP_OPMODE_LISTENONLY`

2.10.29 Asynchronous Memory Copy

Overview

ESP32-C3 has a DMA engine which can help to offload internal memory copy operations from the CPU in an asynchronous way.

The async memcpy API wraps all DMA configurations and operations. The signature of *esp_async_memcpy()* is almost the same as the standard libc `memcpy` function.

The DMA allows multiple memory copy requests to be queued up before the first one is completed, which allows overlap of computation and memory copy. Moreover, it is still possible to know the exact time when a memory copy request is completed by registering an event callback.

Configure and Install Driver

There are several ways to install the async memcpy driver, depending on the underlying DMA engine:

- *esp_async_memcpy_install_gdma_ahb()* is used to install the async memcpy driver based on the AHB GDMA engine.
- *esp_async_memcpy_install()* is a generic API to install the async memcpy driver with a default DMA engine. If the SoC has the CP DMA engine, the default DMA engine is CP DMA. Otherwise, the default DMA engine is AHB GDMA.

Driver configuration is described in *async_memcpy_config_t*:

- `backlog`: This is used to configure the maximum number of memory copy transactions that can be queued up before the first one is completed. If this field is set to zero, then the default value 4 will be applied.
- `dma_burst_size`: Set the burst size in a DMA burst transfer.
- `flags`: This is used to enable some special driver features.

```
async_memcpy_config_t config = ASYNC_MEMCPY_DEFAULT_CONFIG();
// update the maximum data stream supported by underlying DMA engine
config.backlog = 8;
async_memcpy_handle_t driver = NULL;
ESP_ERROR_CHECK(esp_async_memcpy_install(&config, &driver)); // install driver␣
↪with default DMA engine
```

Send Memory Copy Request

esp_async_memcpy() is the API to send memory copy request to DMA engine. It must be called after driver is installed successfully. This API is thread safe, so it can be called from different tasks.

Different from the libc version of `memcpy`, you can optionally pass a callback to *esp_async_memcpy()*, so that you can be notified when the memory copy is finished. Note that the callback is executed in the ISR context, please make sure you will not call any blocking functions in the callback.

The prototype of the callback function is *async_memcpy_isr_cb_t*. The callback function should only return true if it wakes up a high priority task by RTOS APIs like `xSemaphoreGiveFromISR()`.

```
// Callback implementation, running in ISR context
static bool my_async_memcpy_cb(async_memcpy_handle_t mcp_hdl, async_memcpy_event_t␣
↪*event, void *cb_args)
{
    SemaphoreHandle_t sem = (SemaphoreHandle_t)cb_args;
    BaseType_t high_task_wakeup = pdFALSE;
    xSemaphoreGiveFromISR(semphr, &high_task_wakeup); // high_task_wakeup set to␣
↪pdTRUE if some high priority task unblocked
    return high_task_wakeup == pdTRUE;
}
```

(continues on next page)

(continued from previous page)

```
// Create a semaphore used to report the completion of async memcpy
SemaphoreHandle_t semphr = xSemaphoreCreateBinary();

// Called from user's context
ESP_ERROR_CHECK(esp_async_memcpy(driver_handle, to, from, copy_len, my_async_
↪memcpy_cb, my_semaphore));
// Do something else here
xSemaphoreTake(my_semaphore, portMAX_DELAY); // Wait until the buffer copy is done
```

Uninstall Driver

`esp_async_memcpy_uninstall()` is used to uninstall asynchronous memcpy driver. It is not necessary to uninstall the driver after each memcpy operation. If you know your application will not use this driver anymore, then this API can recycle the memory and other hardware resources for you.

API Reference

Header File

- components/esp_hw_support/include/esp_async_memcpy.h
- This header file can be included with:

```
#include "esp_async_memcpy.h"
```

Functions

esp_err_t **esp_async_memcpy_install_gdma_ahb**(const *async_memcpy_config_t* *config, *async_memcpy_handle_t* *mcp)

Install async memcpy driver, with AHB-GDMA as the backend.

Parameters
- **config** -- **[in]** Configuration of async memcpy
- **mcp** -- **[out]** Returned driver handle

Returns
- ESP_OK: Install async memcpy driver successfully
- ESP_ERR_INVALID_ARG: Install async memcpy driver failed because of invalid argument
- ESP_ERR_NO_MEM: Install async memcpy driver failed because out of memory
- ESP_FAIL: Install async memcpy driver failed because of other error

esp_err_t **esp_async_memcpy_install**(const *async_memcpy_config_t* *config, *async_memcpy_handle_t* *mcp)

Install async memcpy driver with the default DMA backend.

Note: On chip with CPDMA support, CPDMA is the default choice. On chip with AHB-GDMA support, AHB-GDMA is the default choice.

Parameters
- **config** -- **[in]** Configuration of async memcpy
- **mcp** -- **[out]** Returned driver handle

Returns
- ESP_OK: Install async memcpy driver successfully
- ESP_ERR_INVALID_ARG: Install async memcpy driver failed because of invalid argument
- ESP_ERR_NO_MEM: Install async memcpy driver failed because out of memory

- ESP_FAIL: Install async memcpy driver failed because of other error

esp_err_t **esp_async_memcpy_uninstall** (*async_memcpy_handle_t* mcp)

Uninstall async memcpy driver.

Parameters **mcp** -- **[in]** Handle of async memcpy driver that returned from `esp_async_memcpy_install`

Returns

- ESP_OK: Uninstall async memcpy driver successfully
- ESP_ERR_INVALID_ARG: Uninstall async memcpy driver failed because of invalid argument
- ESP_FAIL: Uninstall async memcpy driver failed because of other error

esp_err_t **esp_async_memcpy** (*async_memcpy_handle_t* mcp, void *dst, void *src, size_t n, *async_memcpy_isr_cb_t* cb_isr, void *cb_args)

Send an asynchronous memory copy request.

Note: The callback function is invoked in interrupt context, never do blocking jobs in the callback.

Parameters

- **mcp** -- **[in]** Handle of async memcpy driver that returned from `esp_async_memcpy_install`
- **dst** -- **[in]** Destination address (copy to)
- **src** -- **[in]** Source address (copy from)
- **n** -- **[in]** Number of bytes to copy
- **cb_isr** -- **[in]** Callback function, which got invoked in interrupt context. Set to NULL can bypass the callback.
- **cb_args** -- **[in]** User defined argument to be passed to the callback function

Returns

- ESP_OK: Send memory copy request successfully
- ESP_ERR_INVALID_ARG: Send memory copy request failed because of invalid argument
- ESP_FAIL: Send memory copy request failed because of other error

Structures

struct **async_memcpy_event_t**

Async memory copy event data.

Public Members

void ***data**

Event data

struct **async_memcpy_config_t**

Type of async memcpy configuration.

Public Members

uint32_t **backlog**

Maximum number of transactions that can be prepared in the background

size_t **sram_trans_align**

DMA transfer alignment (both in size and address) for SRAM memory

size_t **psram_trans_align**

DMA transfer alignment (both in size and address) for PSRAM memory

size_t **dma_burst_size**

DMA transfer burst size, in bytes

uint32_t **flags**

Extra flags to control async memcpy feature

Macros

ASYNC_MEMCPY_DEFAULT_CONFIG()

Default configuration for async memcpy.

Type Definitions

typedef struct async_memcpy_context_t ***async_memcpy_handle_t**

Async memory copy driver handle.

typedef bool (***async_memcpy_isr_cb_t**)(*async_memcpy_handle_t* mcp_hdl, *async_memcpy_event_t* *event, void *cb_args)

Type of async memcpy interrupt callback function.

Note: User can call OS primitives (semaphore, mutex, etc) in the callback function. Keep in mind, if any OS primitive wakes high priority task up, the callback should return true.

Param mcp_hdl Handle of async memcpy
Param event Event object, which contains related data, reserved for future
Param cb_args User defined arguments, passed from esp_async_memcpy function
Return Whether a high priority task is woken up by the callback function

2.10.30 Watchdogs

Overview

ESP-IDF supports multiple types of watchdogs:

- Hardware Watchdog Timers
- Interrupt Watchdog Timer (IWDT)
- Task Watchdog Timer (TWDT)
- XTAL32K Watchdog Timer (Crystal 32K Watchdog Timer, i.e., XTWDT)

The Interrupt Watchdog is responsible for ensuring that ISRs (Interrupt Service Routines) are not blocked for a prolonged period of time. The TWDT is responsible for detecting instances of tasks running without yielding for a prolonged period.

The various watchdog timers can be enabled using the *Project Configuration Menu*. However, the TWDT can also be enabled during runtime.

Hardware Watchdog Timers

The chips have two groups of watchdog timers:

- Main System Watchdog Timer (MWDT_WDT) - used by Interrupt Watchdog Timer (IWDT) and Task Watchdog Timer (TWDT).
- RTC Watchdog Timer (RTC_WDT) - used to track the boot time from power-up until the user's main function (by default RTC Watchdog is disabled immediately before the user's main function).

Refer to the *Watchdog* section to understand how watchdogs are utilized in the bootloader.

The app's behaviour can be adjusted so the RTC Watchdog remains enabled after app startup. The Watchdog would need to be explicitly reset (i.e., fed) or disabled by the app to avoid the chip reset. To do this, set the *CONFIG_BOOTLOADER_WDT_DISABLE_IN_USER_CODE* option, modify the app as needed, and then recompile the app. In this case, the following APIs should be used:

- `wdt_hal_disable()`: see *To Disable RTC_WDT*
- `wdt_hal_feed()`: see *To Reset the RTC_WDT Counter*

If RTC_WDT is not reset/disabled in time, the chip will be automatically reset. See *RTC Watchdog Timeout* for more information.

Interrupt Watchdog Timer (IWDT)

The purpose of the IWDT is to ensure that interrupt service routines (ISRs) are not blocked from running for a prolonged period of time (i.e., the IWDT timeout period). Preventing ISRs from running in a timely manner is undesirable as it can increase ISR latency, and also prevent task switching (as task switching is executed form an ISR). The things that can block ISRs from running include:

- Disabling interrupts
- Critical Sections (also disables interrupts)
- Other same/higher priority ISRs which block same/lower priority ISRs from running

The IWDT utilizes the MWDT_WDT watchdog timer in Timer Group 1 as its underlying hardware timer and leverages the FreeRTOS tick interrupt on each CPU to feed the watchdog timer. If the tick interrupt on a particular CPU is not run at within the IWDT timeout period, it is indicative that something is blocking ISRs from being run on that CPU (see the list of reasons above).

When the IWDT times out, the default action is to invoke the panic handler and display the panic reason as `Interrupt wdt timeout on CPU0` or `Interrupt wdt timeout on CPU1` (as applicable). Depending on the panic handler's configured behavior (see *CONFIG_ESP_SYSTEM_PANIC*), users can then debug the source of the IWDT timeout (via the backtrace, OpenOCD, gdbstub etc) or simply reset the chip (which may be preferred in a production environment).

If for whatever reason the panic handler is unable to run after an IWDT timeout, the IWDT has a second stage timeout that will hard-reset the chip (i.e., a system reset).

Configuration

- The IWDT is enabled by default via the *CONFIG_ESP_INT_WDT* option.
- The IWDT's timeout is configured by setting the *CONFIG_ESP_INT_WDT_TIMEOUT_MS* option.
  - Note that the default timeout is higher if PSRAM support is enabled, as a critical section or interrupt routine that accesses a large amount of PSRAM takes longer to complete in some circumstances.
  - The timeout should always at least twice longer than the period between FreeRTOS ticks (see *CONFIG_FREERTOS_HZ*).

Tuning If you find the IWDT timeout is triggered because an interrupt or critical section is running longer than the timeout period, consider rewriting the code:

- Critical sections should be made as short as possible. Any non-critical code/computation should be placed outside the critical section.
- Interrupt handlers should also perform the minimum possible amount of computation. Users can consider deferring any computation to a task by having the ISR push data to a task using queues.

Neither critical sections or interrupt handlers should ever block waiting for another event to occur. If changing the code to reduce the processing time is not possible or desirable, it is possible to increase the *CONFIG_ESP_INT_WDT_TIMEOUT_MS* setting instead.

Task Watchdog Timer (TWDT)

The Task Watchdog Timer (TWDT) is used to monitor particular tasks, ensuring that they are able to execute within a given timeout period. The TWDT primarily watches the Idle Tasks of each CPU, however any task can subscribe to be watched by the TWDT. By watching the Idle Tasks of each CPU, the TWDT can detect instances of tasks running for a prolonged period of time without yielding. This can be an indicator of poorly written code that spinloops on a peripheral, or a task that is stuck in an infinite loop.

The TWDT is built around the MWDT_WDT watchdog timer in Timer Group 0. When a timeout occurs, an interrupt is triggered.

Users can define the function `esp_task_wdt_isr_user_handler` in the user code, in order to receive the timeout event and extend the default behavior.

Usage The following functions can be used to watch tasks using the TWDT:

- `esp_task_wdt_init()` to initialize the TWDT and subscribe the idle tasks.
- `esp_task_wdt_add()` subscribes other tasks to the TWDT.
- Once subscribed, `esp_task_wdt_reset()` should be called from the task to feed the TWDT.
- `esp_task_wdt_delete()` unsubscribes a previously subscribed task.
- `esp_task_wdt_deinit()` unsubscribes the idle tasks and deinitializes the TWDT.

In the case where applications need to watch at a more granular level (i.e., ensure that a particular functions/stub/code-path is called), the TWDT allows subscription of `users`.

- `esp_task_wdt_add_user()` to subscribe an arbitrary user of the TWDT. This function returns a user handle to the added user.
- `esp_task_wdt_reset_user()` must be called using the user handle in order to prevent a TWDT timeout.
- `esp_task_wdt_delete_user()` unsubscribes an arbitrary user of the TWDT.

Configuration The default timeout period for the TWDT is set using config item *CONFIG_ESP_TASK_WDT_TIMEOUT_S*. This should be set to at least as long as you expect any single task needs to monopolize the CPU (for example, if you expect the app will do a long intensive calculation and should not yield to other tasks). It is also possible to change this timeout at runtime by calling `esp_task_wdt_init()`.

Note: Erasing large flash areas can be time consuming and can cause a task to run continuously, thus triggering a TWDT timeout. The following two methods can be used to avoid this:

- Increase *CONFIG_ESP_TASK_WDT_TIMEOUT_S* in menuconfig for a larger watchdog timeout period.
- You can also call `esp_task_wdt_init()` to increase the watchdog timeout period before erasing a large flash area.

For more information, you can refer to *SPI Flash API*.

The following config options control TWDT configuration. They are all enabled by default:

- *CONFIG_ESP_TASK_WDT_EN* - enables TWDT feature. If this option is disabled, TWDT cannot be used, even if initialized at runtime.
- *CONFIG_ESP_TASK_WDT_INIT* - the TWDT is initialized automatically during startup. If this option is disabled, it is still possible to initialize the Task WDT at runtime by calling `esp_task_wdt_init()`.
- *CONFIG_ESP_TASK_WDT_CHECK_IDLE_TASK_CPU0* - Idle task is subscribed to the TWDT during startup. If this option is disabled, it is still possible to subscribe the idle task by calling `esp_task_wdt_init()` again.

Note: On a TWDT timeout the default behaviour is to simply print a warning and a backtrace before continuing running the app. If you want a timeout to cause a panic and a system reset then this can be configured through *CONFIG_ESP_TASK_WDT_PANIC*.

XTAL32K Watchdog Timer (XTWDT)

One of the optional clock inputs to the ESP32-C3 is an external 32 kHz crystal oscillator (XTAL32K) that is used as a clock source (`XTAL32K_CLK`) to various subsystems (such as the RTC).

The XTWDT is a dedicated watchdog timer used to ensure that the XTAL32K is functioning correctly. When `XTAL32K_CLK` works as the clock source of `RTC_SLOW_CLK` and stops oscillating, the XTWDT will detect this and generate an interrupt. It also provides functionality for automatically switching over to the internal, but less accurate oscillator as the `RTC_SLOW_CLK` source.

Since the switch to the backup clock is done in hardware it can also happen during Deep Sleep. This means that even if `XTAL32K_CLK` stops functioning while the chip is in Deep Sleep, waiting for a timer to expire, it is still able to wake-up as planned.

If the `XTAL32K_CLK` starts functioning normally again, you can call `esp_xt_wdt_restore_clk` to switch back to this clock source and re-enable the watchdog timer.

Configuration

- When the external 32 KHz crystal or oscillator is selected (*CONFIG_RTC_CLK_SRC*) the XTWDT can be enabled via the *CONFIG_ESP_XT_WDT* configuration option.
- The timeout is configured by setting the *CONFIG_ESP_XT_WDT_TIMEOUT* option.
- The automatic backup clock functionality is enabled via the ref:*CONFIG_ESP_XT_WDT_BACKUP_CLK_ENABLE* configuration option.

JTAG & Watchdogs

While debugging using OpenOCD, the CPUs are halted every time a breakpoint is reached. However if the watchdog timers continue to run when a breakpoint is encountered, they will eventually trigger a reset making it very difficult to debug code. Therefore OpenOCD will disable the hardware timers of both the interrupt and task watchdogs at every breakpoint. Moreover, OpenOCD will not re-enable them upon leaving the breakpoint. This means that interrupt watchdog and task watchdog functionality will essentially be disabled. No warnings or panics from either watchdogs will be generated when the ESP32-C3 is connected to OpenOCD via JTAG.

API Reference

Task Watchdog A full example using the Task Watchdog is available in esp-idf: system/task_watchdog

Header File

- components/esp_system/include/esp_task_wdt.h
- This header file can be included with:

```
#include "esp_task_wdt.h"
```

Functions

esp_err_t **esp_task_wdt_init** (const *esp_task_wdt_config_t* *config)

Initialize the Task Watchdog Timer (TWDT)

This function configures and initializes the TWDT. This function will subscribe the idle tasks if configured to do so. For other tasks, users can subscribe them using esp_task_wdt_add() or esp_task_wdt_add_user(). This function won't start the timer if no task have been registered yet.

Note: esp_task_wdt_init() must only be called after the scheduler is started. Moreover, it must not be called by multiple tasks simultaneously.

Parameters **config** -- **[in]** Configuration structure

Returns

- ESP_OK: Initialization was successful
- ESP_ERR_INVALID_STATE: Already initialized
- Other: Failed to initialize TWDT

esp_err_t **esp_task_wdt_reconfigure** (const *esp_task_wdt_config_t* *config)

Reconfigure the Task Watchdog Timer (TWDT)

The function reconfigures the running TWDT. It must already be initialized when this function is called.

Note: esp_task_wdt_reconfigure() must not be called by multiple tasks simultaneously.

Parameters **config** -- **[in]** Configuration structure

Returns

- ESP_OK: Reconfiguring was successful
- ESP_ERR_INVALID_STATE: TWDT not initialized yet
- Other: Failed to initialize TWDT

esp_err_t **esp_task_wdt_deinit** (void)

Deinitialize the Task Watchdog Timer (TWDT)

This function will deinitialize the TWDT, and unsubscribe any idle tasks. Calling this function whilst other tasks are still subscribed to the TWDT, or when the TWDT is already deinitialized, will result in an error code being returned.

Note: esp_task_wdt_deinit() must not be called by multiple tasks simultaneously.

Returns

- ESP_OK: TWDT successfully deinitialized
- Other: Failed to deinitialize TWDT

esp_err_t **esp_task_wdt_add** (*TaskHandle_t* task_handle)

Subscribe a task to the Task Watchdog Timer (TWDT)

This function subscribes a task to the TWDT. Each subscribed task must periodically call esp_task_wdt_reset() to prevent the TWDT from elapsing its timeout period. Failure to do so will result in a TWDT timeout.

Parameters **task_handle** -- Handle of the task. Input NULL to subscribe the current running task to the TWDT

Returns

- ESP_OK: Successfully subscribed the task to the TWDT
- Other: Failed to subscribe task

esp_err_t **esp_task_wdt_add_user**(const char *user_name, *esp_task_wdt_user_handle_t* *user_handle_ret)

Subscribe a user to the Task Watchdog Timer (TWDT)

This function subscribes a user to the TWDT. A user of the TWDT is usually a function that needs to run periodically. Each subscribed user must periodically call esp_task_wdt_reset_user() to prevent the TWDT from elapsing its timeout period. Failure to do so will result in a TWDT timeout.

Parameters
- **user_name** -- **[in]** String to identify the user
- **user_handle_ret** -- **[out]** Handle of the user

Returns
- ESP_OK: Successfully subscribed the user to the TWDT
- Other: Failed to subscribe user

esp_err_t **esp_task_wdt_reset**(void)

Reset the Task Watchdog Timer (TWDT) on behalf of the currently running task.

This function will reset the TWDT on behalf of the currently running task. Each subscribed task must periodically call this function to prevent the TWDT from timing out. If one or more subscribed tasks fail to reset the TWDT on their own behalf, a TWDT timeout will occur.

Returns
- ESP_OK: Successfully reset the TWDT on behalf of the currently running task
- Other: Failed to reset

esp_err_t **esp_task_wdt_reset_user**(*esp_task_wdt_user_handle_t* user_handle)

Reset the Task Watchdog Timer (TWDT) on behalf of a user.

This function will reset the TWDT on behalf of a user. Each subscribed user must periodically call this function to prevent the TWDT from timing out. If one or more subscribed users fail to reset the TWDT on their own behalf, a TWDT timeout will occur.

Parameters **user_handle** -- **[in]** User handle
- ESP_OK: Successfully reset the TWDT on behalf of the user
- Other: Failed to reset

esp_err_t **esp_task_wdt_delete**(*TaskHandle_t* task_handle)

Unsubscribes a task from the Task Watchdog Timer (TWDT)

This function will unsubscribe a task from the TWDT. After being unsubscribed, the task should no longer call esp_task_wdt_reset().

Parameters **task_handle** -- **[in]** Handle of the task. Input NULL to unsubscribe the current running task.

Returns
- ESP_OK: Successfully unsubscribed the task from the TWDT
- Other: Failed to unsubscribe task

esp_err_t **esp_task_wdt_delete_user**(*esp_task_wdt_user_handle_t* user_handle)

Unsubscribes a user from the Task Watchdog Timer (TWDT)

This function will unsubscribe a user from the TWDT. After being unsubscribed, the user should no longer call esp_task_wdt_reset_user().

Parameters **user_handle** -- **[in]** User handle

Returns
- ESP_OK: Successfully unsubscribed the user from the TWDT
- Other: Failed to unsubscribe user

esp_err_t **esp_task_wdt_status** (*TaskHandle_t* task_handle)

Query whether a task is subscribed to the Task Watchdog Timer (TWDT)

This function will query whether a task is currently subscribed to the TWDT, or whether the TWDT is initialized.

Parameters **task_handle** -- **[in]** Handle of the task. Input NULL to query the current running task.

Returns :

- ESP_OK: The task is currently subscribed to the TWDT
- ESP_ERR_NOT_FOUND: The task is not subscribed
- ESP_ERR_INVALID_STATE: TWDT was never initialized

void **esp_task_wdt_isr_user_handler** (void)

User ISR callback placeholder.

This function is called by task_wdt_isr function (ISR for when TWDT times out). It can be defined in user code to handle TWDT events.

Note: It has the same limitations as the interrupt function. Do not use ESP_LOGx functions inside.

esp_err_t **esp_task_wdt_print_triggered_tasks** (*task_wdt_msg_handler* msg_handler, void *opaque, int *cpus_fail)

Prints or retrieves information about tasks/users that triggered the Task Watchdog Timeout.

This function provides various operations to handle tasks/users that did not reset the Task Watchdog in time. It can print detailed information about these tasks/users, such as their names, associated CPUs, and whether they have been reset. Additionally, it can retrieve the total length of the printed information or the CPU affinity of the failing tasks.

Note:

- If `msg_handler` is not provided, the information will be printed to console using ESP_EARLY_LOGE.
- If `msg_handler` is provided, the function will send the printed information to the provided message handler function.
- If `cpus_fail` is provided, the function will store the CPU affinity of the failing tasks in the provided integer.
- During the execution of this function, logging is allowed in critical sections, as TWDT timeouts are considered fatal errors.

Parameters

- **msg_handler** -- **[in]** Optional message handler function that will be called for each printed line.
- **opaque** -- **[in]** Optional pointer to opaque data that will be passed to the message handler function.
- **cpus_fail** -- **[out]** Optional pointer to an integer where the CPU affinity of the failing tasks will be stored.

Returns

- ESP_OK: The function executed successfully.
- ESP_FAIL: No triggered tasks were found, and thus no information was printed or retrieved.

Structures

struct **esp_task_wdt_config_t**

Task Watchdog Timer (TWDT) configuration structure.

Public Members

uint32_t **timeout_ms**

TWDT timeout duration in milliseconds

uint32_t **idle_core_mask**

Bitmask of the core whose idle task should be subscribed on initialization where 1 << i means that core i's idle task will be monitored by the TWDT

bool **trigger_panic**

Trigger panic when timeout occurs

Type Definitions

typedef struct esp_task_wdt_user_handle_s ***esp_task_wdt_user_handle_t**

Task Watchdog Timer (TWDT) user handle.

typedef void (***task_wdt_msg_handler**)(void *opaque, const char *msg)

Code examples for this API section are provided in the system directory of ESP-IDF examples.

API Guides

4.1 Application Level Tracing Library

4.1.1 Overview

ESP-IDF provides a useful feature for program behavior analysis: application level tracing. It is implemented in the corresponding library and can be enabled in menuconfig. This feature allows to transfer arbitrary data between host and ESP32-C3 via JTAG, UART, or USB interfaces with small overhead on program execution. It is possible to use JTAG and UART interfaces simultaneously. The UART interface is mostly used for connection with SEGGER SystemView tool (see SystemView).

Developers can use this library to send application-specific state of execution to the host and receive commands or other types of information from the opposite direction at runtime. The main use cases of this library are:

1. Collecting application-specific data. See *Application Specific Tracing*.
2. Lightweight logging to the host. See *Logging to Host*.
3. System behavior analysis. See *System Behavior Analysis with SEGGER SystemView*.
4. Source code coverage. See *Gcov (Source Code Coverage)*.

Tracing components used when working over JTAG interface are shown in the figure below.

4.1.2 Modes of Operation

The library supports two modes of operation:

Post-mortem mode: This is the default mode. The mode does not need interaction with the host side. In this mode, tracing module does not check whether the host has read all the data from *HW UP BUFFER*, but directly overwrites old data with the new ones. This mode is useful when only the latest trace data is interesting to the user, e.g., for analyzing program's behavior just before the crash. The host can read the data later on upon user request, e.g., via special OpenOCD command in case of working via JTAG interface.

Streaming mode: Tracing module enters this mode when the host connects to ESP32-C3. In this mode, before writing new data to *HW UP BUFFER*, the tracing module checks that whether there is enough space in it and if necessary, waits for the host to read data and free enough memory. Maximum waiting time is controlled via timeout values passed by users to corresponding API routines. So when application tries to write data to the trace buffer using the finite value of the maximum waiting time, it is possible that this data will be dropped. This is especially true for tracing from time critical code (ISRs, OS scheduler code, etc.) where infinite timeouts can lead to system malfunction. In order to avoid loss of such critical data, developers can enable additional data buffering via menuconfig option

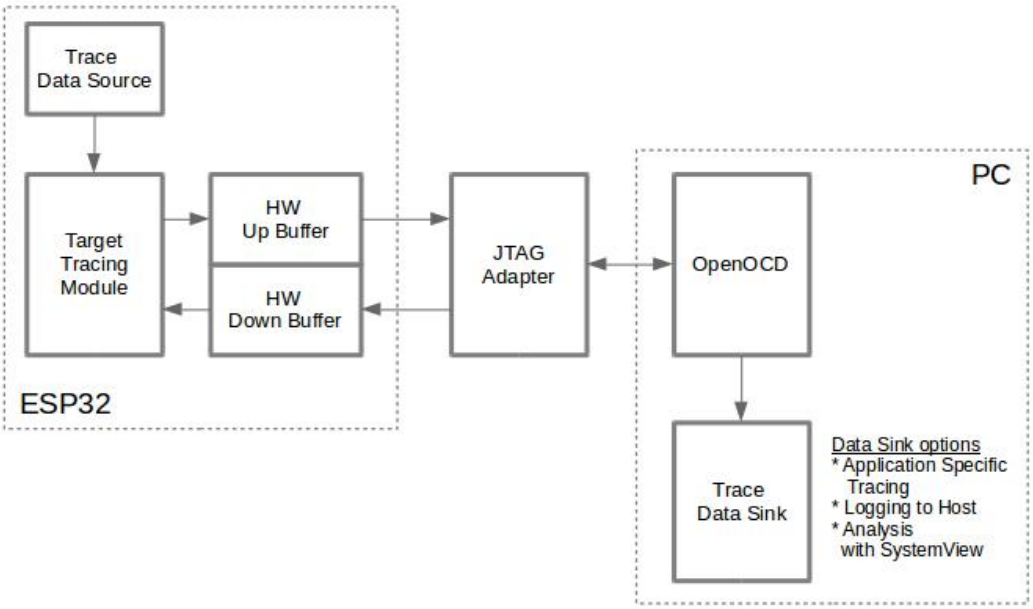

Fig. 1: Tracing Components Used When Working Over JTAG

CONFIG_APPTRACE_PENDING_DATA_SIZE_MAX. This macro specifies the size of data which can be buffered in above conditions. The option can also help to overcome situation when data transfer to the host is temporarily slowed down, e.g., due to USB bus congestions. But it will not help when the average bitrate of the trace data stream exceeds the hardware interface capabilities.

4.1.3 Configuration Options and Dependencies

Using of this feature depends on two components:

1. **Host side:** Application tracing is done over JTAG, so it needs OpenOCD to be set up and running on host machine. For instructions on how to set it up, please see *JTAG Debugging* for details.
2. **Target side:** Application tracing functionality can be enabled in menuconfig. Please go to `Component config` > `Application Level Tracing` menu, which allows selecting destination for the trace data (hardware interface for transport: JTAG or/and UART). Choosing any of the destinations automatically enables the `CONFIG_APPTRACE_ENABLE` option. For UART interfaces, users have to define baud rate, TX and RX pins numbers, and additional UART-related parameters.

Note: In order to achieve higher data rates and minimize the number of dropped packets, it is recommended to optimize the setting of JTAG clock frequency, so that it is at maximum and still provides stable operation of JTAG. See *Optimize JTAG Speed*.

There are two additional menuconfig options not mentioned above:

1. *Threshold for flushing last trace data to host on panic* (*CONFIG_APPTRACE_POSTMORTEM_FLUSH_THRESH*). This option is necessary due to the nature of working over JTAG. In this mode, trace data is exposed to the host in 16 KB blocks. In post-mortem mode, when one block is filled, it is exposed to the host and the previous one becomes unavailable. In other words, the trace data is overwritten in 16 KB granularity. On panic, the latest data from the current input block is exposed to the host and the host can read them for post-analysis. System panic may occur when a very small amount of data are not exposed to the host yet. In this case, the previous 16 KB of collected data will be lost and the host will see the latest, but very small piece of the trace.

It can be insufficient to diagnose the problem. This menuconfig option allows avoiding such situations. It controls the threshold for flushing data in case of apanic. For example, users can decide that it needs no less than 512 bytes of the recent trace data, so if there is less then 512 bytes of pending data at the moment of panic, they will not be flushed and will not overwrite the previous 16 KB. The option is only meaningful in post-mortem mode and when working over JTAG.

2. *Timeout for flushing last trace data to host on panic* (*CONFIG_APPTRACE_ONPANIC_HOST_FLUSH_TMO*). The option is only meaningful in streaming mode and it controls the maximum time that the tracing module will wait for the host to read the last data in case of panic.
3. *UART RX/TX ring buffer size* (*CONFIG_APPTRACE_UART_TX_BUFF_SIZE*). The size of the buffer depends on the amount of data transferred through the UART.
4. *UART TX message size* (*CONFIG_APPTRACE_UART_TX_MSG_SIZE*). The maximum size of the single message to transfer.

4.1.4 How to Use This Library

This library provides APIs for transferring arbitrary data between the host and ESP32-C3. When enabled in menuconfig, the target application tracing module is initialized automatically at the system startup, so all what the user needs to do is to call corresponding APIs to send, receive or flush the data.

Application Specific Tracing

In general, users should decide what type of data should be transferred in every direction and how these data must be interpreted (processed). The following steps must be performed to transfer data between the target and the host:

1. On the target side, users should implement algorithms for writing trace data to the host. Piece of code below shows an example on how to do this.

```
#include "esp_app_trace.h"
...
char buf[] = "Hello World!";
esp_err_t res = esp_apptrace_write(ESP_APPTRACE_DEST_TRAX, buf,␣
↪strlen(buf), ESP_APPTRACE_TMO_INFINITE);
if (res != ESP_OK) {
    ESP_LOGE(TAG, "Failed to write data to host!");
    return res;
}
```

`esp_apptrace_write()` function uses memcpy to copy user data to the internal buffer. In some cases, it can be more optimal to use `esp_apptrace_buffer_get()` and `esp_apptrace_buffer_put()` functions. They allow developers to allocate buffer and fill it themselves. The following piece of code shows how to do this.

```
#include "esp_app_trace.h"
...
int number = 10;
char *ptr = (char *)esp_apptrace_buffer_get(ESP_APPTRACE_DEST_TRAX, 32,
↪ 100/*tmo in us*/);
if (ptr == NULL) {
    ESP_LOGE(TAG, "Failed to get buffer!");
    return ESP_FAIL;
}
sprintf(ptr, "Here is the number %d", number);
esp_err_t res = esp_apptrace_buffer_put(ESP_APPTRACE_DEST_TRAX, ptr,␣
↪100/*tmo in us*/);
if (res != ESP_OK) {
    /* in case of error host tracing tool (e.g., OpenOCD) will report␣
↪incomplete user buffer */
    ESP_LOGE(TAG, "Failed to put buffer!");
    return res;
}
```

Also according to his needs, the user may want to receive data from the host. Piece of code below shows an example on how to do this.

```
#include "esp_app_trace.h"
...
char buf[32];
char down_buf[32];
size_t sz = sizeof(buf);

/* config down buffer */
esp_apptrace_down_buffer_config(down_buf, sizeof(down_buf));
/* check for incoming data and read them if any */
esp_err_t res = esp_apptrace_read(ESP_APPTRACE_DEST_TRAX, buf, &sz, 0/
↪*do not wait*/);
if (res != ESP_OK) {
    ESP_LOGE(TAG, "Failed to read data from host!");
    return res;
}
if (sz > 0) {
    /* we have data, process them */
    ...
}
```

`esp_apptrace_read()` function uses memcpy to copy host data to user buffer. In some casesm it can be more optimal to use `esp_apptrace_down_buffer_get()` and `esp_apptrace_down_buffer_put()` functions. They allow developers to occupy chunk of read buffer and process it in-place. The following piece of code shows how to do this.

```
#include "esp_app_trace.h"
...
char down_buf[32];
uint32_t *number;
size_t sz = 32;

/* config down buffer */
esp_apptrace_down_buffer_config(down_buf, sizeof(down_buf));
char *ptr = (char *)esp_apptrace_down_buffer_get(ESP_APPTRACE_DEST_
↪TRAX, &sz, 100/*tmo in us*/);
if (ptr == NULL) {
    ESP_LOGE(TAG, "Failed to get buffer!");
    return ESP_FAIL;
}
if (sz > 4) {
    number = (uint32_t *)ptr;
    printf("Here is the number %d", *number);
} else {
    printf("No data");
}
esp_err_t res = esp_apptrace_down_buffer_put(ESP_APPTRACE_DEST_TRAX,␣
↪ptr, 100/*tmo in us*/);
if (res != ESP_OK) {
    /* in case of error host tracing tool (e.g., OpenOCD) will report␣
↪incomplete user buffer */
    ESP_LOGE(TAG, "Failed to put buffer!");
    return res;
}
```

2. The next step is to build the program image and download it to the target as described in the *Getting Started Guide*.
3. Run OpenOCD (see *JTAG Debugging*).
4. Connect to OpenOCD telnet server. It can be done using the following command in terminal `telnet <oocd_host> 4444`. If telnet session is opened on the same machine which runs OpenOCD, you can use `localhost` as `<oocd_host>` in the command above.

5. Start trace data collection using special OpenOCD command. This command will transfer tracing data and redirect them to the specified file or socket (currently only files are supported as trace data destination). For description of the corresponding commands, see *OpenOCD Application Level Tracing Commands*.
6. The final step is to process received data. Since the format of data is defined by users, the processing stage is out of the scope of this document. Good starting points for data processor are python scripts in `$IDF_PATH/tools/esp_app_trace`: `apptrace_proc.py` (used for feature tests) and `logtrace_proc.py` (see more details in section *Logging to Host*).

OpenOCD Application Level Tracing Commands *HW UP BUFFER* is shared between user data blocks and the filling of the allocated memory is performed on behalf of the API caller (in task or ISR context). In multithreading environment, it can happen that the task/ISR which fills the buffer is preempted by another high priority task/ISR. So it is possible that the user data preparation process is not completed at the moment when that chunk is read by the host. To handle such conditions, the tracing module prepends all user data chunks with header which contains the allocated user buffer size (2 bytes) and the length of the actually written data (2 bytes). So the total length of the header is 4 bytes. OpenOCD command which reads trace data reports error when it reads incomplete user data chunk, but in any case, it puts the contents of the whole user chunk (including unfilled area) to the output file.

Below is the description of available OpenOCD application tracing commands.

Note: Currently, OpenOCD does not provide commands to send arbitrary user data to the target.

Command usage:

```
esp apptrace [start <options>] | [stop] | [status] | [dump <cores_num> <outfile>]
```

Sub-commands:

start Start tracing (continuous streaming).
stop Stop tracing.
status Get tracing status.
dump Dump all data from (post-mortem dump).

Start command syntax:

```
start <outfile> [poll_period [trace_size [stop_tmo [wait4halt [skip_size]]]]
```

outfile Path to file to save data from both CPUs. This argument should have the following format: `file://path/to/file`.
poll_period Data polling period (in ms) for available trace data. If greater than 0, then command runs in non-blocking mode. By default, 1 ms.
trace_size Maximum size of data to collect (in bytes). Tracing is stopped after specified amount of data is received. By default, -1 (trace size stop trigger is disabled).
stop_tmo Idle timeout (in sec). Tracing is stopped if there is no data for specified period of time. By default, -1 (disable this stop trigger). Optionally set it to value longer than longest pause between tracing commands from target.
wait4halt If 0, start tracing immediately, otherwise command waits for the target to be halted (after reset, by breakpoint etc.) and then automatically resumes it and starts tracing. By default, 0.
skip_size Number of bytes to skip at the start. By default, 0.

Note: If `poll_period` is 0, OpenOCD telnet command line will not be available until tracing is stopped. You must stop it manually by resetting the board or pressing Ctrl+C in OpenOCD window (not one with the telnet session). Another option is to set `trace_size` and wait until this size of data is collected. At this point, tracing stops automatically.

Command usage examples:

1. Collect 2048 bytes of tracing data to the file `trace.log`. The file will be saved in the `openocd-esp32` directory.

   ```
   esp apptrace start file://trace.log 1 2048 5 0 0
   ```

   The tracing data will be retrieved and saved in non-blocking mode. This process will stop automatically after 2048 bytes are collected, or if no data are available for more than 5 seconds.

   Note: Tracing data is buffered before it is made available to OpenOCD. If you see "Data timeout!" message, then it is likely that the target is not sending enough data to empty the buffer to OpenOCD before the timeout. Either increase the timeout or use the function `esp_apptrace_flush()` to flush the data on specific intervals.

2. Retrieve tracing data indefinitely in non-blocking mode.

   ```
   esp apptrace start file://trace.log 1 -1 -1 0 0
   ```

   There is no limitation on the size of collected data and there is no data timeout set. This process may be stopped by issuing `esp apptrace stop` command on OpenOCD telnet prompt, or by pressing Ctrl+C in OpenOCD window.
3. Retrieve tracing data and save them indefinitely.

   ```
   esp apptrace start file://trace.log 0 -1 -1 0 0
   ```

   OpenOCD telnet command line prompt will not be available until tracing is stopped. To stop tracing, press Ctrl+C in the OpenOCD window.
4. Wait for the target to be halted. Then resume the target's operation and start data retrieval. Stop after collecting 2048 bytes of data:

   ```
   esp apptrace start file://trace.log 0 2048 -1 1 0
   ```

   To configure tracing immediately after reset, use the OpenOCD `reset halt` command.

Logging to Host

ESP-IDF implements a useful feature: logging to the host via application level tracing library. This is a kind of semihosting when all *ESP_LOGx* calls send strings to be printed to the host instead of UART. This can be useful because "printing to host" eliminates some steps performed when logging to UART. Most part of the work is done on the host.

By default, ESP-IDF's logging library uses vprintf-like function to write formatted output to dedicated UART. In general, it involves the following steps:

1. Format string is parsed to obtain type of each argument.
2. According to its type, every argument is converted to string representation.
3. Format string combined with converted arguments is sent to UART.

Though the implementation of the vprintf-like function can be optimized to a certain level, all steps above have to be performed in any case and every step takes some time (especially item 3). So it frequently occurs that with additional log added to the program to identify the problem, the program behavior is changed and the problem cannot be reproduced. And in the worst cases, the program cannot work normally at all and ends up with an error or even hangs.

Possible ways to overcome this problem are to use higher UART bitrates (or another faster interface) and/or to move string formatting procedure to the host.

The application level tracing feature can be used to transfer log information to the host using `esp_apptrace_vprintf` function. This function does not perform full parsing of the format string and arguments. Instead, it just calculates the number of arguments passed and sends them along with the format string address to the host. On the host, log data is processed and printed out by a special Python script.

Limitations Current implementation of logging over JTAG has some limitations:

1. No support for tracing from `ESP_EARLY_LOGx` macros.
2. No support for printf arguments whose size exceeds 4 bytes (e.g., `double` and `uint64_t`).
3. Only strings from the .rodata section are supported as format strings and arguments.
4. The maximum number of printf arguments is 256.

How To Use It In order to use logging via trace module, users need to perform the following steps:

1. On the target side, the special vprintf-like function *`esp_apptrace_vprintf()`* needs to be installed. It sends log data to the host. An example is `esp_log_set_vprintf(esp_apptrace_vprintf);`. To send log data to UART again, use `esp_log_set_vprintf(vprintf);`.
2. Follow instructions in items 2-5 in *Application Specific Tracing*.
3. To print out collected log records, run the following command in terminal: `$IDF_PATH/tools/esp_app_trace/logtrace_proc.py /path/to/trace/file /path/to/program/elf/file`.

Log Trace Processor Command Options Command usage:

```
logtrace_proc.py [-h] [--no-errors] <trace_file> <elf_file>
```

Positional arguments:

`trace_file` Path to log trace file.
`elf_file` Path to program ELF file.

Optional arguments:

`-h, --help` Show this help message and exit.
`--no-errors, -n` Do not print errors.

System Behavior Analysis with SEGGER SystemView

Another useful ESP-IDF feature built on top of application tracing library is the system level tracing which produces traces compatible with SEGGER SystemView tool (see SystemView). SEGGER SystemView is a real-time recording and visualization tool that allows to analyze runtime behavior of an application. It is possible to view events in real-time through the UART interface.

How To Use It Support for this feature is enabled by `Component config > Application Level Tracing > FreeRTOS SystemView Tracing` (*CONFIG_APPTRACE_SV_ENABLE*) menuconfig option. There are several other options enabled under the same menu:

1. SytemView destination. Select the destination interface: JTAG or UART. In case of UART, it will be possible to connect SystemView application to the ESP32-C3 directly and receive data in real-time.
2. ESP32-C3 timer to use as SystemView timestamp source: (*CONFIG_APPTRACE_SV_TS_SOURCE*) selects the source of timestamps for SystemView events. In the single core mode, timestamps are generated using ESP32-C3 internal cycle counter running at maximum 240 Mhz (about 4 ns granularity). In the dual-core mode, external timer working at 40 Mhz is used, so the timestamp granularity is 25 ns.
3. Individually enabled or disabled collection of SystemView events (`CONFIG_APPTRACE_SV_EVT_XXX`):
   - Trace Buffer Overflow Event
   - ISR Enter Event
   - ISR Exit Event
   - ISR Exit to Scheduler Event
   - Task Start Execution Event
   - Task Stop Execution Event
   - Task Start Ready State Event
   - Task Stop Ready State Event
   - Task Create Event
   - Task Terminate Event
   - System Idle Event
   - Timer Enter Event

- Timer Exit Event

ESP-IDF has all the code required to produce SystemView compatible traces, so users can just configure necessary project options (see above), build, download the image to target, and use OpenOCD to collect data as described in the previous sections.

4. Select Pro or App CPU in menuconfig options `Component config` > `Application Level Tracing` > `FreeRTOS SystemView Tracing` to trace over the UART interface in real-time.

OpenOCD SystemView Tracing Command Options Command usage:

```
esp sysview [start <options>] | [stop] | [status]
```

Sub-commands:

start Start tracing (continuous streaming).
stop Stop tracing.
status Get tracing status.

Start command syntax:

```
start <outfile1> [outfile2] [poll_period [trace_size [stop_tmo]]]
```

outfile1 Path to file to save data from PRO CPU. This argument should have the following format: `file://path/to/file`.
outfile2 Path to file to save data from APP CPU. This argument should have the following format: `file://path/to/file`.
poll_period Data polling period (in ms) for available trace data. If greater than 0, then command runs in non-blocking mode. By default, 1 ms.
trace_size Maximum size of data to collect (in bytes). Tracing is stopped after specified amount of data is received. By default, -1 (trace size stop trigger is disabled).
stop_tmo Idle timeout (in sec). Tracing is stopped if there is no data for specified period of time. By default, -1 (disable this stop trigger).

Note: If `poll_period` is 0, OpenOCD telnet command line will not be available until tracing is stopped. You must stop it manually by resetting the board or pressing Ctrl+C in the OpenOCD window (not the one with the telnet session). Another option is to set `trace_size` and wait until this size of data is collected. At this point, tracing stops automatically.

Command usage examples:

1. Collect SystemView tracing data to files `pro-cpu.SVDat` and `app-cpu.SVDat`. The files will be saved in `openocd-esp32` directory.

   ```
   esp sysview start file://pro-cpu.SVDat file://app-cpu.SVDat
   ```

   The tracing data will be retrieved and saved in non-blocking mode. To stop this process, enter `esp sysview stop` command on OpenOCD telnet prompt, optionally pressing Ctrl+C in the OpenOCD window.
2. Retrieve tracing data and save them indefinitely.

   ```
   esp sysview start file://pro-cpu.SVDat file://app-cpu.SVDat 0 -1 -1
   ```

   OpenOCD telnet command line prompt will not be available until tracing is stopped. To stop tracing, press Ctrl+C in the OpenOCD window.

Data Visualization After trace data are collected, users can use a special tool to visualize the results and inspect behavior of the program.

It is uneasy and awkward to analyze data for every core in separate instance of the tool. Fortunately, there is an Eclipse plugin called *Impulse* which can load several trace files, thus making it possible to inspect events from both cores in one view. Also, this plugin has no limitation of 1,000,000 events as compared to the free version of SystemView.

Good instructions on how to install, configure, and visualize data in Impulse from one core can be found here.

Note: ESP-IDF uses its own mapping for SystemView FreeRTOS events IDs, so users need to replace the original file mapping `$SYSVIEW_INSTALL_DIR/Description/SYSVIEW_FreeRTOS.txt` with `$IDF_PATH/tools/esp_app_trace/SYSVIEW_FreeRTOS.txt`. Also, contents of that ESP-IDF-specific file should be used when configuring SystemView serializer using the above link.

Gcov (Source Code Coverage)

Basics of Gcov and Gcovr Source code coverage is data indicating the count and frequency of every program execution path that has been taken within a program's runtime. Gcov is a GCC tool that, when used in concert with the compiler, can generate log files indicating the execution count of each line of a source file. The Gcovr tool is a utility for managing Gcov and generating summarized code coverage results.

Generally, using Gcov to compile and run programs on the host will undergo these steps:

1. Compile the source code using GCC with the `--coverage` option enabled. This will cause the compiler to generate a `.gcno` notes files during compilation. The notes files contain information to reconstruct execution path block graphs and map each block to source code line numbers. Each source file compiled with the `--coverage` option should have their own `.gcno` file of the same name (e.g., a `main.c` will generate a `main.gcno` when compiled).
2. Execute the program. During execution, the program should generate `.gcda` data files. These data files contain the counts of the number of times an execution path was taken. The program will generate a `.gcda` file for each source file compiled with the `--coverage` option (e.g., `main.c` will generate a `main.gcda`).
3. Gcov or Gcovr can be used to generate a code coverage based on the `.gcno`, `.gcda`, and source files. Gcov will generate a text-based coverage report for each source file in the form of a `.gcov` file, whilst Gcovr will generate a coverage report in HTML format.

Gcov and Gcovr in ESP-IDF Using Gcov in ESP-IDF is complicated due to the fact that the program is running remotely from the host (i.e., on the target). The code coverage data (i.e., the `.gcda` files) is initially stored on the target itself. OpenOCD is then used to dump the code coverage data from the target to the host via JTAG during runtime. Using Gcov in ESP-IDF can be split into the following steps.

1. *Setting Up a Project for Gcov*
2. *Dumping Code Coverage Data*
3. *Generating Coverage Report*

Setting Up a Project for Gcov

Compiler Option In order to obtain code coverage data in a project, one or more source files within the project must be compiled with the `--coverage` option. In ESP-IDF, this can be achieved at the component level or the individual source file level:

- To cause all source files in a component to be compiled with the `--coverage` option, you can add `target_compile_options(${COMPONENT_LIB} PRIVATE --coverage)` to the `CMakeLists.txt` file of the component.
- To cause a select number of source files (e.g., `source1.c` and `source2.c`) in the same component to be compiled with the `--coverage` option, you can add `set_source_files_properties(source1.c source2.c PROPERTIES COMPILE_FLAGS --coverage)` to the `CMakeLists.txt` file of the component.

When a source file is compiled with the `--coverage` option (e.g., `gcov_example.c`), the compiler will generate the `gcov_example.gcno` file in the project's build directory.

Project Configuration Before building a project with source code coverage, make sure that the following project configuration options are enabled by running `idf.py menuconfig`.

- Enable the application tracing module by selecting `Trace Memory` for the *CONFIG_APPTRACE_DESTINATION1* option.
- Enable Gcov to the host via the *CONFIG_APPTRACE_GCOV_ENABLE*.

Dumping Code Coverage Data Once a project has been complied with the `--coverage` option and flashed onto the target, code coverage data will be stored internally on the target (i.e., in trace memory) whilst the application runs. The process of transferring code coverage data from the target to the host is known as dumping.

The dumping of coverage data is done via OpenOCD (see *JTAG Debugging* on how to setup and run OpenOCD). A dump is triggered by issuing commands to OpenOCD, therefore a telnet session to OpenOCD must be opened to issue such commands (run `telnet localhost 4444`). Note that GDB could be used instead of telnet to issue commands to OpenOCD, however all commands issued from GDB will need to be prefixed as `mon <oocd_command>`.

When the target dumps code coverage data, the `.gcda` files are stored in the project's build directory. For example, if `gcov_example_main.c` of the `main` component is compiled with the `--coverage` option, then dumping the code coverage data would generate a `gcov_example_main.gcda` in `build/esp-idf/main/CMakeFiles/__idf_main.dir/gcov_example_main.c.gcda`. Note that the `.gcno` files produced during compilation are also placed in the same directory.

The dumping of code coverage data can be done multiple times throughout an application's lifetime. Each dump will simply update the `.gcda` file with the newest code coverage information. Code coverage data is accumulative, thus the newest data will contain the total execution count of each code path over the application's entire lifetime.

ESP-IDF supports two methods of dumping code coverage data form the target to the host:

- Instant Run-Time Dumpgit
- Hard-coded Dump

Instant Run-Time Dump An Instant Run-Time Dump is triggered by calling the `ESP32-C3 gcov` OpenOCD command (via a telnet session). Once called, OpenOCD will immediately preempt the ESP32-C3's current state and execute a built-in ESP-IDF Gcov debug stub function. The debug stub function will handle the dumping of data to the host. Upon completion, the ESP32-C3 will resume its current state.

Hard-coded Dump A Hard-coded Dump is triggered by the application itself by calling `esp_gcov_dump()` from somewhere within the application. When called, the application will halt and wait for OpenOCD to connect and retrieve the code coverage data. Once `esp_gcov_dump()` is called, the host must execute the `esp gcov dump` OpenOCD command (via a telnet session). The `esp gcov dump` command will cause OpenOCD to connect to the ESP32-C3, retrieve the code coverage data, then disconnect from the ESP32-C3, thus allowing the application to resume. Hard-coded Dumps can also be triggered multiple times throughout an application's lifetime.

Hard-coded dumps are useful if code coverage data is required at certain points of an application's lifetime by placing `esp_gcov_dump()` where necessary (e.g., after application initialization, during each iteration of an application's main loop).

GDB can be used to set a breakpoint on `esp_gcov_dump()`, then call `mon esp gcov dump` automatically via the use a `gdbinit` script (see Using GDB from *Command Line*).

The following GDB script will add a breakpoint at `esp_gcov_dump()`, then call the `mon esp gcov dump` OpenOCD command.

```
b esp_gcov_dump
commands
mon esp gcov dump
end
```

Note: Note that all OpenOCD commands should be invoked in GDB as: `mon <oocd_command>`.

Generating Coverage Report Once the code coverage data has been dumped, the `.gcno`, `.gcda` and the source files can be used to generate a code coverage report. A code coverage report is simply a report indicating the number of times each line in a source file has been executed.

Both Gcov and Gcovr can be used to generate code coverage reports. Gcov is provided along with the Xtensa toolchain, whilst Gcovr may need to be installed separately. For details on how to use Gcov or Gcovr, refer to Gcov documentation and Gcovr documentation.

Adding Gcovr Build Target to Project To make report generation more convenient, users can define additional build targets in their projects such that the report generation can be done with a single build command.

Add the following lines to the `CMakeLists.txt` file of your project.

```
include($ENV{IDF_PATH}/tools/cmake/gcov.cmake)
idf_create_coverage_report(${CMAKE_CURRENT_BINARY_DIR}/coverage_report)
idf_clean_coverage_report(${CMAKE_CURRENT_BINARY_DIR}/coverage_report)
```

The following commands can now be used:

- `cmake --build build/ --target gcovr-report` will generate an HTML coverage report in `$(BUILD_DIR_BASE)/coverage_report/html` directory.
- `cmake --build build/ --target cov-data-clean` will remove all coverage data files.

4.2 Application Startup Flow

This note explains various steps which happen before `app_main` function of an ESP-IDF application is called.

The high level view of startup process is as follows:

1. *First Stage Bootloader* in ROM loads second-stage bootloader image to RAM (IRAM & DRAM) from flash offset 0x0.
2. *Second Stage Bootloader* loads partition table and main app image from flash. Main app incorporates both RAM segments and read-only segments mapped via flash cache.
3. *Application Startup* executes. At this point the second CPU and RTOS scheduler are started.

This process is explained in detail in the following sections.

4.2.1 First Stage Bootloader

After SoC reset, the CPU will start running immediately to perform initialization. The reset vector code is located in the mask ROM of the ESP32-C3 chip and cannot be modified.

Startup code called from the reset vector determines the boot mode by checking `GPIO_STRAP_REG` register for bootstrap pin states. Depending on the reset reason, the following takes place:

1. Reset from deep sleep: if the value in `RTC_CNTL_STORE6_REG` is non-zero, and CRC value of RTC memory in `RTC_CNTL_STORE7_REG` is valid, use `RTC_CNTL_STORE6_REG` as an entry point address and jump immediately to it. If `RTC_CNTL_STORE6_REG` is zero, or `RTC_CNTL_STORE7_REG` contains invalid CRC, or once the code called via `RTC_CNTL_STORE6_REG` returns, proceed with boot as if it was a power-on reset. **Note**: to run customized code at this point, a deep sleep stub mechanism is provided. Please see *deep sleep* documentation for this.
2. For power-on reset, software SoC reset, and watchdog SoC reset: check the `GPIO_STRAP_REG` register if a custom boot mode (such as UART Download Mode) is requested. If this is the case, this custom loader mode is executed from ROM. Otherwise, proceed with boot as if it was due to software CPU reset. Consult ESP32-C3 datasheet for a description of SoC boot modes and how to execute them.

3. For software CPU reset and watchdog CPU reset: configure SPI flash based on EFUSE values, and attempt to load the code from flash. This step is described in more detail in the next paragraphs.

Note: During normal boot modes the RTC watchdog is enabled when this happens, so if the process is interrupted or stalled then the watchdog will reset the SOC automatically and repeat the boot process. This may cause the SoC to strap into a new boot mode, if the strapping GPIOs have changed.

Second stage bootloader binary image is loaded from the start of flash at offset 0x0.

4.2.2 Second Stage Bootloader

In ESP-IDF, the binary image which resides at offset 0x0 in flash is the second stage bootloader. Second stage bootloader source code is available in components/bootloader directory of ESP-IDF. Second stage bootloader is used in ESP-IDF to add flexibility to flash layout (using partition tables), and allow for various flows associated with flash encryption, secure boot, and over-the-air updates (OTA) to take place.

When the first stage bootloader is finished checking and loading the second stage bootloader, it jumps to the second stage bootloader entry point found in the binary image header.

Second stage bootloader reads the partition table found by default at offset 0x8000 (*configurable value*). See *partition tables* documentation for more information. The bootloader finds factory and OTA app partitions. If OTA app partitions are found in the partition table, the bootloader consults the `otadata` partition to determine which one should be booted. See *Over The Air Updates (OTA)* for more information.

For a full description of the configuration options available for the ESP-IDF bootloader, see *Bootloader*.

For the selected partition, second stage bootloader reads the binary image from flash one segment at a time:

- For segments with load addresses in internal *IRAM (Instruction RAM)* or *DRAM (Data RAM)*, the contents are copied from flash to the load address.
- For segments which have load addresses in *DROM (Data Stored in flash)* or *IROM (Code Executed from flash)* regions, the flash MMU is configured to provide the correct mapping from the flash to the load address.

Once all segments are processed - meaning code is loaded and flash MMU is set up, second stage bootloader verifies the integrity of the application and then jumps to the application entry point found in the binary image header.

4.2.3 Application Startup

Application startup covers everything that happens after the app starts executing and before the `app_main` function starts running inside the main task. This is split into three stages:

- Port initialization of hardware and basic C runtime environment.
- System initialization of software services and FreeRTOS.
- Running the main task and calling `app_main`.

Note: Understanding all stages of ESP-IDF app initialization is often not necessary. To understand initialization from the application developer's perspective only, skip forward to *Running the Main Task*.

Port Initialization

ESP-IDF application entry point is `call_start_cpu0` function found in components/esp_system/port/cpu_start.c. This function is executed by the second stage bootloader, and never returns.

This port-layer initialization function initializes the basic C Runtime Environment ("CRT") and performs initial configuration of the SoC's internal hardware:

- Reconfigure CPU exceptions for the app (allowing app interrupt handlers to run, and causing *Fatal Errors* to be handled using the options configured for the app rather than the simpler error handler provided by ROM).
- If the option *CONFIG_BOOTLOADER_WDT_ENABLE* is not set then the RTC watchdog timer is disabled.
- Initialize internal memory (data & bss).
- Finish configuring the MMU cache.
- Set the CPU clocks to the frequencies configured for the project.
- Initialize memory protection if configured.

Once `call_start_cpu0` completes running, it calls the "system layer" initialization function `start_cpu0` found in components/esp_system/startup.c.

System Initialization

The main system initialization function is `start_cpu0`. By default, this function is weak-linked to the function `start_cpu0_default`. This means that it is possible to override this function to add some additional initialization steps.

The primary system initialization stage includes:

- Log information about this application (project name, *App Version*, etc.) if default log level enables this.
- Initialize the heap allocator (before this point all allocations must be static or on the stack).
- Initialize newlib component syscalls and time functions.
- Configure the brownout detector.
- Setup libc stdin, stdout, and stderr according to the *serial console configuration*.
- Perform any security-related checks, including burning efuses that should be burned for this configuration (including *permanently limiting ROM download modes*).
- Initialize SPI flash API support.
- Call global C++ constructors and any C functions marked with `__attribute__((constructor))`.

Secondary system initialization allows individual components to be initialized. If a component has an initialization function annotated with the `ESP_SYSTEM_INIT_FN` macro, it will be called as part of secondary initialization. Component initialization functions have priorities assigned to them to ensure the desired initialization order. The priorities are documented in esp_system/system_init_fn.txt and `ESP_SYSTEM_INIT_FN` definition in source code are checked against this file.

Running the Main Task

After all other components are initialized, the main task is created and the FreeRTOS scheduler starts running.

After doing some more initialization tasks (that require the scheduler to have started), the main task runs the application-provided function `app_main` in the firmware.

The main task that runs `app_main` has a fixed RTOS priority (one higher than the minimum) and a *configurable stack size*.

Unlike normal FreeRTOS tasks (or embedded C `main` functions), the `app_main` task is allowed to return. If this happens, The task is cleaned up and the system will continue running with other RTOS tasks scheduled normally. Therefore, it is possible to implement `app_main` as either a function that creates other application tasks and then returns, or as a main application task itself.

4.3 BluFi

4.3.1 Overview

The BluFi for ESP32-C3 is a Wi-Fi network configuration function via Bluetooth channel. It provides a secure protocol to pass Wi-Fi configuration and credentials to ESP32-C3. Using this information, ESP32-C3 can then connect to an AP or establish a SoftAP.

Fragmenting, data encryption, and checksum verification in the BluFi layer are the key elements of this process.

You can customize symmetric encryption, asymmetric encryption, and checksum support customization. Here we use the DH algorithm for key negotiation, 128-AES algorithm for data encryption, and CRC16 algorithm for checksum verification.

4.3.2 The BluFi Flow

The BluFi networking flow includes the configuration of the SoftAP and Station.

The following uses Station as an example to illustrate the core parts of the procedure, including broadcast, connection, service discovery, negotiation of the shared key, data transmission, and connection status backhaul.

1. Set the ESP32-C3 into GATT Server mode and then it will send broadcasts with specific *advertising data*. You can customize this broadcast as needed, which is not a part of the BluFi Profile.
2. Use the App installed on the mobile phone to search for this particular broadcast. The mobile phone will connect to ESP32-C3 as the GATT Client once the broadcast is confirmed. The App used during this part is up to you.
3. After the GATT connection is successfully established, the mobile phone will send a data frame for key negotiation to ESP32-C3 (see the section *The Frame Formats Defined in BluFi* for details).
4. After ESP32-C3 receives the data frame of key negotiation, it will parse the content according to the user-defined negotiation method.
5. The mobile phone works with ESP32-C3 for key negotiation using the encryption algorithms, such as DH, RSA, or ECC.
6. After the negotiation process is completed, the mobile phone will send a control frame for security-mode setup to ESP32-C3.
7. When receiving this control frame, ESP32-C3 will be able to encrypt and decrypt the communication data using the shared key and the security configuration.
8. The mobile phone sends the data frame defined in the section of *The Frame Formats Defined in BluFi*,with the Wi-Fi configuration information to ESP32-C3, including SSID, password, etc.
9. The mobile phone sends a control frame of Wi-Fi connection request to ESP32-C3. When receiving this control frame, ESP32-C3 will regard the communication of essential information as done and get ready to connect to the Wi-Fi.
10. After connecting to the Wi-Fi, ESP32-C3 will send a control frame of Wi-Fi connection status report to the mobile phone. At this point, the networking procedure is completed.

Note:

1. After ESP32-C3 receives the control frame of security-mode configuration, it will execute the operations in accordance with the defined security mode.
2. The data lengths before and after symmetric encryption/decryption must stay the same. It also supports in-place encryption and decryption.

4.3.3 The Flow Chart of BluFi

4.3.4 The Frame Formats Defined in BluFi

The frame formats for the communication between the mobile phone App and ESP32-C3 are defined as follows:

The frame format with no fragment:

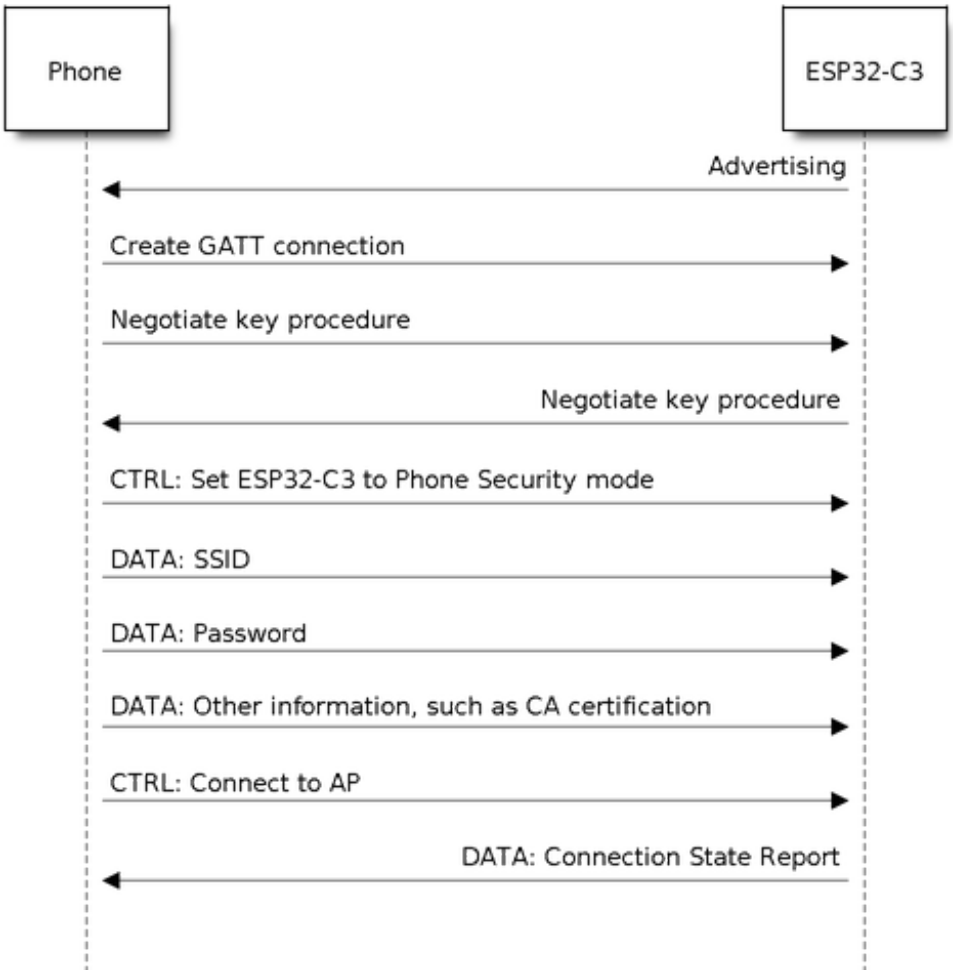

Fig. 2: BluFi Flow Chart

Field	Value (Byte)
Type (Least Significant Bit)	1
Frame Control	1
Sequence Number	1
Data Length	1
Data	${Data Length}
CheckSum (Most Significant Bit)	2

If the frag frame bit in the **Frame Control** field is enabled, there would be a 2-byte **Total Content Length** field in the **Data** field. This **Total Content Length** field indicates the length of the remaining part of the frame and also tells the remote how much memory needs to be allocated.

The frame format with fragments:

Field	Value (Byte)
Type (Least Significant Bit)	1
Frame Control (Frag)	1
Sequence Number	1
Data Length	1
Data	• Total Content Length: 2 • Content: ${Data Length} - 2
CheckSum (Most Significant Bit)	2

Normally, the control frame does not contain data bits, except for ACK Frame.

The format of ACK Frame:

Field	Value (Byte)
Type - ACK (Least Significant Bit)	1
Frame Control	1
Sequence Number	1
Data Length	1
Data	Acked Sequence Number: 2
CheckSum (Most Significant Bit)	2

1. Type
   Type field takes 1 byte and is divided into **Type** and **Subtype**. **Type** uses the lower two bits, indicating whether the frame is a data frame or a control frame. **Subtype** uses the upper six bits, indicating the specific meaning of this data frame or control frame.
   - The control frame is not encrypted for the time being and supports to be verified.
   - The data frame supports to be encrypted and verified.

1.1 Control Frame (Binary: 0x0 b'00)

Control Frame	Implication	Explanation	Note
0x0 (b'000000)	ACK	The data field of the ACK frame uses the same sequence value of the frame to reply to.	The data field consumes a byte and its value is the same as the sequence field of the frame to reply to.
0x1 (b'000001)	Set the ESP device to the security mode.	To inform the ESP device of the security mode to use when sending data, which is allowed to be reset multiple times during the process. Each setting affects the subsequent security mode used. If it is not set, the ESP device will send the control frame and data frame with no checksum and encryption by default. The data transmission from the mobile phone to the ESP device is controlled by this control frame.	The data field consumes a byte. The higher four bits are for the security mode setting of the control frame, and the lower four bits are for the security mode setting of the data frame. • b'0000: no checksum and no encryption; • b'0001: with checksum but no encryption; • b'0010: no checksum but with encryption; • b'0011: with both checksum and encryption.
0x2 (b'000010)	Set the opmode of Wi-Fi.	The frame contains opmode settings for configuring the Wi-Fi mode of the ESP device.	data[0] is for opmode settings, including: • 0x00: NULL • 0x01: STA • 0x02: SoftAP • 0x03: SoftAP & STA Please set the SSID/Password/Max Connection Number of the AP mode in the first place if an AP gets involved.
0x3 (b'000011)	Connect the ESP device to the AP.	To notify the ESP device that the essential information has been sent and it is allowed to connect to the AP.	No data field is contained.
0x4 (b'000100)	Disconnect the ESP device from the AP.		No data field is contained.
0x5 (b'000101)	To get the information of the ESP device's Wi-Fi mode and it's status.		• No data field is contained. When receiving this control frame, the ESP device will send back a follow-up frame of Wi-Fi connection state report to the mobile phone with the information of the current opmode, connection status, SSID, and so on. • The types of information sent to the mobile phone is defined by the application installed on the phone.
0x6 (b'000110)	Disconnect the STA device from the SoftAP (in SoftAP mode).		Data[0~5] is taken as the MAC address for the STA device. If there is a second STA device, then it uses data[6-11] and the rest can be done in the same manner.
0x7 (b'000111)	Get the version information.		
0x8 (b'001000)	Disconnect the BLE GATT link.		The ESP device will disconnect the BLE GATT link after receives this command.
0x9 (b'001001)	Get the Wi-Fi list.	To get the ESP device to scan the Wi-Fi access points around.	No data field is contained. When receiving this control frame, the ESP device will send back a follow-up frame of Wi-Fi list report to the mobile phone.

1.2 Data Frame (Binary: 0x1 b'01)

Data Frame	Implication	Explanation	Note
0x0 (b'000000)	Send the negotiation data.	The negotiation data will be sent to the callback function registered in the application layer.	The length of the data depends on the length field.
0x1 (b'000001)	Send the SSID for STA mode.	To send the BSSID of the AP for the STA device to connect under the condition that the SSID is hidden.	Please refer to Note 1 below.
0x2 (b'000010)	Send the SSID for STA mode.	To send the SSID of the AP for the STA device to connect.	Please refer to Note 1 below.
0x3 (b'000011)	Send the password for STA mode.	To send the password of the AP for the STA device to connect.	Please refer to Note 1 below.
0x4 (b'000100)	Send the SSID for SoftAP mode.		Please refer to Note 1 below.
0x5 (b'000101)	Send the password for SoftAPmode.		Please refer to Note 1 below.
0x6 (b'000110)	Set the maximum connection number for SoftAP mode.		data[0] represents the value of the connection number, ranging from 1 to 4. When the transmission direction is ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
0x7 (b'000111)	Set the authentication mode for SoftAP mode.		data[0]: • 0x00: OPEN • 0x01: WEP • 0x02: WPA_PSK • 0x03: WPA2_PSK • 0x04: WPA_WPA2_PSK When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
0x8 (b'001000)	Set the number of channels for SoftAP mode.		data[0] represents the quantity of the supported channels, ranging from 1 to 14. When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
0x9 (b'001001)	Username	It provides the username of the GATT client when using encryption of enterprise level.	The length of the data depends on the length field.
0xa (b'001010)	CA Certification	It provides the CA Certification when using encryption of enterprise level.	Please refer to Note 2 below.
0xb (b'001011)	Client Certification	It provides the client certification when using encryption of enterprise level. Whether the private key is contained or not depends on the content of the certification.	Please refer to Note 2 below.
0xc (b'001100)	Server Certification	It provides the sever certification when using encryption of enterprise level. Whether the private key is contained or not depends on the content of the certification.	Please refer to Note 2 below.
0xd (b'001101)	Client Private Key	It provides the private key of the client when using encryption of enterprise level.	Please refer to Note 2 below.

Note:

- Note 1: The length of the data depends on the data length field. When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
- Note 2: The length of the data depends on the data length field. The frame supports to be fragmented if the data length is not long enough.

2. Frame Control
   The **Frame Control** field takes one byte and each bit has a different meaning.

Bit	Meaning
0x01	Indicates whether the frame is encrypted. • 1 means encrypted. • 0 means unencrypted. The encrypted part of the frame includes the full clear data before the DATA field is encrypted (no checksum). Control frame is not encrypted, so this bit is 0.
0x02	Indicates whether a frame contains a checksum (such as SHA1, MD5, CRC) for the end of the frame. Data field includes sequence, data length, and clear text. Both the control frame and the data frame can choose whether to contain a check bit or not.
0x04	Indicates the data direction. • 0 means from the mobile phone to the ESP device. • 1 means from the ESP device to the mobile phone.
0x08	Indicates whether the other person is required to reply to an ACK. • 0 indicates not required to reply to an ACK. • 1 indicates required to reply to an ACK.
0x10	Indicates whether there are subsequent data fragments. • 0 indicates that there is no subsequent data fragment for this frame. • 1 indicates that there are subsequent data fragments which used to transmit longer data. In the case of a frag frame, the total length of the current content section + subsequent content section is given in the first two bytes of the data field (that is, the content data of the maximum support 64 K).
0x10~0x80	Reserved

3. Sequence Number
   The **Sequence Number** field is the field for sequence control. When a frame is sent, the value of this field is automatically incremented by 1 regardless of the type of frame, which prevents Replay Attack. The sequence would be cleared after each reconnection.
4. Data Length
   The **Data Length** field indicates the length of the data field, which does not include CheckSum.
5. Data
   Content of the **Data** field can be different according to various values of Type or Subtype. Please refer to the table above.
6. CheckSum
   The **CheckSum** field takes two bytes, which is used to check "sequence + data length + clear text data".

4.3.5 The Security Implementation of ESP32-C3

1. Securing Data
   To ensure that the transmission of the Wi-Fi SSID and password is secure, the message needs to be encrypted using symmetric encryption algorithms, such as AES, DES, and so on. Before using symmetric encryption algorithms, the devices are required to negotiate (or generate) a shared key using an asymmetric encryption algorithm (DH, RSA, ECC, etc).
2. Ensuring Data Integrity

To ensure data integrity, you need to add a checksum algorithm, such as SHA1, MD5, CRC, etc.

3. Securing Identity (Signature)
   Algorithm like RSA can be used to secure identity. But for DH, it needs other algorithms as an companion for signature.
4. Replay Attack Prevention
   It is added to the Sequence Number field and used during the checksum verification.
   For the coding of ESP32-C3, you can determine and develop the security processing, such as key negotiation. The mobile application sends the negotiation data to ESP32-C3, and then the data will be sent to the application layer for processing. If the application layer does not process it, you can use the DH encryption algorithm provided by BluFi to negotiate the key.
   The application layer needs to register several security-related functions to BluFi:

```
typedef void (*esp_blufi_negotiate_data_handler_t)(uint8_t *data, int len, uint8_t␣
↪**output_data, int *output_len, bool *need_free)
```

This function is for ESP32-C3 to receive normal data during negotiation. After processing is completed, the data will be transmitted using Output_data and Output_len.

BluFi will send output_data from Negotiate_data_handler after Negotiate_data_handler is called.

Here are two "*", which means the length of the data to be emitted is unknown. Therefore, it requires the function to allocate itself (malloc) or point to the global variable to inform whether the memory needs to be freed by NEED_FREE.

```
typedef int (* esp_blufi_encrypt_func_t)(uint8_t iv8, uint8_t *crypt_data, int␣
↪crypt_len)
```

The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as a 8-bit of IV.

```
typedef int (* esp_blufi_decrypt_func_t)(uint8_t iv8, uint8_t *crypt_data, int␣
↪crypt_len)
```

The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as an 8-bit of IV.

```
typedef uint16_t (*esp_blufi_checksum_func_t)(uint8_t iv8, uint8_t *data, int len)
```

This function is used to compute CheckSum and return a value of CheckSum. BluFi uses the returned value to compare the CheckSum of the frame.

4.3.6 GATT Related Instructions

UUID

BluFi Service UUID: 0xFFFF, 16 bit

BluFi (the mobile > ESP32-C3): 0xFF01, writable

Blufi (ESP32-C3 > the mobile phone): 0xFF02, readable and callable

4.4 Bluetooth® Overview

This document provides an architecture overview of the Bluetooth stack in ESP-IDF and some quick links to related documents and application examples.

ESP32-C3 supports Bluetooth 5.0 (LE) and is certified for Bluetooth LE 5.4.

The Bluetooth stack in ESP-IDF is a layered architecture that enables Bluetooth functionality on ESP32-C3 chip series. The table below shows its architecture.

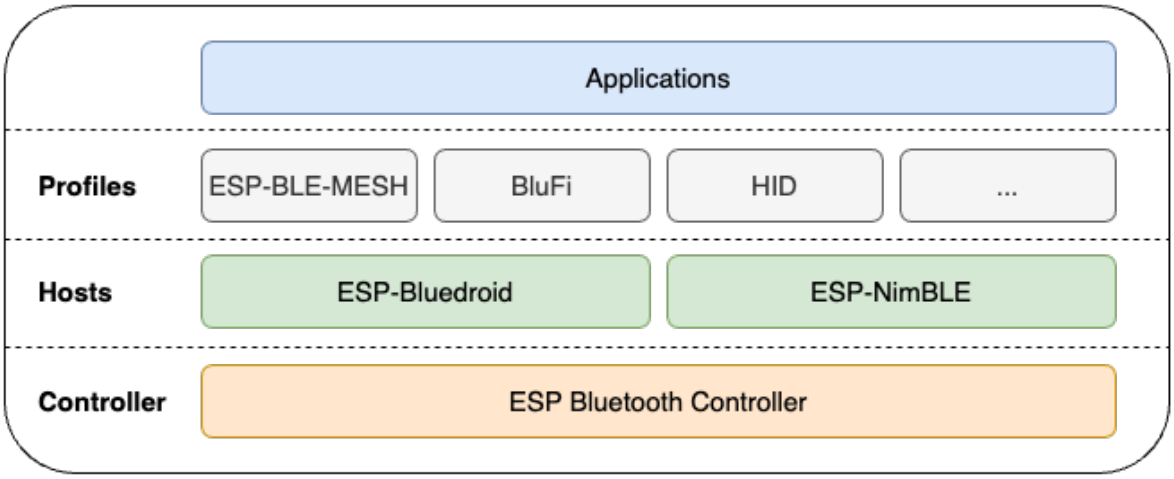

Fig. 3: ESP32-C3 Bluetooth Stack Architecture

The table below shows whether the Bluetooth modules are supported in a specific chip series.

Chip Series	Controller	ESP-Bluedroid	ESP-NimBLE	ESP-BLE-MESH	BluFi
ESP32	Y	Y	Y	Y	Y
ESP32-S2	–	–	–	–	–
ESP32-S3	Y	Y	Y	Y	Y
ESP32-C2	Y	Y	Y	–	Y
ESP32-C3	Y	Y	Y	Y	Y
ESP32-C6	Y	Y	Y	Y	Y
ESP32-H2	Y	Y	Y	Y	–

The following sections briefly describe each layer and provide quick links to the related documents and application examples.

4.4.1 ESP Bluetooth Controller

At the bottom layer is ESP Bluetooth Controller, which encompasses various modules such as PHY, Baseband, Link Controller, Link Manager, Device Manager, and HCI. It handles hardware interface management and link management. It provides functions in the form of libraries and is accessible through APIs. This layer directly interacts with the hardware and low-level Bluetooth protocols.

- *API reference*
- Application examples

4.4.2 Hosts

There are two hosts, ESP-Bluedroid and ESP-NimBLE. The major difference between them is as follows:

- Although both support Bluetooth LE, ESP-NimBLE requires less heap and flash size.

ESP-Bluedroid

ESP-Bluedroid is a modified version of the native Android Bluetooth stack, Bluedroid. It consists of two layers: the Bluetooth Upper Layer (BTU) and the Bluetooth Transport Controller layer (BTC). The BTU layer is responsible

for processing bottom layer Bluetooth protocols such as L2CAP, GATT/ATT, SMP, GAP, and other profiles. The BTU layer provides an interface prefixed with "bta". The BTC layer is mainly responsible for providing a supported interface, prefixed with "esp", to the application layer, processing GATT-based profiles and handling miscellaneous tasks. All the APIs are located in the ESP_API layer. Developers should use the Bluetooth APIs prefixed with "esp".

ESP-Bluedroid for ESP32-C3 supports Bluetooth LE only. Classic Bluetooth is not supported.

- API references
  - *Bluetooth® Common*
  - *Bluetooth LE*
- Application examples

ESP-NimBLE

ESP-NimBLE is a host stack built on top of the NimBLE host stack developed by Apache Mynewt. The NimBLE host stack is ported for ESP32-C3 chip series and FreeRTOS. The porting layer is kept clean by maintaining all the existing APIs of NimBLE along with a single ESP-NimBLE API for initialization, making it simpler for the application developers.

ESP-NimBLE supports Bluetooth LE only. Classic Bluetooth is not supported.

- Apache Mynewt NimBLE User Guide
- API references
  - NimBLE API references
  - *ESP-NimBLE API references for initialization*
- Application examples

4.4.3 Profiles

Above the host stacks are the profile implementations by Espressif and some common profiles. Depending on your configuration, these profiles can run on ESP-Bluedroid or ESP-NimBLE.

ESP-BLE-MESH

Built on top of Zephyr Bluetooth Mesh stack, the ESP-BLE-MESH implementation supports device provisioning and node control. It also supports such node features as Proxy, Relay, Low power and Friend.

- *ESP-BLE-MESH documentation*: feature list, get started, architecture, description of application examples, frequently asked questions, etc.
- Application examples

BluFi

The BluFi for ESP32-C3 is a Wi-Fi network configuration function via Bluetooth channel. It provides a secure protocol to pass Wi-Fi configuration and credentials to ESP32-C3. Using this information, ESP32-C3 can then connect to an AP or establish a softAP.

- *BluFi documentation*
- Application examples

4.4.4 Applications

At the uppermost layer are applications. You can build your own applications on top of the ESP-Bluedroid and ESP-NimBLE stacks, leveraging the provided APIs and profiles to create Bluetooth-enabled applications tailored to specific use cases.

4.5 Bootloader

The ESP-IDF Software Bootloader performs the following functions:

1. Minimal initial configuration of internal modules;
2. Initialize *Flash Encryption* and/or *Secure* features, if configured;
3. Select the application partition to boot, based on the partition table and ota_data (if any);
4. Load this image to RAM (IRAM & DRAM) and transfer management to the image that was just loaded.

Bootloader is located at the address 0x0 in the flash.

For a full description of the startup process including the ESP-IDF bootloader, see *Application Startup Flow*.

4.5.1 Bootloader Compatibility

It is recommended to update to newer *versions of ESP-IDF*: when they are released. The OTA (over the air) update process can flash new apps in the field but cannot flash a new bootloader. For this reason, the bootloader supports booting apps built from newer versions of ESP-IDF.

The bootloader does not support booting apps from older versions of ESP-IDF. When updating ESP-IDF manually on an existing product that might need to downgrade the app to an older version, keep using the older ESP-IDF bootloader binary as well.

Note: If testing an OTA update for an existing product in production, always test it using the same ESP-IDF bootloader binary that is deployed in production.

SPI Flash Configuration

Each ESP-IDF application or bootloader .bin file contains a header with *CONFIG_ESPTOOLPY_FLASHMODE*, *CONFIG_ESPTOOLPY_FLASHFREQ*, *CONFIG_ESPTOOLPY_FLASHSIZE* embedded in it. These are used to configure the SPI flash during boot.

The *First Stage Bootloader* in ROM reads the *Second Stage Bootloader* header information from flash and uses this information to load the rest of the *Second Stage Bootloader* from flash. However, at this time the system clock speed is lower than configured and not all flash modes are supported. When the *Second Stage Bootloader* then runs, it will reconfigure the flash using values read from the currently selected app binary's header (and NOT from the *Second Stage Bootloader* header). This allows an OTA update to change the SPI flash settings in use.

4.5.2 Log Level

The default bootloader log level is "Info". By setting the *CONFIG_BOOTLOADER_LOG_LEVEL* option, it is possible to increase or decrease this level. This log level is separate from the log level used in the app (see *Logging library*).

Reducing bootloader log verbosity can improve the overall project boot time by a small amount.

4.5.3 Factory Reset

Sometimes it is desirable to have a way for the device to fall back to a known-good state, in case of some problem with an update.

To roll back to the original "factory" device configuration and clear any user settings, configure the config item *CONFIG_BOOTLOADER_FACTORY_RESET* in the bootloader.

The factory reset mechanism allows the device to be factory reset in two ways:

- Clear one or more data partitions. The *CONFIG_BOOTLOADER_DATA_FACTORY_RESET* option allows users to specify which data partitions will be erased when the factory reset is executed.
  Users can specify the names of partitions as a comma-delimited list with optional spaces for readability. (Like this: `nvs, phy_init, nvs_custom`).
  Make sure that the names of partitions specified in the option are the same as those found in the partition table. Partitions of type "app" cannot be specified here.
- Boot from "factory" app partition. Enabling the *CONFIG_BOOTLOADER_OTA_DATA_ERASE* option will cause the device to boot from the default "factory" app partition after a factory reset (or if there is no factory app partition in the partition table then the default ota app partition is selected instead). This reset process involves erasing the OTA data partition which holds the currently selected OTA partition slot. The "factory" app partition slot (if it exists) is never updated via OTA, so resetting to this allows reverting to a "known good" firmware application.

Either or both of these configuration options can be enabled independently.

In addition, the following configuration options control the reset condition:

- *CONFIG_BOOTLOADER_NUM_PIN_FACTORY_RESET*- The input GPIO number used to trigger a factory reset. This GPIO must be pulled low or high (configurable) on reset to trigger this.
- *CONFIG_BOOTLOADER_HOLD_TIME_GPIO*- this is hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.
- *CONFIG_BOOTLOADER_FACTORY_RESET_PIN_LEVEL* - configure whether a factory reset should trigger on a high or low level of the GPIO. If the GPIO has an internal pullup then this is enabled before the pin is sampled, consult the ESP32-C3 datasheet for details on pin internal pullups.

If an application needs to know if the factory reset has occurred, users can call the function `bootloader_common_get_rtc_retain_mem_factory_reset_state()`.

- If the status is read as true, the function will return the status, indicating that the factory reset has occurred. The function then resets the status to false for subsequent factory reset judgement.
- If the status is read as false, the function will return the status, indicating that the factory reset has not occurred, or the memory where this status is stored is invalid.

Note that this feature reserves some RTC FAST memory (the same size as the *CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP* feature).

4.5.4 Boot from Test Firmware

It is possible to write a special firmware app for testing in production, and boot this firmware when needed. The project partition table will need a dedicated app partition entry for this testing app, type `app` and subtype `test` (see *Partition Tables*).

Implementing a dedicated test app firmware requires creating a totally separate ESP-IDF project for the test app (each project in ESP-IDF only builds one app). The test app can be developed and tested independently of the main project, and then integrated at production testing time as a pre-compiled .bin file which is flashed to the address of the main project's test app partition.

To support this functionality in the main project's bootloader, set the configuration item *CONFIG_BOOTLOADER_APP_TEST* and configure the following three items:

- *CONFIG_BOOTLOADER_NUM_PIN_APP_TEST* - GPIO number to boot test partition. The selected GPIO will be configured as an input with internal pull-up enabled. This GPIO must be pulled low or high (configurable) on reset to trigger this.
  Once the GPIO input is released and the device has been rebooted, the default boot sequence will be enabled again to boot the factory partition or any OTA app partition slot.
- *CONFIG_BOOTLOADER_HOLD_TIME_GPIO* - this is the hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.
- *CONFIG_BOOTLOADER_APP_TEST_PIN_LEVEL* - configure whether a test partition boot should trigger on a high or low level of the GPIO. If the GPIO has an internal pull-up, then this is enabled before the pin is sampled. Consult the ESP32-C3 datasheet for details on pin internal pull-ups.

4.5.5 Rollback

Rollback and anti-rollback features must be configured in the bootloader as well.

Consult the *App Rollback* and *Anti-rollback* sections in the *OTA API reference document*.

4.5.6 Watchdog

The chips come equipped with two groups of watchdog timers: Main System Watchdog Timer (MWDT_WDT) and RTC Watchdog Timer (RTC_WDT). Both watchdog timer groups are enabled when the chip is powered up. However, in the bootloader, they will both be disabled. If *CONFIG_BOOTLOADER_WDT_ENABLE* is set (which is the default behavior), RTC_WDT is re-enabled. It tracks the time from the bootloader is enabled until the user's main function is called. In this scenario, RTC_WDT remains operational and will automatically reset the chip if no application successfully starts within 9 seconds. This functionality is particularly useful in preventing lockups caused by an unstable power source during startup.

- The timeout period can be adjusted by setting *CONFIG_BOOTLOADER_WDT_TIME_MS* and recompiling the bootloader.
- The RTC Watchdog can be disabled in the bootloader by disabling the *CONFIG_BOOTLOADER_WDT_ENABLE* setting and recompiling the bootloader. This is not recommended.
- See *Hardware Watchdog Timers* to learn how RTC_WDT is used in the application.

4.5.7 Bootloader Size

When enabling additional bootloader functions, including *Flash Encryption* or Secure Boot, and especially if setting a high *CONFIG_BOOTLOADER_LOG_LEVEL* level, then it is important to monitor the bootloader .bin file's size.

When using the default *CONFIG_PARTITION_TABLE_OFFSET* value 0x8000, the size limit is 0x8000 bytes.

If the bootloader binary is too large, then the bootloader build will fail with an error "Bootloader binary size [..] is too large for partition table offset". If the bootloader binary is flashed anyhow then the ESP32-C3 will fail to boot - errors will be logged about either invalid partition table or invalid bootloader checksum.

Options to work around this are:

- Set *bootloader compiler optimization* back to "Size" if it has been changed from this default value.
- Reduce *bootloader log level*. Setting log level to Warning, Error or None all significantly reduce the final binary size (but may make it harder to debug).
- Set *CONFIG_PARTITION_TABLE_OFFSET* to a higher value than 0x8000, to place the partition table later in the flash. This increases the space available for the bootloader. If the *partition table* CSV file contains explicit partition offsets, they will need changing so no partition has an offset lower than `CONFIG_PARTITION_TABLE_OFFSET + 0x1000`. (This includes the default partition CSV files supplied with ESP-IDF.)

When Secure Boot V2 is enabled, there is also an absolute binary size limit of 64 KB (0x10000 bytes) (excluding the 4 KB signature), because the bootloader is first loaded into a fixed size buffer for verification.

4.5.8 Fast Boot from Deep-Sleep

The bootloader has the *CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP* option which allows the wake-up time from Deep-sleep to be reduced (useful for reducing power consumption). This option is available when the *CONFIG_SECURE_BOOT* option is disabled or *CONFIG_SECURE_BOOT_INSECURE* is enabled along with Secure Boot. The reduction in time is achieved by ignoring image verification.

During the first boot, the bootloader stores the address of the application being launched in the RTC FAST memory. After waking up from deep sleep, this address is used to boot the application again without any checks, resulting in a significantly faster load.

4.5.9 Custom Bootloader

The current bootloader implementation allows a project to extend it or modify it. There are two ways of doing it: by implementing hooks or by overriding it. Both ways are presented in custom_bootloader folder in ESP-IDF examples:

- *bootloader_hooks* which presents how to connect some hooks to the bootloader initialization
- *bootloader_override* which presents how to override the bootloader implementation

In the bootloader space, you cannot use the drivers and functions from other components. If necessary, then the required functionality should be placed in the project's *bootloader_components* directory (note that this will increase its size).

If the bootloader grows too large then it can collide with the partition table, which is flashed at offset 0x8000 by default. Increase the *partition table offset* value to place the partition table later in the flash. This increases the space available for the bootloader.

4.6 Build System

This document explains the implementation of the ESP-IDF build system and the concept of "components". Read this document if you want to know how to organize and build a new ESP-IDF project or component.

4.6.1 Overview

An ESP-IDF project can be seen as an amalgamation of a number of components. For example, for a web server that shows the current humidity, there could be:

- The ESP-IDF base libraries (libc, ROM bindings, etc)
- The Wi-Fi drivers
- A TCP/IP stack
- The FreeRTOS operating system
- A web server
- A driver for the humidity sensor
- Main code tying it all together

ESP-IDF makes these components explicit and configurable. To do that, when a project is compiled, the build system will look up all the components in the ESP-IDF directories, the project directories and (optionally) in additional custom component directories. It then allows the user to configure the ESP-IDF project using a text-based menu system to customize each component. After the components in the project are configured, the build system will compile the project.

Concepts

- A "project" is a directory that contains all the files and configuration to build a single "app" (executable), as well as additional supporting elements such as a partition table, data/filesystem partitions, and a bootloader.
- "Project configuration" is held in a single file called `sdkconfig` in the root directory of the project. This configuration file is modified via `idf.py menuconfig` to customize the configuration of the project. A single project contains exactly one project configuration.
- An "app" is an executable that is built by ESP-IDF. A single project will usually build two apps - a "project app" (the main executable, ie your custom firmware) and a "bootloader app" (the initial bootloader program which launches the project app).
- "components" are modular pieces of standalone code that are compiled into static libraries (.a files) and linked to an app. Some are provided by ESP-IDF itself, others may be sourced from other places.
- "Target" is the hardware for which an application is built. A full list of supported targets in your version of ESP-IDF can be seen by running *idf.py --list-targets*.

Some things are not part of the project:

- "ESP-IDF" is not part of the project. Instead, it is standalone, and linked to the project via the `IDF_PATH` environment variable which holds the path of the `esp-idf` directory. This allows the ESP-IDF framework to be decoupled from your project.
- The toolchain for compilation is not part of the project. The toolchain should be installed in the system command line PATH.

4.6.2 Using the Build System

`idf.py`

The `idf.py` command-line tool provides a front-end for easily managing your project builds. It manages the following tools:

- CMake, which configures the project to be built
- Ninja which builds the project
- esptool.py for flashing the target.

You can read more about configuring the build system using `idf.py` *here*.

Using CMake Directly

idf.py is a wrapper around CMake for convenience. However, you can also invoke CMake directly if you prefer.

When `idf.py` does something, it prints each command that it runs for easy reference. For example, the `idf.py build` command is the same as running these commands in a bash shell (or similar commands for Windows Command Prompt):

```
mkdir -p build
cd build
cmake .. -G Ninja    # or 'Unix Makefiles'
ninja
```

In the above list, the `cmake` command configures the project and generates build files for use with the final build tool. In this case, the final build tool is Ninja: running `ninja` actually builds the project.

It's not necessary to run `cmake` more than once. After the first build, you only need to run `ninja` each time. `ninja` will automatically re-invoke `cmake` if the project needs reconfiguration.

If using CMake with `ninja` or `make`, there are also targets for more of the `idf.py` sub-commands. For example, running `make menuconfig` or `ninja menuconfig` in the build directory will work the same as `idf.py menuconfig`.

Note: If you're already familiar with CMake, you may find the ESP-IDF CMake-based build system unusual because it wraps a lot of CMake's functionality to reduce boilerplate. See *writing pure CMake components* for some information about writing more "CMake style" components.

Flashing with Ninja or Make It's possible to build and flash directly from ninja or make by running a target like:

```
ninja flash
```

Or:

```
make app-flash
```

Available targets are: `flash`, `app-flash` (app only), `bootloader-flash` (bootloader only).

When flashing this way, optionally set the `ESPPORT` and `ESPBAUD` environment variables to specify the serial port and baud rate. You can set environment variables in your operating system or IDE project. Alternatively, set them directly on the command line:

```
ESPPORT=/dev/ttyUSB0 ninja flash
```

Note: Providing environment variables at the start of the command like this is Bash shell Syntax. It will work on Linux and macOS. It won't work when using Windows Command Prompt, but it will work when using Bash-like shells on Windows.

Or:

```
make -j3 app-flash ESPPORT=COM4 ESPBAUD=2000000
```

Note: Providing variables at the end of the command line is `make` syntax, and works for `make` on all platforms.

Using CMake in an IDE

You can also use an IDE with CMake integration. The IDE will want to know the path to the project's `CMakeLists.txt` file. IDEs with CMake integration often provide their own build tools (CMake calls these "generators") to build the source files as part of the IDE.

When adding custom non-build steps like "flash" to the IDE, it is recommended to execute `idf.py` for these "special" commands.

For more detailed information about integrating ESP-IDF with CMake into an IDE, see *Build System Metadata*.

Setting up the Python Interpreter

ESP-IDF works well with Python version 3.8+.

`idf.py` and other Python scripts will run with the default Python interpreter, i.e., `python`. You can switch to a different one like `python3 $IDF_PATH/tools/idf.py ...`, or you can set up a shell alias or another script to simplify the command.

If using CMake directly, running `cmake -D PYTHON=python3 ...` will cause CMake to override the default Python interpreter.

If using an IDE with CMake, setting the `PYTHON` value as a CMake cache override in the IDE UI will override the default Python interpreter.

To manage the Python version more generally via the command line, check out the tools pyenv or virtualenv. These let you change the default Python version.

4.6.3 Example Project

An example project directory tree might look like this:

```
- myProject/
             - CMakeLists.txt
             - sdkconfig
             - dependencies.lock
             - bootloader_components/ - boot_component/ - CMakeLists.txt
                                                        - Kconfig
                                                        - src1.c
             - components/ - component1/ - CMakeLists.txt
                                         - Kconfig
                                         - src1.c
                           - component2/ - CMakeLists.txt
```

(continues on next page)

(continued from previous page)

```
                                        - Kconfig
                                        - src1.c
                                        - include/ - component2.h
            - managed_components/ - namespace__component-name/ - CMakelists.txt
                                                                - src1.c
                                                                - idf_component.yml
                                                                - include/ - src1.h
            - main/       - CMakeLists.txt
                          - src1.c
                          - src2.c
                          - idf_component.yml
            - build/
```

This example "myProject" contains the following elements:

- A top-level project CMakeLists.txt file. This is the primary file which CMake uses to learn how to build the project; and may set project-wide CMake variables. It includes the file /tools/cmake/project.cmake which implements the rest of the build system. Finally, it sets the project name and defines the project.
- "sdkconfig" project configuration file. This file is created/updated when `idf.py menuconfig` runs, and holds the configuration for all of the components in the project (including ESP-IDF itself). The `sdkconfig` file may or may not be added to the source control system of the project.
- "dependencies.lock" file contains the list of all managed components, and their versions, that are currently in used in the project. The `dependencies.lock` file is generated or updated automatically when IDF Component Manager is used to add or update project components. So this file should never be edited manually! If the project does not have `idf_component.yml` files in any of its components, `dependencies.lock` will not be created.
- Optional "idf_component.yml" file contains metadata about the component and its dependencies. It is used by the IDF Component Manager to download and resolve these dependencies. More information about this file can be found in the idf_component.yml section.
- Optional "bootloader_components" directory contains components that need to be compiled and linked inside the bootloader project. A project does not have to contain custom bootloader components of this kind, but it can be useful in case the bootloader needs to be modified to embed new features.
- Optional "components" directory contains components that are part of the project. A project does not have to contain custom components of this kind, but it can be useful for structuring reusable code or including third-party components that aren't part of ESP-IDF. Alternatively, `EXTRA_COMPONENT_DIRS` can be set in the top-level CMakeLists.txt to look for components in other places.
- "main" directory is a special component that contains source code for the project itself. "main" is a default name, the CMake variable `COMPONENT_DIRS` includes this component but you can modify this variable. See the *renaming main* section for more info. If you have a lot of source files in your project, we recommend grouping most into components instead of putting them all in "main".
- "build" directory is where the build output is created. This directory is created by `idf.py` if it doesn't already exist. CMake configures the project and generates interim build files in this directory. Then, after the main build process is run, this directory will also contain interim object files and libraries as well as final binary output files. This directory is usually not added to source control or distributed with the project source code.
- "managed_components" directory is created by the IDF Component Manager to store components managed by this tool. Each managed component typically includes a `idf_component.yml` manifest file defining the component's metadata, such as version and dependencies. However, for components sourced from Git repositories, the manifest file is optional. Users should avoid manually modifying the contents of the "managed_components" directory. If alterations are needed, the component can be copied to the `components` directory. The "managed_components" directory is usually not versioned in Git and not distributed with the project source code.

Component directories each contain a component `CMakeLists.txt` file. This file contains variable definitions to control the build process of the component, and its integration into the overall project. See *Component CMakeLists Files* for more details.

Each component may also include a `Kconfig` file defining the *component configuration* options that can be set via `menuconfig`. Some components may also include `Kconfig.projbuild` and `project_include.cmake` files, which are special files for *overriding parts of the project*.

4.6.4 Project CMakeLists File

Each project has a single top-level `CMakeLists.txt` file that contains build settings for the entire project. By default, the project CMakeLists can be quite minimal.

Minimal Example CMakeLists

Minimal project:

```
cmake_minimum_required(VERSION 3.16)
include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)
```

Mandatory Parts

The inclusion of these three lines, in the order shown above, is necessary for every project:

- `cmake_minimum_required(VERSION 3.16)` tells CMake the minimum version that is required to build the project. ESP-IDF is designed to work with CMake 3.16 or newer. This line must be the first line in the CMakeLists.txt file.
- `include($ENV{IDF_PATH}/tools/cmake/project.cmake)` pulls in the rest of the CMake functionality to configure the project, discover all the components, etc.
- `project(myProject)` creates the project itself, and specifies the project name. The project name is used for the final binary output files of the app - ie `myProject.elf`, `myProject.bin`. Only one project can be defined per CMakeLists file.

Optional Project Variables

These variables all have default values that can be overridden for custom behavior. Look in /tools/cmake/project.cmake for all of the implementation details.

- `COMPONENT_DIRS`: Directories to search for components. Defaults to `IDF_PATH/components`, `PROJECT_DIR/components`, and `EXTRA_COMPONENT_DIRS`. Override this variable if you don't want to search for components in these places.
- `EXTRA_COMPONENT_DIRS`: Optional list of additional directories to search for components. Paths can be relative to the project directory, or absolute.
- `COMPONENTS`: A list of component names to build into the project. Defaults to all components found in the `COMPONENT_DIRS` directories. Use this variable to "trim down" the project for faster build times. Note that any component which "requires" another component via the REQUIRES or PRIV_REQUIRES arguments on component registration will automatically have it added to this list, so the `COMPONENTS` list can be very short.
- `BOOTLOADER_IGNORE_EXTRA_COMPONENT`: A list of components, placed in `bootloader_components/`, that should be ignored by the bootloader compilation. Use this variable if a bootloader component needs to be included conditionally inside the project.

Any paths in these variables can be absolute paths, or set relative to the project directory.

To set these variables, use the cmake set command ie `set(VARIABLE "VALUE")`. The `set()` commands should be placed after the `cmake_minimum(...)` line but before the `include(...)` line.

Renaming `main` Component

The build system provides special treatment to the `main` component. It is a component that gets automatically added to the build provided that it is in the expected location, PROJECT_DIR/main. All other components in the build are also added as its dependencies, saving the user from hunting down dependencies and providing a build that works right out of the box. Renaming the `main` component causes the loss of these behind-the-scenes heavy lifting, requiring the user to specify the location of the newly renamed component and manually specify its dependencies. Specifically, the steps to renaming `main` are as follows:

1. Rename `main` directory.
2. Set `EXTRA_COMPONENT_DIRS` in the project CMakeLists.txt to include the renamed `main` directory.
3. Specify the dependencies in the renamed component's CMakeLists.txt file via REQUIRES or PRIV_REQUIRES arguments *on component registration*.

Overriding Default Build Specifications

The build sets some global build specifications (compile flags, definitions, etc.) that gets used in compiling all sources from all components.

For example, one of the default build specifications set is the compile option `-Wextra`. Suppose a user wants to use override this with `-Wno-extra`, it should be done after `project()`:

```
cmake_minimum_required(VERSION 3.16)
include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)

idf_build_set_property(COMPILE_OPTIONS "-Wno-error" APPEND)
```

This ensures that the compile options set by the user won't be overridden by the default build specifications, since the latter are set inside `project()`.

4.6.5 Component CMakeLists Files

Each project contains one or more components. Components can be part of ESP-IDF, part of the project's own components directory, or added from custom component directories (*see above*).

A component is any directory in the `COMPONENT_DIRS` list which contains a `CMakeLists.txt` file.

Searching for Components

The list of directories in `COMPONENT_DIRS` is searched for the project's components. Directories in this list can either be components themselves (ie they contain a *CMakeLists.txt* file), or they can be top-level directories whose sub-directories are components.

When CMake runs to configure the project, it logs the components included in the build. This list can be useful for debugging the inclusion/exclusion of certain components.

Multiple Components with the Same Name

When ESP-IDF is collecting all the components to compile, it will do this in the order specified by `COMPONENT_DIRS`; by default, this means ESP-IDF's internal components first (`IDF_PATH/components`), then any components in directories specified in `EXTRA_COMPONENT_DIRS`, and finally the project's components (`PROJECT_DIR/components`). If two or more of these directories contain component sub-directories with the same name, the component in the last place searched is used. This allows, for example, overriding ESP-IDF components with a modified version by copying that component from the ESP-IDF components directory to the project components directory and then modifying it there. If used in this way, the ESP-IDF directory itself can remain untouched.

Note: If a component is overridden in an existing project by moving it to a new location, the project will not automatically see the new component path. Run `idf.py reconfigure` (or delete the project build folder) and then build again.

Minimal Component CMakeLists

The minimal component `CMakeLists.txt` file simply registers the component to the build system using `idf_component_register`:

```
idf_component_register(SRCS "foo.c" "bar.c"
                       INCLUDE_DIRS "include"
                       REQUIRES mbedtls)
```

- `SRCS` is a list of source files (`*.c`, `*.cpp`, `*.cc`, `*.S`). These source files will be compiled into the component library.
- `INCLUDE_DIRS` is a list of directories to add to the global include search path for any component which requires this component, and also the main source files.
- `REQUIRES` is not actually required, but it is very often required to declare what other components this component will use. See *component requirements*.

A library with the name of the component will be built and linked to the final app.

Directories are usually specified relative to the `CMakeLists.txt` file itself, although they can be absolute.

There are other arguments that can be passed to `idf_component_register`. These arguments are discussed *here*.

See *example component requirements* and *example component CMakeLists* for more complete component `CMakeLists.txt` examples.

Preset Component Variables

The following component-specific variables are available for use inside component CMakeLists, but should not be modified:

- `COMPONENT_DIR`: The component directory. Evaluates to the absolute path of the directory containing `CMakeLists.txt`. The component path cannot contain spaces. This is the same as the `CMAKE_CURRENT_SOURCE_DIR` variable.
- `COMPONENT_NAME`: Name of the component. Same as the name of the component directory.
- `COMPONENT_ALIAS`: Alias of the library created internally by the build system for the component.
- `COMPONENT_LIB`: Name of the library created internally by the build system for the component.
- `COMPONENT_VERSION`: Component version specified by idf_component.yml and set by IDF Component Manager.

The following variables are set at the project level, but available for use in component CMakeLists:

- `CONFIG_*`: Each value in the project configuration has a corresponding variable available in cmake. All names begin with `CONFIG_`. *More information here*.
- `ESP_PLATFORM`: Set to 1 when the CMake file is processed within the ESP-IDF build system.

Build/Project Variables

The following are some project/build variables that are available as build properties and whose values can be queried using `idf_build_get_property` from the component CMakeLists.txt:

- `PROJECT_NAME`: Name of the project, as set in project CMakeLists.txt file.
- `PROJECT_DIR`: Absolute path of the project directory containing the project CMakeLists. Same as the `CMAKE_SOURCE_DIR` variable.
- `COMPONENTS`: Names of all components that are included in this build, formatted as a semicolon-delimited CMake list.
- `IDF_VER`: Git version of ESP-IDF (produced by `git describe`)
- `IDF_VERSION_MAJOR`, `IDF_VERSION_MINOR`, `IDF_VERSION_PATCH`: Components of ESP-IDF version, to be used in conditional expressions. Note that this information is less precise than that provided by `IDF_VER` variable. `v4.0-dev-*`, `v4.0-beta1`, `v4.0-rc1` and `v4.0` will all have the same values of `IDF_VERSION_*` variables, but different `IDF_VER` values.

- `IDF_TARGET`: Name of the target for which the project is being built.
- `PROJECT_VER`: Project version.
  - If *CONFIG_APP_PROJECT_VER_FROM_CONFIG* option is set, the value of *CONFIG_APP_PROJECT_VER* will be used.
  - Else, if `PROJECT_VER` variable is set in project CMakeLists.txt file, its value will be used.
  - Else, if the `PROJECT_DIR/version.txt` exists, its contents will be used as `PROJECT_VER`.
  - Else, if `VERSION` argument is passed to the `project()` call in the CMakeLists.txt file as `project(... VERSION x.y.z.w )` then it will be used as `PROJECT_VER`. The `VERSION` argument must be compliant with the cmake standard.
  - Else, if the project is located inside a Git repository, the output of git description will be used.
  - Otherwise, `PROJECT_VER` will be "1".
- `EXTRA_PARTITION_SUBTYPES`: CMake list of extra partition subtypes. Each subtype description is a comma-separated string with `type_name, subtype_name, numeric_value` format. Components may add new subtypes by appending them to this list.

Other build properties are listed *here*.

Controlling Component Compilation

To pass compiler options when compiling source files belonging to a particular component, use the target_compile_options function:

```
target_compile_options(${COMPONENT_LIB} PRIVATE -Wno-unused-variable)
```

To apply the compilation flags to a single source file, use the CMake set_source_files_properties command:

```
set_source_files_properties(mysrc.c
    PROPERTIES COMPILE_FLAGS
    -Wno-unused-variable
)
```

This can be useful if there is upstream code that emits warnings.

Note: CMake set_source_files_properties command is not applicable when the source files have been populated with help of the `SRC_DIRS` variable in `idf_component_register`. See *File Globbing & Incremental Builds* for more details.

When using these commands, place them after the call to `idf_component_register` in the component CMakeLists file.

4.6.6 Component Configuration

Each component can also have a `Kconfig` file, alongside `CMakeLists.txt`. This contains configuration settings to add to the configuration menu for this component.

These settings are found under the "Component Settings" menu when menuconfig is run.

To create a component Kconfig file, it is easiest to start with one of the Kconfig files distributed with ESP-IDF.

For an example, see *Adding conditional configuration*.

4.6.7 Preprocessor Definitions

The ESP-IDF build system adds the following C preprocessor definitions on the command line:

- `ESP_PLATFORM` : Can be used to detect that build happens within ESP-IDF.
- `IDF_VER` : Defined to a git version string. E.g. `v2.0` for a tagged release or `v1.0-275-g0efaa4f` for an arbitrary commit.

4.6.8 Component Requirements

When compiling each component, the ESP-IDF build system recursively evaluates its dependencies. This means each component needs to declare the components that it depends on ("requires").

When Writing a Component

```
idf_component_register(...
                       REQUIRES mbedtls
                       PRIV_REQUIRES console spiffs)
```

- `REQUIRES` should be set to all components whose header files are #included from the *public* header files of this component.
- `PRIV_REQUIRES` should be set to all components whose header files are #included from *any source files* in this component, unless already listed in `REQUIRES`. Also, any component which is required to be linked in order for this component to function correctly.
- The values of `REQUIRES` and `PRIV_REQUIRES` should not depend on any configuration choices (`CONFIG_xxx` macros). This is because requirements are expanded before the configuration is loaded. Other component variables (like include paths or source files) can depend on configuration choices.
- Not setting either or both `REQUIRES` variables is fine. If the component has no requirements except for the *Common component requirements* needed for RTOS, libc, etc.

If a component only supports some target chips (values of `IDF_TARGET`) then it can specify `REQUIRED_IDF_TARGETS` in the `idf_component_register` call to express these requirements. In this case, the build system will generate an error if the component is included in the build, but does not support the selected target.

Note: In CMake terms, `REQUIRES` & `PRIV_REQUIRES` are approximate wrappers around the CMake functions `target_link_libraries(... PUBLIC ...)` and `target_link_libraries(... PRIVATE ...)`.

Example of Component Requirements

Imagine there is a `car` component, which uses the `engine` component, which uses the `spark_plug` component:

```
- autoProject/
             - CMakeLists.txt
             - components/ - car/ - CMakeLists.txt
                                  - car.c
                                  - car.h
                           - engine/ - CMakeLists.txt
                                     - engine.c
                                     - include/ - engine.h
                           - spark_plug/  - CMakeLists.txt
                                          - spark_plug.c
                                          - spark_plug.h
```

Car Component The `car.h` header file is the public interface for the `car` component. This header includes `engine.h` directly because it uses some declarations from this header:

```
/* car.h */
#include "engine.h"

#ifdef ENGINE_IS_HYBRID
#define CAR_MODEL "Hybrid"
#endif
```

And car.c includes `car.h` as well:

```
/* car.c */
#include "car.h"
```

This means the `car/CMakeLists.txt` file needs to declare that `car` requires `engine`:

```
idf_component_register(SRCS "car.c"
                       INCLUDE_DIRS "."
                       REQUIRES engine)
```

- `SRCS` gives the list of source files in the `car` component.
- `INCLUDE_DIRS` gives the list of public include directories for this component. Because the public interface is `car.h`, the directory containing `car.h` is listed here.
- `REQUIRES` gives the list of components required by the public interface of this component. Because `car.h` is a public header and includes a header from `engine`, we include `engine` here. This makes sure that any other component which includes `car.h` will be able to recursively include the required `engine.h` also.

Engine Component The `engine` component also has a public header file `include/engine.h`, but this header is simpler:

```
/* engine.h */
#define ENGINE_IS_HYBRID

void engine_start(void);
```

The implementation is in `engine.c`:

```
/* engine.c */
#include "engine.h"
#include "spark_plug.h"

...
```

In this component, `engine` depends on `spark_plug` but this is a private dependency. `spark_plug.h` is needed to compile `engine.c`, but not needed to include `engine.h`.

This means that the `engine/CMakeLists.txt` file can use `PRIV_REQUIRES`:

```
idf_component_register(SRCS "engine.c"
                       INCLUDE_DIRS "include"
                       PRIV_REQUIRES spark_plug)
```

As a result, source files in the `car` component don't need the `spark_plug` include directories added to their compiler search path. This can speed up compilation, and stops compiler command lines from becoming longer than necessary.

Spark Plug Component The `spark_plug` component doesn't depend on anything else. It has a public header file `spark_plug.h`, but this doesn't include headers from any other components.

This means that the `spark_plug/CMakeLists.txt` file doesn't need any `REQUIRES` or `PRIV_REQUIRES` clauses:

```
idf_component_register(SRCS "spark_plug.c"
                       INCLUDE_DIRS ".")
```

Source File Include Directories

Each component's source file is compiled with these include path directories, as specified in the passed arguments to `idf_component_register`:

```
idf_component_register(..
                       INCLUDE_DIRS "include"
                       PRIV_INCLUDE_DIRS "other")
```

- The current component's `INCLUDE_DIRS` and `PRIV_INCLUDE_DIRS`.
- The `INCLUDE_DIRS` belonging to all other components listed in the `REQUIRES` and `PRIV_REQUIRES` parameters (ie all the current component's public and private dependencies).
- Recursively, all of the `INCLUDE_DIRS` of those components `REQUIRES` lists (ie all public dependencies of this component's dependencies, recursively expanded).

Main Component Requirements

The component named `main` is special because it automatically requires all other components in the build. So it's not necessary to pass `REQUIRES` or `PRIV_REQUIRES` to this component. See *renaming main* for a description of what needs to be changed if no longer using the `main` component.

Common Component Requirements

To avoid duplication, every component automatically requires some "common" IDF components even if they are not mentioned explicitly. Headers from these components can always be included.

The list of common components is: cxx, newlib, freertos, esp_hw_support, heap, log, soc, hal, esp_rom, esp_common, esp_system, xtensa/riscv.

Including Components in the Build

- By default, every component is included in the build.
- If you set the `COMPONENTS` variable to a minimal list of components used directly by your project, then the build will expand to also include required components. The full list of components will be:
  - Components mentioned explicitly in `COMPONENTS`.
  - Those components' requirements (evaluated recursively).
  - The "common" components that every component depends on.
- Setting `COMPONENTS` to the minimal list of required components can significantly reduce compile times.

Circular Dependencies

It's possible for a project to contain Component A that requires (`REQUIRES` or `PRIV_REQUIRES`) Component B, and Component B that requires Component A. This is known as a dependency cycle or a circular dependency.

CMake will usually handle circular dependencies automatically by repeating the component library names twice on the linker command line. However this strategy doesn't always work, and the build may fail with a linker error about "Undefined reference to ...", referencing a symbol defined by one of the components inside the circular dependency. This is particularly likely if there is a large circular dependency, i.e., A > B > C > D > A.

The best solution is to restructure the components to remove the circular dependency. In most cases, a software architecture without circular dependencies has desirable properties of modularity and clean layering and will be more maintainable in the long term. However, removing circular dependencies is not always possible.

To bypass a linker error caused by a circular dependency, the simplest workaround is to increase the CMake LINK_INTERFACE_MULTIPLICITY property of one of the component libraries. This causes CMake to repeat this library and its dependencies more than two times on the linker command line.

For example:

```
set_property(TARGET ${COMPONENT_LIB} APPEND PROPERTY LINK_INTERFACE_MULTIPLICITY 3)
```

- This line should be placed after `idf_component_register` in the component CMakeLists.txt file.

- If possible, place this line in the component that creates the circular dependency by depending on a lot of other components. However, the line can be placed inside any component that is part of the cycle. Choosing the component that owns the source file shown in the linker error message, or the component that defines the symbol(s) mentioned in the linker error message, is a good place to start.
- Usually increasing the value to 3 (default is 2) is enough, but if this doesn't work then try increasing the number further.
- Adding this option will make the linker command line longer, and the linking stage slower.

Advanced Workaround: Undefined Symbols If only one or two symbols are causing a circular dependency, and all other dependencies are linear, then there is an alternative method to avoid linker errors: Specify the specific symbols required for the "reverse" dependency as undefined symbols at link time.

For example, if component A depends on component B but component B also needs to reference `reverse_ops` from component A (but nothing else), then you can add a line like the following to the component B CMakeLists.txt to resolve the cycle at link time:

```
# This symbol is provided by 'Component A' at link time
target_link_libraries(${COMPONENT_LIB} INTERFACE "-u reverse_ops")
```

- The `-u` argument means that the linker will always include this symbol in the link, regardless of dependency ordering.
- This line should be placed after `idf_component_register` in the component CMakeLists.txt file.
- If 'Component B' doesn't need to access any headers of 'Component A', only link to a few symbol(s), then this line can be used instead of any `REQUIRES` from B to A. This further simplifies the component structure in the build system.

See the target_link_libraries documentation for more information about this CMake function.

Requirements in the Build System Implementation

- Very early in the CMake configuration process, the script `expand_requirements.cmake` is run. This script does a partial evaluation of all component CMakeLists.txt files and builds a graph of component requirements (this *graph may have cycles*). The graph is used to generate a file `component_depends.cmake` in the build directory.
- The main CMake process then includes this file and uses it to determine the list of components to include in the build (internal `BUILD_COMPONENTS` variable). The `BUILD_COMPONENTS` variable is sorted so dependencies are listed first, however, as the component dependency graph has cycles this cannot be guaranteed for all components. The order should be deterministic given the same set of components and component dependencies.
- The value of `BUILD_COMPONENTS` is logged by CMake as "Component names: "
- Configuration is then evaluated for the components included in the build.
- Each component is included in the build normally and the CMakeLists.txt file is evaluated again to add the component libraries to the build.

Component Dependency Order The order of components in the `BUILD_COMPONENTS` variable determines other orderings during the build:

- Order that *Project_include.cmake* files are included in the project.
- Order that the list of header paths is generated for compilation (via `-I` argument). (Note that for a given component's source files, only that component's dependency's header paths are passed to the compiler.)

Adding Link-Time Dependencies The ESP-IDF CMake helper function `idf_component_add_link_dependency` adds a link-only dependency between one component and another. In almost all cases, it is better to use the `PRIV_REQUIRES` feature in `idf_component_register` to create a dependency. However, in some cases, it's necessary to add the link-time dependency of another component to this component, i.e., the reverse order to `PRIV_REQUIRES` (for example: *Overriding Default Chip Drivers*).

To make another component depend on this component at link time:

```
idf_component_add_link_dependency(FROM other_component)
```

Place this line after the line with `idf_component_register`.

It's also possible to specify both components by name:

```
idf_component_add_link_dependency(FROM other_component TO that_component)
```

4.6.9 Overriding Parts of the Project

Project_include.cmake

For components that have build requirements that must be evaluated before any component CMakeLists files are evaluated, you can create a file called `project_include.cmake` in the component directory. This CMake file is included when `project.cmake` is evaluating the entire project.

`project_include.cmake` files are used inside ESP-IDF, for defining project-wide build features such as `esptool.py` command line arguments and the `bootloader` "special app".

Unlike component `CMakeLists.txt` files, when including a `project_include.cmake` file the current source directory (`CMAKE_CURRENT_SOURCE_DIR` and working directory) is the project directory. Use the variable `COMPONENT_DIR` for the absolute directory of the component.

Note that `project_include.cmake` isn't necessary for the most common component uses, such as adding include directories to the project, or `LDFLAGS` to the final linking step. These values can be customized via the `CMakeLists.txt` file itself. See *Optional Project Variables* for details.

`project_include.cmake` files are included in the order given in `BUILD_COMPONENTS` variable (as logged by CMake). This means that a component's `project_include.cmake` file will be included after it's all dependencies' `project_include.cmake` files, unless both components are part of a dependency cycle. This is important if a `project_include.cmake` file relies on variables set by another component. See also *above*.

Take great care when setting variables or targets in a `project_include.cmake` file. As the values are included in the top-level project CMake pass, they can influence or break functionality across all components!

KConfig.projbuild

This is an equivalent to `project_include.cmake` for *Component Configuration* KConfig files. If you want to include configuration options at the top level of menuconfig, rather than inside the "Component Configuration" sub-menu, then these can be defined in the KConfig.projbuild file alongside the `CMakeLists.txt` file.

Take care when adding configuration values in this file, as they will be included across the entire project configuration. Where possible, it's generally better to create a KConfig file for *Component Configuration*.

Wrappers to Redefine or Extend Existing Functions

Thanks to the linker's wrap feature, it is possible to redefine or extend the behavior of an existing ESP-IDF function. To do so, you will need to provide the following CMake declaration in your project's `CMakeLists.txt` file:

```
target_link_libraries(${COMPONENT_LIB} INTERFACE "-Wl,--wrap=function_to_redefine")
```

Where `function_to_redefine` is the name of the function to redefine or extend. This option will let the linker replace all the calls to `function_to_redefine` functions in the binary libraries with calls to `__wrap_function_to_redefine` function. Thus, you must define this new symbol in your application.

The linker will provide a new symbol named `__real_function_to_redefine` which points to the former implementation of the function to redefine. It can be called from the new implementation, making it an extension of the former one.

This mechanism is shown in the example build_system/wrappers. Check examples/build_system/wrappers/README.md for more details.

Override the Default Bootloader

Thanks to the optional `bootloader_components` directory present in your ESP-IDf project, it is possible to override the default ESP-IDF bootloader. To do so, a new `bootloader_components/main` component should be defined, which will make the project directory tree look like the following:

- **myProject/**
  - CMakeLists.txt
  - sdkconfig
  - **bootloader_components/ - main/ - CMakeLists.txt**
    - Kconfig
    - my_bootloader.c
  - **main/ - CMakeLists.txt**
    - app_main.c
  - build/

Here the `my_bootloader.c` file becomes source code for the new bootloader, which means that it will need to perform all the required operations to set up and load the `main` application from flash.

It is also possible to conditionally replace the bootloader depending on a certain condition, such as the target for example. This can be achieved thanks to the `BOOTLOADER_IGNORE_EXTRA_COMPONENT` CMake variable. This list can be used to tell the ESP-IDF bootloader project to ignore and not compile the given components present in `bootloader_components`. For example, if one wants to use the default bootloader for ESP32 target, then `myProject/CMakeLists.txt` should look like the following:

```
include($ENV{IDF_PATH}/tools/cmake/project.cmake)

if(${IDF_TARGET} STREQUAL "esp32")
    set(BOOTLOADER_IGNORE_EXTRA_COMPONENT "main")
endif()

project(main)
```

It is important to note that this can also be used for any other bootloader components than `main`. In all cases, the prefix `bootloader_component` must not be specified.

See custom_bootloader/bootloader_override for an example of overriding the default bootloader.

4.6.10 Configuration-Only Components

Special components which contain no source files, only `Kconfig.projbuild` and `KConfig`, can have a one-line `CMakeLists.txt` file which calls the function `idf_component_register()` with no arguments specified. This function will include the component in the project build, but no library will be built *and* no header files will be added to any included paths.

4.6.11 Debugging CMake

For full details about CMake and CMake commands, see the CMake v3.16 documentation.

Some tips for debugging the ESP-IDF CMake-based build system:

- When CMake runs, it prints quite a lot of diagnostic information including lists of components and component paths.
- Running `cmake -DDEBUG=1` will produce more verbose diagnostic output from the IDF build system.
- Running `cmake` with the `--trace` or `--trace-expand` options will give a lot of information about control flow. See the cmake command line documentation.

When included from a project CMakeLists file, the `project.cmake` file defines some utility modules and global variables and then sets `IDF_PATH` if it was not set in the system environment.

It also defines an overridden custom version of the built-in CMake `project` function. This function is overridden to add all of the ESP-IDF specific project functionality.

Warning On Undefined Variables

By default, the function of warnings on undefined variables is disabled.

To enable this function, we can pass the `--warn-uninitialized` flag to CMake or pass the `--cmake-warn-uninitialized` flag to `idf.py` so it will print a warning if an undefined variable is referenced in the build. This can be very useful to find buggy CMake files.

Browse the /tools/cmake/project.cmake file and supporting functions in /tools/cmake/ for more details.

4.6.12 Example Component CMakeLists

Because the build environment tries to set reasonable defaults that will work most of the time, component `CMakeLists.txt` can be very small or even empty (see *Minimal Component CMakeLists*). However, overriding *preset_component_variables* is usually required for some functionality.

Here are some more advanced examples of component CMakeLists files.

Adding Conditional Configuration

The configuration system can be used to conditionally compile some files depending on the options selected in the project configuration.

`Kconfig`:

```
config FOO_ENABLE_BAR
    bool "Enable the BAR feature."
    help
        This enables the BAR feature of the FOO component.
```

`CMakeLists.txt`:

```
 set(srcs "foo.c" "more_foo.c")

 if(CONFIG_FOO_ENABLE_BAR)
     list(APPEND srcs "bar.c")
 endif()

idf_component_register(SRCS "${srcs}"
                       ...)
```

This example makes use of the CMake if function and list APPEND function.

This can also be used to select or stub out an implementation, as such:

`Kconfig`:

```
config ENABLE_LCD_OUTPUT
    bool "Enable LCD output."
    help
        Select this if your board has an LCD.

config ENABLE_LCD_CONSOLE
    bool "Output console text to LCD"
    depends on ENABLE_LCD_OUTPUT
```

(continues on next page)

(continued from previous page)

```
    help
        Select this to output debugging output to the LCD

config ENABLE_LCD_PLOT
    bool "Output temperature plots to LCD"
    depends on ENABLE_LCD_OUTPUT
    help
        Select this to output temperature plots
```

CMakeLists.txt:

```
if(CONFIG_ENABLE_LCD_OUTPUT)
   set(srcs lcd-real.c lcd-spi.c)
else()
   set(srcs lcd-dummy.c)
endif()

# We need font if either console or plot is enabled
if(CONFIG_ENABLE_LCD_CONSOLE OR CONFIG_ENABLE_LCD_PLOT)
   list(APPEND srcs "font.c")
endif()

idf_component_register(SRCS "${srcs}"
                       ...)
```

Conditions Which Depend on the Target

The current target is available to CMake files via `IDF_TARGET` variable.

In addition to that, if target `xyz` is used (`IDF_TARGET=xyz`), then Kconfig variable `CONFIG_IDF_TARGET_XYZ` will be set.

Note that component dependencies may depend on `IDF_TARGET` variable, but not on Kconfig variables. Also one can not use Kconfig variables in `include` statements in CMake files, but `IDF_TARGET` can be used in such context.

Source Code Generation

Some components will have a situation where a source file isn't supplied with the component itself but has to be generated from another file. Say our component has a header file that consists of the converted binary data of a BMP file, converted using a hypothetical tool called bmp2h. The header file is then included in as C source file called graphics_lib.c:

```
add_custom_command(OUTPUT logo.h
     COMMAND bmp2h -i ${COMPONENT_DIR}/logo.bmp -o log.h
     DEPENDS ${COMPONENT_DIR}/logo.bmp
     VERBATIM)

add_custom_target(logo DEPENDS logo.h)
add_dependencies(${COMPONENT_LIB} logo)

set_property(DIRECTORY "${COMPONENT_DIR}" APPEND PROPERTY
     ADDITIONAL_CLEAN_FILES logo.h)
```

This answer is adapted from the CMake FAQ entry, which contains some other examples that will also work with ESP-IDF builds.

In this example, logo.h will be generated in the current directory (the build directory) while logo.bmp comes with the component and resides under the component path. Because logo.h is a generated file, it should be cleaned when the project is cleaned. For this reason, it is added to the ADDITIONAL_CLEAN_FILES property.

Note: If generating files as part of the project CMakeLists.txt file, not a component CMakeLists.txt, then use build property `PROJECT_DIR` instead of `${COMPONENT_DIR}` and `${PROJECT_NAME}.elf` instead of `${COMPONENT_LIB}`.)

If a a source file from another component included `logo.h`, then `add_dependencies` would need to be called to add a dependency between the two components, to ensure that the component source files were always compiled in the correct order.

Embedding Binary Data

Sometimes you have a file with some binary or text data that you'd like to make available to your component, but you don't want to reformat the file as a C source.

You can specify argument `EMBED_FILES` in the component registration, giving space-delimited names of the files to embed:

```
idf_component_register(...
                       EMBED_FILES server_root_cert.der)
```

Or if the file is a string, you can use the variable `EMBED_TXTFILES`. This will embed the contents of the text file as a null-terminated string:

```
idf_component_register(...
                       EMBED_TXTFILES server_root_cert.pem)
```

The file's contents will be added to the .rodata section in flash, and are available via symbol names as follows:

```
extern const uint8_t server_root_cert_pem_start[] asm("_binary_server_root_cert_
↪pem_start");
extern const uint8_t server_root_cert_pem_end[]   asm("_binary_server_root_cert_
↪pem_end");
```

The names are generated from the full name of the file, as given in `EMBED_FILES`. Characters /, ., etc. are replaced with underscores. The _binary prefix in the symbol name is added by objcopy and is the same for both text and binary files.

To embed a file into a project, rather than a component, you can call the function `target_add_binary_data` like this:

```
target_add_binary_data(myproject.elf "main/data.bin" TEXT)
```

Place this line after the `project()` line in your project CMakeLists.txt file. Replace `myproject.elf` with your project name. The final argument can be `TEXT` to embed a null-terminated string, or `BINARY` to embed the content as-is.

For an example of using this technique, see the "main" component of the file_serving example protocols/http_server/file_serving/main/CMakeLists.txt - two files are loaded at build time and linked into the firmware.

It is also possible to embed a generated file:

```
add_custom_command(OUTPUT my_processed_file.bin
                   COMMAND my_process_file_cmd my_unprocessed_file.bin)
target_add_binary_data(my_target "my_processed_file.bin" BINARY)
```

In the example above, `my_processed_file.bin` is generated from `my_unprocessed_file.bin` through some command `my_process_file_cmd`, then embedded into the target.

To specify a dependence on a target, use the `DEPENDS` argument:

```
add_custom_target(my_process COMMAND ...)
target_add_binary_data(my_target "my_embed_file.bin" BINARY DEPENDS my_process)
```

The `DEPENDS` argument to `target_add_binary_data` ensures that the target executes first.

Code and Data Placements

ESP-IDF has a feature called linker script generation that enables components to define where its code and data will be placed in memory through linker fragment files. These files are processed by the build system, and is used to augment the linker script used for linking app binary. See *Linker Script Generation* for a quick start guide as well as a detailed discussion of the mechanism.

Fully Overriding the Component Build Process

Obviously, there are cases where all these recipes are insufficient for a certain component, for example when the component is basically a wrapper around another third-party component not originally intended to be compiled under this build system. In that case, it's possible to forego the ESP-IDF build system entirely by using a CMake feature called ExternalProject. Example component CMakeLists:

```
# External build process for quirc, runs in source dir and
# produces libquirc.a
externalproject_add(quirc_build
    PREFIX ${COMPONENT_DIR}
    SOURCE_DIR ${COMPONENT_DIR}/quirc
    CONFIGURE_COMMAND ""
    BUILD_IN_SOURCE 1
    BUILD_COMMAND make CC=${CMAKE_C_COMPILER} libquirc.a
    INSTALL_COMMAND ""
    )

 # Add libquirc.a to the build process
 add_library(quirc STATIC IMPORTED GLOBAL)
 add_dependencies(quirc quirc_build)

 set_target_properties(quirc PROPERTIES IMPORTED_LOCATION
      ${COMPONENT_DIR}/quirc/libquirc.a)
 set_target_properties(quirc PROPERTIES INTERFACE_INCLUDE_DIRECTORIES
      ${COMPONENT_DIR}/quirc/lib)

 set_directory_properties( PROPERTIES ADDITIONAL_CLEAN_FILES
      "${COMPONENT_DIR}/quirc/libquirc.a")
```

(The above CMakeLists.txt can be used to create a component named `quirc` that builds the quirc project using its own Makefile.)

- `externalproject_add` defines an external build system.
  - `SOURCE_DIR`, `CONFIGURE_COMMAND`, `BUILD_COMMAND` and `INSTALL_COMMAND` should always be set. `CONFIGURE_COMMAND` can be set to an empty string if the build system has no "configure" step. `INSTALL_COMMAND` will generally be empty for ESP-IDF builds.
  - Setting `BUILD_IN_SOURCE` means the build directory is the same as the source directory. Otherwise, you can set `BUILD_DIR`.
  - Consult the ExternalProject documentation for more details about `externalproject_add()`
- The second set of commands adds a library target, which points to the "imported" library file built by the external system. Some properties need to be set in order to add include directories and tell CMake where this file is.
- Finally, the generated library is added to ADDITIONAL_CLEAN_FILES. This means `make clean` will delete this library. (Note that the other object files from the build won't be deleted.)

ExternalProject Dependencies and Clean Builds CMake has some unusual behavior around external project builds:

- ADDITIONAL_CLEAN_FILES only works when "make" or "ninja" is used as the build system. If an IDE build system is used, it won't delete these files when cleaning.
- However, the ExternalProject configure & build commands will *always* be re-run after a clean is run.
- Therefore, there are two alternative recommended ways to configure the external build command:
  1. Have the external `BUILD_COMMAND` run a full clean compile of all sources. The build command will be run if any of the dependencies passed to `externalproject_add` with `DEPENDS` have changed, or if this is a clean build (ie any of `idf.py clean`, `ninja clean`, or `make clean` was run.)
  2. Have the external `BUILD_COMMAND` be an incremental build command. Pass the parameter `BUILD_ALWAYS 1` to `externalproject_add`. This means the external project will be built each time a build is run, regardless of dependencies. This is only recommended if the external project has correct incremental build behavior, and doesn't take too long to run.

The best of these approaches for building an external project will depend on the project itself, its build system, and whether you anticipate needing to frequently recompile the project.

4.6.13 Custom Sdkconfig Defaults

For example projects or other projects where you don't want to specify a full sdkconfig configuration, but you do want to override some key values from the ESP-IDF defaults, it is possible to create a file `sdkconfig.defaults` in the project directory. This file will be used when creating a new config from scratch, or when any new config value hasn't yet been set in the `sdkconfig` file.

To override the name of this file or to specify multiple files, set the `SDKCONFIG_DEFAULTS` environment variable or set `SDKCONFIG_DEFAULTS` in top-level `CMakeLists.txt`. File names that are not specified as full paths are resolved relative to current project's directory.

When specifying multiple files, use a semicolon as the list separator. Files listed first will be applied first. If a particular key is defined in multiple files, the definition in the latter file will override definitions from former files.

Some of the IDF examples include a `sdkconfig.ci` file. This is part of the continuous integration (CI) test framework and is ignored by the normal build process.

Target-dependent Sdkconfig Defaults

If and only if an `sdkconfig.defaults` file exists, the build system will also attempt to load defaults from an `sdkconfig.defaults.TARGET_NAME` file, where `TARGET_NAME` is the value of `IDF_TARGET`. For example, for `esp32` target, default settings will be taken from `sdkconfig.defaults` first, and then from `sdkconfig.defaults.esp32`. If there are no generic default settings, an empty `sdkconfig.defaults` still needs to be created if the build system should recognize any additional target-dependent `sdkconfig.defaults.TARGET_NAME` files.

If `SDKCONFIG_DEFAULTS` is used to override the name of defaults file/files, the name of target-specific defaults file will be derived from `SDKCONFIG_DEFAULTS` value/values using the rule above. When there are multiple files in `SDKCONFIG_DEFAULTS`, target-specific file will be applied right after the file bringing it in, before all latter files in `SDKCONFIG_DEFAULTS`

For example, if `SDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig_devkit1"`, and there is a file `sdkconfig.defaults.esp32` in the same folder, then the files will be applied in the following order: (1) sdkconfig.defaults (2) sdkconfig.defaults.esp32 (3) sdkconfig_devkit1.

4.6.14 Flash Arguments

There are some scenarios that we want to flash the target board without IDF. For this case we want to save the built binaries, esptool.py and esptool write_flash arguments. It's simple to write a script to save binaries and esptool.py.

After running a project build, the build directory contains binary output files (`.bin` files) for the project and also the following flashing data files:

- `flash_project_args` contains arguments to flash the entire project (app, bootloader, partition table, PHY data if this is configured).
- `flash_app_args` contains arguments to flash only the app.
- `flash_bootloader_args` contains arguments to flash only the bootloader.

You can pass any of these flasher argument files to `esptool.py` as follows:

```
python esptool.py --chip esp32 write_flash @build/flash_project_args
```

Alternatively, it is possible to manually copy the parameters from the argument file and pass them on the command line.

The build directory also contains a generated file `flasher_args.json` which contains project flash information, in JSON format. This file is used by `idf.py` and can also be used by other tools which need information about the project build.

4.6.15 Building the Bootloader

The bootloader is a special "subproject" inside /components/bootloader/subproject. It has its own project CMakeLists.txt file and builds separate .ELF and .BIN files to the main project. However, it shares its configuration and build directory with the main project.

The subproject is inserted as an external project from the top-level project, by the file /components/bootloader/project_include.cmake. The main build process runs CMake for the subproject, which includes discovering components (a subset of the main components) and generating a bootloader-specific config (derived from the main `sdkconfig`).

4.6.16 Writing Pure CMake Components

The ESP-IDF build system "wraps" CMake with the concept of "components", and helper functions to automatically integrate these components into a project build.

However, underneath the concept of "components" is a full CMake build system. It is also possible to make a component which is pure CMake.

Here is an example minimal "pure CMake" component CMakeLists file for a component named `json`:

```
add_library(json STATIC
cJSON/cJSON.c
cJSON/cJSON_Utils.c)

target_include_directories(json PUBLIC cJSON)
```

- This is actually an equivalent declaration to the IDF `json` component /components/json/CMakeLists.txt.
- This file is quite simple as there are not a lot of source files. For components with a large number of files, the globbing behavior of ESP-IDF's component logic can make the component CMakeLists style simpler.)
- Any time a component adds a library target with the component name, the ESP-IDF build system will automatically add this to the build, expose public include directories, etc. If a component wants to add a library target with a different name, dependencies will need to be added manually via CMake commands.

4.6.17 Using Third-Party CMake Projects with Components

CMake is used for a lot of open-source C and C++ projects —code that users can tap into for their applications. One of the benefits of having a CMake build system is the ability to import these third-party projects, sometimes even without modification! This allows for users to be able to get functionality that may not yet be provided by a component, or use another library for the same functionality.

Importing a library might look like this for a hypothetical library `foo` to be used in the `main` component:

```
# Register the component
idf_component_register(...)

# Set values of hypothetical variables that control the build of `foo`
set(FOO_BUILD_STATIC OFF)
set(FOO_BUILD_TESTS OFF)

# Create and import the library targets
add_subdirectory(foo)

# Publicly link `foo` to `main` component
target_link_libraries(main PUBLIC foo)
```

For an actual example, take a look at build_system/cmake/import_lib. Take note that what needs to be done in order to import the library may vary. It is recommended to read up on the library's documentation for instructions on how to import it from other projects. Studying the library's CMakeLists.txt and build structure can also be helpful.

It is also possible to wrap a third-party library to be used as a component in this manner. For example, the mbedtls component is a wrapper for Espressif's fork of mbedtls. See its component CMakeLists.txt .

The CMake variable `ESP_PLATFORM` is set to 1 whenever the ESP-IDF build system is being used. Tests such as `if (ESP_PLATFORM)` can be used in generic CMake code if special IDF-specific logic is required.

Using ESP-IDF Components from External Libraries

The above example assumes that the external library `foo` (or `tinyxml` in the case of the `import_lib` example) doesn't need to use any ESP-IDF APIs apart from common APIs such as libc, libstdc++, etc. If the external library needs to use APIs provided by other ESP-IDF components, this needs to be specified in the external CMakeLists.txt file by adding a dependency on the library target `idf::<componentname>`.

For example, in the `foo/CMakeLists.txt` file:

```
add_library(foo bar.c fizz.cpp buzz.cpp)

if(ESP_PLATFORM)
  # On ESP-IDF, bar.c needs to include esp_flash.h from the spi_flash component
  target_link_libraries(foo PRIVATE idf::spi_flash)
endif()
```

4.6.18 Using Prebuilt Libraries with Components

Another possibility is that you have a prebuilt static library (`.a` file), built by some other build process.

The ESP-IDF build system provides a utility function `add_prebuilt_library` for users to be able to easily import and use prebuilt libraries:

```
add_prebuilt_library(target_name lib_path [REQUIRES req1 req2 ...] [PRIV_REQUIRES␣
↪req1 req2 ...])
```

where:

- `target_name`- name that can be used to reference the imported library, such as when linking to other targets
- `lib_path`- path to prebuilt library; may be an absolute or relative path to the component directory

Optional arguments `REQUIRES` and `PRIV_REQUIRES` specify dependency on other components. These have the same meaning as the arguments for `idf_component_register`.

Take note that the prebuilt library must have been compiled for the same target as the consuming project. Configuration relevant to the prebuilt library must also match. If not paid attention to, these two factors may contribute to subtle bugs in the app.

For an example, take a look at build_system/cmake/import_prebuilt.

4.6.19 Using ESP-IDF in Custom CMake Projects

ESP-IDF provides a template CMake project for easily creating an application. However, in some instances the user might already have an existing CMake project or may want to create a custom one. In these cases it is desirable to be able to consume IDF components as libraries to be linked to the user's targets (libraries/executables).

It is possible to do so by using the *build system APIs provided* by tools/cmake/idf.cmake. For example:

```
cmake_minimum_required(VERSION 3.16)
project(my_custom_app C)

# Include CMake file that provides ESP-IDF CMake build system APIs.
include($ENV{IDF_PATH}/tools/cmake/idf.cmake)

# Include ESP-IDF components in the build, may be thought as an equivalent of
# add_subdirectory() but with some additional processing and magic for ESP-IDF␣
↪build
# specific build processes.
idf_build_process(esp32)

# Create the project executable and plainly link the newlib component to it using
# its alias, idf::newlib.
add_executable(${CMAKE_PROJECT_NAME}.elf main.c)
target_link_libraries(${CMAKE_PROJECT_NAME}.elf idf::newlib)

# Let the build system know what the project executable is to attach more targets,␣
↪dependencies, etc.
idf_build_executable(${CMAKE_PROJECT_NAME}.elf)
```

The example in build_system/cmake/idf_as_lib demonstrates the creation of an application equivalent to hello world application using a custom CMake project.

4.6.20 ESP-IDF CMake Build System API

Idf-build-commands

```
idf_build_get_property(var property [GENERATOR_EXPRESSION])
```

Retrieve a *build property* *property* and store it in *var* accessible from the current scope. Specifying *GENERATOR_EXPRESSION* will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.

```
idf_build_set_property(property val [APPEND])
```

Set a *build property* *property* with value *val*. Specifying *APPEND* will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

```
idf_build_component(component_dir)
```

Present a directory *component_dir* that contains a component to the build system. Relative paths are converted to absolute paths with respect to current directory. All calls to this command must be performed before *idf_build_process*.

This command does not guarantee that the component will be processed during build (see the *COMPONENTS* argument description for *idf_build_process*)

```
idf_build_process(target
                  [PROJECT_DIR project_dir]
                  [PROJECT_VER project_ver]
                  [PROJECT_NAME project_name]
```

(continues on next page)

(continued from previous page)

```
                    [SDKCONFIG sdkconfig]
                    [SDKCONFIG_DEFAULTS sdkconfig_defaults]
                    [BUILD_DIR build_dir]
                    [COMPONENTS component1 component2 ...])
```

Performs the bulk of the behind-the-scenes magic for including ESP-IDF components such as component configuration, libraries creation, dependency expansion and resolution. Among these functions, perhaps the most important from a user's perspective is the libraries creation by calling each component's `idf_component_register`. This command creates the libraries for each component, which are accessible using aliases in the form idf::*component_name*. These aliases can be used to link the components to the user's own targets, either libraries or executables.

The call requires the target chip to be specified with *target* argument. Optional arguments for the call include:

- PROJECT_DIR - directory of the project; defaults to CMAKE_SOURCE_DIR
- PROJECT_NAME - name of the project; defaults to CMAKE_PROJECT_NAME
- PROJECT_VER - version/revision of the project; defaults to "1"
- SDKCONFIG - output path of generated sdkconfig file; defaults to PROJECT_DIR/sdkconfig or CMAKE_SOURCE_DIR/sdkconfig depending if PROJECT_DIR is set
- SDKCONFIG_DEFAULTS - list of files containing default config to use in the build (list must contain full paths); defaults to empty. For each value *filename* in the list, the config from file *filename.target*, if it exists, is also loaded.
- BUILD_DIR - directory to place ESP-IDF build-related artifacts, such as generated binaries, text files, components; defaults to CMAKE_BINARY_DIR
- COMPONENTS - select components to process among the components known by the build system (added via *idf_build_component*). This argument is used to trim the build. Other components are automatically added if they are required in the dependency chain, i.e., the public and private requirements of the components in this list are automatically added, and in turn the public and private requirements of those requirements, so on and so forth. If not specified, all components known to the build system are processed.

```
idf_build_executable(executable)
```

Specify the executable *executable* for ESP-IDF build. This attaches additional targets such as dependencies related to flashing, generating additional binary files, etc. Should be called after `idf_build_process`.

```
idf_build_get_config(var config [GENERATOR_EXPRESSION])
```

Get the value of the specified config. Much like build properties, specifying *GENERATOR_EXPRESSION* will retrieve the generator expression string for that config, instead of the actual value, which can be used with CMake commands that support generator expressions. Actual config values are only known after call to `idf_build_process`, however.

Idf-build-properties

These are properties that describe the build. Values of build properties can be retrieved by using the build command `idf_build_get_property`. For example, to get the Python interpreter used for the build:

```
idf_build_get_property(python PYTHON)
message(STATUS "The Python interpreter is: ${python}")
```

- BUILD_DIR - build directory; set from `idf_build_process` BUILD_DIR argument
- BUILD_COMPONENTS - list of components included in the build; set by `idf_build_process`
- BUILD_COMPONENT_ALIASES - list of library alias of components included in the build; set by `idf_build_process`
- C_COMPILE_OPTIONS - compile options applied to all components' C source files
- COMPILE_OPTIONS - compile options applied to all components' source files, regardless of it being C or C++
- COMPILE_DEFINITIONS - compile definitions applied to all component source files

- CXX_COMPILE_OPTIONS - compile options applied to all components' C++ source files
- DEPENDENCIES_LOCK - lock file path used in component manager. The default value is *dependencies.lock* under the project path.
- EXECUTABLE - project executable; set by call to `idf_build_executable`
- EXECUTABLE_NAME - name of project executable without extension; set by call to `idf_build_executable`
- EXECUTABLE_DIR - path containing the output executable
- IDF_COMPONENT_MANAGER - the component manager is enabled by default, but if this property is set to `0` it was disabled by the IDF_COMPONENT_MANAGER environment variable
- IDF_PATH - ESP-IDF path; set from IDF_PATH environment variable, if not, inferred from the location of `idf.cmake`
- IDF_TARGET - target chip for the build; set from the required target argument for `idf_build_process`
- IDF_VER - ESP-IDF version; set from either a version file or the Git revision of the IDF_PATH repository
- INCLUDE_DIRECTORIES - include directories for all component source files
- KCONFIGS - list of Kconfig files found in components in build; set by `idf_build_process`
- KCONFIG_PROJBUILDS - list of Kconfig.projbuild files found in components in build; set by `idf_build_process`
- PROJECT_NAME - name of the project; set from `idf_build_process` PROJECT_NAME argument
- PROJECT_DIR - directory of the project; set from `idf_build_process` PROJECT_DIR argument
- PROJECT_VER - version of the project; set from `idf_build_process` PROJECT_VER argument
- PYTHON - Python interpreter used for the build; set from PYTHON environment variable if available, if not "python" is used
- SDKCONFIG - full path to output config file; set from `idf_build_process` SDKCONFIG argument
- SDKCONFIG_DEFAULTS - list of files containing default config to use in the build; set from `idf_build_process` SDKCONFIG_DEFAULTS argument
- SDKCONFIG_HEADER - full path to C/C++ header file containing component configuration; set by `idf_build_process`
- SDKCONFIG_CMAKE - full path to CMake file containing component configuration; set by `idf_build_process`
- SDKCONFIG_JSON - full path to JSON file containing component configuration; set by `idf_build_process`
- SDKCONFIG_JSON_MENUS - full path to JSON file containing config menus; set by `idf_build_process`

Idf-component-commands

```
idf_component_get_property(var component property [GENERATOR_EXPRESSION])
```

Retrieve a specified *component*'s *component property*, *property* and store it in *var* accessible from the current scope. Specifying *GENERATOR_EXPRESSION* will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.

```
idf_component_set_property(component property val [APPEND])
```

Set a specified *component*'s *component property*, *property* with value *val*. Specifying *APPEND* will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

```
idf_component_register([[SRCS src1 src2 ...] | [[SRC_DIRS dir1 dir2 ...] [EXCLUDE_
↪SRCS src1 src2 ...]]
                       [INCLUDE_DIRS dir1 dir2 ...]
                       [PRIV_INCLUDE_DIRS dir1 dir2 ...]
                       [REQUIRES component1 component2 ...]
                       [PRIV_REQUIRES component1 component2 ...]
                       [LDFRAGMENTS ldfragment1 ldfragment2 ...]
                       [REQUIRED_IDF_TARGETS target1 target2 ...]
                       [EMBED_FILES file1 file2 ...]
                       [EMBED_TXTFILES file1 file2 ...]
```

(continues on next page)

(continued from previous page)

```
                        [KCONFIG kconfig]
                        [KCONFIG_PROJBUILD kconfig_projbuild]
                        [WHOLE_ARCHIVE])
```

Register a component to the build system. Much like the `project()` CMake command, this should be called from the component's CMakeLists.txt directly (not through a function or macro) and is recommended to be called before any other command. Here are some guidelines on what commands can **not** be called before `idf_component_register`:

- commands that are not valid in CMake script mode
- custom commands defined in project_include.cmake
- build system API commands except `idf_build_get_property`; although consider whether the property may not have been set yet

Commands that set and operate on variables are generally okay to call before `idf_component_register`.

The arguments for `idf_component_register` include:

- SRCS - component source files used for creating a static library for the component; if not specified, component is a treated as a config-only component and an interface library is created instead.
- SRC_DIRS, EXCLUDE_SRCS - used to glob source files (.c, .cpp, .S) by specifying directories, instead of specifying source files manually via SRCS. Note that this is subject to the *limitations of globbing in CMake*. Source files specified in EXCLUDE_SRCS are removed from the globbed files.
- INCLUDE_DIRS - paths, relative to the component directory, which will be added to the include search path for all other components which require the current component
- PRIV_INCLUDE_DIRS - directory paths, must be relative to the component directory, which will be added to the include search path for this component's source files only
- REQUIRES - public component requirements for the component
- PRIV_REQUIRES - private component requirements for the component; ignored on config-only components
- LDFRAGMENTS - component linker fragment files
- REQUIRED_IDF_TARGETS - specify the only target the component supports
- KCONFIG - override the default Kconfig file
- KCONFIG_PROJBUILD - override the default Kconfig.projbuild file
- WHOLE_ARCHIVE - if specified, the component library is surrounded by `-Wl,--whole-archive`, `-Wl,--no-whole-archive` when linked. This has the same effect as setting `WHOLE_ARCHIVE` component property.

The following are used for *embedding data into the component*, and is considered as source files when determining if a component is config-only. This means that even if the component does not specify source files, a static library is still created internally for the component if it specifies either:

- EMBED_FILES - binary files to be embedded in the component
- EMBED_TXTFILES - text files to be embedded in the component

Idf-component-properties

These are properties that describe a component. Values of component properties can be retrieved by using the build command `idf_component_get_property`. For example, to get the directory of the `freertos` component:

```
idf_component_get_property(dir freertos COMPONENT_DIR)
message(STATUS "The 'freertos' component directory is: ${dir}")
```

- COMPONENT_ALIAS - alias for COMPONENT_LIB used for linking the component to external targets; set by `idf_build_component` and alias library itself is created by `idf_component_register`
- COMPONENT_DIR - component directory; set by `idf_build_component`
- COMPONENT_OVERRIDEN_DIR - contains the directory of the original component if *this component overrides another component*
- COMPONENT_LIB - name for created component static/interface library; set by `idf_build_component` and library itself is created by `idf_component_register`

- COMPONENT_NAME - name of the component; set by `idf_build_component` based on the component directory name
- COMPONENT_TYPE - type of the component, whether LIBRARY or CONFIG_ONLY. A component is of type LIBRARY if it specifies source files or embeds a file
- EMBED_FILES - list of files to embed in component; set from `idf_component_register` EMBED_FILES argument
- EMBED_TXTFILES - list of text files to embed in component; set from `idf_component_register` EMBED_TXTFILES argument
- INCLUDE_DIRS - list of component include directories; set from `idf_component_register` INCLUDE_DIRS argument
- KCONFIG - component Kconfig file; set by `idf_build_component`
- KCONFIG_PROJBUILD - component Kconfig.projbuild; set by `idf_build_component`
- LDFRAGMENTS - list of component linker fragment files; set from `idf_component_register` LDFRAGMENTS argument
- MANAGED_PRIV_REQUIRES - list of private component dependencies added by the IDF component manager from dependencies in `idf_component.yml` manifest file
- MANAGED_REQUIRES - list of public component dependencies added by the IDF component manager from dependencies in `idf_component.yml` manifest file
- PRIV_INCLUDE_DIRS - list of component private include directories; set from `idf_component_register` PRIV_INCLUDE_DIRS on components of type LIBRARY
- PRIV_REQUIRES - list of private component dependencies; set from value of `idf_component_register` PRIV_REQUIRES argument and dependencies in `idf_component.yml` manifest file
- REQUIRED_IDF_TARGETS - list of targets the component supports; set from `idf_component_register` REQUIRED_IDF_TARGETS argument
- REQUIRES - list of public component dependencies; set from value of `idf_component_register` REQUIRES argument and dependencies in `idf_component.yml` manifest file
- SRCS - list of component source files; set from SRCS or SRC_DIRS/EXCLUDE_SRCS argument of `idf_component_register`
- WHOLE_ARCHIVE - if this property is set to `TRUE` (or any boolean "true" CMake value: 1, `ON`, `YES`, `Y`), the component library is surrounded by `-Wl,--whole-archive`, `-Wl,--no-whole-archive` when linked. This can be used to force the linker to include every object file into the executable, even if the object file doesn't resolve any references from the rest of the application. This is commonly used when a component contains plugins or modules which rely on link-time registration. This property is `FALSE` by default. It can be set to `TRUE` from the component CMakeLists.txt file.

4.6.21 File Globbing & Incremental Builds

The preferred way to include source files in an ESP-IDF component is to list them manually via SRCS argument to `idf_component_register`:

```
idf_component_register(SRCS library/a.c library/b.c platform/platform.c
                       ...)
```

This preference reflects the CMake best practice of manually listing source files. This could, however, be inconvenient when there are lots of source files to add to the build. The ESP-IDF build system provides an alternative way for specifying source files using `SRC_DIRS`:

```
idf_component_register(SRC_DIRS library platform
                       ...)
```

This uses globbing behind the scenes to find source files in the specified directories. Be aware, however, that if a new source file is added and this method is used, then CMake won't know to automatically re-run and this file won't be added to the build.

The trade-off is acceptable when you're adding the file yourself, because you can trigger a clean build or run `idf.py reconfigure` to manually re-run CMake. However, the problem gets harder when you share your project with others who may check out a new version using a source control tool like Git...

For components which are part of ESP-IDF, we use a third party Git CMake integration module (/tools/cmake/third_party/GetGitRevisionDescription.cmake) which automatically re-runs CMake any time the repository commit changes. This means if you check out a new ESP-IDF version, CMake will automatically re-run.

For project components (not part of ESP-IDF), there are a few different options:

- If keeping your project file in Git, ESP-IDF will automatically track the Git revision and re-run CMake if the revision changes.
- If some components are kept in a third git repository (not the project repository or ESP-IDF repository), you can add a call to the `git_describe` function in a component CMakeLists file in order to automatically trigger re-runs of CMake when the Git revision changes.
- If not using Git, remember to manually run `idf.py reconfigure` whenever a source file may change.
- To avoid this problem entirely, use `SRCS` argument to `idf_component_register` to list all source files in project components.

The best option will depend on your particular project and its users.

4.6.22 Build System Metadata

For integration into IDEs and other build systems, when CMake runs the build process generates a number of metadata files in the `build/` directory. To regenerate these files, run `cmake` or `idf.py reconfigure` (or any other `idf.py` build command).

- `compile_commands.json` is a standard format JSON file which describes every source file which is compiled in the project. A CMake feature generates this file, and many IDEs know how to parse it.
- `project_description.json` contains some general information about the ESP-IDF project, configured paths, etc.
- `flasher_args.json` contains esptool.py arguments to flash the project's binary files. There are also `flash_*_args` files which can be used directly with esptool.py. See *Flash arguments*.
- `CMakeCache.txt` is the CMake cache file which contains other information about the CMake process, toolchain, etc.
- `config/sdkconfig.json` is a JSON-formatted version of the project configuration values.
- `config/kconfig_menus.json` is a JSON-formatted version of the menus shown in menuconfig, for use in external IDE UIs.

JSON Configuration Server

A tool called `kconfserver` is provided to allow IDEs to easily integrate with the configuration system logic. `kconfserver` is designed to run in the background and interact with a calling process by reading and writing JSON over process stdin & stdout.

You can run `kconfserver` from a project via `idf.py confserver` or `ninja kconfserver`, or a similar target triggered from a different build generator.

For more information about `kconfserver`, see the esp-idf-kconfig documentation.

4.6.23 Build System Internals

Build Scripts

The listfiles for the ESP-IDF build system reside in /tools/cmake. The modules which implement core build system functionality are as follows:

- build.cmake - Build related commands i.e., build initialization, retrieving/setting build properties, build processing.
- component.cmake - Component related commands i.e., adding components, retrieving/setting component properties, registering components.

- kconfig.cmake - Generation of configuration files (sdkconfig, sdkconfig.h, sdkconfig.cmake, etc.) from Kconfig files.
- ldgen.cmake - Generation of final linker script from linker fragment files.
- target.cmake - Setting build target and toolchain file.
- utilities.cmake - Miscellaneous helper commands.

Aside from these files, there are two other important CMake scripts in /tools/cmake:

- idf.cmake - Sets up the build and includes the core modules listed above. Included in CMake projects in order to access ESP-IDF build system functionality.
- project.cmake - Includes `idf.cmake` and provides a custom `project()` command that takes care of all the heavy lifting of building an executable. Included in the top-level CMakeLists.txt of standard ESP-IDF projects.

The rest of the files in /tools/cmake are support or third-party scripts used in the build process.

Build Process

This section describes the standard ESP-IDF application build process. The build process can be broken down roughly into four phases:

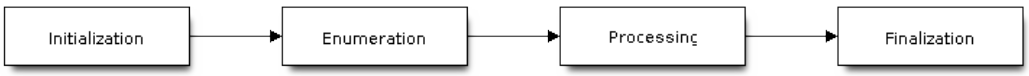

Fig. 4: ESP-IDF Build System Process

Initialization This phase sets up necessary parameters for the build.

- **Upon inclusion of `idf.cmake` in `project.cmake`, the following steps are performed:**
  - Set `IDF_PATH` from environment variable or inferred from path to `project.cmake` included in the top-level CMakeLists.txt.
  - Add /tools/cmake to `CMAKE_MODULE_PATH` and include core modules plus the various helper/third-party scripts.
  - Set build tools/executables such as default Python interpreter.
  - Get ESP-IDF git revision and store as `IDF_VER`.
  - Set global build specifications i.e., compile options, compile definitions, include directories for all components in the build.
  - Add components in components to the build.
- **The initial part of the custom `project()` command performs the following steps:**
  - Set `IDF_TARGET` from environment variable or CMake cache and the corresponding `CMAKE_TOOLCHAIN_FILE` to be used.
  - Add components in `EXTRA_COMPONENT_DIRS` to the build.
  - Prepare arguments for calling command `idf_build_process()` from variables such as `COMPONENTS`/`EXCLUDE_COMPONENTS`, `SDKCONFIG`, `SDKCONFIG_DEFAULTS`.

The call to `idf_build_process()` command marks the end of this phase.

Enumeration

This phase builds a final list of components to be processed in the build, and is performed in the first half of `idf_build_process()`.

- Retrieve each component's public and private requirements. A child process is created which executes each component's CMakeLists.txt in script mode. The values

of `idf_component_register` REQUIRES and PRIV_REQUIRES argument is returned to the parent build process. This is called early expansion. The variable `CMAKE_BUILD_EARLY_EXPANSION` is defined during this step.
- Recursively include components based on public and private requirements.
- Unless IDF Component Manager is disabled, it is called to resolve the dependencies of the components: - Looks for manifests and dependencies contained in the project. - Starts the version solving process to resolve the dependencies of the components. - When the version solving process succeeds, the IDF Component Manager downloads dependencies, integrates them into the build, and creates a `dependencies.lock` file that contains a list of the exact versions of the dependencies installed by the IDF Component Manager.

Processing

This phase processes the components in the build, and is the second half of `idf_build_process()`.

- Load project configuration from sdkconfig file and generate an sdkconfig.cmake and sdkconfig.h header. These define configuration variables/macros that are accessible from the build scripts and C/C++ source/header files, respectively.
- Include each component's `project_include.cmake`.
- Add each component as a subdirectory, processing its CMakeLists.txt. The component CMakeLists.txt calls the registration command, `idf_component_register` which adds source files, include directories, creates component library, links dependencies, etc.

Finalization

This phase is everything after `idf_build_process()`.

- Create executable and link the component libraries to it.
- Generate project metadata files such as project_description.json and display relevant information about the project built.

Browse /tools/cmake/project.cmake for more details.

4.6.24 Migrating from ESP-IDF GNU Make System

Some aspects of the CMake-based ESP-IDF build system are very similar to the older GNU Make-based system. The developer needs to provide values the include directories, source files etc. There is a syntactical difference, however, as the developer needs to pass these as arguments to the registration command, `idf_component_register`.

Automatic Conversion Tool

An automatic project conversion tool is available in *tools/cmake/convert_to_cmake.py* in ESP-IDF v4.x releases. The script was removed in v5.0 because of its *make* build system dependency.

No Longer Available in CMake

Some features are significantly different or removed in the CMake-based system. The following variables no longer exist in the CMake-based build system:

- `COMPONENT_BUILD_DIR`: Use `CMAKE_CURRENT_BINARY_DIR` instead.
- `COMPONENT_LIBRARY`: Defaulted to `$(COMPONENT_NAME).a`, but the library name could be overridden by the component. The name of the component library can no longer be overridden by the component.
- `CC`, `LD`, `AR`, `OBJCOPY`: Full paths to each tool from the gcc xtensa cross-toolchain. Use `CMAKE_C_COMPILER`, `CMAKE_C_LINK_EXECUTABLE`, `CMAKE_OBJCOPY`, etc instead. Full list here.
- `HOSTCC`, `HOSTLD`, `HOSTAR`: Full names of each tool from the host native toolchain. These are no longer provided, external projects should detect any required host toolchain manually.

- `COMPONENT_ADD_LDFLAGS`: Used to override linker flags. Use the CMake target_link_libraries command instead.
- `COMPONENT_ADD_LINKER_DEPS`: List of files that linking should depend on. target_link_libraries will usually infer these dependencies automatically. For linker scripts, use the provided custom CMake function `target_linker_scripts`.
- `COMPONENT_SUBMODULES`: No longer used, the build system will automatically enumerate all submodules in the ESP-IDF repository.
- `COMPONENT_EXTRA_INCLUDES`: Used to be an alternative to `COMPONENT_PRIV_INCLUDEDIRS` for absolute paths. Use `PRIV_INCLUDE_DIRS` argument to `idf_component_register` for all cases now (can be relative or absolute).
- `COMPONENT_OBJS`: Previously, component sources could be specified as a list of object files. Now they can be specified as a list of source files via `SRCS` argument to *idf_component_register*.
- `COMPONENT_OBJEXCLUDE`: Has been replaced with `EXCLUDE_SRCS` argument to `idf_component_register`. Specify source files (as absolute paths or relative to component directory), instead.
- `COMPONENT_EXTRA_CLEAN`: Set property `ADDITIONAL_CLEAN_FILES` instead but note *CMake has some restrictions around this functionality*.
- `COMPONENT_OWNBUILDTARGET` & `COMPONENT_OWNCLEANTARGET`: Use CMake ExternalProject instead. See *Fully Overriding the Component Build Process* for full details.
- `COMPONENT_CONFIG_ONLY`: Call `idf_component_register` without any arguments instead. See *Configuration-Only Components*.
- `CFLAGS`, `CPPFLAGS`, `CXXFLAGS`: Use equivalent CMake commands instead. See *Controlling Component Compilation*.

No Default Values

Unlike in the legacy Make-based build system, the following have no default values:

- Source directories (`COMPONENT_SRCDIRS` variable in Make, `SRC_DIRS` argument to `idf_component_register` in CMake)
- Include directories (`COMPONENT_ADD_INCLUDEDIRS` variable in Make, `INCLUDE_DIRS` argument to `idf_component_register` in CMake)

No Longer Necessary

- In the legacy Make-based build system, it is required to also set `COMPONENT_SRCDIRS` if `COMPONENT_SRCS` is set. In CMake, the equivalent is not necessary i.e., specifying `SRC_DIRS` to `idf_component_register` if `SRCS` is also specified (in fact, `SRCS` is ignored if `SRC_DIRS` is specified).

Flashing from Make

`make flash` and similar targets still work to build and flash. However, project `sdkconfig` no longer specifies serial port and baud rate. Environment variables can be used to override these. See *Flashing with Ninja or Make* for more details.

4.7 RF Coexistence

4.7.1 Overview

ESP boards now support three modules: Bluetooth (BT & BLE), IEEE802.15.4, and Wi-Fi. Each type of board has only one 2.4 GHz ISM band RF module, shared by two or three modules. Consequently, a module cannot receive

or transmit data while another module is engaged in data transmission or reception. In such scenarios, ESP32-C3 employs the time-division multiplexing method to manage the reception and transmission of packets.

4.7.2 Supported Coexistence Scenario for ESP32-C3

Table 1: Supported Features of Wi-Fi and BLE Coexistence

			BLE			
			Scan	Advertising	Connecting	Connected
Wi-Fi	STA	Scan	Y	Y	Y	Y
		Connecting	Y	Y	Y	Y
		Connected	Y	Y	Y	Y
	SOFTAP	TX Beacon	Y	Y	Y	Y
		Connecting	C1	C1	C1	C1
		Connected	C1	C1	C1	C1
	Sniffer	RX	C1	C1	C1	C1
	ESP-NOW	RX	S	S	S	S
		TX	Y	Y	Y	Y

Note: Y: supported and performance is stable C1: supported but the performance is unstable X: not supported S: supported and performance is stable in STA mode, otherwise not supported

4.7.3 Coexistence Mechanism and Policy

Coexistence Mechanism

The RF resource allocation mechanism is based on priority. As shown below, both Bluetooth module and Wi-Fi module request RF resources from the coexistence module, and the coexistence module decides who will use the RF resource based on their priority.

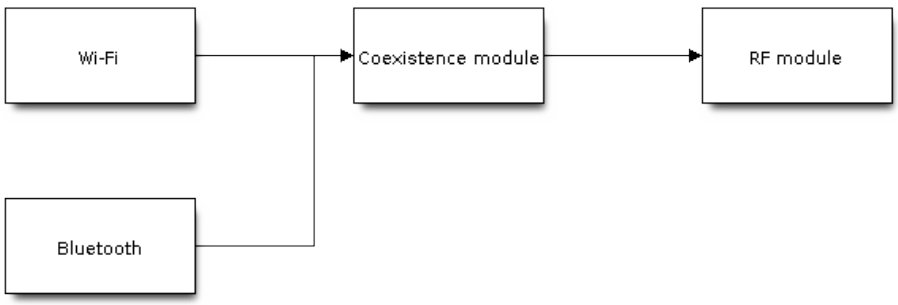

Fig. 5: Coexistence Mechanism

Coexistence Policy

Coexistence Period and Time Slice Wi-Fi and BLE have their fixed time slice to use the RF. In the Wi-Fi time slice, Wi-Fi will send a higher priority request to the coexistence arbitration module. Similarly, BLE can enjoy

higher priority at their own time slice. The duration of the coexistence period and the proportion of each time slice are divided into four categories according to the Wi-Fi status:

1) IDLE status: RF module is controlled by Bluetooth module.
2) CONNECTED status: the coexistence period starts at the Target Beacon Transmission Time (TBTT) and is more than 100 ms.
3) SCAN status: Wi-Fi slice and coexistence period are longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.
4) CONNECTING status: Wi-Fi slice is longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.

According to the coexistence logic, different coexistence periods and time slice strategies will be selected based on the Wi-Fi and Bluetooth usage scenarios. A Coexistence policy corresponding to a certain usage scenarios is called a "coexistence scheme". For example, the scenario of Wi-Fi CONNECTED and BLE CONNECTED has a corresponding coexistence scheme. In this scheme, the time slices of Wi-Fi and BLE in a coexistence period each account for 50%. The time allocation is shown in the following figure:

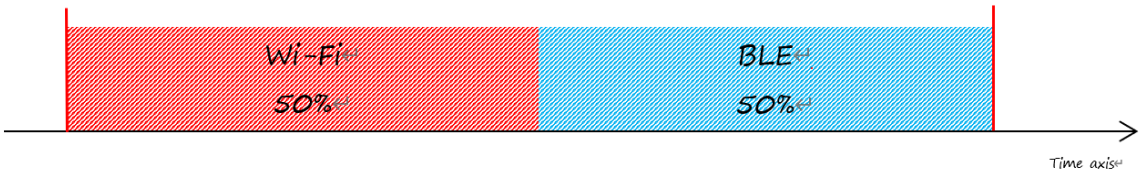

Fig. 6: Time Slice Under the Status of Wi-Fi CONNECTED and BLE CONNECTED

Dynamic Priority The coexistence module assigns varying priorities to different statuses of each module, and these priorities are dynamic. For example, in every N BLE Advertising events, there is always one event with high priority. If a high-priority BLE Advertising event occurs within the Wi-Fi time slice, the right to use the RF may be preempted by BLE.

Wi-Fi Connectionless Modules Coexistence To some extent, some combinations of connectionless power-saving parameters *Window* and *Interval* would lead to extra Wi-Fi priority request out of Wi-Fi time slice. It`s for obtaining RF resources at coexistence for customized parameters, while leading to impact on Bluetooth performance.

If connectionless power-saving parameters are configured with default values, the coexistence module would perform in stable mode and the behaviour above would not happen. So please configure Wi-Fi connectionless power-saving parameters to default values unless you have plenty of coexistence performance tests for customized parameters.

Please refer to *connectionless module power save* to get more detail.

4.7.4 How to Use the Coexistence Feature

Coexistence API

For most coexistence cases, ESP32-C3 will switch the coexistence status automatically without calling API. However, ESP32-C3 provides two APIs for the coexistence of BLE MESH and Wi-Fi. When the status of BLE MESH changes, call `esp_coex_status_bit_clear` to clear the previous status first and then call `esp_coex_status_bit_set` to set the current status.

BLE MESH Coexistence Status As the firmware of Wi-Fi and Bluetooth are not aware of the current scenario of the upper layer application, some coexistence schemes require application code to call the coexistence API to take effect. The application layer needs to pass the working status of BLE MESH to the coexistence module for selecting the coexistence scheme.

- ESP_COEX_BLE_ST_MESH_CONFIG: network is provisioning

- ESP_COEX_BLE_ST_MESH_TRAFFIC: data is transmitting
- ESP_COEX_BLE_ST_MESH_STANDBY: in idle status with no significant data interaction

Coexistence API Error Codes

All coexistence APIs have custom return values, i.e., error codes. These error codes can be categorized as:

- No error. For example, the return value ESP_OK siginifies the API returned successfully.
- Recoverable errors. For example, the return value ESP_ERR_INVALID_ARG signifies API parameter errors.

Setting Coexistence Compile-time Options

- After writing the coexistence program, you must check *CONFIG_ESP_COEX_SW_COEXIST_ENABLE* option through menuconfig to open coexistence configuration on software, otherwise the coexistence function mentioned above cannot be used.
- When using LE Coded PHY during a BLE connection, to avoid affecting Wi-Fi performance due to the long duration of Bluetooth packets, you can select *BT_CTRL_COEX_PHY_CODED_TX_RX_TLIM_EN* in the sub-options of *CONFIG_BT_CTRL_COEX_PHY_CODED_TX_RX_TLIM* to limit the maximum time of TX/RX.
- You can reduce the memory consumption by configuring the following options on menuconfig.
  - *CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY*: enable the configuration of dynamic memory for Bluetooth protocol stack.
  - *CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM*: reduce the number of Wi-Fi static RX buffers.
  - *CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM*: reduce the number of Wi-Fi dynamic RX buffers.
  - *CONFIG_ESP_WIFI_TX_BUFFER*: enable the configuration of dynamic allocation TX buffers.
  - *CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM*: reduce the number of Wi-Fi dynamic TX buffers.
  - *CONFIG_ESP_WIFI_TX_BA_WIN*: reduce the number of Wi-Fi Block Ack TX windows.
  - *CONFIG_ESP_WIFI_RX_BA_WIN*: reduce the number of Wi-Fi Block Ack RX windows.
  - *CONFIG_ESP_WIFI_MGMT_SBUF_NUM*: reduce the number of Wi-Fi Management Short Buffer.
  - *CONFIG_ESP_WIFI_RX_IRAM_OPT*: turning off this configuration option will reduce the IRAM memory by approximately 17 KB.
  - *CONFIG_LWIP_TCP_SND_BUF_DEFAULT*: reduce the default TX buffer size for TCP sockets.
  - *CONFIG_LWIP_TCP_WND_DEFAULT*: reduce the default size of the RX window for TCP sockets.
  - *CONFIG_LWIP_TCP_RECVMBOX_SIZE*: reduce the size of the TCP receive mailbox. Receive mailbox buffers data within active connections and handles data flow during connections。
  - *CONFIG_LWIP_TCP_ACCEPTMBOX_SIZE*: reduce the size of the TCP accept mailbox. Accept mailbox queues incoming connection requests and manages the initiation of new connections.
  - *CONFIG_LWIP_UDP_RECVMBOX_SIZE*: reduce the size of the UDP receive mailbox.
  - *CONFIG_LWIP_TCPIP_RECVMBOX_SIZE*: reduce the size of TCPIP task receive mailbox.

Note: As the coexistence configuration option relies on the presence of any two enabled modules, please ensure that both modules are activated before configuring any coexistence features.

4.8 C Support

ESP-IDF is primarily written in C and provides C APIs. ESP-IDF uses Newlib as its C Standard Library implementation (the Newlib version is specified in newlib/sbom.yml). In general, all C features that are supported by the compiler (currently GCC) can be used in ESP-IDF, unless specified in *Unsupported C Features* below.

4.8.1 C Version

GNU dialect of ISO C17 (`--std=gnu17`) is the current default C version in ESP-IDF.

To compile the source code of a certain component using a different language standard, set the desired compiler flag in the component's `CMakeLists.txt` file:

```
idf_component_register( ... )
target_compile_options(${COMPONENT_LIB} PRIVATE -std=gnu11)
```

If the public header files of the component also need to be compiled with the same language standard, replace the flag `PRIVATE` with `PUBLIC`.

4.8.2 Unsupported C Features

The following features are not supported in ESP-IDF.

Nested Function Pointers

The **GNU dialect of ISO C17** supports nested functions. However, ESP-IDF does not support referencing nested functions as pointers. This is due to the fact that the GCC compiler generates a trampoline (i.e., small piece of executable code) on the stack when a pointer to a nested function is referenced. ESP-IDF does not permit executing code from a stack, thus use of pointers to nested functions is not supported.

4.9 C++ Support

ESP-IDF is primarily written in C and provides C APIs. However, ESP-IDF supports development of applications in C++. This document covers various topics relevant to C++ development.

The following C++ features are supported:

- *Exception Handling*
- *Multithreading*
- *Runtime Type Information (RTTI)*
- *Thread Local Storage* (`thread_local` keyword)
- All C++ features implemented by GCC, except for some *Limitations*. See GCC documentation for details on features implemented by GCC.

4.9.1 `esp-idf-cxx` Component

esp-idf-cxx component provides higher-level C++ APIs for some of the ESP-IDF features. This component is available from the ESP-IDF Component Registry.

4.9.2 C++ Language Standard

By default, ESP-IDF compiles C++ code with C++23 language standard with GNU extensions (`-std=gnu++23`).

To compile the source code of a certain component using a different language standard, set the desired compiler flag in the component's `CMakeLists.txt` file:

```
idf_component_register( ... )
target_compile_options(${COMPONENT_LIB} PRIVATE -std=gnu++11)
```

Use `PUBLIC` instead of `PRIVATE` if the public header files of the component also need to be compiled with the same language standard.

4.9.3 Multithreading

C++ threads, mutexes, and condition variables are supported. C++ threads are built on top of pthreads, which in turn wrap FreeRTOS tasks.

See cxx/pthread for an example of creating threads in C++.

Note: The destructor of std::jthread can only safely be called from a task that has been created by *Thread APIs* or by the C++ threading library API.

4.9.4 Exception Handling

Support for C++ Exceptions in ESP-IDF is disabled by default, but can be enabled using the *CONFIG_COMPILER_CXX_EXCEPTIONS* option.

If an exception is thrown, but there is no `catch` block, the program is terminated by the `abort` function, and the backtrace is printed. See *Fatal Errors* for more information about backtraces.

C++ Exceptions should **only** be used for exceptional cases, i.e., something happening unexpectedly and occurs rarely, such as events that happen less frequently than 1/100 times. **Do not** use them for control flow (see also the section about resource usage below). For more information on how to use C++ Exceptions, see the ISO C++ FAQ and CPP Core Guidelines.

See cxx/exceptions for an example of C++ exception handling.

C++ Exception Handling and Resource Usage

Enabling exception handling normally increases application binary size by a few KB.

Additionally, it may be necessary to reserve some amount of RAM for the exception emergency memory pool. Memory from this pool is used if it is not possible to allocate an exception object from the heap.

The amount of memory in the emergency pool can be set using the *CONFIG_COMPILER_CXX_EXCEPTIONS_EMG_POOL_SIZE* variable.

Some additional stack memory (around 200 bytes) is also used if and only if a C++ Exception is actually thrown, because it requires calling some functions from the top of the stack to initiate exception handling.

The run time of code using C++ exceptions depends on what actually happens at run time.

- If no exception is thrown, the code tends to be somewhat faster since there is no need to check error codes.
- If an exception is thrown, the run time of the code that handles exceptions is orders of magnitude slower than code returning an error code.

If an exception is thrown, the run time of the code that unwinds the stack is orders of magnitude slower than code returning an error code. The significance of the increased run time will depend on the application's requirements and implementation of error handling (e.g., requiring user input or messaging to a cloud). As a result, exception-throwing code should never be used in real-time critical code paths.

4.9.5 Runtime Type Information (RTTI)

Support for RTTI in ESP-IDF is disabled by default, but can be enabled using *CONFIG_COMPILER_CXX_RTTI* option.

Enabling this option compiles all C++ files with RTTI support enabled, which allows using `dynamic_cast` conversion and `typeid` operator. Enabling this option typically increases the binary size by tens of kB.

See cxx/rtti for an example of using RTTI in ESP-IDF.

4.9.6 Developing in C++

The following sections provide tips on developing ESP-IDF applications in C++.

Combining C and C++ Code

When an application is developed using both C and C++, it is important to understand the concept of language linkage.

In order for a C++ function to be callable from C code, it has to be both **declared** and **defined** with C linkage (`extern "C"`):

```
// declaration in the .h file:
#ifdef __cplusplus
extern "C" {
#endif

void my_cpp_func(void);

#ifdef __cplusplus
}
#endif

// definition in a .cpp file:
extern "C" void my_cpp_func(void) {
    // ...
}
```

In order for a C function to be callable from C++, it has to be **declared** with C linkage:

```
// declaration in .h file:
#ifdef __cplusplus
extern "C" {
#endif

void my_c_func(void);

#ifdef __cplusplus
}
#endif

// definition in a .c file:
void my_c_func(void) {
    // ...
}
```

Defining `app_main` in C++

ESP-IDF expects the application entry point, `app_main`, to be defined with C linkage. When `app_main` is defined in a .cpp source file, it has to be designated as `extern "C"`:

```
extern "C" void app_main()
{
}
```

Designated Initializers

Many of the ESP-IDF components use *Configuration Structures* as arguments to the initialization functions. ESP-IDF examples written in C routinely use designated initializers to fill these structures in a readable and a maintainable way.

C and C++ languages have different rules with regards to the designated initializers. For example, C++23 (currently the default in ESP-IDF) does not support out-of-order designated initialization, nested designated initialization, mixing of designated initializers and regular initializers, and designated initialization of arrays. Therefore, when porting ESP-IDF C examples to C++, some changes to the structure initializers may be necessary. See the C++ aggregate initialization reference for more details.

`iostream`

`iostream` functionality is supported in ESP-IDF, with a couple of caveats:

1. Normally, ESP-IDF build process eliminates the unused code. However, in the case of iostreams, simply including `<iostream>` header in one of the source files significantly increases the binary size by about 200 kB.
2. By default, ESP-IDF uses a simple non-blocking implementation of the standard input stream (`stdin`). To get the usual behavior of `std::cin`, the application has to initialize the UART driver and enable the blocking mode as shown in common_components/protocol_examples_common/stdin_out.c.

4.9.7 Limitations

- Linker script generator does not support function level placements for functions with C++ linkage.
- Various section attributes (such as `IRAM_ATTR`) are ignored when used with template functions.
- Vtables are placed into Flash and are not accessible when the flash cache is disabled. Therefore, virtual function calls should be avoided in *IRAM-Safe Interrupt Handlers*. Placement of Vtables cannot be adjusted using the linker script generator, yet.
- C++ filesystem (`std::filesystem`) features are not supported.

4.9.8 What to Avoid

Do not use `setjmp`/`longjmp` in C++. `longjmp` blindly jumps up the stack without calling any destructors, easily introducing undefined behavior and memory leaks. Use C++ exceptions instead, they guarantee correctly calling destructors. If you cannot use C++ exceptions, use alternatives (except `setjmp`/`longjmp` themselves) such as simple return codes.

4.10 Code Quality

Code quality refers to how well-written and maintainable a piece of software code is. It encompasses aspects like readability, efficiency, reliability, and adherence to coding standards. High-quality code is easier to understand, modify, and extend, leading to reduced development time and fewer bugs.

4.10.1 Guides

Static Analyzer

A static analyzer is a tool that checks source code for errors and vulnerabilities without running it. It helps developers find issues early, improving code quality.

GNU Static Analyzer The GNU Static Analyzer is distributed with GCC (refer to GCC documentation). It can be enabled with *CONFIG_COMPILER_STATIC_ANALYZER* to perform code checks during application builds.

Suppressing Warnings GNU Static Analyzer is still under development and may give some false-positive warnings. Here is an example of how to suppress unwanted warnings using IDF:

```
#include "esp_compiler.h"
/* .... */
  ESP_COMPILER_DIAGNOSTIC_PUSH_IGNORE("-Wanalyzer-null-dereference")
  *((volatile int *) 0) = 0;
  ESP_COMPILER_DIAGNOSTIC_POP("-Wanalyzer-null-dereference")
/* .... */
```

Clang Static Analyzer See *IDF Clang-Tidy*

4.11 Core Dump

4.11.1 Overview

A core dump is a set of software state information that is automatically saved by the panic handler when a fatal error occurs. Core dumps are useful for conducting post-mortem analysis of the software's state at the moment of failure. ESP-IDF provides support for generating core dumps.

A core dump contains snapshots of all tasks in the system at the moment of failure, where each snapshot includes a task's control block (TCB) and stack. By analyzing the task snapshots, it is possible to find out what task, at what instruction (line of code), and what call stack of that task lead to the crash. It is also possible to dump the contents of variables on demand, provided those variables are assigned special core dump attributes.

Core dump data is saved to a core dump file according to a particular format, see *Core dump internals* for more details. However, ESP-IDF's `idf.py` command provides special subcommands to decode and analyze the core dump file.

4.11.2 Configurations

Destination

The *CONFIG_ESP_COREDUMP_TO_FLASH_OR_UART* option enables or disables core dump, and selects the core dump destination if enabled. When a crash occurs, the generated core dump file can either be saved to flash, or output to a connected host over UART.

Format & Size

The *CONFIG_ESP_COREDUMP_DATA_FORMAT* option controls the format of the core dump file, namely ELF format or Binary format.

The ELF format contains extended features and allows more information regarding erroneous tasks and crashed software to be saved. However, using the ELF format causes the core dump file to be larger. This format is recommended for new software designs and is flexible enough to be extended in future revisions to save more information.

The Binary format is kept for compatibility reasons. Binary format core dump files are smaller while provide better performance.

The *CONFIG_ESP_COREDUMP_MAX_TASKS_NUM* option configures the number of task snapshots saved by the core dump.

Core dump data integrity checking is supported via the `Components > Core dump > Core dump data integrity check` option.

Reserved Stack Size

Core dump routines run from a separate stack due to core dump itself needing to parse and save all other task stacks. The *CONFIG_ESP_COREDUMP_STACK_SIZE* option controls the size of the core dump's stack in number of bytes.

Setting this option to 0 bytes will cause the core dump routines to run from the ISR stack, thus saving a bit of memory. Setting the option greater than zero will cause a separate stack to be instantiated.

Note: If a separate stack is used, the recommended stack size should be larger than 1300 bytes to ensure that the core dump routines themselves do not cause a stack overflow.

Core Dump Memory Regions

By default, core dumps typically save CPU registers, tasks data and summary of the panic reason. When the *CONFIG_ESP_COREDUMP_CAPTURE_DRAM* option is selected, `.bss` and `.data` sections and `heap` data will also be part of the dump.

For a better debugging experience, it is recommended to dump these sections. However, this will result in a larger coredump file. The required additional storage space may vary based on the amount of DRAM the application uses.

Note: This feature is only enabled when using the ELF file format.

4.11.3 Core Dump to Flash

When the core dump file is saved to flash, the file is saved to a special core dump partition in flash. Specifying the core dump partition will reserve space on the flash chip to store the core dump file.

The core dump partition is automatically declared when using the default partition table provided by ESP-IDF. However, when using a custom partition table, you need to declare the core dump partition, as illustrated below:

```
# Name,   Type, SubType, Offset,  Size
# Note: if you have increased the bootloader size, make sure to update the offsets␣
↪to avoid overlap
nvs,      data, nvs,     0x9000,  0x6000
phy_init, data, phy,     0xf000,  0x1000
factory,  app,  factory, 0x10000, 1M
coredump, data, coredump,,        64K
```

Important: If *Flash Encryption* is enabled on the device, please add an `encrypted` flag to the core dump partition declaration. Please note that the core dump cannot be read from encrypted partitions using `idf.py coredump-info` or `idf.py coredump-debug` commands. It is recommended to read the core dump from ESP which will automatically decrypt the partition and send it for analysis, which can be done by running e.g. `idf.py coredump-info -c <path-to-core-dump>`.

```
coredump, data, coredump,,       64K, encrypted
```

There are no special requirements for the partition name. It can be chosen according to the application's needs, but the partition type should be `data` and the sub-type should be `coredump`. Also, when choosing partition size, note that the core dump file introduces a constant overhead of 20 bytes and a per-task overhead of 12 bytes. This overhead

does not include the size of TCB and stack for every task. So the partition size should be at least `20 + max tasks number x (12 + TCB size + max task stack size)` bytes.

An example of the generic command to analyze core dump from flash is:

```
idf.py coredump-info
```

or

```
idf.py coredump-debug
```

Note: The `idf.py coredump-info` and `idf.py coredump-debug` commands are wrappers around the *esp-coredump* tool for easier use in the ESP-IDF environment. For more information see *Core Dump Commands* section.

4.11.4 Core Dump to UART

When the core dump file is output to UART, the output file is Base64-encoded. The *CONFIG_ESP_COREDUMP_DECODE* option allows for selecting whether the output file is automatically decoded by the ESP-IDF monitor or kept encoded for manual decoding.

Automatic Decoding

If *CONFIG_ESP_COREDUMP_DECODE* is set to automatically decode the UART core dump, ESP-IDF monitor will automatically decode the data, translate any function addresses to source code lines, and display it in the monitor. The output to ESP-IDF monitor would resemble the following output:

The *CONFIG_ESP_COREDUMP_UART_DELAY* allows for an optional delay to be added before the core dump file is output to UART.

```

...
===================== ESP32 CORE DUMP END =====================
===============================================================
```

Manual Decoding

If you set *CONFIG_ESP_COREDUMP_DECODE* to no decoding, then the raw Base64-encoded body of core dump is output to UART between the following header and footer of the UART output:

```
================= CORE DUMP START =================
<body of Base64-encoded core dump, save it to file on disk>
================= CORE DUMP END ===================
```

It is advised to manually save the core dump text body to a file. The `CORE DUMP START` and `CORE DUMP END` lines must not be included in a core dump text file. The saved text can the be decoded using the following command:

```
idf.py coredump-info -c </path/to/saved/base64/text>
```

or

```
idf.py coredump-debug -c </path/to/saved/base64/text>
```

4.11.5 Core Dump Commands

ESP-IDF provides special commands to help to retrieve and analyze core dumps:

- `idf.py coredump-info` - prints crashed task's registers, call stack, list of available tasks in the system, memory regions, and contents of memory stored in core dump (TCBs and stacks).
- `idf.py coredump-debug` - creates core dump ELF file and runs GDB debug session with this file. You can examine memory, variables, and task states manually. Note that since not all memory is saved in the core dump, only the values of variables allocated on the stack are meaningful.

For advanced users who want to pass additional arguments or use custom ELF files, it is possible to use the esp-coredump tool directly. For more information, use in ESP-IDF environment:

```
esp-coredump --help
```

4.11.6 ROM Functions in Backtraces

It is a possible that at the moment of a crash, some tasks and/or the crashed task itself have one or more ROM functions in their call stacks. Since ROM is not part of the program ELF, it is impossible for GDB to parse such call stacks due to GDB analyzing functions' prologues to decode backtraces. Thus, call stack parsing will break with an error message upon the first ROM function that is encountered.

To overcome this issue, the ROM ELF provided by Espressif is loaded automatically by ESP-IDF monitor based on the target and its revision. More details about ROM ELFs can be found in esp-rom-elfs.

4.11.7 Dumping Variables on Demand

Sometimes you want to read the last value of a variable to understand the root cause of a crash. Core dump supports retrieving variable data over GDB by applying special attributes to declared variables.

Supported Notations and RAM Regions

- `COREDUMP_DRAM_ATTR` places the variable into the DRAM area, which is included in the dump.
- `COREDUMP_RTC_ATTR` places the variable into the RTC area, which is included in the dump.
- `COREDUMP_RTC_FAST_ATTR` places the variable into the RTC_FAST area, which is included in the dump.

Example

1. In *Project Configuration Menu*, enable *COREDUMP TO FLASH*, then save and exit.
2. In your project, create a global variable in the DRAM area, such as:

```
// uint8_t global_var;
COREDUMP_DRAM_ATTR uint8_t global_var;
```

3. In the main application, set the variable to any value and `assert(0)` to cause a crash.

```
global_var = 25;
assert(0);
```

4. Build, flash, and run the application on a target device and wait for the dumping information.
5. Run the command below to start core dumping in GDB, where `PORT` is the device USB port:

```
idf.py coredump-debug
```

6. In GDB shell, type `p global_var` to get the variable content:

```
(gdb) p global_var
$1 = 25 '\031'
```

4.11.8 Running `idf.py coredump-info` and `idf.py coredump-debug`

`idf.py coredump-info --help` and `idf.py coredump-debug --help` commands can be used to get more details on usage.

Anatomy of Core Dump Image

A core dump file's format can be configured to use the ELF format, or a legacy binary format. The ELF format is recommended for all new designs as it provides more information regarding the software's state at the moment the crash occurs, e.g., CPU registers and memory contents.

The memory state embeds a snapshot of all tasks mapped in the memory space of the program. The CPU state contains register values when the core dump has been generated. The core dump file uses a subset of the ELF structures to register this information.

Loadable ELF segments are used to store the process' memory state, while ELF notes (`ELF.PT_NOTE`) are used to store the process' metadata (e.g., PID, registers, signal etc). In particular, the CPU's status is stored in a note with a special name and type (`CORE`, `NT_PRSTATUS type`).

Here is an overview of the core dump layout:

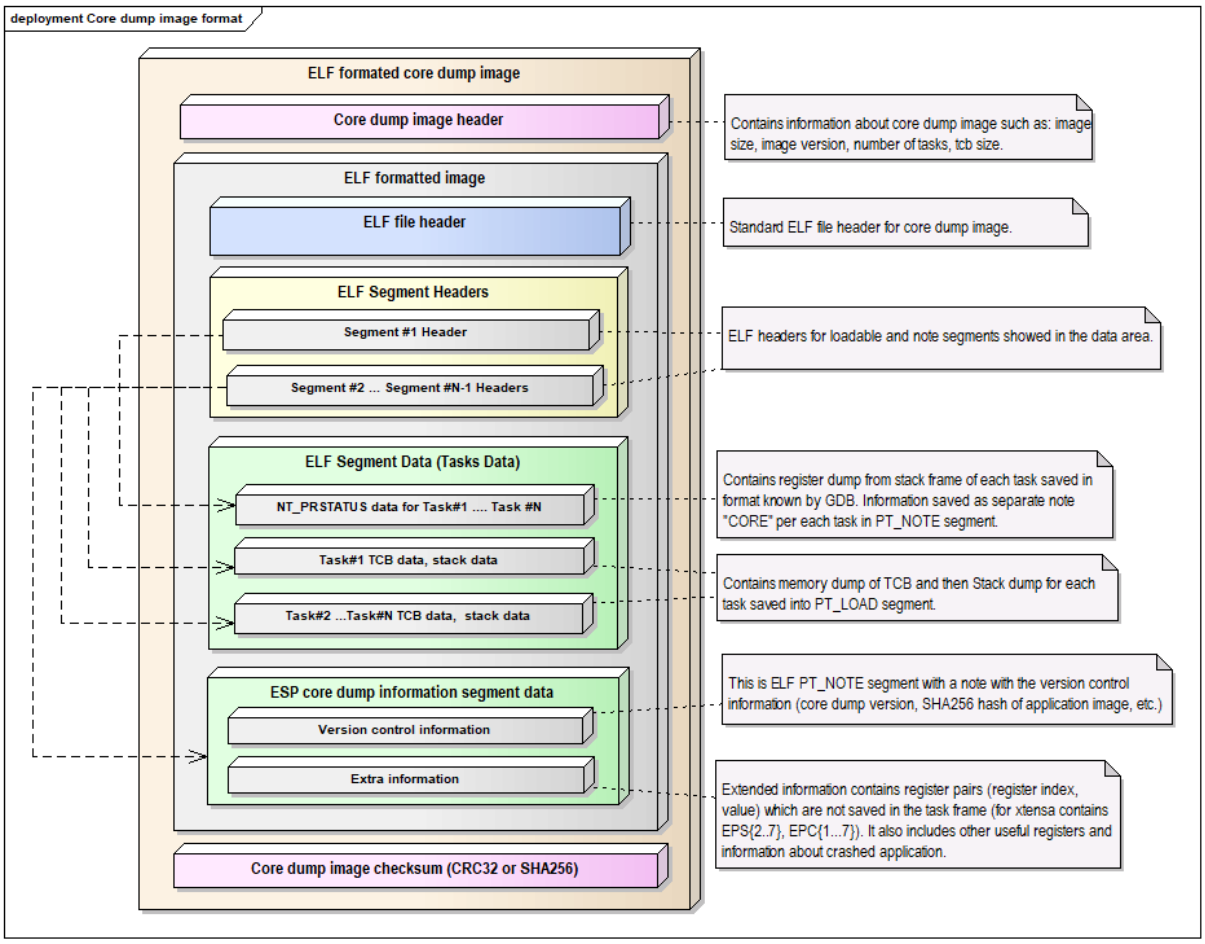

Fig. 7: Core Dump ELF Image Format

Note: The format of the image file shown in the above pictures represents the current version of the image and can be changed in future releases.

Overview of Implementation The figure below describes some basic aspects related to the implementation of the core dump:

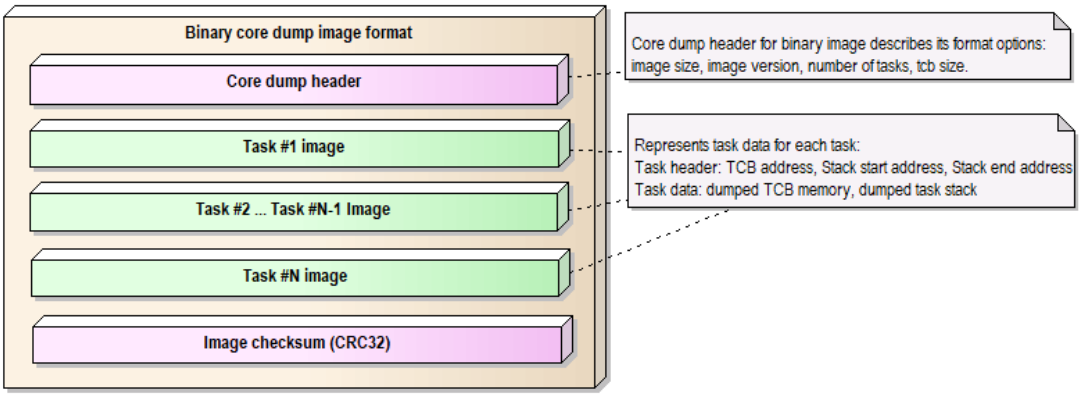

Fig. 8: Core Dump Binary Image Format

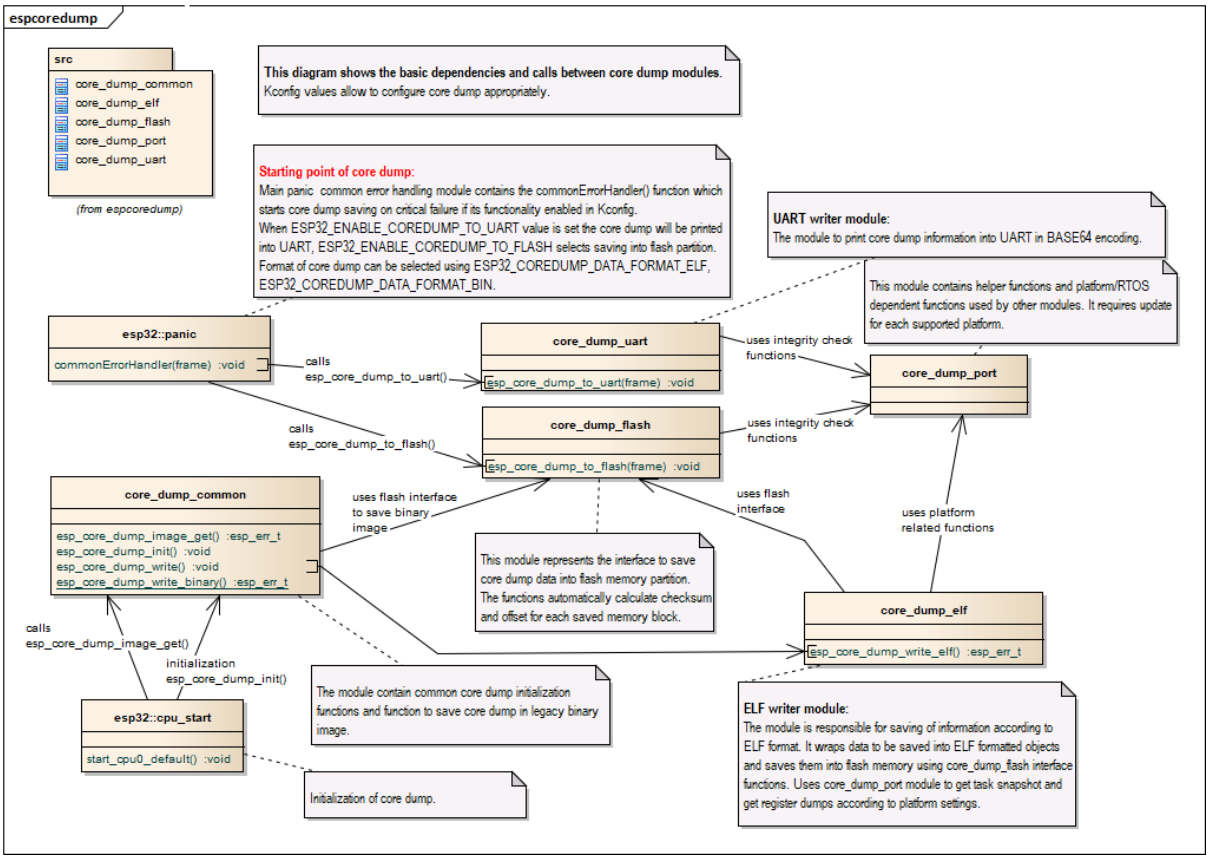

Fig. 9: Core Dump Implementation Overview

Note: The diagram above hides some details and represents the current implementation of the core dump which can be changed later.

4.12 Current Consumption Measurement of Modules

You may want to know the current consumption of a module in Deep-sleep mode, *other power-saving modes*, and Active mode to develop some applications sensitive to power consumption. This section introduces how to measure the current consumption of a module running such an application.

4.12.1 Notes to Measurement

Can We Use a Development Board?

For ESP32-C3, using a development board directly to measure current consumption of the corresponding module is not recommended, as some circuits still consume power on the board even when you flash the chip with the deep_sleep example. Therefore, you need to cut off the power supply circuit to the module to measure the module's current. This method is inconvenient and increases measurement costs.

How to Choose an Appropriate Ammeter?

In the deep_sleep example, the module will be woken up every 20 seconds. In Deep-sleep mode, the current in the module is just several microamps (μA), while in active mode, the current is in the order of milliamps (mA). The high dynamic current range makes accurate measurement difficult. Ordinary ammeters cannot dynamically switch the measurement range fast enough.

Additionally, ordinary ammeters have a relatively high internal resistance, resulting in a significant voltage drop. This may cause the module to enter an unstable state, as it is powered by a voltage smaller than the minimum required voltage supply.

Therefore, an ammeter suitable for measuring current in Deep-sleep mode should have low internal resistance and, ideally, switch current ranges dynamically. We recommend two options: the Joulescope ammeter and the Power Profiler Kit II from Nordic.

Joulescope Ammeter The Joulescope ammeter combines high-speed sampling and rapid dynamic current range switching to provide accurate and seamless current and energy measurements, even for devices with rapidly varying current consumption. Joulescope accurately measures electrical current over nine orders of magnitude from amps down to nanoamps. This wide range allows for accurate and precise current measurements for devices. Additionally, Joulescope has a total voltage drop of 25 mV at 1 A, which keeps the module running normally. These two features make Joulescope a perfect option for measuring the module switching between Deep-sleep mode and wake-up mode.

Joulescope has no display screen. You need to connect it to a PC to visualize the current waveforms of the measured module. For specific instructions, please follow the documentation provided by the manufacturer.

Nordic Power Profiler Kit II The Nordic Power Profiler Kit II has an advanced analog measurement unit with a high dynamic measurement range. This allows for accurate power consumption measurements for the entire range typically seen in low-power embedded applications, all the way from several microamps to 1 A. The resolution varies between 100 nA and 1 mA, depending on the measurement range, and is high enough to detect small spikes often seen in low-power optimized systems.

4.12.2 Hardware Connection

To measure the power consumption of a bare module, you need an ESP-Prog to flash the deep_sleep example to the module and power the module during measurement, a suitable ammeter (here we use the Joulescope ammeter), a computer, and of course a bare module with necessary jumper wires. For the connection, please refer to the following figure.

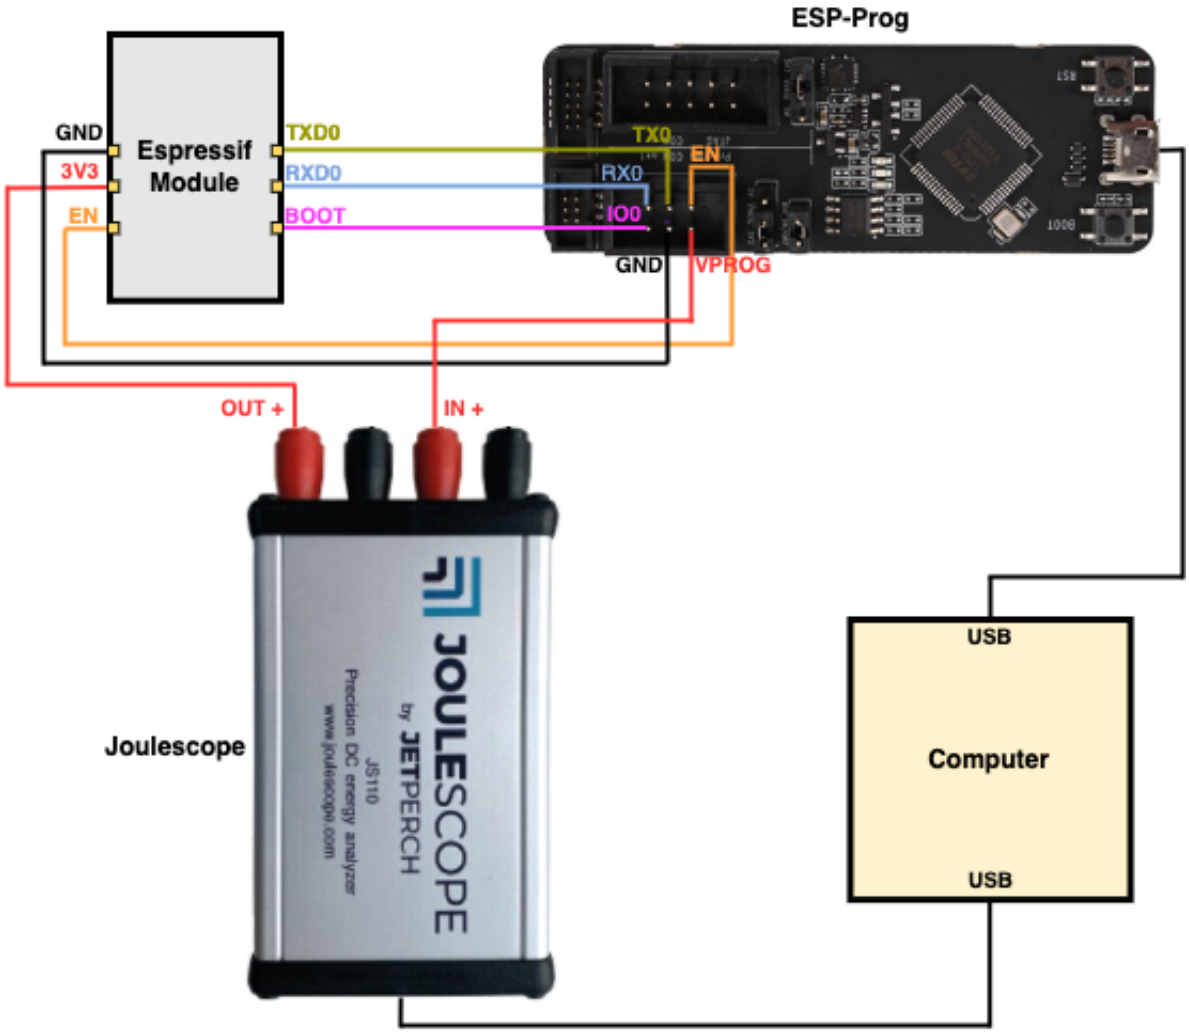

Fig. 10: Hardware Connection (click to enlarge)

Please connect the pins of **UART TX**, **UART RX**, **SPI Boot**, **Enable**, and **Ground** on the measured module with corresponding pins on ESP-Prog, and connect the **VPROG** pin on ESP-Prog with the **IN+** port on the Joulescope ammeter and connect its **OUT+** port with the **Power supply (3V3)** pin on the measured module. For the specific names of these pins in different modules, please refer to the list below.

Table 2: Pin Names of Modules Based on ESP32-C3 Chip

Function of Module Pin	Pin Name
UART TX	TXD0
UART RX	RXD0
SPI Boot	IO9
Enable	EN
Power Supply	3V3
Ground	GND

For modules based on the ESP32-C3 chip, the names of UART TX and UART RX pins may also be TXD and RXD,

TX and RX, or TX0 and RX0.

For details of the pin names, please refer to the datasheet of specific module.

4.12.3 Measurement Steps

ESP32-S3-WROOM-1 is used as an example in the measurement, and other modules can be measured similarly. For the specific current consumption of chips in different modes, please refer to the Current Consumption subsection in the corresponding chip datasheet.

You can refer to the following steps to measure the current in Deep-sleep mode.

- Connect the aforementioned devices according to the hardware connection.
- Flash the deep_sleep example to the module. For details, please refer to Start a Project on Linux and macOS for a computer with Linux or macOS system or Start a Project on Windows for a computer with Windows system.
- By default, the module will be woken up every 20 seconds (you can change the timing by modifying the code of this example). To check if the example runs as expected, you can monitor the module operation by running `idf.py -p PORT monitor` (please replace PORT with your serial port name).
- Open the Joulescope software to see the current waveform as shown in the image below.

From the waveforms, you can obtain that the current of the module in Deep-sleep mode is 8.14 µA. In addition, you can also see the current of the module in active mode, which is about 23.88 mA. The waveforms also show that the average power consumption during Deep-sleep mode is 26.85 µW, and the average power consumption during active mode is 78.32 mW.

The figure below shows the total power consumption of one cycle is 6.37 mW.

By referring to these power consumption in different modes, you can estimate the power consumption of your applications and choose the appropriate power source.

4.13 Deep-sleep Wake Stubs

4.13.1 Introduction

The wakeup time from Deep-sleep mode is much longer, compared to Light-sleep and Modem-sleep modes as ROM and RAM are both powered down in this case, and the CPU needs more time for SPI booting. However, ESP32-C3 supports running a "Deep-sleep wake stub" when coming out of Deep-sleep. This function runs immediately as soon as the chip wakes up - before any normal initialization, bootloader, or ESP-IDF code has run.

Specifically, after waking up from Deep-sleep mode, ESP32-C3 starts partial initialization. Then RTC fast memory will be validated with CRC. If validation passes, the wake stub code will be executed.

As ESP32-C3 has just woken up from Deep-sleep, most of the peripherals are in the reset state. The SPI flash has not been mapped. Thus, wake stub code can only call functions implemented in ROM or loaded into RTC fast memory, which retains content during Deep-sleep.

From the above, by utilizing the wake stub functionality in an application, you can quickly run some code when waking up from Deep-sleep mode, without having to wait for the whole boot-up process. However, the stub size is restricted by the size of RTC fast memory.

ESP32-C3 only supports RTC fast memory. The wake stub code and data that it utilizes should be loaded into RTC fast memory.

Next we will introduce how to implement the wake stub code in an application.

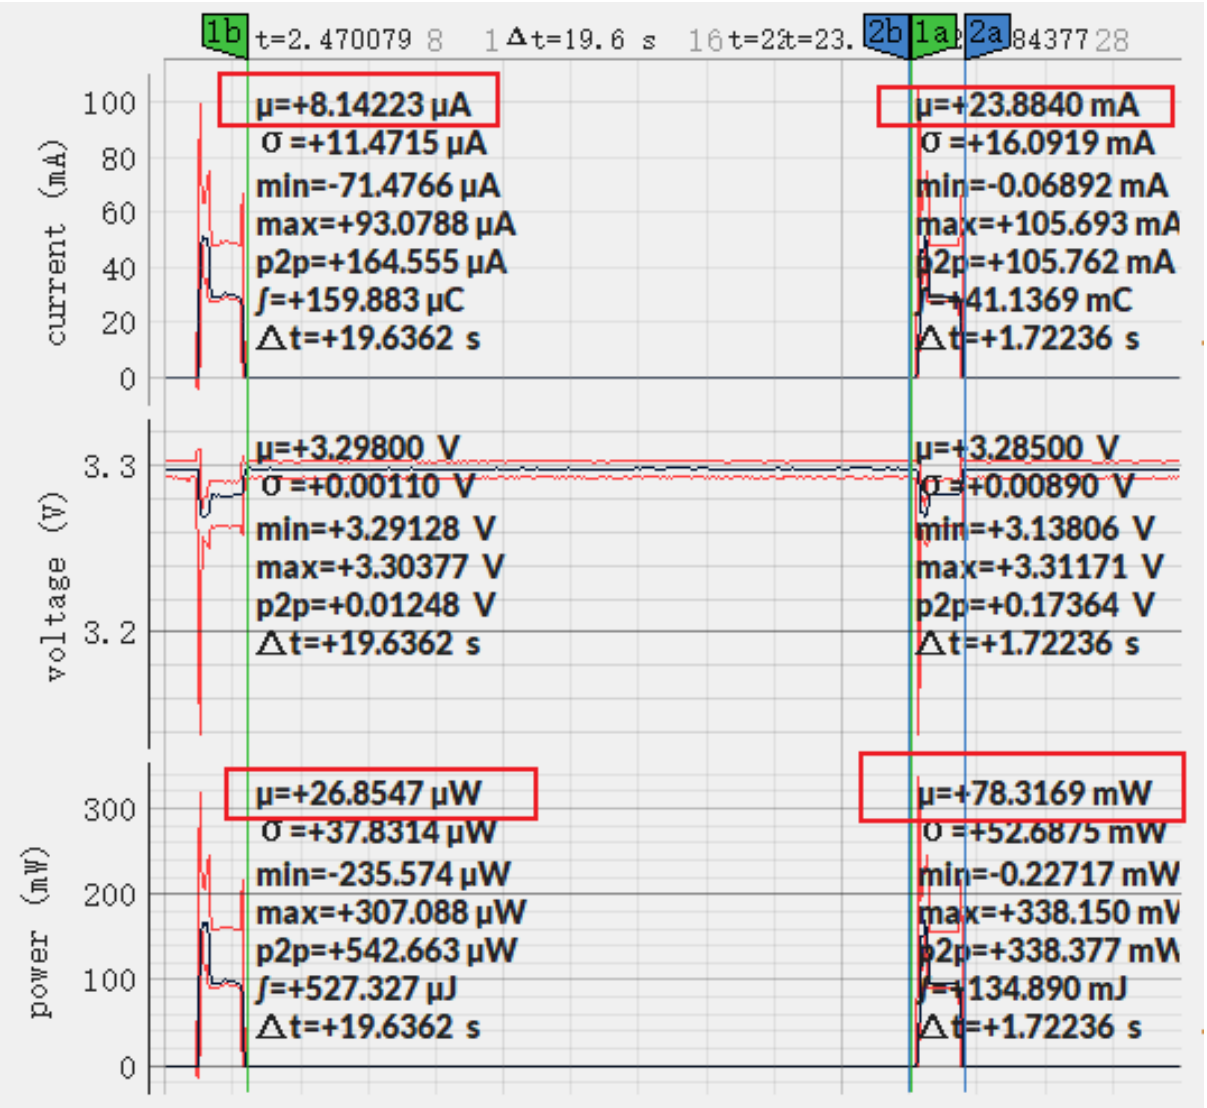

Fig. 11: Current Waveform of ESP32-S3-WROOM-1 (click to enlarge)

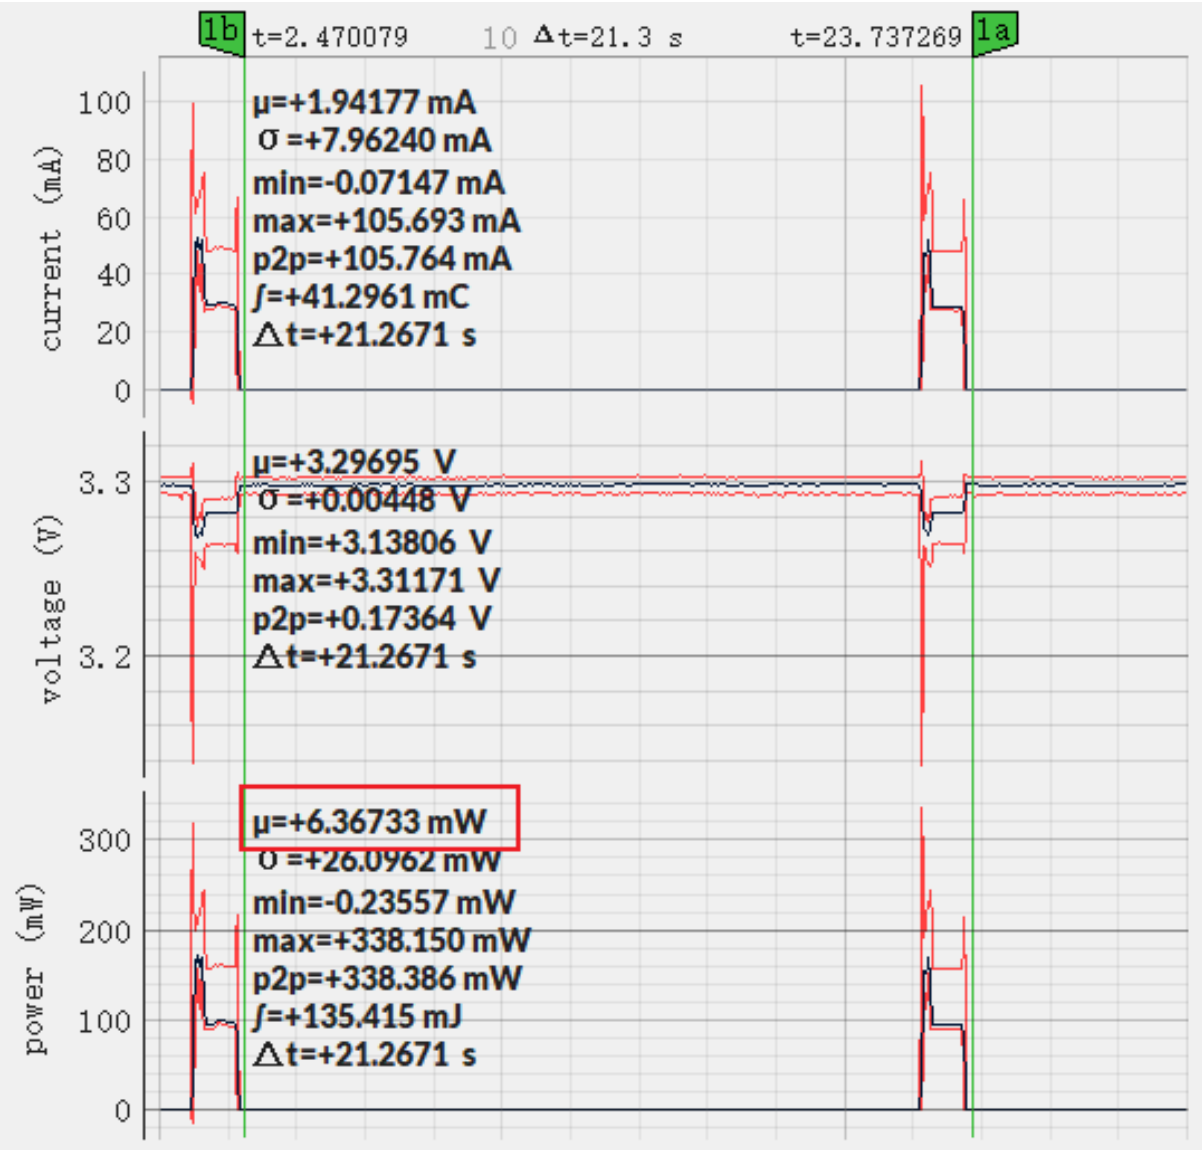

Fig. 12: Power Consumption of ESP32-S3-WROOM-1 (click to enlarge)

4.13.2 Implement wake stub

The wake stub in esp-idf is realized by the function *esp_wake_deep_sleep()*. This function is executed whenever the SoC wakes from Deep-sleep. As this function is weakly-linked to the default function *esp_default_wake_deep_sleep()*, if your application contains a function with the name `esp_wake_deep_sleep()`, the default version *esp_default_wake_deep_sleep()* in esp-idf will be overridden.

Please note that implementing the function *esp_wake_deep_sleep()* in your application is not mandatory for utilizing the Deep-sleep functionality. It becomes necessary only if you want to introduce certain behavior immediately upon the SoC's wake-up.

When you develop a customized wake stub, the first step it should do is to call the default function *esp_default_wake_deep_sleep()*.

In addition, you can switch between different wake stubs by calling the function *esp_set_deep_sleep_wake_stub()* during runtime.

Implementing the wake stub function in your application includes the following steps:

- Loading wake stub code into RTC fast memory
- Loading data into RTC fast memory

Load Wake Stub Code into RTC Fast Memory

The wake stub code can only call functions present in ROM or loaded into RTC fast memory. All other RAM locations are unintiailized and contain random data. While the wake stub code can use other RAM areas for temporary storage, the contents of these areas will be overwritten either upon returning to Deep-sleep mode or upon initiating esp-idf.

Wake stub code is a part of the main esp-idf application. During regular execution of esp-idf, functions can call the wake stub code or access RTC memory, treating them as a regular part of the application.

Wake stub code must reside in RTC fast memory. This can be realized in two ways.

- Employ the attribute `RTC_IRAM_ATTR` to place *esp_wake_deep_sleep()* into RTC fast memory:

```
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    // Add additional functionality here
}
```

The first approach is suitable for short and simple code segments or for source files including both "normal" and "RTC" code.

- Place the function *esp_wake_deep_sleep()* into any source file with name starting with `rtc_wake_stub`. For files with such names `rtc_wake_stub*`, their contents can be automatically put into RTC fast memory by the linker.

The second method is preferable when writing longer code segments in RTC fast memory.

However, any string constants used in this way must be declared as arrays and marked with `RTC_RODATA_ATTR`, as shown in the example above.

- Place the data into any source file with name starting with `rtc_wake_stub`, as demonstrated in the example source file system/deep_sleep_wake_stub/main/rtc_wake_stub_example.c.

```
if (s_count >= s_max_count) {
    // Reset s_count
    s_count = 0;

    // Set the default wake stub.
    // There is a default version of this function provided in esp-idf.
```

(continues on next page)

(continued from previous page)

```
    esp_default_wake_deep_sleep();

    // Return from the wake stub function to continue
    // booting the firmware.
    return;
}
```

The second approach is advisable when incorporating strings or more complex code segments.

You can enable the Kconfig option *CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP* to reduce wake-up time. See more information in *Fast boot from Deep-sleep*.

All of the above functions are declared in esp_hw_support/include/esp_sleep.h.

Load Wake Stub Data into RTC Fast memory

Data used by wake stub code must be resident in RTC fast memory.

The data can be specified in the following two methods:

- Use the `RTC_DATA_ATTR` and `RTC_RODATA_ATTR` to specify writable or read-only data, respectively.

```
RTC_DATA_ATTR int wake_count;

void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    static RTC_RODATA_ATTR const char fmt_str[] = "Wake count %d\n";
    esp_rom_printf(fmt_str, wake_count++);
}
```

The attributes `RTC_FAST_ATTR` and `RTC_SLOW_ATTR` can be used to specify data that will be force placed into RTC fast memory and RTC slow memory respectively. However, ESP32-C3 includes RTC fast memory only, so both these two attributes will map to this region.

4.13.3 Example

ESP-IDF provides an example to show how to implement the Deep-sleep wake stub.

- system/deep_sleep_wake_stub

4.14 Error Handling

4.14.1 Overview

Identifying and handling run-time errors is important for developing robust applications. There can be multiple kinds of run-time errors:

- Recoverable errors:
  - Errors indicated by functions through return values (error codes)
  - C++ exceptions, thrown using `throw` keyword
- Unrecoverable (fatal) errors:
  - Failed assertions (using `assert` macro and equivalent methods, see *Assertions*) and `abort()` calls.
  - CPU exceptions: access to protected regions of memory, illegal instruction, etc.
  - System level checks: watchdog timeout, cache access error, stack overflow, stack smashing, heap corruption, etc.

This guide explains ESP-IDF error handling mechanisms related to recoverable errors, and provides some common error handling patterns.

For instructions on diagnosing unrecoverable errors, see *Fatal Errors*.

4.14.2 Error Codes

The majority of ESP-IDF-specific functions use `esp_err_t` type to return error codes. `esp_err_t` is a signed integer type. Success (no error) is indicated with `ESP_OK` code, which is defined as zero.

Various ESP-IDF header files define possible error codes using preprocessor defines. Usually these defines start with `ESP_ERR_` prefix. Common error codes for generic failures (out of memory, timeout, invalid argument, etc.) are defined in `esp_err.h` file. Various components in ESP-IDF may define additional error codes for specific situations.

For the complete list of error codes, see *Error Code Reference*.

4.14.3 Converting Error Codes to Error Messages

For each error code defined in ESP-IDF components, `esp_err_t` value can be converted to an error code name using `esp_err_to_name()` or `esp_err_to_name_r()` functions. For example, passing `0x101` to `esp_err_to_name()` will return a `ESP_ERR_NO_MEM` string. Such strings can be used in log output to make it easier to understand which error has happened.

Additionally, `esp_err_to_name_r()` function will attempt to interpret the error code as a standard POSIX error code, if no matching `ESP_ERR_` value is found. This is done using `strerror_r` function. POSIX error codes (such as `ENOENT`, `ENOMEM`) are defined in `errno.h` and are typically obtained from `errno` variable. In ESP-IDF this variable is thread-local: multiple FreeRTOS tasks have their own copies of `errno`. Functions which set `errno` only modify its value for the task they run in.

This feature is enabled by default, but can be disabled to reduce application binary size. See *CONFIG_ESP_ERR_TO_NAME_LOOKUP*. When this feature is disabled, `esp_err_to_name()` and `esp_err_to_name_r()` are still defined and can be called. In this case, `esp_err_to_name()` will return `UNKNOWN ERROR`, and `esp_err_to_name_r()` will return `Unknown error 0xXXXX(YYYYY)`, where `0xXXXX` and `YYYYY` are the hexadecimal and decimal representations of the error code, respectively.

4.14.4 `ESP_ERROR_CHECK` Macro

`ESP_ERROR_CHECK` macro serves similar purpose as `assert`, except that it checks `esp_err_t` value rather than a `bool` condition. If the argument of `ESP_ERROR_CHECK` is not equal `ESP_OK`, then an error message is printed on the console, and `abort()` is called.

Error message will typically look like this:

```
ESP_ERROR_CHECK failed: esp_err_t 0x107 (ESP_ERR_TIMEOUT) at 0x400d1fdf

file: "/Users/user/esp/example/main/main.c" line 20
func: app_main
expression: sdmmc_card_init(host, &card)

Backtrace: 0x40086e7c:0x3ffb4ff0 0x40087328:0x3ffb5010 0x400d1fdf:0x3ffb5030␣
↪0x400d0816:0x3ffb5050
```

Note: If *ESP-IDF monitor* is used, addresses in the backtrace will be converted to file names and line numbers.

- The first line mentions the error code as a hexadecimal value, and the identifier used for this error in source code. The latter depends on *CONFIG_ESP_ERR_TO_NAME_LOOKUP* option being set. Address in the program where error has occurred is printed as well.

- Subsequent lines show the location in the program where *ESP_ERROR_CHECK* macro was called, and the expression which was passed to the macro as an argument.
- Finally, backtrace is printed. This is part of panic handler output common to all fatal errors. See *Fatal Errors* for more information about the backtrace.

4.14.5 ESP_ERROR_CHECK_WITHOUT_ABORT Macro

ESP_ERROR_CHECK_WITHOUT_ABORT macro serves similar purpose as `ESP_ERROR_CHECK`, except that it will not call `abort()`.

4.14.6 ESP_RETURN_ON_ERROR Macro

ESP_RETURN_ON_ERROR macro checks the error code, if the error code is not equal *ESP_OK*, it prints the message and returns the error code.

4.14.7 ESP_GOTO_ON_ERROR Macro

ESP_GOTO_ON_ERROR macro checks the error code, if the error code is not equal *ESP_OK*, it prints the message, sets the local variable `ret` to the code, and then exits by jumping to `goto_tag`.

4.14.8 ESP_RETURN_ON_FALSE Macro

ESP_RETURN_ON_FALSE macro checks the condition, if the condition is not equal `true`, it prints the message and returns with the supplied `err_code`.

4.14.9 ESP_GOTO_ON_FALSE Macro

ESP_GOTO_ON_FALSE macro checks the condition, if the condition is not equal `true`, it prints the message, sets the local variable `ret` to the supplied `err_code`, and then exits by jumping to `goto_tag`.

4.14.10 CHECK MACROS Examples

Some examples

```
static const char* TAG = "Test";

esp_err_t test_func(void)
{
    esp_err_t ret = ESP_OK;

    ESP_ERROR_CHECK(x);                                          // err message␣
↪printed if `x` is not `ESP_OK`, and then `abort()`.
    ESP_ERROR_CHECK_WITHOUT_ABORT(x);                            // err message␣
↪printed if `x` is not `ESP_OK`, without `abort()`.
    ESP_RETURN_ON_ERROR(x, TAG, "fail reason 1");                // err message␣
↪printed if `x` is not `ESP_OK`, and then function returns with code `x`.
    ESP_GOTO_ON_ERROR(x, err, TAG, "fail reason 2");             // err message␣
↪printed if `x` is not `ESP_OK`, `ret` is set to `x`, and then jumps to `err`.
    ESP_RETURN_ON_FALSE(a, err_code, TAG, "fail reason 3");      // err message␣
↪printed if `a` is not `true`, and then function returns with code `err_code`.
    ESP_GOTO_ON_FALSE(a, err_code, err, TAG, "fail reason 4");   // err message␣
↪printed if `a` is not `true`, `ret` is set to `err_code`, and then jumps to␣
↪`err`.
```

(continues on next page)

(continued from previous page)

```
err:
    // clean up
    return ret;
}
```

Note: If the option *CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT* in Kconfig is enabled, the error message will be discarded, while the other action works as is.

The `ESP_RETURN_XX` and `ESP_GOTO_xx` macros cannot be called from ISR. While there are `xx_ISR` versions for each of them, e.g., `ESP_RETURN_ON_ERROR_ISR`, these macros could be used in ISR.

4.14.11 Error Handling Patterns

1. Attempt to recover. Depending on the situation, we may try the following methods:
   - retry the call after some time;
   - attempt to de-initialize the driver and re-initialize it again;
   - fix the error condition using an out-of-band mechanism (e.g reset an external peripheral which is not responding).

   Example:

   ```
   esp_err_t err;
   do {
       err = sdio_slave_send_queue(addr, len, arg, timeout);
       // keep retrying while the sending queue is full
   } while (err == ESP_ERR_TIMEOUT);
   if (err != ESP_OK) {
       // handle other errors
   }
   ```

2. Propagate the error to the caller. In some middleware components this means that a function must exit with the same error code, making sure any resource allocations are rolled back.

   Example:

   ```
   sdmmc_card_t* card = calloc(1, sizeof(sdmmc_card_t));
   if (card == NULL) {
       return ESP_ERR_NO_MEM;
   }
   esp_err_t err = sdmmc_card_init(host, &card);
   if (err != ESP_OK) {
       // Clean up
       free(card);
       // Propagate the error to the upper layer (e.g., to notify the␣
   ↪user).
       // Alternatively, application can define and return custom error␣
   ↪code.
       return err;
   }
   ```

3. Convert into unrecoverable error, for example using `ESP_ERROR_CHECK`. See *ESP_ERROR_CHECK macro* section for details.

   Terminating the application in case of an error is usually undesirable behavior for middleware components, but is sometimes acceptable at application level.

   Many ESP-IDF examples use `ESP_ERROR_CHECK` to handle errors from various APIs. This is not the best practice for applications, and is done to make example code more concise.

   Example:

   ```
   ESP_ERROR_CHECK(spi_bus_initialize(host, bus_config, dma_chan));
   ```

4.14.12 C++ Exceptions

See *Exception Handling*.

4.15 ESP-BLE-MESH

Bluetooth® mesh networking enables many-to-many (m:m) device communications and is optimized for creating large-scale device networks.

Devices may relay data to other devices not in direct radio range of the originating device. In this way, mesh networks can span very large physical areas and contain large numbers of devices. It is ideally suited for building automation, sensor networks, and other IoT solutions where tens, hundreds, or thousands of devices need to reliably and securely communicate with one another.

Bluetooth mesh is not a wireless communications technology, but a networking technology. This technology is dependent upon Bluetooth Low Energy (BLE) - a wireless communications protocol stack.

Built on top of Zephyr Bluetooth Mesh stack, the ESP-BLE-MESH implementation supports device provisioning and node control. It also supports such node features as Proxy, Relay, Low power and Friend.

Please see the *ESP-BLE-MESH Architecture* for information about the implementation of ESP-BLE-MESH architecture and *ESP-BLE-MESH API Reference* for information about respective API.

ESP-BLE-MESH is implemented and certified based on the latest Mesh Profile v1.0.1, users can refer here for the certification details of ESP-BLE-MESH.

Note: If you are looking for Wi-Fi based implementation of mesh for ESP32-C3, please check another product by Espressif called ESP-WIFI-MESH. For more information and documentation see *ESP-WIFI-MESH*.

4.15.1 Getting Started with ESP-BLE-MESH

This section is intended to help you get started with ESP-BLE-MESH for the hardware based on the ESP32-C3 chip by Espressif.

We are going to demonstrate process of setting and operation of a small ESP-BLE-MESH network of three nodes. This process will cover device provisioning and node configuration, and then sending on/off commands to Generic OnOff Server Models on specific nodes.

If you are new to ESP-IDF, please first set up development environment, compile , flash and run example application following top level ESP-IDF *Get Started* documentation.

What You Need

Hardware:

- Three ESP32-C3 boards, see *options*.
- USB cables to connect the boards.
- Computer configured with ESP-IDF.
- Mobile phone or tablet running Android or iOS.

Software:

- Example application bluetooth/esp_ble_mesh/onoff_models/onoff_server code to load to the ESP32-C3 boards.
- Mobile App: **nRF Mesh** for Android or iOS. Optionally you can use some other Apps:
  - EspBleMesh Android App
  - Silicon Labs Android or iOS App

Installation Step by Step

This is a detailed roadmap to walk you through the installation process.

Step 1. Check Hardware Both ESP32-DevKitC and ESP-WROVER-KIT development boards are supported for ESP-BLE-MESH implementation. You can choose particular board through menuconfig: `idf.py menuconfig` > `Example Configuration` > `Board selection for ESP-BLE-MESH`

Note: If you plan to use ESP32-DevKitC, connect a RGB LED to GPIO pins 25, 26 and 27.

Step 2. Configure Software Enter the bluetooth/esp_ble_mesh/onoff_models/onoff_server example directory, run `idf.py menuconfig` to select your board and then run `idf.py build` to compile the example.

Step 3. Upload Application to Nodes After the bluetooth/esp_ble_mesh/onoff_models/onoff_server example is compiled successfully, users can run `idf.py flash` to upload the same generated binary files into each of the three development boards.

Once boards are powered on, the RGB LED on each board should turn **GREEN**.

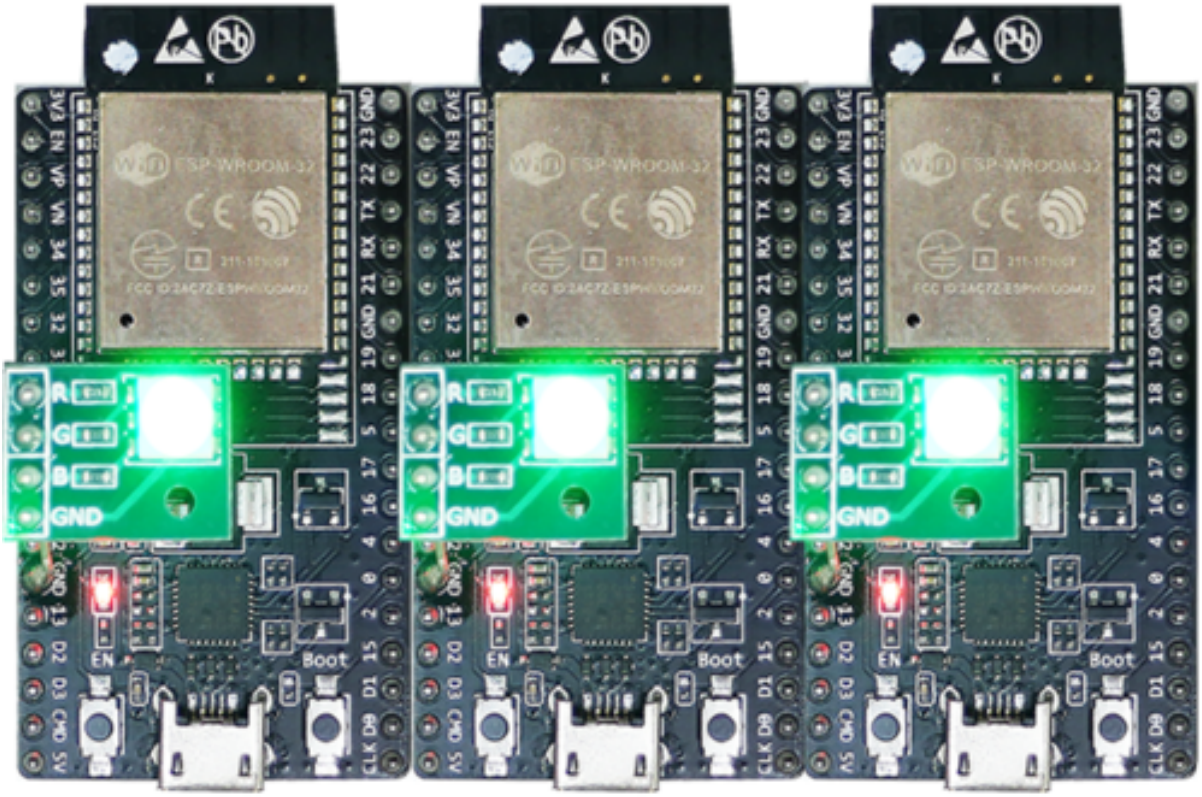

Fig. 13: ESP-BLE-MESH Devices Power On

Step 4. Provision Nodes In this section, we will use the **nRF Mesh Android** App to demonstrate how to provision an unprovisioned device. Users can also get its iOS version from the App Store.

4.1 Scanner The Scanner is App's functionality to search for unprovisioned devices in range. Open the App, press **Scanner** at the bottom and the search will start. After a short while we should see three unprovisioned devices displayed.

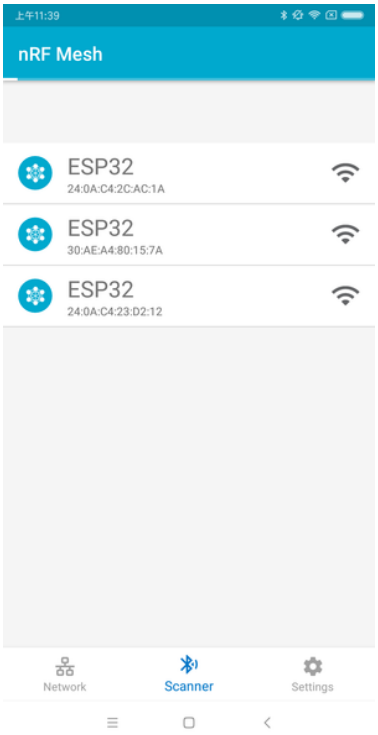

Fig. 14: nRF Mesh - Scanner

4.2 Identify Users can select any unprovisioned device, then the App will try to set up a connection with the selected device. After the Bluetooth LE connection is established successfully (sometimes users need to try multiple times to get connected), and proper ESP-BLE-MESH GATT Service is discovered, users can see the **IDENTIFY** interface button on the screen. The IDENTIFY operation can be used to tell users which device is going to be provisioned.

Note: The IDENTIFY operation also needs some cooperation on the device side, then users can see which device is in the provisioning process. Currently when pressing the **IDENTIFY** interface button, no signs can been seen from the device except from the log on the serial monitor.

After the **IDENTIFY** interface button is pressed, users can see the **PROVISION** interface button.

4.3 Provision Then, the App will try to provision the unprovisioned device. When the device is provisioned successfully, the RGB LED on the board will turn off, and the App will implement the following procedures:

1. Disconnect with the node
2. Try to reconnect with the node
3. Connect successfully and discover ESP-BLE-MESH GATT Service
4. Get Composition Data of the node and add AppKey to it

When all the procedures are finished, the node is configured properly. And after pressing **OK**, users can see that unicast address is assigned, and Composition Data of the node is decoded successfully.

Sometimes in procedure 2, the App may fail to reconnect with the node. In this case, after pressing **OK**, users can see that only unicast address of the node has been assigned, but no Composition Data has been got. Then users need to press **CONNECT** on the top right, and the previously provisioned node will be displayed on the screen, and users need to choose it and try to connect with the node.

After connecting successfully, the App will show the interface buttons which can be used to get Composition Data and add AppKey.

If the device is the second or the third one which has been provisioned by the App, and after pressing **CONNECT**, users can see two or three nodes on the screen. In this situation, users can choose any device to connect with, once

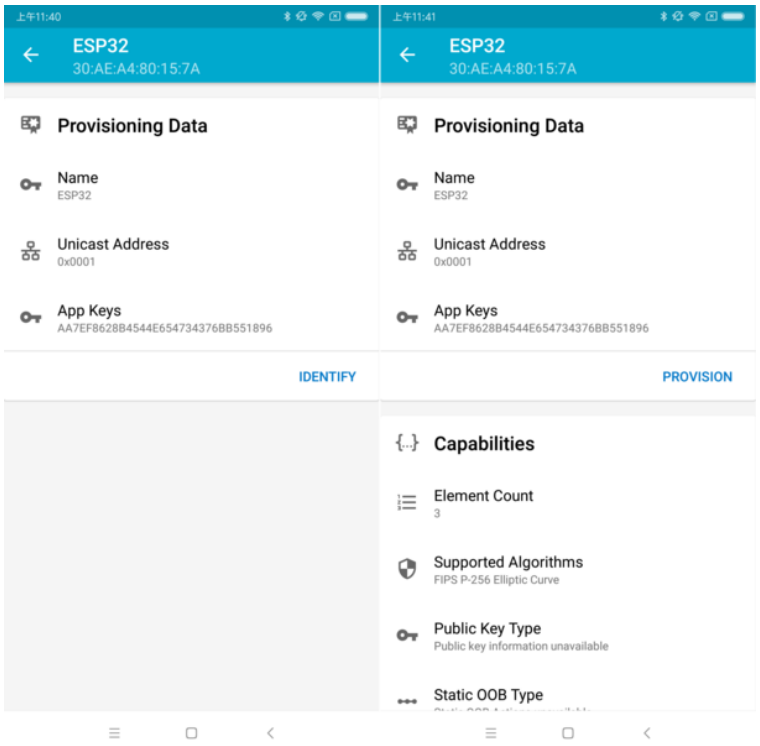

Fig. 15: nRF Mesh - IDENTIFY - PROVISION

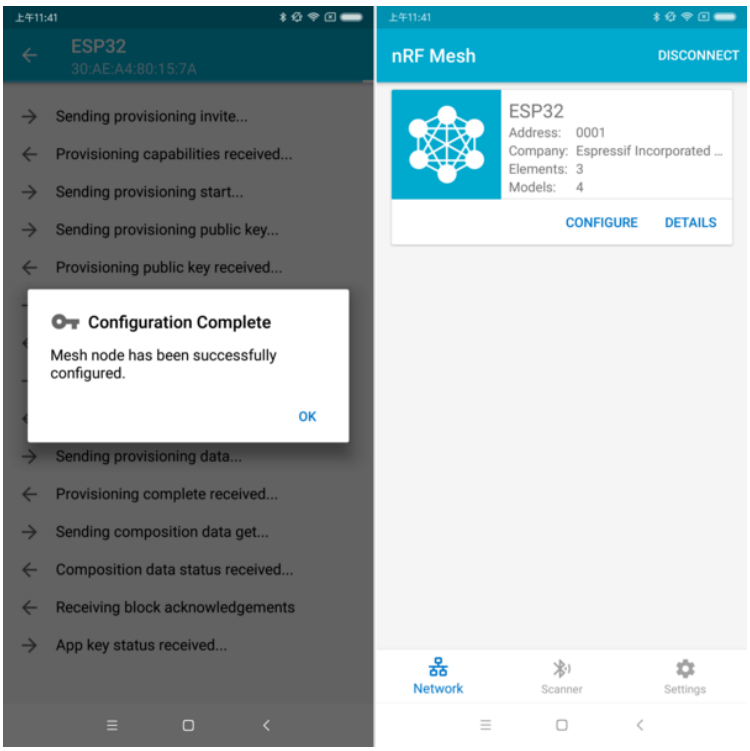

Fig. 16: nRF Mesh - Configuration Complete

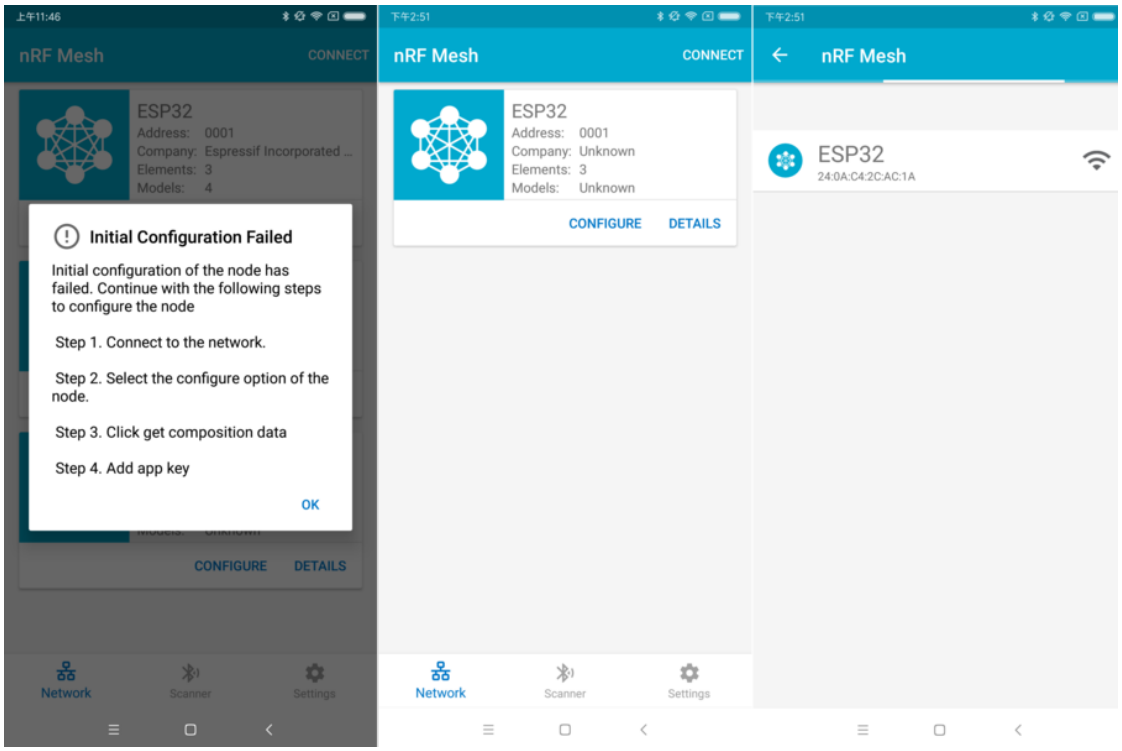

Fig. 17: nRF Mesh - Initial Configuration Failed

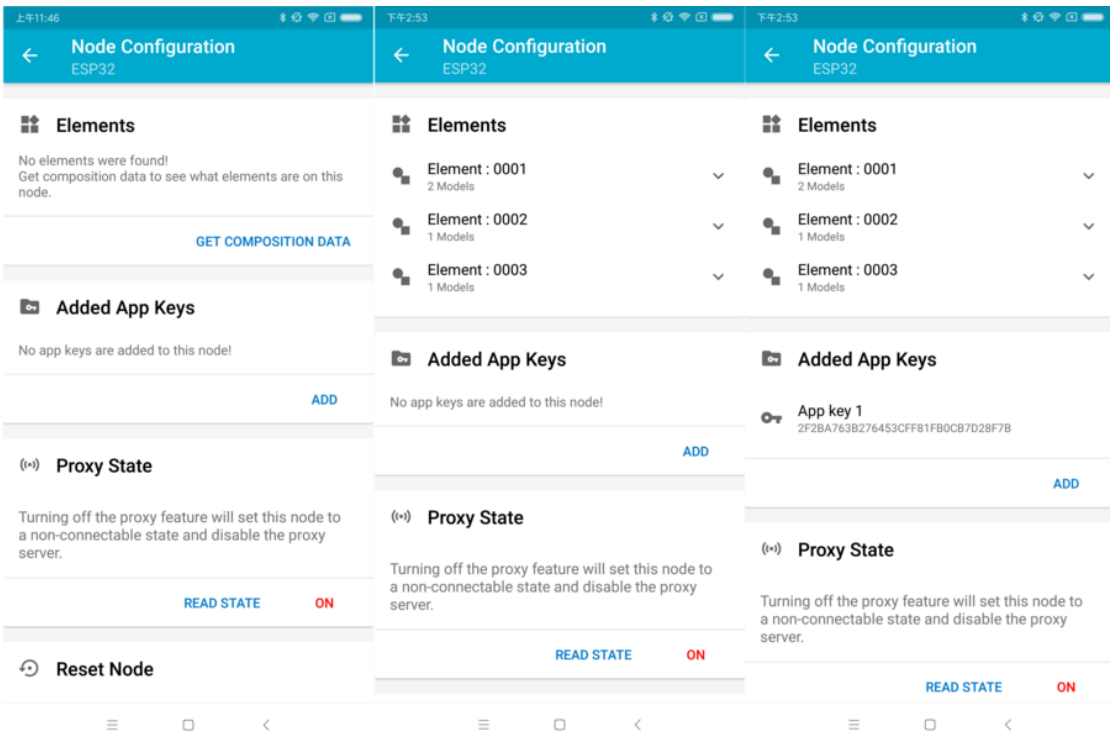

Fig. 18: nRF Mesh - Reconnect - Initial Configuration

succeed then go back to the main screen to choose the node which needs to be configured.

Here an example of three devices listed.

- The left picture shows that the third device is provisioned successfully, but the App failed to connect with it. When it tries to reconnect with the third node, three nodes are displayed on the App.
- The right picture shows that after connecting with any node successfully, the App displays the information of the three nodes. Users can see that the App has got the Composition Data of the first and the second nodes, but for the third one, only the unicast address has been assigned to it while the Composition Data is unknown.

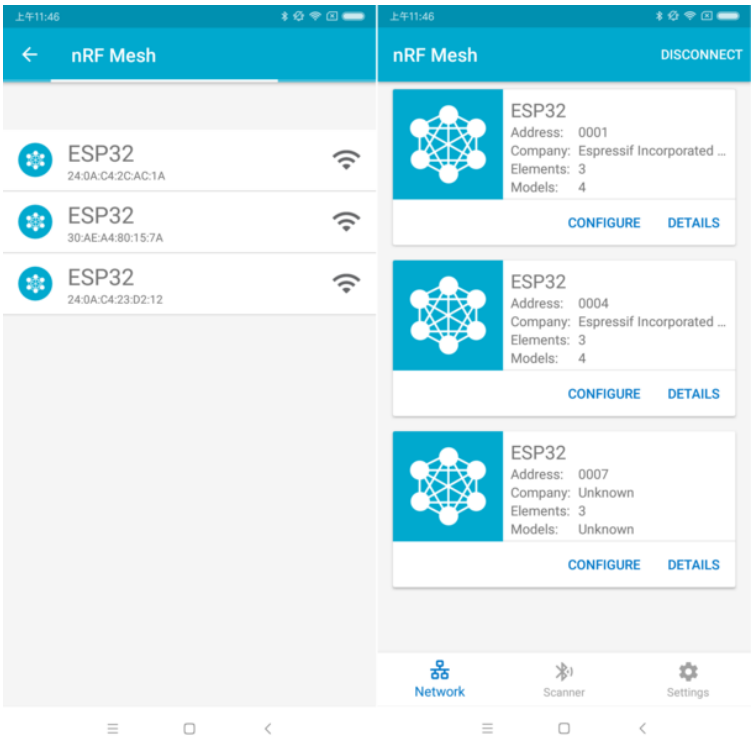

Fig. 19: nRF Mesh - Reconnect - Three Nodes

4.4 Configuration When provisioning and initial configuration are finished, users can start to configure the node, such as binding AppKey with each model with the elements, setting publication information to it, etc.

Example below shows how to bind AppKey with Generic OnOff Server Model within the Primary Element.

Note: No need to bind AppKey with the Configuration Server Model, since it only uses the DevKey to encrypt messages in the Upper Transport Layer.

Step 5. Operate Network After all the Generic OnOff Server Models within the three elements are bound with proper AppKey, users can use the App to turn on/off the RGB LED.

In the bluetooth/esp_ble_mesh/onoff_models/onoff_server example, the first Generic OnOff Server Model is used to control the **RED** color, the second one is used to control the **GREEN** color and the third one is used to control the **BLUE** color.

The following screenshot shows different board with different color on.

Note: For **nRF Mesh** iOS App [version 1.0.4], when the node contains more than one element, the App is not behaving correctly. If users try to turn on/off the second or the third Generic OnOff Server Model, the message sent by the App is destinated to the first Generic OnOff Server Model within the Primary Element.

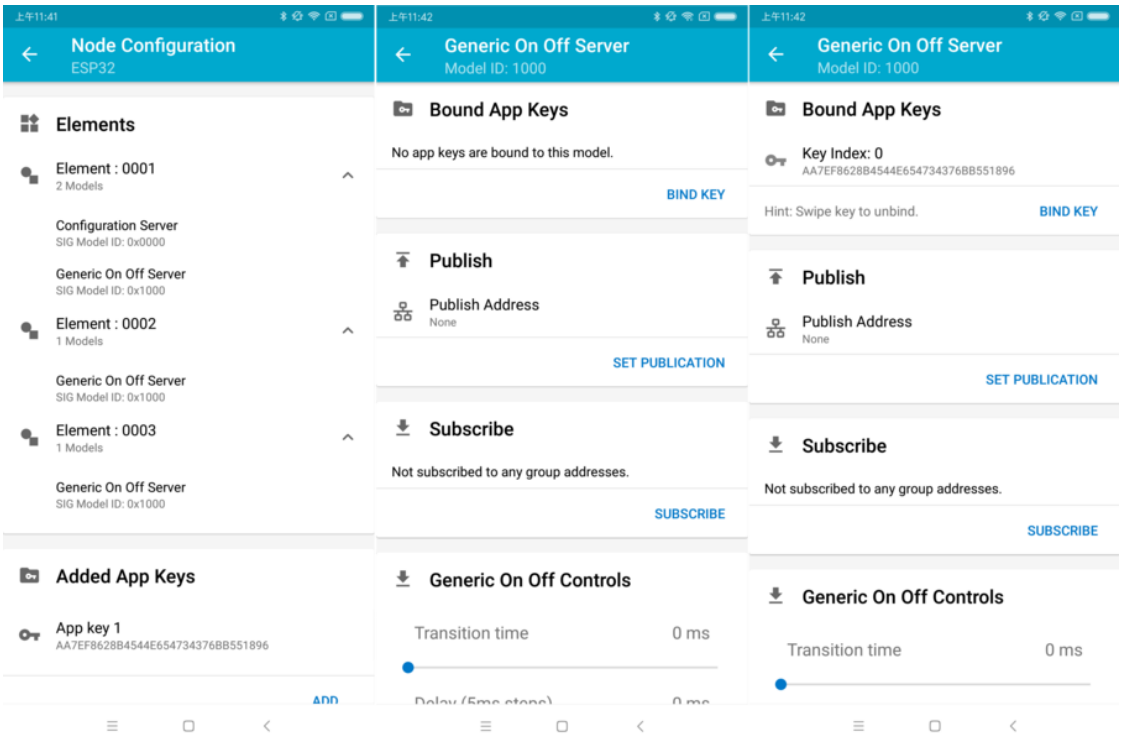

Fig. 20: nRF Mesh - Model Bind AppKey

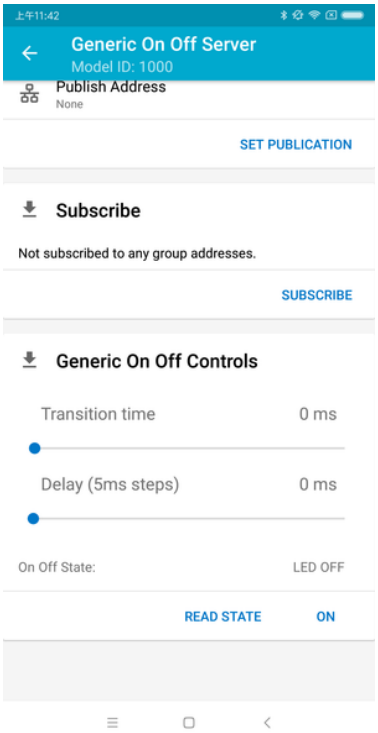

Fig. 21: nRF Mesh - Generic OnOff Control

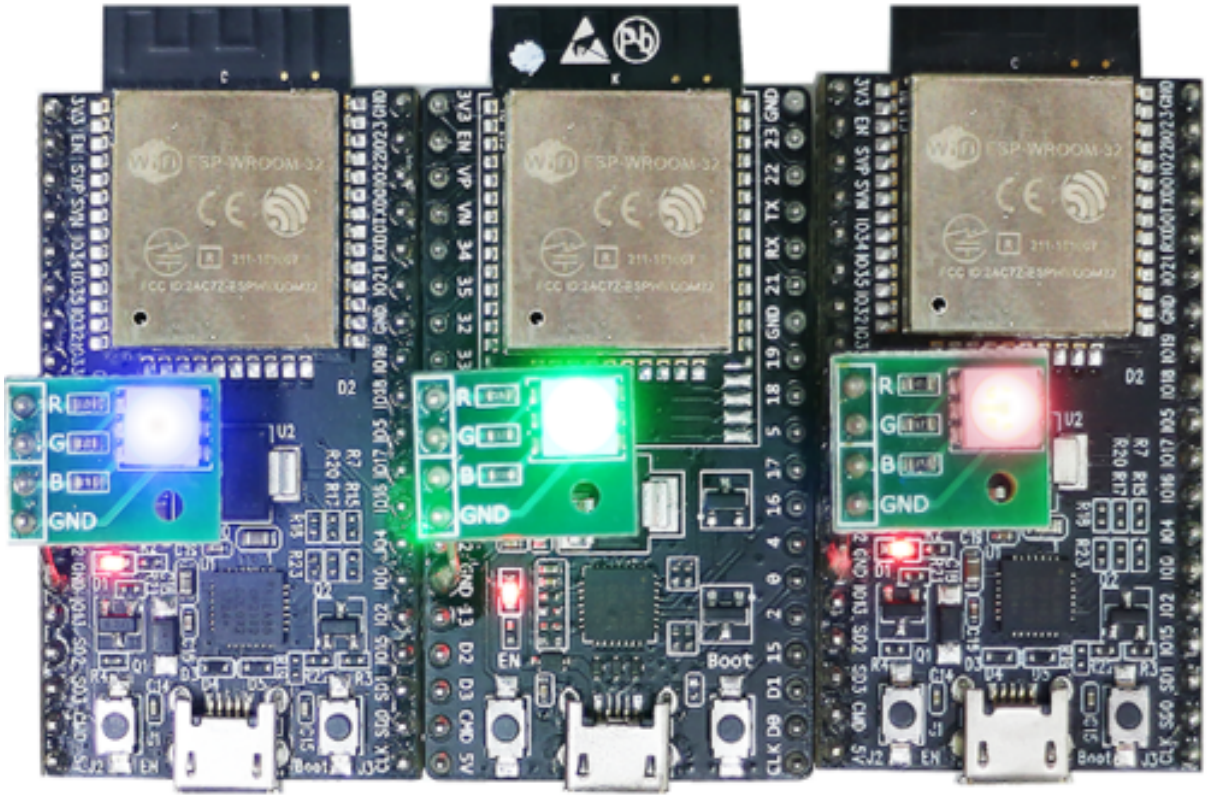

Fig. 22: Three ESP-BLE-MESH Nodes On

4.15.2 ESP-BLE-MESH Examples

- OnOff Server - shows the use of ESP-BLE-MESH as a node having a Configuration Server model and a Generic OnOff Server model. A ESP-BLE-MESH Provisioner can then provision the unprovisioned device and control a RGB LED representing on/off state, see example code .
- OnOff Client - shows how a Generic OnOff Client model works within a node. The node has a Configuration Server model and a Generic OnOff Client model, see example code .
- Provisioner - shows how a device can act as an ESP-BLE-MESH Provisioner to provision devices. The Provisioner has a Configuration Server model, a Configuration Client model and a Generic OnOff Client model, see example code .
- Fast Provisioning - Client and Server - this example is used for showing how fast provisioning can be used in order to create a mesh network. It takes no more than 60 seconds to provision 100 devices, see example client code and example server code .
- BLE-Mesh and Wi-Fi Coexistence - an example that demonstrates the Wi-Fi and Bluetooth (BLE/BR/EDR) coexistence feature of ESP32-C3. Simply put, users can use the Wi-Fi while operating Bluetooth, see example code .
- Remote Provisioning (v1.1) - Client, Server and device - this example is used to demonstrate the new remote provisioning feature introduced in the Mesh Protocol v1.1, see example client code , example server code and example device code .
- Directed Forwarding (v1.1) - Client and Server - this example is used to demonstrate the new directed forwarding feature introduced in the Mesh Protocol v1.1. Only nodes along the path will forward the directed messages, while other nodes will not actively participate in forwarding, see example client code and example server code .

ESP-BLE-MESH Architecture

This document introduces ESP-BLE-MESH architecture overview, ESP-BLE-MESH architecture implementation as well as ESP-BLE-MESH auxiliary routines.

- ESP-BLE-MESH Architecture Overview
  - Describes the five major parts of ESP-BLE-MESH architecture and the functionality of each part.
- ESP-BLE-MESH Architecture Implementation
  - Describes the basic functions of ESP-BLE-MESH files, the correspondence between files and ESP-BLE-MESH architecture, and the interface for calling among files.
- ESP-BLE-MESH Auxiliary Routines
  - Describe the auxiliary routines of ESP-BLE-MESH, such as Mesh network management, Mesh features, etc.

1. ESP-BLE-MESH Architecture Overview Currently ESP-BLE-MESH has implemented most functions of Mesh Profile and all the Client Models defined in Mesh Model specification. Those missing functions/models are under development and will be provided soon. ESP-BLE-MESH architecture has been granted the official Bluetooth certification.

ESP-BLE-MESH architecture includes five key parts:

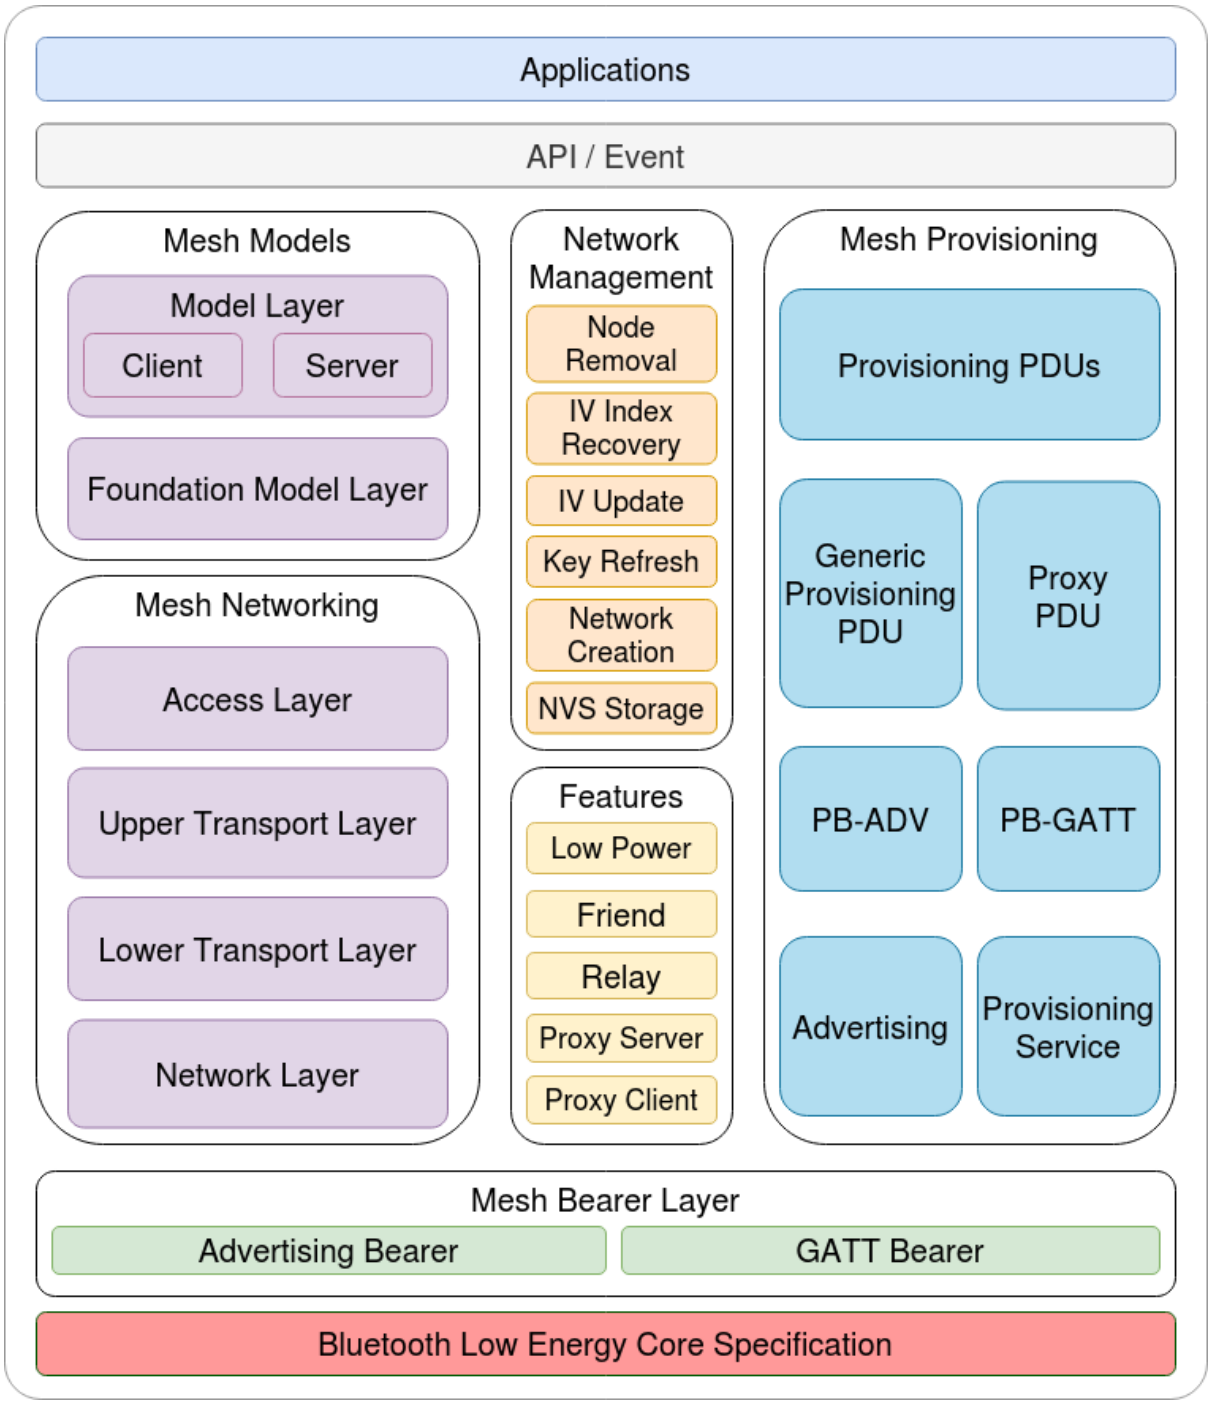

Fig. 23: Figure 1.1 ESP-BLE-MESH Architecture Diagram

- `Mesh Protocol Stack`
  - `Mesh Networking` is responsible for processing of messages of ESP-BLE-MESH nodes.
  - `Mesh Provisioning` is responsible for provisioning flow of ESP-BLE-MESH devices.
  - `Mesh Models` is responsible for the implementation of SIG-defined models.
- `Network Management`
  - Implements several network management procedures, including node removal procedure, IV Index recovery procedure, etc.
- `Features`
  - Include several ESP-BLE-MESH features, e.g., Low Power feature, Friend feature, Relay feature, etc.
- `Mesh Bearer Layer`
  - Includes `Advertising Bearer` and `GATT Bearer`. The bearer layer is crucial to ESP-BLE-MESH protocol stack which is built on Bluetooth Low-Energy technology, because the protocol stack must make use of the bearer layer to transmit data via the BLE advertising channel and connection channel.
- `Applications`
  - Based on ESP-BLE-MESH protocol stack and `Mesh Models`.
  - By calling API and handling Event, `Applications` interact with `Mesh Networking` and `Mesh Provisioning` in ESP-BLE-MESH protocol stack, as well as a series of Models provided by `Mesh Models`.

1.1 Mesh Protocol Stack

1.1.1 Mesh Networking `Mesh Networking` in the protocol stack architecture implements the following functions:

- The communication between nodes in the Mesh network.
- Encryption and decryption of messages in the Mesh network.
- Management of Mesh network resources (Network Key, IV Index, etc.).
- Segmentation and reassembly of Mesh network messages.
- Model mapping of messages between different models.
- For more features, please see *ESP-BLE-MESH Feature List*.

The implementation of `Mesh Networking` functions is based on hierarchy structure. Functions of each layer are shown in Table 1.1:

Table 3: Table 1.1 Mesh Networking Architecture Description

Layer	Function
Access Layer	Access Layer not only defines the format of application data, but also defines and controls the encryption and decryption of the data packets conducted by Upper Transport Layer.
Upper Transport Layer	Upper Transport Layer encrypts, decrypts, and authenticates application data to and from the access layer; it also handles special messages called "transport control messages", including messages related to "friendship" and heartbeat messages.
Lower Transport Layer	Lower Transport Layer handles segmentation and reassembly of PDU.
Network Layer	Network Layer defines the address type and format of the network messages, and implements the relay function of the device.

1.1.2 Mesh Provisioning `Mesh Provisioning` in the protocol stack architecture implements the following functions:

- Provisioning of unprovisioned devices.
- Allocation of Mesh network resources (unicast address, IV Index, NetKey, etc.).
- Four authentication methods support during provisioning.
- For more features, please see *ESP-BLE-MESH Feature List*.

The implementation of `Mesh Provisioning` functions is based on hierarchy structure. Functions of each layer are shown in Table 1.2:

Table 4: Table 1.2 Mesh Provisioning Architecture Description

Layer	Function
Provisioning PDUs	Provisioning PDUs from different layers are handled using provisioning protocol.
Generic Provisioning PDU/Proxy PDU	The Provisioning PDUs are transmitted to an unprovisioned device using a Generic Provisioning layer or Proxy protocol layer.
PB-ADV/PB-GATT	These layers define how the Provisioning PDUs are transmitted as transactions that can be segmented and reassembled.
Advertising/Provisioning Service	The provisioning bearers define how sessions are established such that the transactions from the generic provisioning layer can be delivered to a single device.

1.1.3 Mesh Models `Mesh Models` in the protocol stack architecture implements the following functions:

- Configuration Client/Server Models
- Health Client/Server Models
- Generic Client/Server Models
- Sensor Client/Server Models
- Time and Scenes Client/Server Models
- Lighting Client/Server Models

Functions of each layer are shown in Table 1.3:

Table 5: Table 1.3 Mesh Models Architecture Description

Layer	Function
Model Layer	Model Layer implements models used to standardize the operation of typical user scenarios, including Generic Client/Server Models, Sensor Client/Server Models, Time and Scenes Client/Server Models, Lighting Client/Server Models and several vendor models.
Foundation Model Layer	Foundation Model Layer implements models related to ESP-BLE-MESH configuration, management, self diagnosis, etc.

1.2 Mesh Network Management `Network Management` implements the following functions:

- Node removal procedure is used to remove a node from the network.
- IV Index recovery procedure is used to recover a node's IV Index.
- IV update procedure is used to update the nodes' IV Index.
- Key refresh procedure is used to update the nodes' NetKey, AppKey, etc.
- Network creation procedure is used to create a mesh network.
- NVS storage is used to store node's networking information.

1.3 Mesh Features `Features` includes the following options:

- Low Power feature is used to reduce node's power consumption.
- Friend feature is used to store messages for Low Power nodes.
- Relay feature is used to relay/forward Network PDUs received by a node over the advertising bearer.
- Proxy Server/Client are two node roles in proxy protocol, which enable nodes to send and receive Network PDUs, mesh beacons, proxy configuration messages and Provisioning PDUs over a connection-oriented bearer.

1.4 Mesh Bearer Layer `Bearers` in the protocol stack architecture are responsible for passing of data between ESP-BLE-MESH protocol stack and Bluetooth Low Energy Core.

`Bearers` can be taken as a carrier layer based on Bluetooth Low Energy Core, which implements the function of receiving and transmitting data for the ESP-BLE-MESH protocol stack.

Table 6: Table 1.3 Mesh Bearers Description

Layer	Function
GATT Bearer	The GATT Bearer uses the Proxy protocol to transmit and receive `Proxy PDUs` between two devices over a GATT connection.
Advertising Bearer	When using the Advertising Bearer, a mesh packet shall be sent in the Advertising Data of a `Bluetooth Low Energy advertising PDU` using the Mesh Message AD Type.

1.5 Mesh Applications The `Applications` in the protocol stack architecture implement the corresponding functions by calling the API provided by the ESP-BLE-MESH protocol stack and processing the Event reported by the protocol stack. There are some common applications, such as gateway, lighting and etc.

Interaction between application layer (`Applications`) and `API/Event`

- Application layer calls API
  - Call the provisioning-related API for provisioning.
  - Call the model-related API to send messages.
  - Call the device-attributes-related API to get local information about the device.
- Application layer processes Event
  The application layer is designed based on events, which take parameters to the application layer. Events are mainly divided into two categories.
  - **The events completed by calling API.**
    - Such as nodes sending messages.
  - **The events that the protocol stack actively reports to the application layer.**
    - The Event that the protocol stack actively reports.
    - The Event that Model actively reports.
- The event is reported by the callback function registered by the application layer, and the callback function also contains the corresponding processing of the event.

Interaction between `API / Event` and ESP-BLE-MESH protocol stack

- API used by user mainly calls functions provided by `Mesh Networking`, `Mesh Provisioning` and `Mesh Models`.
- The interaction between `API / Event` and the protocol stack does not operate across the hierarchy of the protocol stack. For example, API does not call functions related to `Network Layer`.

2. ESP-BLE-MESH Architecture Implementation The design and implementation of ESP-BLE-MESH architecture is based on layers and modules. In details, Section 2.1 (Mesh Networking Implementation), Section 2.2 (Mesh Provisioning Implementation) and Section 2.3 (Mesh Bearers Implementation) are based on layers, and Section 2.4 (Mesh Models Implementation) is on modules.

- **Layer-based Approach**: With Layer-based approach, the architecture is designed according to the layers specified in the Mesh Profile Specification. Each layer has its unique files which include APIs of this layer and etc. The specific design is shown in Figure 2.1.
- **Module-based Approach**: Every file implements an independent function that can be called by other programs.

The design of ESP-BLE-MESH architecture uses layer-based approach. The sequence of layers which data packets are processed through is fixed, i.e., the processing of packets will form a `message flow`. Thus, we could see flows of messages from the Protocol Stack Interface Diagram in Figure 2.1.

2.1 Mesh Protocol Stack Implementation

2.1.1 Mesh Networking Implementation The list of files and the functions implemented in each file in `Mesh Networking` are shown in Table 2.1:

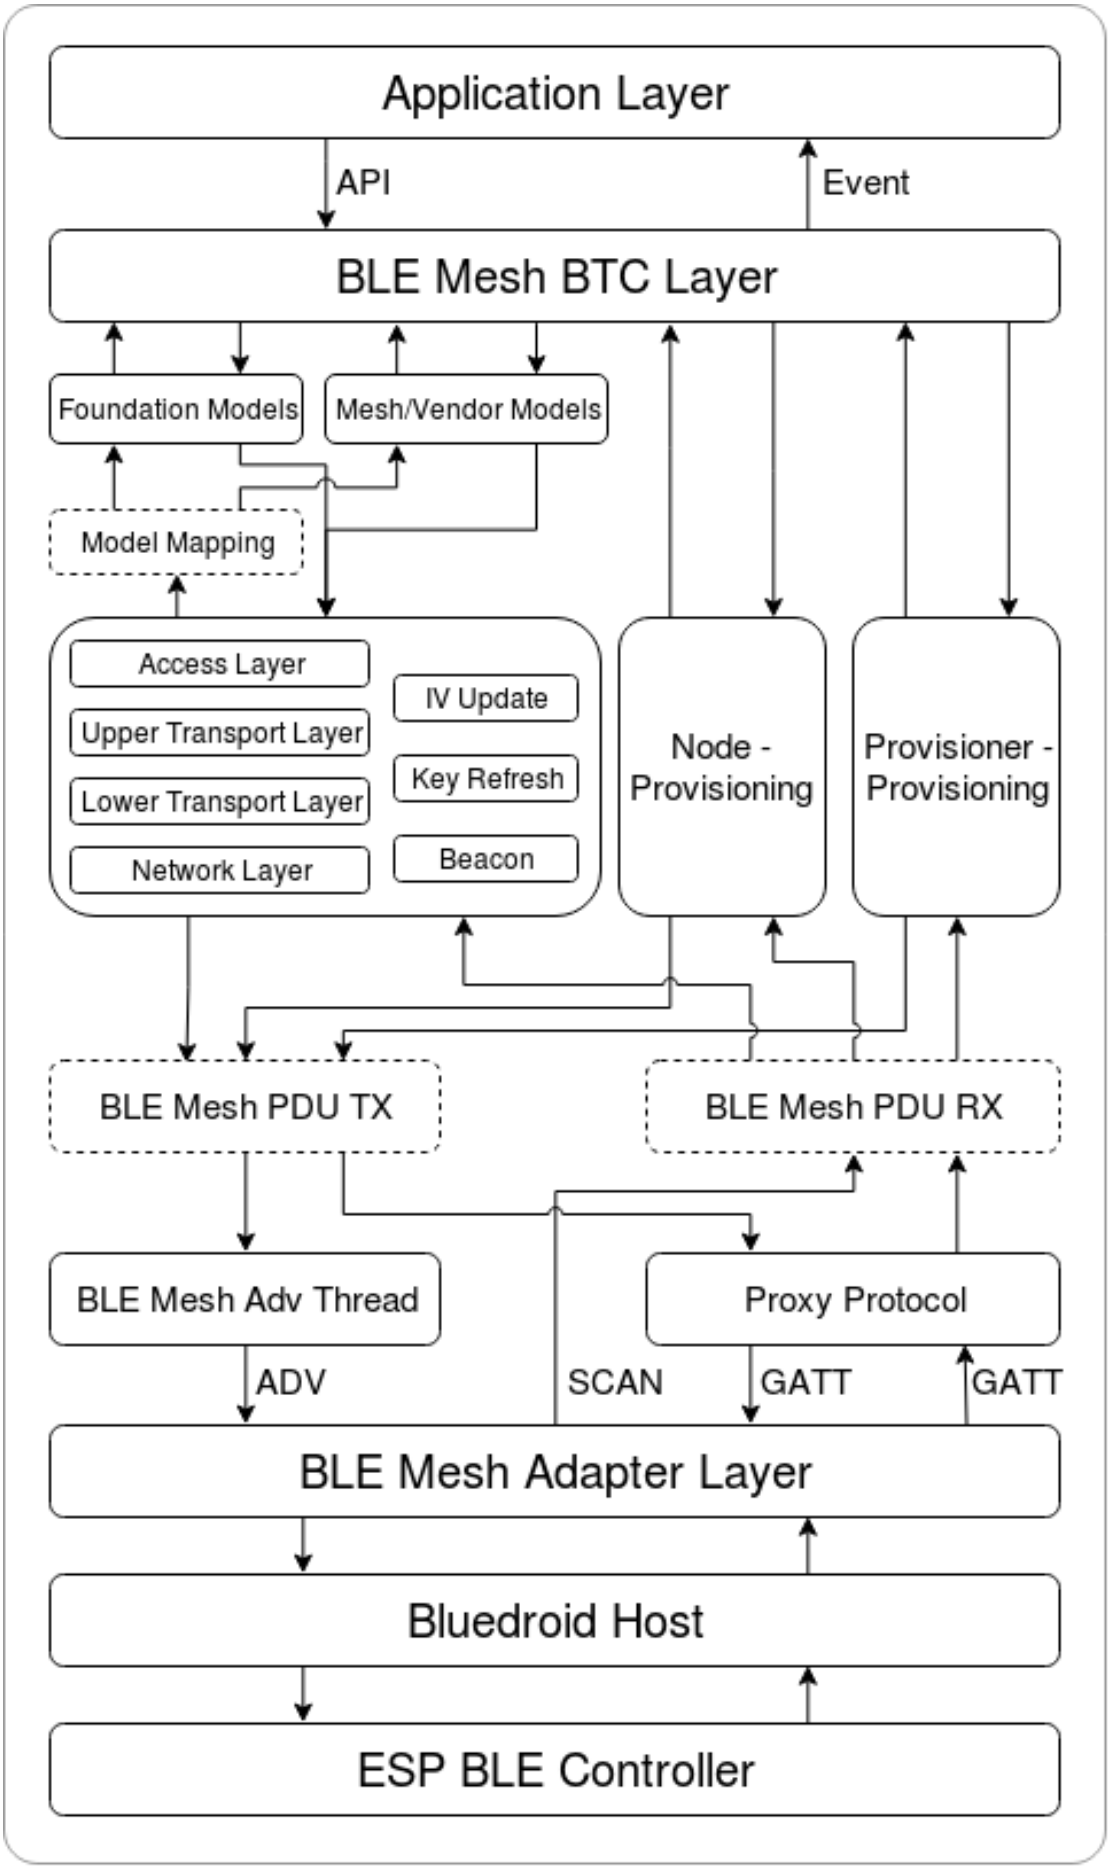

Fig. 24: Figure 2.1 ESP-BLE-MESH Architecture Implementation Diagram

Table 7: Table 2.1 Mesh Networking File Description :widths: 40 150 :header-rows: 1

File	Functionality
access.c	ESP-BLE-MESH Access Layer
transport.c	ESP-BLE-MESH Lower/Upper Transport Layer
net.c	ESP-BLE-MESH Network Layer
adv.c	A task used to send ESP-BLE-MESH advertising packets, a callback used to handle received advertising packets and APIs used to allocate adv buffers

2.1.2 Mesh Provisioning Implementation The implementation of Mesh Provisioning is divided into two chunks due to the Node/Provisioner coexistence.

Specific files that provide implementation of provisioning of Node are shown in Table 2.2:

Table 8: Table 2.2 Mesh Provisioning (Node) File Description

File	Functionality
prov_node.c	ESP-BLE-MESH Node provisioning (PB-ADV & PB-GATT)
proxy_server.c	ESP-BLE-MESH Proxy Server related functionalities
beacon.c	APIs used to handle ESP-BLE-MESH Beacons

Specific files that implement functions of Provisioner are shown in Table 2.3:

Table 9: Table 2.3 Mesh Provisioning (Provisioner) File Description

File	Functionality
prov_pvnr.c	ESP-BLE-MESH Provisioner provisioning (PB-ADV & PB-GATT)
proxy_client.c	ESP-BLE-MESH Proxy Client related functionalities
pvnr_mgmt.c	ESP-BLE-MESH Provisioner networking related functionalities

2.1.3 Mesh Models Implementation Mesh Models are used to implement the specific functions of model in nodes. Server model is used to maintain node status. Client model is used to obtain and modify node state.

Table 10: Table 2.4 Mesh Models File Description

File	Functionality
cfg_cli.c	Send Configuration Client messages and receive corresponding response messages
cfg_srv.c	Receive Configuration Client messages and send proper response messages
health_cli.c	Send Health Client messages and receive corresponding response messages
health_srv.c	Receive Health Client messages and send proper response messages
client_common.c	ESP-BLE-MESH model related operations
generic_client.c	Send ESP-BLE-MESH Generic Client messages and receive corresponding response messages
lighting_client.c	Send ESP-BLE-MESH Lighting Client messages and receive corresponding response messages
sensor_client.c	Send ESP-BLE-MESH Sensor Client messages and receive corresponding response messages
time_scene_client.c	Send ESP-BLE-MESH Time Scene Client messages and receive corresponding response messages
generic_server.c	Receive ESP-BLE-MESH Generic Client messages and send corresponding response messages
lighting_server.c	Receive ESP-BLE-MESH Lighting Client messages and send corresponding response messages
sensor_server.c	Receive ESP-BLE-MESH Sensor Client messages and send corresponding response messages
time_scene_server.c	Receive ESP-BLE-MESH Time Scene Client messages and send corresponding response messages

2.2 Mesh Bearers Implementation Portability is fully considered in the implementation of Mesh Bearers. When the ESP-BLE-MESH protocol stack is being ported to other platforms, users only need to modify adapter.c (example of NimBLE version).

Table 11: Table 2.5 Mesh Bearers File Description

File	Functionality
adapter.c	ESP-BLE-MESH Bearer Layer adapter , This file provides the interfaces used to receive and send ESP-BLE-MESH ADV & GATT related packets.

Note: adapter.c is the implementation of `Advertising Bearer` and `GATT Bearer` in Mesh Networking framework.

2.3 Mesh Applications Implementation We have provided a series of application examples for customer development, and users can develop products based on *ESP-BLE-MESH Examples*.

3. Auxiliary Routine Auxiliary routine refers to optional functions in the ESP-BLE-MESH protocol stack. The design of the auxiliary routine generally implement the truncation of code through *CONFIG_BLE_MESH*.

3.1 Features

- Low Power
- Friend
- Relay
- Proxy Client/Server

3.2 Network Management

- Node Removal procedure
- IV Index Recovery procedure
- IV Update procedure
- Key Refresh procedure
- Network Creation procedure
- NVS Storage

3.3 Auxiliary Routine Implementation When adopting the design of independent module, the two main factors should be considered:

- The module can not be implemented hierarchically, and it can be completely independent, which means it does not rely on the implementation of other modules.
- The functions in the module will be used repeatedly, so it is reasonable to design it into a module. Independent module is shown in Table 3.1:

Table 12: Table 3.1 Module File Description

File	Functionality
lpn.c	ESP-BLE-MESH Low Power functionality
friend.c	ESP-BLE-MESH Friend functionality
net.c	ESP-BLE-MESH Relay feature, network creation, IV Update procedure, IV Index recovery procedure, Key Refresh procedure related functionalities
proxy_server.c	ESP-BLE-MESH Proxy Server related functionalities
proxy_client.c	ESP-BLE-MESH Proxy Client related functionalities
settings.c	ESP-BLE-MESH NVS storage functionality
main.c	ESP-BLE-MESH stack initialize, stack enable, node removal related functionalities

ESP-BLE-MESH FAQ

This document provides a summary of frequently asked questions about developing with ESP-BLE-MESH, and is divided into seven sections:

- *1. Provisioner Development*
- *2. Node Development*
- *3. ESP-BLE-MESH and Wi-Fi Coexistence*
- *4. Fast Provisioning*
- *5. Log Help*
- *6. Example Help*
- *7. Others*

Users could refer to the sections for quick answer to their questions. This document will be updated based on the feedback collected via various channels.

1. Provisioner Development Generally, a Provisioner is used to provision unprovisioned devices and form a mesh network. And after provisioning, roles of the unprovisioned devices will be changed to those of a node.

1.1 What Is the Flow for an Unprovisioned Device to Join ESP-BLE-MESH Network?

There are two phases for a device to join ESP-BLE-MESH network via a Provisioner, namely, provisioning and configuration.

- The phase of provisioning is to assign unicast address, add NetKey and etc. to a device. By provisioning, the device joins the ESP-BLE-MESH network and its role is changed from an unprovisioned device to a node.

- The phase of configuration is to add AppKeys to the node and bind AppKeys to corresponding models. And some items are optional during configuration, including adding subscription addresses to the node, set publication information, etc. By configuration, the node can actually transmit messages to a Provisioner and receive messages from it.

1.2 If a Provisioner Wants to Change States of a Node, What Requirements Should Be Met for a Provisioner?

- Client model that corresponds to server model of the node is required.
- NetKey and AppKey used to encrypt messages shall be owned by both the node and the Provisioner.
- The address owned by the node shall be known, which could be its unicast address or subscription address.

1.3 How Can NetKey and AppKey Be Used?

- NetKey is used for encryption of messages in Network Layer. Nodes with the same NetKey are assumed to be in the same subnet while those with different NetKeys cannot communicate with each other.
- AppKey is used for encryption of messages in Upper Transport Layer. If client model and server model are bound to different AppKeys, the communication cannot be achieved.

1.4 How to Generate a NetKey or AppKey for Provisioner? Can We Use a Fixed NetKey or AppKey?

- The API `esp_ble_mesh_provisioner_add_local_net_key()` can be used to add a NetKey with a fixed or random value.
- The API `esp_ble_mesh_provisioner_add_local_app_key()` can be used to add an AppKey with a fixed or random value.

1.5 Is the Unicast Address of Provisioner Fixed?

The value of `prov_unicast_addr` in `esp_ble_mesh_prov_t` is used to set the unicast address of Provisioner, it can be set only once during initialization and cannot be changed afterwards.

1.6 Can the Address of Provisioner Serve as Destination Address of the Node-reporting-status Message?

The unicast address of Provisioner can be set only once during initialization and cannot be changed afterwards. In theory, it can serve as the destination address of the node-reporting-status message, provided that the unicast address of the Provisioner is known by nodes. Nodes can know the unicast address of Provisioner during configuration since Provisioner sends messages to them with its unicast address used as the source address.

Subscription address can also be used. Provisioner subscribes to a group address or virtual address, and nodes send messages to the subscription address.

1.7 Is the Unicast Address of the Node That Is Firstly Provisioned by ProvIsioner to ESP-BLE-MESH Network Fixed?

The value of `prov_start_address` in `esp_ble_mesh_prov_t` is used to set the starting address when the Provisioner provisions unprovisioned devices, i.e., the unicast address of the node it firstly provisioned. It can be set only once during initialization and cannot be changed afterwards.

1.8 Is the Unicast Address of the Node That Mobile App Firstly Provisioned Fixed?

The App will decide the unicast address, and currently most of them are fixed.

1.9 How to Know Which Unprovisioned Device Is the ProvIsioner That Is Provisioning Currently?

The value of `prov_attention` in *esp_ble_mesh_prov_t* is used by Provisioner set to unprovisioned device during provisioning. It can be set only once during initialization and cannot be changed afterwards. When the unprovisioned device is joining the mesh network, it can display in a specific way like flashing light to notify Provisioner that it is being provisioned.

1.10 How Many Ways to Authenticate the Devices During Provisioning? Which Way Was Used in the provided examples ?

There are four authentication methods, i.e., No OOB, Static OOB, Output OOB and Input OOB. In the provided examples, No OOB is used.

1.11 What Information Can Be Carried by the Advertising Packets of the Unprovisioned Device Before Provisioning into the Network?

- Device UUID
- OOB Info
- URL Hash (optional)

1.12 Can Such Information Be Used for Device Identification?

For example, each unprovisioned device contains a unique Device UUID, which can be used for device identification.

1.13 How Is the Unicast Address Assigned When the Node Provisioned by ProvIsioner Contains Multiple Elements?

- Provisioner will assign an unicast address for the primary element of the node, and unicast address of the remaining elements are incremented one by one.
- For example: If an unprovisioned device has three elements, i.e., the primary element, the second element and the third element. After provisioning, the primary element address of the node is 0x0002 while the second element address is 0x0003, and the third element address is 0x0004.

1.14 How Can Provisioner Get and Parse the Composition Data of Nodes Through Configuration Client Model?

- Provisioner can get the Composition Data of nodes using the *Configuration Client Model* API *esp_ble_mesh_config_client_set_state()* with `comp_data_get` in the parameter *esp_ble_mesh_cfg_client_get_state_t* set properly.
- Users can refer to the following code to parse the Composition Data:

```
#include <stdio.h>
#include <string.h>
#include <stdint.h>

//test date: 0C001A0001000800030000010501000000800100001003103F002A00
//0C00 1A00 0100 0800 0300 0001 05 01 0000 0080 0100 0010 0310 3F002A00

// CID is 0x000C
// PID is 0x001A
// VID is 0x0001
// CRPL is 0x0008
// Features is 0x0003 - Relay and Friend features.
// Loc is "front" - 0x0100
// NumS is 5
// NumV is 1
// The Bluetooth SIG Models supported are: 0x0000, 0x8000, 0x0001, 0x1000,
↪ 0x1003
```

(continues on next page)

(continued from previous page)

```
// The Vendor Models supported are: Company Identifier 0x003F and Model␣
↪Identifier 0x002A

typedef struct {
    int16_t cid;
    int16_t pid;
    int16_t vid;
    int16_t crpl;
    int16_t features;
    int16_t all_models;
    uint8_t sig_models;
    uint8_t vnd_models;
} esp_ble_mesh_composition_head;

typedef struct {

                        0x3F, 0x00, 0x2A, 0x00};
    int ret;

    ret = decode_comp_data(&head, &data, mystr, sizeof(mystr));
    if (ret == -1) {
        printf("decode_comp_data error");
    }
}
```

1.15 How Can Provisioner Further Configure Nodes Through Obtained Composition Data?

Provisioner do the following configuration by calling the *Configuration Client Model* API *esp_ble_mesh_config_client_set_state()*.

- Add AppKey to nodes with `app_key_add` in the parameter *esp_ble_mesh_cfg_client_set_state_t* set properly.
- Add subscription address to the models of nodes with `model_sub_add` in the parameter *esp_ble_mesh_cfg_client_set_state_t* set properly.
- Set publication information to the models of nodes with `model_pub_set` in the parameter *esp_ble_mesh_cfg_client_set_state_t* set properly.

1.16 Can Nodes Add Corresponding Configurations for Themselves?

This method can be used in special cases like testing period.

- Here is an example to show nodes add new group addresses for their models.

```
esp_err_t example_add_fast_prov_group_address(uint16_t model_id, uint16_t␣
↪group_addr)
{
    const esp_ble_mesh_comp_t *comp = NULL;
    esp_ble_mesh_elem_t *element = NULL;
    esp_ble_mesh_model_t *model = NULL;
    int i, j;

    if (!ESP_BLE_MESH_ADDR_IS_GROUP(group_addr)) {
        return ESP_ERR_INVALID_ARG;
    }

    comp = esp_ble_mesh_get_composition_data();
    if (!comp) {
        return ESP_FAIL;
    }

    for (i = 0; i < comp->element_count; i++) {
```

(continues on next page)

(continued from previous page)

```
        element = &comp->elements[i];
        model = esp_ble_mesh_find_sig_model(element, model_id);
        if (!model) {
            continue;
        }
        for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
            if (model->groups[j] == group_addr) {
                break;
            }
        }
        if (j != ARRAY_SIZE(model->groups)) {
            ESP_LOGW(TAG, "%s: Group address already exists, element␣
↪index: %d", __func__, i);
            continue;
        }
        for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
            if (model->groups[j] == ESP_BLE_MESH_ADDR_UNASSIGNED) {
                model->groups[j] = group_addr;
                break;
            }
        }
        if (j == ARRAY_SIZE(model->groups)) {
            ESP_LOGE(TAG, "%s: Model is full of group addresses, element␣
↪index: %d", __func__, i);
        }
    }

    return ESP_OK;
}
```

Note: When the NVS storage of the node is enabled, group address added and AppKey bound by this method will not be saved in the NVS when the device is powered off currently. These configuration information can only be saved if they are configured by Configuration Client Model.

1.17 How Does Provisioner Control Nodes by Grouping?

Generally there are two approaches to implement group control in ESP-BLE-MESH network, group address approach and virtual address approach. And supposing there are 10 devices, i.e., five devices with blue lights and five devices with red lights.

- Method 1: 5 blue lights can subscribe to a group address, 5 red lights subscribe to another one. By sending messages to different group addresses, Provisioner can realize group control.
- Method 2: 5 blue lights can subscribe to a virtual address, 5 red lights subscribe to another one. By sending messages to different virtual addresses, Provisioner can realize group control.

1.18 How Does Provisioner Add Nodes to Multiple Subnets?

Provisioner can add multiple NetKeys to nodes during configuration, and nodes sharing the same NetKey belong to the same subnet. Provisioner can communicate with nodes on different subnets by using different NetKeys.

1.19 How Does ProvIsioner Know If a Node in the Mesh Network Is Offline?

Node offline is usually defined as: the condition that the node cannot be properly communicated with other nodes in the mesh network due to power failure or some other reasons.

There is no connection between nodes and nodes in the ESP-BLE-MESH network. They communicate with each other through advertising channels.

An example is given here to show how to detect a node is offline by Provisioner.

- The node can periodically send heartbeat messages to Provisioner. And if Provisioner failed to receive heartbeat messages in a certain period, the node is considered to be offline.

Note: The heartbeat message should be designed into a single package (less than 11 bytes), so the transmission and reception of it can be more efficient.

1.20 What Operations Should Be Performed When Provisioner Removes Nodes from the Network?

Usually when Provisioner tries to remove node from the mesh network, the procedure includes three main steps:

- Firstly, Provisioner adds the node that need to be removed to the "blacklist".
- Secondly, Provisioner performs the *Key Refresh procedure*.
- Lastly, the node performs node reset procedure, and switches itself to an unprovisioned device.

1.21 In the Key Refresh Procedure, How Does Provisioner Update the Netkey Owned by Nodes?

- Provisioner updates the NetKey of nodes using the *Configuration Client Model* API `esp_ble_mesh_config_client_set_state()` with `net_key_update` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Provisioner updates the AppKey of nodes using the *Configuration Client Model* API `esp_ble_mesh_config_client_set_state()` with `app_key_update` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.

1.22 How Does Provisioner Manage Nodes in the Mesh Network?

ESP-BLE-MESH implements several functions related to basic node management in the example, such as `esp_ble_mesh_store_node_info()`. And ESP-BLE-MESH also provides the API `esp_ble_mesh_provisioner_set_node_name()` which can be used to set the node's local name and the API `esp_ble_mesh_provisioner_get_node_name()` which can be used to get the node's local name.

1.23 What Does Provisioner Need When Trying to Control the Server Model of Nodes?

Provisioner must include corresponding client model before controlling the server model of nodes.

Provisioner shall add its local NetKey and AppKey.

- Provisioner add NetKey by calling the API `esp_ble_mesh_provisioner_add_local_net_key()`.
- Provisioner add AppKey by calling the API `esp_ble_mesh_provisioner_add_local_app_key()`.

Provisioner shall configure its own client model.

- Provisioner bind AppKey to its own client model by calling the API `esp_ble_mesh_provisioner_bind_app_key_to_local_model()`.

1.24 How Does Provisioner Control the Server Model of Nodes?

ESP-BLE-MESH supports all SIG-defined client models. Provisioner can use these client models to control the server models of nodes. And the client models are divided into 6 categories with each category has the corresponding functions.

- Configuration Client Model
  - The API `esp_ble_mesh_config_client_get_state()` can be used to get the `esp_ble_mesh_cfg_client_get_state_t` values of Configuration Server Model.
  - The API `esp_ble_mesh_config_client_set_state()` can be used to set the `esp_ble_mesh_cfg_client_set_state_t` values of Configuration Server Model.

- Health Client Model
  - The API `esp_ble_mesh_health_client_get_state()` can be used to get the `esp_ble_mesh_health_client_get_state_t` values of Health Server Model.
  - The API `esp_ble_mesh_health_client_set_state()` can be used to set the `esp_ble_mesh_health_client_set_state_t` values of Health Server Model.
- Generic Client Models
  - The API `esp_ble_mesh_generic_client_get_state()` can be used to get the `esp_ble_mesh_generic_client_get_state_t` values of Generic Server Models.
  - The API `esp_ble_mesh_generic_client_set_state()` can be used to set the `esp_ble_mesh_generic_client_set_state_t` values of Generic Server Models.
- Lighting Client Models
  - The API `esp_ble_mesh_light_client_get_state()` can be used to get the `esp_ble_mesh_light_client_get_state_t` values of Lighting Server Models.
  - The API `esp_ble_mesh_light_client_set_state()` can be used to set the `esp_ble_mesh_light_client_set_state_t` values of Lighting Server Models.
- Sensor Client Models
  - The API `esp_ble_mesh_sensor_client_get_state()` can be used to get the `esp_ble_mesh_sensor_client_get_state_t` values of Sensor Server Model.
  - The API `esp_ble_mesh_sensor_client_set_state()` can be used to set the `esp_ble_mesh_sensor_client_set_state_t` values of Sensor Server Model.
- **Time and Scenes Client Models**
  - The API `esp_ble_mesh_time_scene_client_get_state()` can be used to get the `esp_ble_mesh_time_scene_client_get_state_t` values of Time and Scenes Server Models.
  - The API `esp_ble_mesh_time_scene_client_set_state()` can be used to set the `esp_ble_mesh_time_scene_client_set_state_t` values of Time and Scenes Server Models.

2. Node Development

2.1 What Kind of Models Are Included by Nodes?

- In ESP-BLE-MESH, nodes are all composed of a series of models with each model implements some functions of the node.
- Model has two types, client model and server model. Client model can get and set the states of server model.
- Model can also be divided into SIG model and vendor model. All behaviors of SIG models are officially defined while behaviors of vendor models are defined by users.

2.2 Is the Format of Messages Corresponding to Each Model Fixed?

- Messages, which consist of opcode and payload, are divided by opcode.
- The type and the format of the messages corresponding to models are both fixed, which means the messages transmitted between models are fixed.

2.3 Which Functions Can Be Used to Send Messages with the Models of Nodes?

- For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` to send messages.
- For server models, users can use the API `esp_ble_mesh_server_model_send_msg()` to send messages.
- For publication, users call the API `esp_ble_mesh_model_publish()` to publish messages.

2.4 How to Achieve the Transmission of Messages Without Packet Loss?

Acknowledged message is needed if users want to transmit messages without packet loss. The default time to wait for corresponding response is set in *CONFIG_BLE_MESH_CLIENT_MSG_TIMEOUT*. If the sender waits for the response until the timer expires, the corresponding timeout event would be triggered.

Note: Response timeout can be set in the API `esp_ble_mesh_client_model_send_msg()`. The default value (4 seconds) would be applied if the parameter `msg_timeout` is set to **0**.

2.5 How to Send Unacknowledged Messages?

For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` with the parameter `need_rsp` set to `false` to send unacknowledged messages.

For server models, the messages sent by using the API `esp_ble_mesh_server_model_send_msg()` are always unacknowledged messages.

2.6 How to Add Subscription Address to Models?

Subscription address can be added through Configuration Client Model.

2.7 What Is the Difference Between Messages Sent and Published by Models?

Messages sent by calling the API `esp_ble_mesh_client_model_send_msg()` or `esp_ble_mesh_server_model_send_msg()` will be sent in the duration determined by the Network Transmit state.

Messages published by calling the API `esp_ble_mesh_model_publish()` will be published determined by the Model Publication state. And the publication of messages is generally periodic or with a fixed number of counts. The publication period and publication count are controlled by the Model Publication state, and can be configured through Configuration Client Model.

2.8 How Many Bytes Can Be Carried When Sending Unsegmented Messages?

The total payload length (which can be set by users) of unsegmented message is 11 octets, so if the opcode of the message is 2 octets, then the message can carry 9-octets of valid information. For vendor messages, due to the 3-octets opcode, the remaining payload length is 8 octets.

2.9 When Should the Relay Feature of Nodes Be Enabled?

Users can enable the Relay feature of all nodes when nodes detected in the mesh network are sparse.

For dense mesh network, users can choose to just enable the Relay feature of several nodes.

And users can enable the Relay feature by default if the mesh network size is unknown.

2.10 When Should the Proxy Feature of Node Be Enabled?

If the unprovisioned device is expected to be provisioned by a phone, then it should enable the Proxy feature since almost all the phones do not support sending ESP-BLE-MESH packets through advertising bearer currently. And after the unprovisioned device is provisioned successfully and becoming a Proxy node, it will communicate with the phone using GATT bearer and using advertising bearer to communicate with other nodes in the mesh network.

2.11 How to Use the Proxy Filter?

The Proxy filter is used to reduce the number of Network PDUs exchanged between a Proxy Client (e.g., the phone) and a Proxy Server (e.g., the node). And with the Proxy filter, Proxy Client can explicitly request to receive only mesh messages with certain destination addresses from Proxy Server.

2.12 When a Message Can Be Relayed by a Relay Node?

If a message need to be relayed, the following conditions should be met.

- The message is in the mesh network.
- The message is not sent to the unicast address of the node.
- The value of TTL in the message is greater than 1.

2.13 If a Message Is Segmented into Several Segments, Should the Other Relay Nodes Just Relay When One of These Segments Is Received or Wait Until the Message Is Received Completely?

Relay nodes will forward segments when one of them are received rather than keeping waiting until all the segments are received.

2.14 What Is the Principle of Reducing Power Consumption Using Low Power Feature?

- When the radio is turned on for listening, the device is consuming energy. When low power feature of the node is enabled, it will turn off its radio in the most of the time.
- And cooperation is needed between low power node and friend node, thus low power node can receive messages at an appropriate or lower frequency without the need to keep listening.
- When there are some new messages for low power node, its friend node will store the messages for it. And low power node can poll friend nodes to see if there are new messages at a fixed interval.

2.15 How to Continue the Communication on the Network After Powering-down and Powering-up Again?

Enable the configuration `Store ESP-BLE-MESH Node configuration persistently` in *menuconfig*.

2.16 How to Send out the Self-test Results of Nodes?

It is recommended that nodes can publish its self-test results periodically through Health Server Model.

2.17 How to Transmit Information Between Nodes?

One possible application scenario for transmitting information between nodes is that spray nodes would be triggered once smoke alarm detected high smoke concentration. There are two approaches in implementation.

- Approach 1 is that spray node subscribes to a group address. When smoke alarm detects high smoke concentration, it will publish a message whose destination address is the group address which has been subscribed by spray node.
- Approach 2 is that Provisioner can configure the unicast address of spray node to the smoke alarm. When high smoke concentration is detected, smoke alarm can use send messages to the spray node with the spray node's unicast address as the destination address.

2.18 Is Gateway a Must for Nodes Communication?

- Situation 1: nodes only communicate within the mesh network. In this situation, no gateway is need. ESP-BLE-MESH network is a flooded network, messages in the network have no fixed paths, and nodes can communicate with each other freely.
- Situation 2: if users want to control the nodes remotely, for example turn on some nodes before getting home, then a gateway is needed.

2.19 When Will the IV Update Procedure Be Performed?

IV Update procedure would be performed once sequence number of messages sent detected by the bottom layer of node reached a critical value.

2.20 How to Perform IV Update Procedure?

Nodes can perform IV Update procedure with Secure Network Beacon.

3. ESP-BLE-MESH and Wi-Fi Coexistence

3.1 Which Modes Does Wi-Fi Support When it Coexists with ESP-BLE-MESH?

Currently only Wi-Fi station mode supports the coexistence.

3.2 Why Is the Wi-Fi Throughput So Low When Wi-Fi and ESP-BLE-MESH Coexist?

Some configurations in menuconfig shall be enabled to support PSRAM.

- `ESP32-C3-specific > Support for external, SPI-connected RAM > Try to allocate memories of Wi-Fi and LWIP...`
- `Bluetooth > Bluedroid Enable > BT/BLE will first malloc the memory from the PSRAM`
- `Bluetooth > Bluedroid Enable > Use dynamic memory allocation in BT/BLE stack`
- `Bluetooth > Bluetooth controller > BLE full scan feature supported`
- `Wi-Fi > Software controls Wi-Fi/Bluetooth coexistence > Wi-Fi`

4. Fast Provisioning

4.1 Why Is Fast Provisioning Needed?

Normally when they are several unprovisioned devices, users can provision them one by one. But when it comes to a large number of unprovisioned devices (e.g., 100), provisioning them one by one will take huge amount of time. With fast provisioning, users can provision 100 unprovisioned devices in about 50 seconds.

4.2 Why EspBleMesh App Would Wait for a Long Time During Fast Provisioning?

After the App provisioned one Proxy node, it will disconnect from the App during fast provisioning, and reconnect with the App when all the nodes are provisioned.

4.3 Why Is the Number of Node Addresses Displayed in the App Is More than That of Existing Node Addresses?

Each time after a fast provisioning process, and before starting a new one, the node addresses in the App should be cleared, otherwise the number of the node address will be incorrect.

4.4 What Is the Usage of the count Value Which Was Input in EspBleMesh App?

The **count** value is provided to the Proxy node which is provisioned by the App so as to determine when to start Proxy advertising in advance.

4.5 When will Configuration Client Model of the node running fast_prov_server example start to work?

Configuration Client Model will start to work after the Temporary Provisioner functionality is enabled.

4.6 Will the Temporary Provisioner Functionality Be Enabled All the Time?

After the nodes receive messages used to turn on/off lights, all the nodes will disable its Temporary Provisioner functionality and become nodes.

5. Log Help You can find meaning of errors or warnings when they appear at the bottom of ESP-BLE-MESH stack.

5.1 What Is the Meaning of Warning `ran out of retransmit attempts?`

When the node transmits a segmented message, and due to some reasons, the receiver does not receive the complete message. Then the node will retransmit the message. When the retransmission count reaches the maximum number, which is 4 currently, then this warning will appear.

5.2 What Is the Meaning of Warning `Duplicate found in Network Message Cache?`

When the node receives a message, it will compare the message with the ones stored in the network cache. If the same has been found in the cache, which means it has been received before, then the message will be dropped.

5.3 What Is the Meaning of Warning `Incomplete timer expired?`

When the node does not receive all the segments of a segmented message during a certain period (e.g., 10 seconds), then the Incomplete timer will expire and this warning will appear.

5.4 What Is the Meaning of Warning `No matching TX context for ack?`

When the node receives a segment ack and it does not find any self-send segmented message related with this ack, then this warning will appear.

5.5 What Is the Meaning of Warning `No free slots for new incoming segmented messages?`

When the node has no space for receiving new segmented message, this warning will appear. Users can make the space larger through the configuration *CONFIG_BLE_MESH_RX_SEG_MSG_COUNT*.

5.6 What Is the Meaning of Error `Model not bound to Appkey 0x0000?`

When the node sends messages with a model and the model has not been bound to the AppKey with AppKey Index 0x000, then this error will appear.

5.7 What Is the Meaning of Error `Busy sending message to DST xxxx?`

This error means client model of the node has transmitted a message to the target node and now is waiting for a response, users can not send messages to the same node with the same unicast address. After the corresponding response is received or timer is expired, then another message can be sent.

6. Example Help

6.1 How Are the ESP-BLE-MESH Callback Functions Classified?

- The API `esp_ble_mesh_register_prov_callback()` is used to register callback function used to handle provisioning and networking related events.
- The API `esp_ble_mesh_register_config_client_callback()` is used to register callback function used to handle Configuration Client Model related events.
- The API `esp_ble_mesh_register_config_server_callback()` is used to register callback function used to handle Configuration Server Model related events.
- The API `esp_ble_mesh_register_health_client_callback()` is used to register callback function used to handle Health Client Model related events.
- The API `esp_ble_mesh_register_health_server_callback()` is used to register callback function used to handle Health Server Model related events.

- The API `esp_ble_mesh_register_generic_client_callback()` is used to register callback function used to handle Generic Client Models related events.
- The API `esp_ble_mesh_register_light_client_callback()` is used to register callback function used to handle Lighting Client Models related events.
- The API `esp_ble_mesh_register_sensor_client_callback()` is used to register callback function used to handle Sensor Client Model related events.
- The API `esp_ble_mesh_register_time_scene_client_callback()` is used to register callback function used to handle Time and Scenes Client Models related events.
- The API `esp_ble_mesh_register_custom_model_callback()` is used to register callback function used to handle vendor model and unrealized server models related events.

7. Others

7.1 How to Print the Message Context?

The examples use `ESP_LOG_BUFFER_HEX()` to print the message context while the ESP-BLE-MESH protocol stack uses `bt_hex()`.

7.2 Which API Can Be Used to Restart ESP32-C3?

The API `esp_restart()`.

7.3 How to Monitor the Remaining Space of the Stack of a Task?

The API `vTaskList()` can be used to print the remaining space of the task stack periodically.

7.4 How to Change the Level of Log Without Changing the Menuconfig Output Level?

The API `esp_log_level_set()` can be used to change the log output level rather than using menuconfig to change it.

ESP-BLE-MESH Terminology

Table 13: Table 1 ESP-BLE-MESH Terminology - Role

Term	Official Definition	Detailed Explanation
Unprovisioned Device	A device that is not a member of a mesh network is known as an unprovisioned device.	Examples: lighting devices, temperature control devices, manufacturing equipment and electric doors, etc.
Node	A node is a provisioned device.	The role of unprovisioned device will change to node after being provisioned to ESP-BLE-MESH network. Nodes (such as lighting devices, temperature control devices, manufacturing equipment, and electric doors) are devices that can send, receive, or relay messages in ESP-BLE-MESH network, and they can optionally support one or more subnets.
Relay Node	A node that supports the Relay feature and has the Relay feature enabled is known as a Relay node.	Relay nodes can receive and resend ESP-BLE-MESH messages, so the messages can be transferred further. Users can decide whether or not to enable forwarding function of nodes according to nodes' status. Messages can be relayed for multiple times, and each relay is considered as a "hop". Messages can hop up to 126 times, which is enough for message transmission in a wide area.
Proxy Node	A node that supports the Proxy feature and has the Proxy feature enabled is known as a Proxy node.	Proxy nodes receive messages from one bearer (it generally includes advertising bearer and GATT bearer) and resend it from another one. The purpose is to connect communication equipment that only support GATT bearer to ESP-BLE-MESH network. Generally, mobile apps need a Proxy node to access Mesh network. Without Proxy nodes, mobile apps cannot communicate with members in Mesh network.
Friend Node	A node that supports the Friend feature, has the Friend feature enabled, and has a friendship with a node that supports the Low Power feature is known as a Friend node.	Friend node, like the backup of Low Power node (LPN), can store messages that are sent to Low Power node and security updates; the stored information will be transferred to Low Power node when Low Power node needs it. Low Power node must establish "friendship" with another node that supports the Friend Feature to reduce duty cycle of its receiver, thus power consumption of Low Power node can be reduced. Low Power node needs to find a Friend node to establish a friendship with it. The process involved is called "friendship establishment". Cooperation between Low Power node and Friend nodes enables Low Power node to schedule the use of the radio, thus Low Power node can receive messages at an appropriate or lower frequency without the need of keeping listening. Low Power node will poll Friend node to see if there is new message.
Low Power Node	A node that supports the Low Power feature and has a friendship with a node that supports the Friend feature is known as a Low Power node.	By polling, Low Power node gets information from Friend node, such as messages, security updates, and etc.
Provisioner	A node that is capable of adding a device to a mesh network.	The device that can provision unprovisioned devices is called a Provisioner. This process usually needs to be implemented through an app that is typically provided by the product manufacturer and can be used on a gateway, a smartphone, tablet or other carriers.

Table 14: Table 2 ESP-BLE-MESH Terminology - Composition

Term	Official Definition	Detailed Explanation
State	A value representing a condition of an element that is exposed by an element of a node.	Each node in a ESP-BLE-MESH network has an independent set of state values that indicate certain states of the device, like brightness, and color of lighting device. Change of state value will lead to change of the physical state of devices. For example, changing the on/off state of a device is actually turning on/off the device.
Model	A model defines the basic functionality of a node.	A node may contain multiple models, and each model defines basic functionalities of nodes, like the states needed by the nodes, the messages controlling the states, and actions resulted from messages handling. The function implementation of the nodes is based on models, which can be divided into SIG Model and Vendor Model, with the former defined by SIG and latter defined by users.
Element	An addressable entity within a device.	A node can contain one or more elements, with each having a unicast address and one or more models, and the models contained by the same element must not be the same.
Composition Data State	The Composition Data state contains information about a node, the elements it includes, and the supported models.	By reading the value of the Composition Data state, users can know basic information of the node, such as the number of elements, and the models in each element. Provisioner gets this message to further provision the device, such as configuring subscription address and publishing address of nodes.

Table 15: Table 3 ESP-BLE-MESH Terminology - Features

Term	Official Definition	Detailed Explanation
Low Power Feature	The ability to operate within a mesh network at significantly reduced receiver duty cycles only in conjunction with a node supporting the Friend feature.	Low Power feature reduces power consumption of nodes. When a Low Power node is searching for a Friend node, and there are multiple Friend nodes nearby, it selects the most suitable Friend node through algorithm.
Friend Feature	The ability to help a node supporting the Low Power feature to operate by storing messages destined for those nodes.	By enabling friend feature, the node can help to store information for Low Power node. The nodes enabled with friend feature may cause more power and memory consumption.
Relay Feature	The ability to receive and retransmit mesh messages over the advertising bearer to enable larger networks.	The relay feature enables ESP-BLE-MESH messages to hop among nodes for multiple times, and the transmission distance can exceed the range of direct radio transmission between two nodes, thereby covering the entire network. When a node is enabled with the relay feature to relay messages, it only relays the messages of its own subnet, and does not relay the messages of other subnets. The data integrity will not be considered when the node enabled with relay feature relays segmented messages. The node would relay every segmented message once it receives one rather than waiting for the complete message.
Proxy Feature	The ability to receive and retransmit mesh messages between GATT and advertising bearers.	The purpose of the proxy feature is to allow nodes without an advertising bearer to access the ESP-BLE-MESH network. The proxy feature is typically used in nodes that need to connect to mobile apps.

Table 16: Table 4 ESP-BLE-MESH Terminology - Provisioning

Term	Official Definition	Detailed Explanation
PB-ADV	PB-ADV is a provisioning bearer used to provision a device using Generic Provisioning PDUs over the advertising channels.	PB-ADV transfers packets generated during the provisioning process over the advertising channels. This way can only be used for provisioning when provisioner and unprovisioned device both support PB-ADV.
PB-GATT	PB-GATT is a provisioning bearer used to provision a device using Proxy PDUs to encapsulate Provisioning PDUs within the Mesh Provisioning Service.	PB-GATT uses connection channels to transfer packets generated during the provisioning process. If an unprovisioned device wants to be provisioned through this method, it needs to implement the related Mesh Provisioning Service. Unprovisioned devices which don't implement such service cannot be provisioned into mesh network through PB-GATT bearer.
PB-Remote	The PB-Remote provisioning bearer uses the existing mesh network to provision an unprovisioned device that is not within immediate radio range of the Provisioner.	PB-Remote uses the PB-ADV bearer or the PB-GATT bearer for the last hop to the unprovisioned device.
Provisioning	Provisioning is a process of adding an unprovisioned device to a mesh network, managed by a Provisioner.	The process of provisioning turns the "unprovisioned device" into a "node", making it a member of the ESP-BLE-MESH network.
Authentication Method	Authentication is a step during the provisioning of nodes.	There are four authentication methods for unprovisioned devices: Output OOB, Input OOB, Static OOB, and No OOB.
Input OOB	Input Out-of-Band	For example, a Provisioner generates and displays a random number, and then prompts users to take appropriate actions to input the random number into the unprovisioned device. Taking lighting switch as an example, users can press the button for several times in a certain period of time to input the random number displayed on the Provisioner. Authentication method of the Input OOB is similar to that of Output OOB, but the role of the device is reversed.
Output OOB	Output Out-of-Band	For example, an unprovisioned device will choose a random number and output the number in a way that is compatible with its functionality. If the unprovisioned device is a bulb, it can flash a specified number of times. If the unprovisioned device has an LCD screen, the random number can display as a multi-digit value. Users who start provisioning should input the observed number to authenticate the unprovisioned device.
Static OOB	Static Out-of-Band	Authentication method of Static OOB: use Static OOB information. Use 0 as Static OOB information if No OOB information is needed. Use Static OOB information to authenticate devices which are going through provisioning if OOB information is needed.
No OOB	No Out-of-Band	Authentication method of No OOB: Set the value of the Static OOB field to 0. Using this way is like not authenticating the unprovisioned devices.
Certificate based Provisioning	Certificate-based Out-of-Band	The certificate-based provisioning feature makes use of Public Key Infrastructure to authenticate unprovisioned device's public key and UUID information.

Table 17: Table 5 ESP-BLE-MESH Terminology - Address

Term	Official Definition	Detailed Explanation
Unassigned Address	This is a special address type, with a value of 0x0000. Its use indicates that an Element has not yet been configured or had a Unicast Address assigned to it.	The addresses owned by elements which has not been configured yet or no address has been allocated are unassigned addresses. These elements will not be used for messages transfer because they have no fixed address. Unassigned address is recommended to set as the value of the address before setting the address of user code.
Unicast Address	A unicast address is a unique address allocated to each element.	During provisioning, the Provisioner will assign a unicast address to each element of node within the life cycle of the nodes in the network. A unicast address may appear in the source/destination address field of a message. Messages sent to a unicast address can only be processed by the element that owns the unicast address.
Virtual Address	A virtual address represents a set of destination addresses. Each virtual address logically represents a Label UUID, which is a 128-bit value that does not have to be managed centrally.	Associated with specific UUID labels, a virtual address may serve as the publishing or subscription address of the model. A UUID label is a 128-bit value associated with elements of one or more nodes. For virtual addresses, the 15th and 14th bits are set to 1 and 0 respectively; bits from 13th to 0 are set to hash values (providing 16384 hash values). The hash is a derivation of the Label UUID. To use subscribing elements to check the full 128-bit UUID is very inefficient while hash values provide a more efficient way to determine which elements that which messages are finally sent to.
Group Address	A group address is an address that is programmed into zero or more elements	Group address is another kind of multicast address in the ESP-BLE-MESH network, which is usually used to group nodes. A message sent to the all-proxies address shall be processed by the primary element of all nodes that have the proxy functionality enabled. A message sent to the all-friends address shall be processed by the primary element of all nodes that have the friend functionality enabled. A message sent to the all-relays address shall be processed by the primary element of all nodes that have the relay functionality enabled. A message sent to the all-nodes address shall be processed by the primary element of all nodes.

Table 18: Table 6 ESP-BLE-MESH Terminology - Security

Term	Official Definition	Detailed Explanation
Device Key (DevKey)	There is also a device key, which is a special application key that is unique to each node, is known only to the node and a Configuration Client, and is used to secure communications between the node and a Configuration Client.	The device key enables you to provision the devices, configure the nodes. The device key is used to encrypt Configuration Messages, i.e., the message transferred between the Provisioner and the node when the device is configured.
Application Key (AppKey)	Application keys are used to secure communications at the upper transport layer.	Application key is used for decryption of application data before delivering application data to application layer and encryption of them during the delivery of application layer. Some nodes in the network have a specific purpose and can restrict access to potentially sensitive data based on the needs of the application. With specific application keys, these nodes are associated with specific applications. Generally speaking, the fields using different application keys include security (access control of buildings, machine rooms and CEO offices), lighting (plant, exterior building and sidewalks) and HVAC systems. Application keys are bound to Network keys. This means application keys are only used in a context of a Network key they are bound to. An application key shall only be bound to a single Network key.
Flooding Security Material	The flooding security material is derived from the network key (NetKey) and can be used by other nodes in the same network. Messages encrypted with flooding security material can be decoded by any node in the same network.	The corresponding friendship messages encrypted with the friendship security material: 1. Friend Poll, 2. Friend Update, 3. Friend Subscription List, add/delete/confirm, 4. The Stored Messages" sent by friend nodes to Low Power node. The corresponding friendship messages encrypted with the flooding security material: 1. Friend Clear, 2. Friend Clear Confirm. Based on the setup of the applications, the messages sent from the Low Power node to the friend nodes will be encrypted with the friendship security material or flooding security material, with the former being used by the messages transmitted between Low Power node and friend nodes and the latter being used by other network messages.
Directed Security Material	The directed security material is derived from the network key (NetKey) and can be used by other nodes in the directed forwarding path.	The messages that need to be forwarded through the directed forwarding path need to be encrypted with the directed security material. Messages encrypted with directed security material can be decoded by any node in the same directed forwarding path.

Table 19: Table 7 ESP-BLE-MESH Terminology - Message

Term	Official Definition	Detailed Explanation
Reassembly/Segmentation	Segmentation and reassembly (SAR) is a method of communication network, which is divided into small units before transmitting packets and reassembled in a proper order at the communication receiving end.	The lower transport layer will automatically segment the message whose size is too big. The receiving end will return a response message, and the transmitting end will send the data packet again that the receiving end does not receive according to the response message. This is automatically completed by the lower transport layer. Unsegmented messages have at most 15 bytes, of which 4 bytes are transMIC, so the remaining is 11 bytes; in the case of segmentation, there are 12 valid bytes in the first several packets, and 8 in the last one. Special case: A shorter packet requires mandatory segmentation from lower transport layer, in which case the valid byte is 8 bytes.
Unacknowledged/Acknowledged	There are two types of messages: Unacknowledged or Acknowledged	Based on the whether or not the receiving end needs to send the response message, the messages sent are divided into two kinds. The sending end should set the maximum number of retransmission.

Table 20: Table 8 ESP-BLE-MESH Terminology - Foundation Models

Term	Official Definition	Detailed Explanation
Configuration Server Model	This model is used to represent a mesh network configuration of a device.	The node must contain the Configuration Server Model, which is responsible for maintaining configuration-related states. The states that Configuration Server Model maintains include: NetKey List, AppKey List, Model to AppKey List, Node Identity, Key Refresh Phase, Heartbeat Publish, Heartbeat Subscription, Network Transmit, Relay Retransmit etc.
Configuration Client Model	The model is used to represent an element that can control and monitor the configuration of a node.	The Configuration Client Model uses messages to control the state maintained by the Configuration Server Model. The Provisioner must contain the Configuration Client Model, with which the configuration messages, like Configuration Composition Data Get can be sent.
Health Server Model	This model is used to represent a mesh network diagnostics of a device.	The Health Server Model is primarily used by devices to check their states and see if there is an error. The states maintained by Health Server model include: Current Fault, Registered Fault, Health Period, and Attention Timer.
Health Client Model	The model is used to represent an element that can control and monitor the health of a node.	The Health Client Model uses messages to control the state maintained by the Health Server Model. The model can get the self-test information of other nodes through the message "Health Fault Get".
Remote Provisioning Server model	The model is used to support the functionality of provisioning a remote device over the mesh network and to perform the Node Provisioning Protocol Interface procedures.	The Remote Provisioning Server model is a root model and a main model that does not extend any other models.
Remote Provisioning Client model	The model is used to support the functionality of provisioning devices into a mesh network by interacting with a mesh node that supports the Remote Provisioning Server model.	The Remote Provisioning Client is a root model and a main model that does not extend any other models. The Remote Provisioning Client may operate on states defined by the Remote Provisioning Server model using Remote Provisioning messages.
Directed Forwarding Configuration Server model	The model is used to support the configuration of the directed forwarding functionality of a node.	The Directed Forwarding Configuration Server model is a main model that extends the Configuration Server model.
Directed Forwarding Configuration Client model	The model is used to support the functionality of a node that can configure the directed forwarding functionality of another node.	The Directed Forwarding Configuration Client model is a root model and a main model that does not extend any other models. The Directed Forwarding Configuration Client model may operate on states defined by the Directed Forwarding Configuration Server model using Directed Forwarding Configuration messages.
Bridge Configuration Server model	The model is used to support the configuration of the subnet bridge functionality of a node.	The Bridge Configuration Server model is a main model that extends the Configuration Server model.
Bridge Configuration	The model is used to support the functionality of a node that can configure the subnet bridge functionality of another node.	The Bridge Configuration Client model is a root model and a main model that does not extend any other models. The Bridge Configuration Client model may operate on states defined by the Bridge Configuration Server model using Bridge

Table 21: Table 9 ESP-BLE-MESH Terminology - Network Management

Term	Official Definition	Detailed Explanation
Key Refresh procedure	This procedure is used when the security of one or more network keys and/or one or more of the application keys has been compromised or could be compromised.	Key Refresh Procedure is used to update network key and application key of ESP-BLE-MESH network. Key Refresh Procedure is used when the security of one or more network keys and/or one or more application keys is threatened or potentially threatened. Keys are usually updated after some nodes in the network are removed.
IV (Initialization Vector) Update Procedure	A node can also use an IV Update procedure to signal to peer nodes that it is updating the IV Index.	The IV Update procedure is used to update the value of ESP-BLE-MESH network's IV Index. This value is related to the random number required for message encryption. To ensure that the value of the random number is not repeated, this value is periodically incremented. IV Index is a 32-bit value and a shared network resource. For example, all nodes in a mesh network share the same IV Index value. Starting from 0x00000000, the IV Index increments during the IV Update procedure and maintained by a specific process, ensuring the IV Index shared in the mesh network is the same. This can be done when the node believes that it has the risk of exhausting its sequence number, or when it determines that another node is nearly exhausting its sequence number. Note: The update time must not be less than 96 hours. It can be triggered when a secure network beacon is received, or when the node determines that its sequence number is greater than a certain value.

4.16 ESP-WIFI-MESH

This guide provides information regarding the ESP-WIFI-MESH protocol. Please see the *ESP-WIFI-MESH API Reference* for more information about API usage.

4.16.1 Overview

ESP-WIFI-MESH is a networking protocol built atop the Wi-Fi protocol. ESP-WIFI-MESH allows numerous devices (henceforth referred to as nodes) spread over a large physical area (both indoors and outdoors) to be interconnected under a single WLAN (Wireless Local-Area Network). ESP-WIFI-MESH is self-organizing and self-healing meaning the network can be built and maintained autonomously.

The ESP-WIFI-MESH guide is split into the following sections:

1. *Introduction*
2. *ESP-WIFI-MESH Concepts*
3. *Building a Network*
4. *Managing a Network*
5. *Data Transmission*
6. *Channel Switching*
7. *Performance*
8. *Further Notes*

4.16.2 Introduction

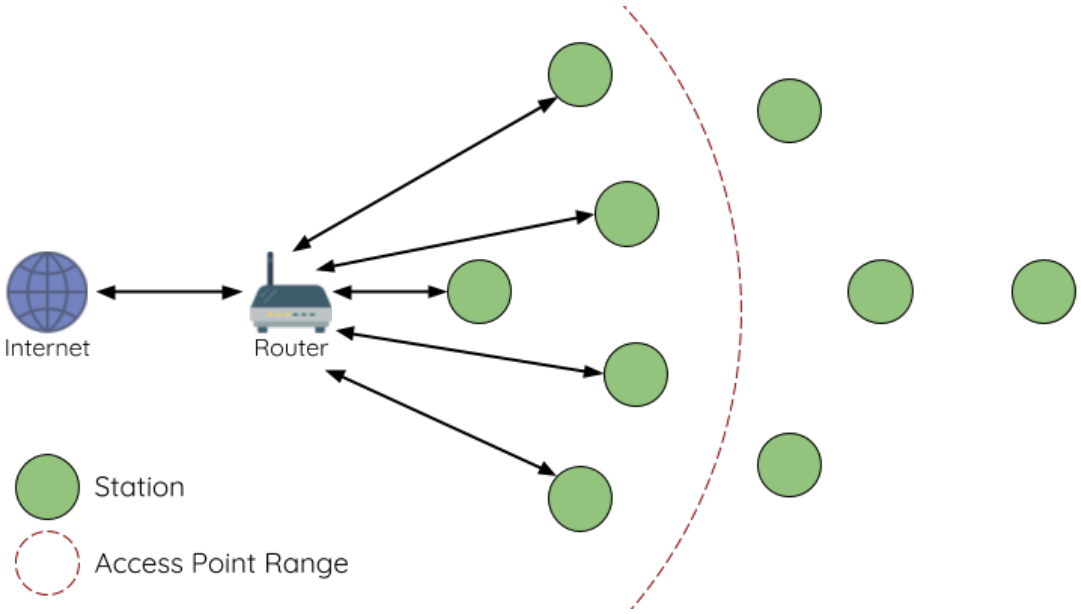

Fig. 25: Traditional Wi-Fi Network Architecture

A traditional infrastructure Wi-Fi network is a point-to-multipoint network where a single central node known as the access point (AP) is directly connected to all other nodes known as stations. The AP is responsible for arbitrating and forwarding transmissions between the stations. Some APs also relay transmissions to/from an external IP network via a router. Traditional infrastructure Wi-Fi networks suffer the disadvantage of limited coverage area due to the requirement that every station must be in range to directly connect with the AP. Furthermore, traditional Wi-Fi networks are susceptible to overloading as the maximum number of stations permitted in the network is limited by the capacity of the AP.

ESP-WIFI-MESH differs from traditional infrastructure Wi-Fi networks in that nodes are not required to connect to a central node. Instead, nodes are permitted to connect with neighboring nodes. Nodes are mutually responsible for relaying each others transmissions. This allows an ESP-WIFI-MESH network to have much greater coverage area as nodes can still achieve interconnectivity without needing to be in range of the central node. Likewise, ESP-WIFI-MESH is also less susceptible to overloading as the number of nodes permitted on the network is no longer limited by a single central node.

4.16.3 ESP-WIFI-MESH Concepts

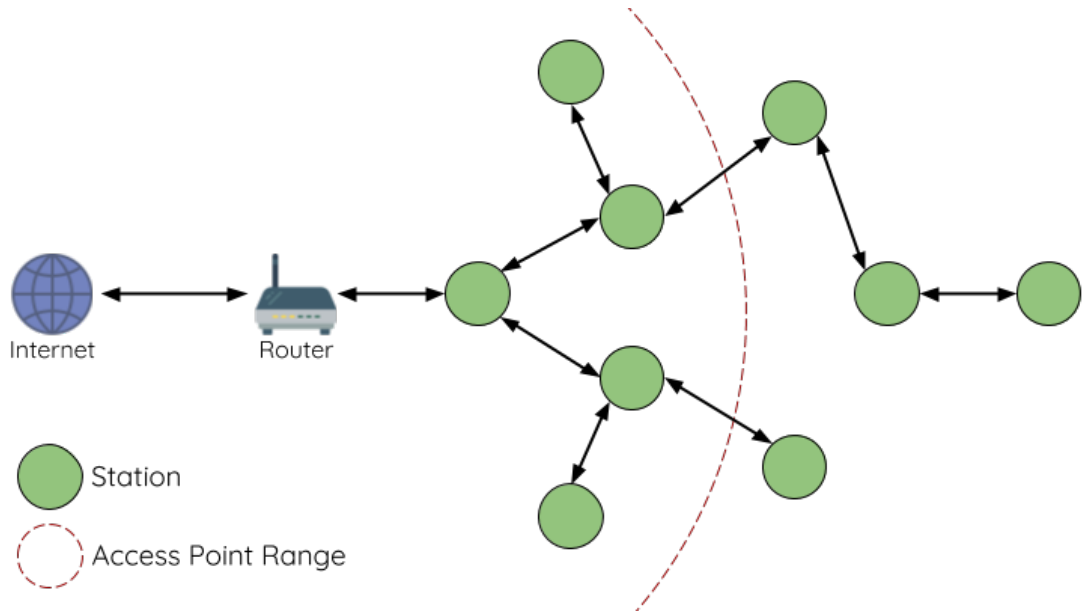

Fig. 26: ESP-WIFI-MESH Network Architecture

Terminology

Term	Description
Node	Any device that **is** or **can be** part of an ESP-WIFI-MESH network
Root Node	The top node in the network
Child Node	A node X is a child node when it is connected to another node Y where the connection makes node X more distant from the root node than node Y (in terms of number of connections).
Parent Node	The converse notion of a child node
Descendant Node	Any node reachable by repeated proceeding from parent to child
Sibling Nodes	Nodes that share the same parent node
Connection	A traditional Wi-Fi association between an AP and a station. A node in ESP-WIFI-MESH will use its station interface to associate with the softAP interface of another node, thus forming a connection. The connection process includes the authentication and association processes in Wi-Fi.
Upstream Connection	The connection from a node to its parent node
Downstream Connection	The connection from a node to one of its child nodes
Wireless Hop	The portion of the path between source and destination nodes that corresponds to a single wireless connection. A data packet that traverses a single connection is known as **single-hop** whereas traversing multiple connections is known as **multi-hop**.
Subnetwork	A subnetwork is subdivision of an ESP-WIFI-MESH network which consists of a node and all of its descendant nodes. Therefore the subnetwork of the root node consists of all nodes in an ESP-WIFI-MESH network.
MAC Address	Media Access Control Address used to uniquely identify each node or router within an ESP-WIFI-MESH network.
DS	Distribution System (External IP Network)

Tree Topology

ESP-WIFI-MESH is built atop the infrastructure Wi-Fi protocol and can be thought of as a networking protocol that combines many individual Wi-Fi networks into a single WLAN. In Wi-Fi, stations are limited to a single connection with an AP (upstream connection) at any time, whilst an AP can be simultaneously connected to multiple stations (downstream connections). However ESP-WIFI-MESH allows nodes to simultaneously act as a station and an AP.

Therefore a node in ESP-WIFI-MESH can have **multiple downstream connections using its softAP interface**, whilst simultaneously having **a single upstream connection using its station interface**. This naturally results in a tree network topology with a parent-child hierarchy consisting of multiple layers.

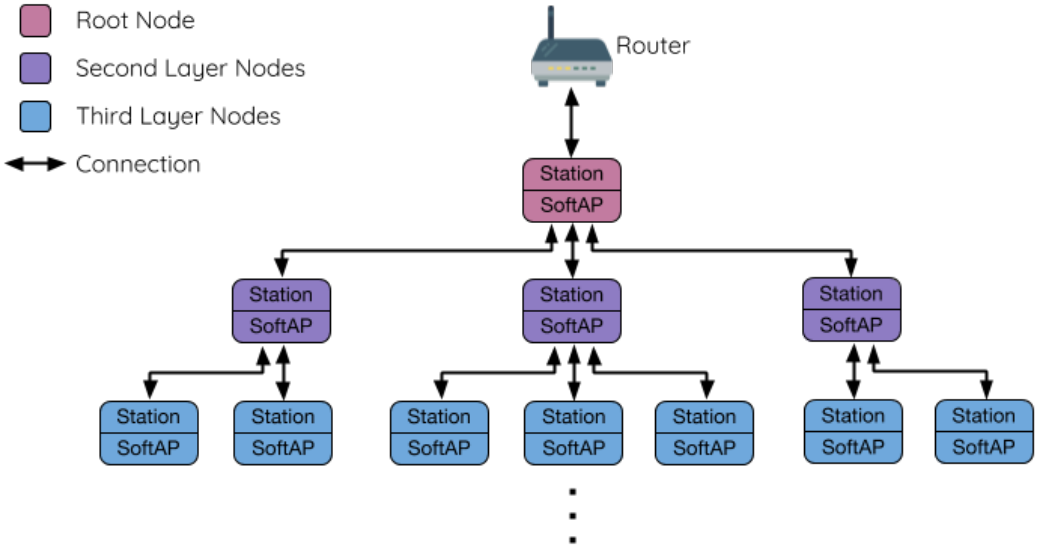

Fig. 27: ESP-WIFI-MESH Tree Topology

ESP-WIFI-MESH is a multiple hop (multi-hop) network meaning nodes can transmit packets to other nodes in the network through one or more wireless hops. Therefore, nodes in ESP-WIFI-MESH not only transmit their own packets, but simultaneously serve as relays for other nodes. Provided that a path exists between any two nodes on the physical layer (via one or more wireless hops), any pair of nodes within an ESP-WIFI-MESH network can communicate.

Note: The size (total number of nodes) in an ESP-WIFI-MESH network is dependent on the maximum number of layers permitted in the network, and the maximum number of downstream connections each node can have. Both of these variables can be configured to limit the size of the network.

Node Types

Root Node: The root node is the top node in the network and serves as the only interface between the ESP-WIFI-MESH network and an external IP network. The root node is connected to a conventional Wi-Fi router and relays packets to/from the external IP network to nodes within the ESP-WIFI-MESH network. **There can only be one root node within an ESP-WIFI-MESH network** and the root node's upstream connection may only be with the router. Referring to the diagram above, node A is the root node of the network.

Leaf Nodes: A leaf node is a node that is not permitted to have any child nodes (no downstream connections). Therefore a leaf node can only transmit or receive its own packets, but cannot forward the packets of other nodes. If a node is situated on the network's maximum permitted layer, it will be assigned as a leaf node. This prevents the node from forming any downstream connections thus ensuring the network does not add an extra layer. Some nodes without a softAP interface (station only) will also be assigned as leaf nodes due to the requirement of a softAP interface for any downstream connections. Referring to the diagram above, nodes L/M/N are situated on the networks maximum permitted layer hence have been assigned as leaf nodes .

Intermediate Parent Nodes: Connected nodes that are neither the root node or a leaf node are intermediate parent nodes. An intermediate parent node must have a single upstream connection (a single parent node), but can have zero to multiple downstream connections (zero to multiple child nodes). Therefore an intermediate parent node can transmit and receive packets, but also forward packets sent from its upstream and downstream connections. Referring to the diagram above, nodes B to J are intermediate parent nodes. **Intermediate parent nodes without**

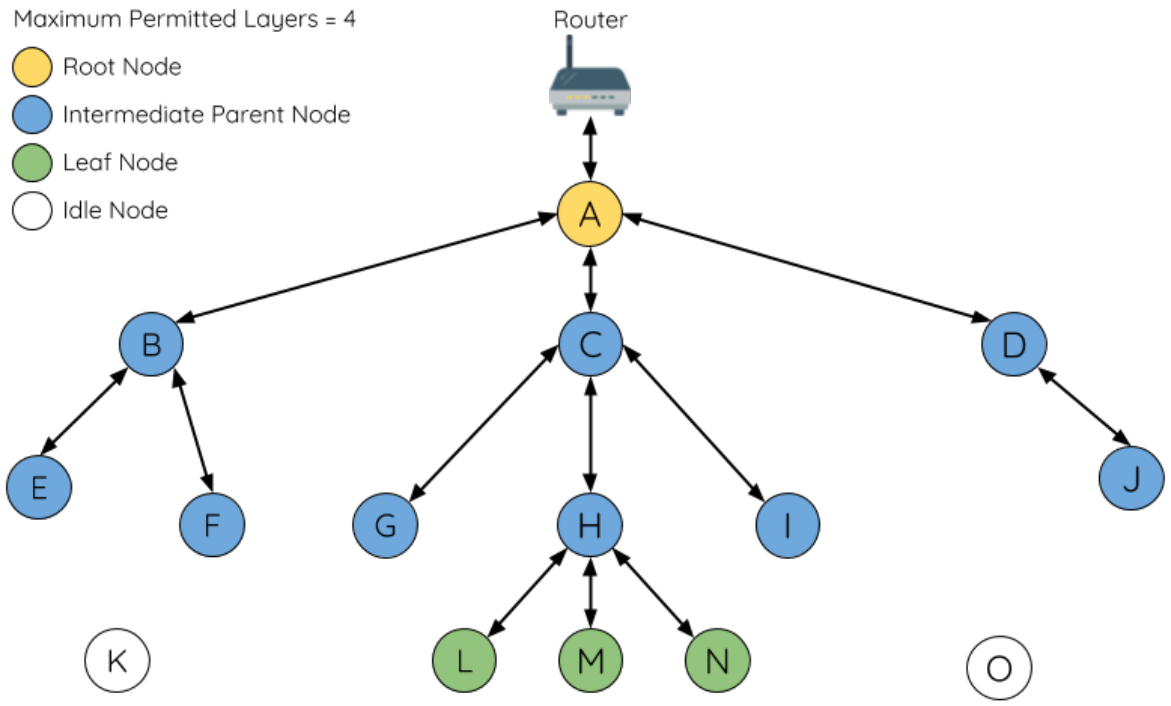

Fig. 28: ESP-WIFI-MESH Node Types

downstream connections such as nodes E/F/G/I/J are not equivalent to leaf nodes as they are still permitted to form downstream connections in the future.

Idle Nodes: Nodes that have yet to join the network are assigned as idle nodes. Idle nodes will attempt to form an upstream connection with an intermediate parent node or attempt to become the root node under the correct circumstances (see *Automatic Root Node Selection*). Referring to the diagram above, nodes K and O are idle nodes.

Beacon Frames & RSSI Thresholding

Every node in ESP-WIFI-MESH that is able to form downstream connections (i.e., has a softAP interface) will periodically transmit Wi-Fi beacon frames. A node uses beacon frames to allow other nodes to detect its presence and know of its status. Idle nodes will listen for beacon frames to generate a list of potential parent nodes, one of which the idle node will form an upstream connection with. ESP-WIFI-MESH uses the Vendor Information Element to store metadata such as:

- Node Type (Root, Intermediate Parent, Leaf, Idle)
- Current layer of Node
- Maximum number of layers permitted in the network
- Current number of child nodes
- Maximum number of downstream connections to accept

The signal strength of a potential upstream connection is represented by RSSI (Received Signal Strength Indication) of the beacon frames of the potential parent node. To prevent nodes from forming a weak upstream connection, ESP-WIFI-MESH implements an RSSI threshold mechanism for beacon frames. If a node detects a beacon frame with an RSSI below a preconfigured threshold, the transmitting node will be disregarded when forming an upstream connection.

Panel A of the illustration above demonstrates how the RSSI threshold affects the number of parent node candidates an idle node has.

Panel B of the illustration above demonstrates how an RF shielding object can lower the RSSI of a potential parent node. Due to the RF shielding object, the area in which the RSSI of node X is above the threshold is significantly

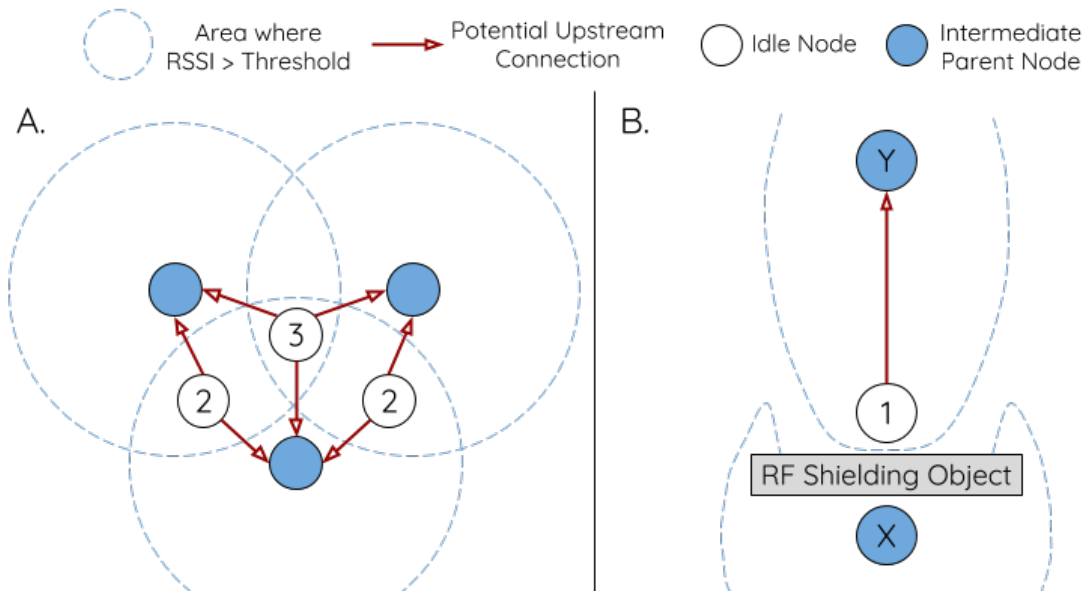

Fig. 29: Effects of RSSI Thresholding

reduced. This causes the idle node to disregard node X even though node X is physically adjacent. The idle node will instead form an upstream connection with the physically distant node Y due to a stronger RSSI.

Note: Nodes technically still receive all beacon frames on the MAC layer. The RSSI threshold is an ESP-WIFI-MESH feature that simply filters out all received beacon frames that are below the preconfigured threshold.

Preferred Parent Node

When an idle node has multiple parent nodes candidates (potential parent nodes), the idle node will form an upstream connection with the **preferred parent node**. The preferred parent node is determined based on the following criteria:

- Which layer the parent node candidate is situated on
- The number of downstream connections (child nodes) the parent node candidate currently has

The selection of the preferred parent node will always prioritize the parent node candidate on the shallowest layer of the network (including the root node). This helps minimize the total number of layers in an ESP-WIFI-MESH network when upstream connections are formed. For example, given a second layer node and a third layer node, the second layer node will always be preferred.

If there are multiple parent node candidates within the same layer, the parent node candidate with the least child nodes will be preferred. This criteria has the effect of balancing the number of downstream connections amongst nodes of the same layer.

Panel A of the illustration above demonstrates an example of how the idle node G selects a preferred parent node given the five parent node candidates B/C/D/E/F. Nodes on the shallowest layer are preferred, hence nodes B/C are prioritized since they are second layer nodes whereas nodes D/E/F are on the third layer. Node C is selected as the preferred parent node due it having fewer downstream connections (fewer child nodes) compared to node B.

Panel B of the illustration above demonstrates the case where the root node is within range of the idle node G. In other words, the root node's beacon frames are above the RSSI threshold when received by node G. The root node is always the shallowest node in an ESP-WIFI-MESH network hence is always the preferred parent node given multiple parent node candidates.

Note: Users may also define their own algorithm for selecting a preferred parent node, or force a node to only

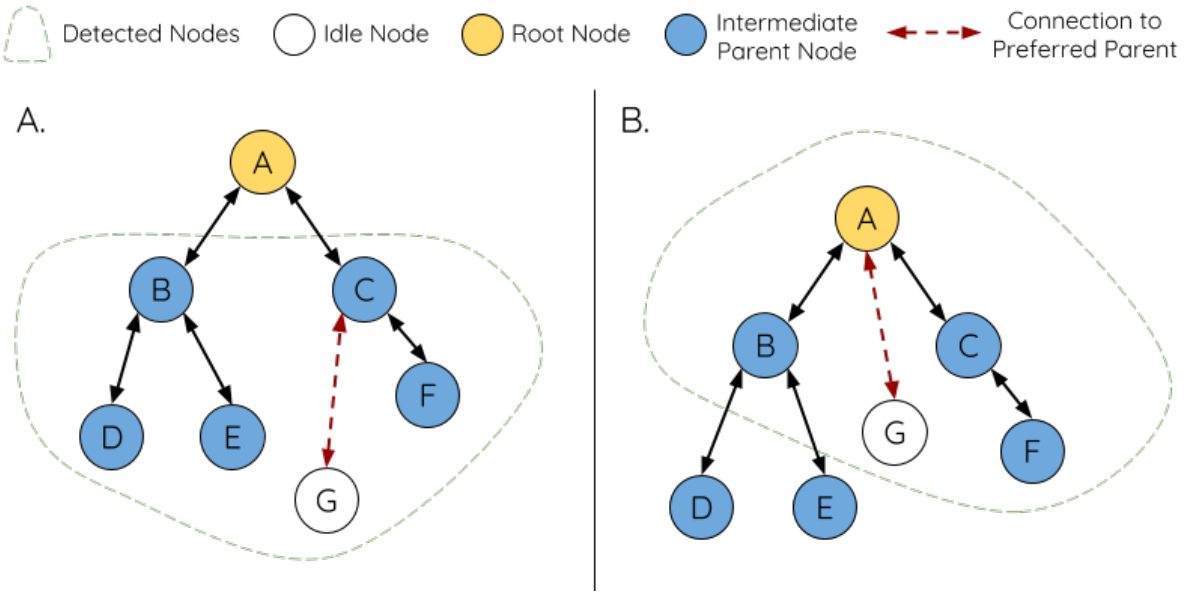

Fig. 30: Preferred Parent Node Selection

connect with a specific parent node (see the Mesh Manual Networking Example).

Routing Tables

Each node within an ESP-WIFI-MESH network will maintain its individual routing table used to correctly route ESP-WIFI-MESH packets (see *ESP-WIFI-MESH Packet*) to the correct destination node. The routing table of a particular node will **consist of the MAC addresses of all nodes within the particular node's subnetwork** (including the MAC address of the particular node itself). Each routing table is internally partitioned into multiple subtables with each subtable corresponding to the subnetwork of each child node.

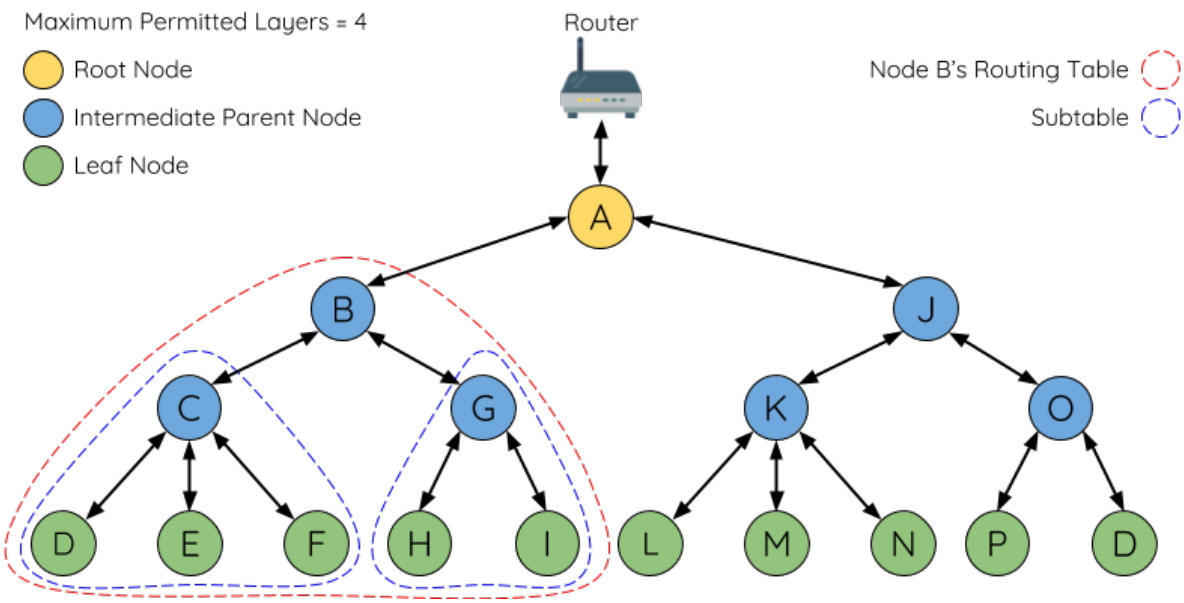

Fig. 31: ESP-WIFI-MESH Routing Tables Example

Using the diagram above as an example, the routing table of node B would consist of the MAC addresses of nodes B to I (i.e., equivalent to the subnetwork of node B). Node B's routing table is internally partitioned into two subtables

containing of nodes C to F and nodes G to I (i.e., equivalent to the subnetworks of nodes C and G respectively).

ESP-WIFI-MESH utilizes routing tables to determine whether an ESP-WIFI-MESH packet should be forwarded upstream or downstream based on the following rules.

1. If the packet's destination MAC address is within the current node's routing table and is not the current node, select the subtable that contains the destination MAC address and forward the data packet downstream to the child node corresponding to the subtable.

2. If the destination MAC address is not within the current node's routing table, forward the data packet upstream to the current node's parent node. Doing so repeatedly will result in the packet arriving at the root node where the routing table should contain all nodes within the network.

Note: Users can call `esp_mesh_get_routing_table()` to obtain a node's routing table, or `esp_mesh_get_routing_table_size()` to obtain the size of a node's routing table. `esp_mesh_get_subnet_nodes_list()` can be used to obtain the corresponding subtable of a specific child node. Likewise `esp_mesh_get_subnet_nodes_num()` can be used to obtain the size of the subtable.

4.16.4 Building a Network

General Process

> **Warning:** Before the ESP-WIFI-MESH network building process can begin, certain parts of the configuration must be uniform across each node in the network (see `mesh_cfg_t`). Each node must be configured with **the same Mesh Network ID, router configuration, and softAP configuration**.

An ESP-WIFI-MESH network building process involves selecting a root node, then forming downstream connections layer by layer until all nodes have joined the network. The exact layout of the network can be dependent on factors such as root node selection, parent node selection, and asynchronous power-on reset. However, the ESP-WIFI-MESH network building process can be generalized into the following steps:

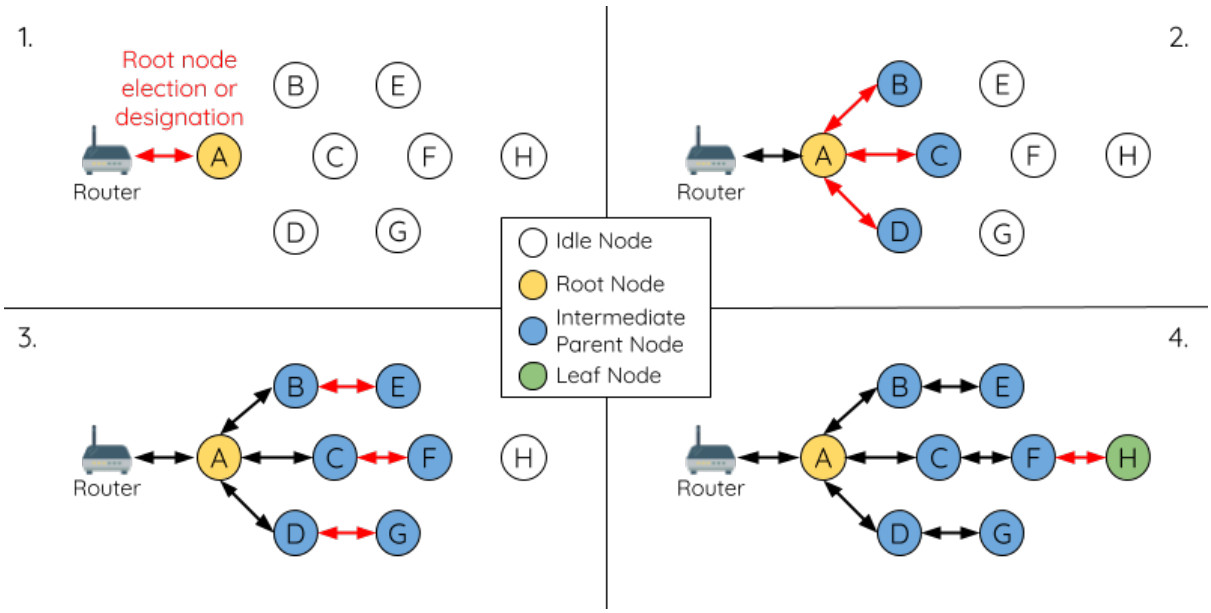

Fig. 32: ESP-WIFI-MESH Network Building Process

1. Root Node Selection The root node can be designated during configuration (see section on *User Designated Root Node*), or dynamically elected based on the signal strength between each node and the router (see *Automatic Root Node Selection*). Once selected, the root node will connect with the router and begin allowing downstream connections to form. Referring to the figure above, node A is selected to be the root node hence node A forms an upstream connection with the router.

2. Second Layer Formation Once the root node has connected to the router, idle nodes in range of the root node will begin connecting with the root node thereby forming the second layer of the network. Once connected, the second layer nodes become intermediate parent nodes (assuming maximum permitted layers > 2) hence the next layer to form. Referring to the figure above, nodes B to D are in range of the root node. Therefore nodes B to D form upstream connections with the root node and become intermediate parent nodes.

3. Formation of Remaining Layers The remaining idle nodes will connect with intermediate parent nodes within range thereby forming a new layer in the network. Once connected, the idles nodes become intermediate parent node or leaf nodes depending on the networks maximum permitted layers. This step is repeated until there are no more idle nodes within the network or until the maximum permitted layer of the network has been reached. Referring to the figure above, nodes E/F/G connect with nodes B/C/D respectively and become intermediate parent nodes themselves.

4. Limiting Tree Depth To prevent the network from exceeding the maximum permitted number of layers, nodes on the maximum layer will automatically become leaf nodes once connected. This prevents any other idle node from connecting with the leaf node thereby prevent a new layer form forming. However if an idle node has no other potential parent node, it will remain idle indefinitely. Referring to the figure above, the network's number of maximum permitted layers is set to four. Therefore when node H connects, it becomes a leaf node to prevent any downstream connections from forming.

Automatic Root Node Selection

The automatic selection of a root node involves an election process amongst all idle nodes based on their signal strengths with the router. Each idle node will transmit their MAC addresses and router RSSI values via Wi-Fi beacon frames. **The MAC address is used to uniquely identify each node in the network** whilst the **router RSSI** is used to indicate a node's signal strength with reference to the router.

Each node will then simultaneously scan for the beacon frames from other idle nodes. If a node detects a beacon frame with a stronger router RSSI, the node will begin transmitting the contents of that beacon frame (i.e., voting for the node with the stronger router RSSI). The process of transmission and scanning will repeat for a preconfigured minimum number of iterations (10 iterations by default) and result in the beacon frame with the strongest router RSSI being propagated throughout the network.

After all iterations, each node will individually check for its **vote percentage** (`number of votes/number of nodes participating in election`) to determine if it should become the root node. **If a node has a vote percentage larger than a preconfigured threshold (90% by default), the node will become a root node**.

The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is automatically selected.

1. On power-on reset, each node begins transmitting beacon frames consisting of their own MAC addresses and their router RSSIs.

2. Over multiple iterations of transmission and scanning, the beacon frame with the strongest router RSSI is propagated throughout the network. Node C has the strongest router RSSI (-10 dB) hence its beacon frame is propagated throughout the network. All nodes participating in the election vote for node C thus giving node C a vote percentage of 100%. Therefore node C becomes a root node and connects with the router.

3. Once Node C has connected with the router, nodes A/B/D/E connectwith node C as it is the preferred parent node (i.e., the shallowest node). Nodes A/B/D/E form the second layer of the network.

4. Node F and G connect with nodes D and E respectively and the network building process is complete.

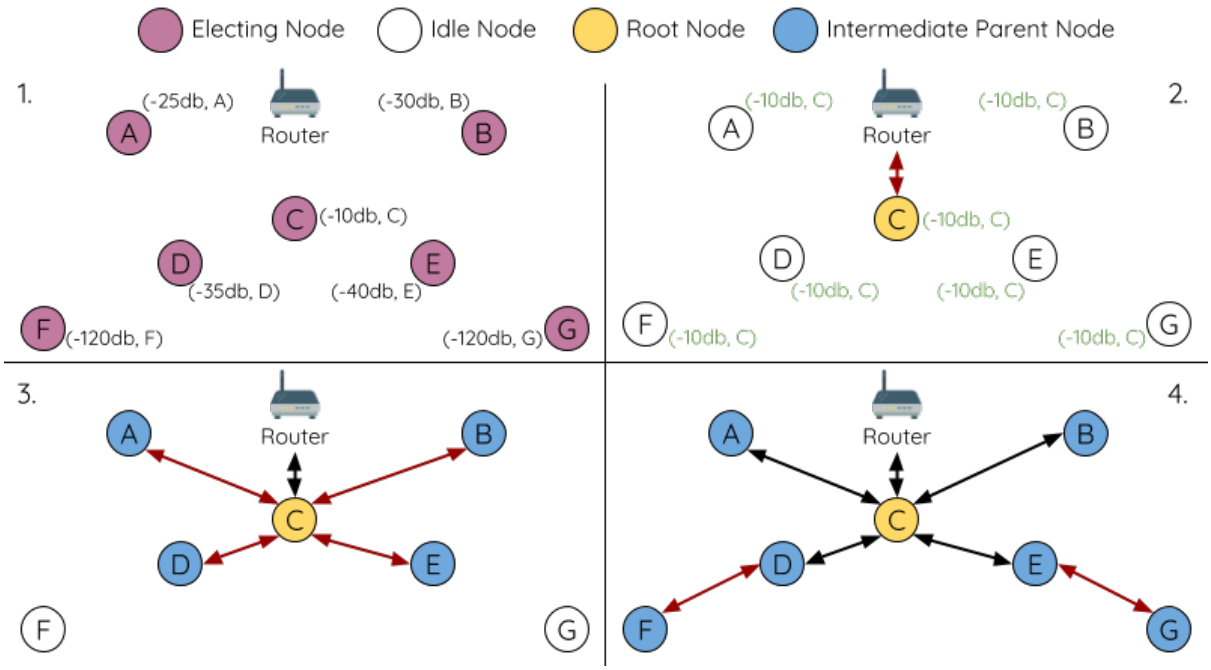

Fig. 33: Root Node Election Example

Note: The minimum number of iterations for the election process can be configured using `esp_mesh_set_attempts()`. Users should adjust the number of iterations based on the number of nodes within the network (i.e., the larger the network the larger number of scan iterations required).

Warning: **Vote percentage threshold** can also be configured using `esp_mesh_set_vote_percentage()`. Setting a low vote percentage threshold **can result in two or more nodes becoming root nodes** within the same ESP-WIFI-MESH network leading to the building of multiple networks. If such is the case, ESP-WIFI-MESH has internal mechanisms to autonomously resolve the **root node conflict**. The networks of the multiple root nodes will be combined into a single network with a single root node. However, root node conflicts where two or more root nodes have the same router SSID but different router BSSID are not handled.

User Designated Root Node

The root node can also be designated by user which will entail the designated root node to directly connect with the router and forgo the election process. When a root node is designated, all other nodes within the network must also forgo the election process to prevent the occurrence of a root node conflict. The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is designated by the user.

1. Node A is designated the root node by the user therefore directly connects with the router. All other nodes forgo the election process.

2. Nodes C/D connect with node A as their preferred parent node. Both nodes form the second layer of the network.

3. Likewise, nodes B/E connect with node C, and node F connects with node D. Nodes B/E/F form the third layer of the network.

4. Node G connects with node E, forming the fourth layer of the network. However the maximum permitted number of layers in this network is configured as four, therefore node G becomes a leaf node to prevent any new layers from forming.

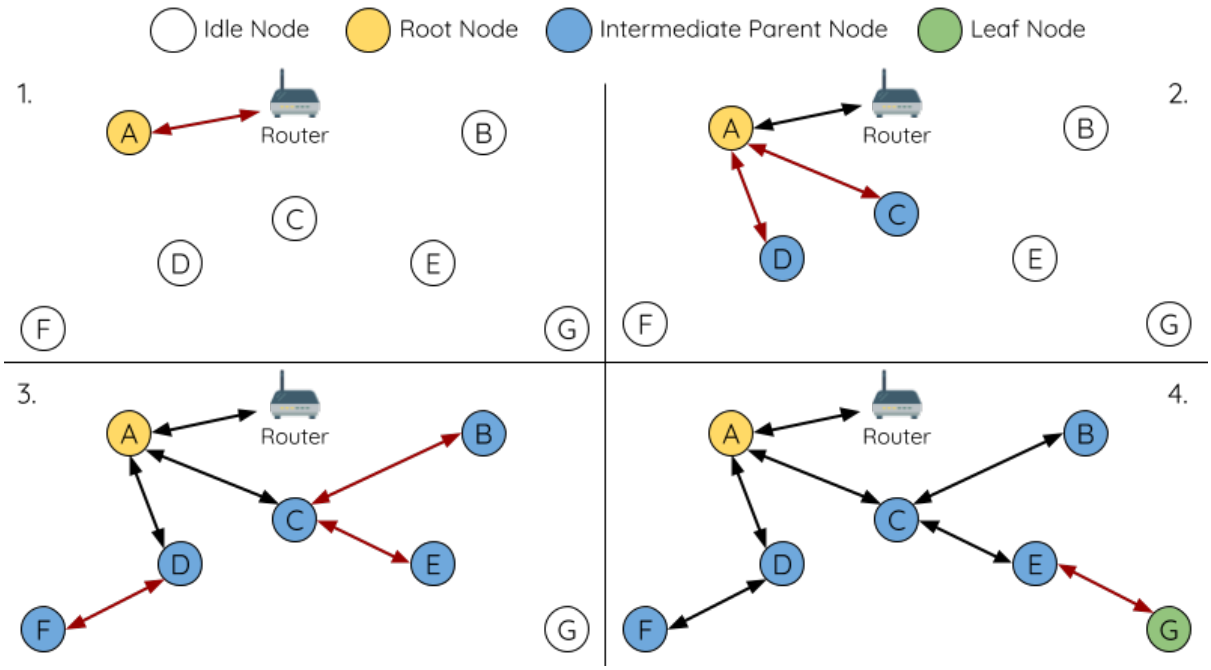

Fig. 34: Root Node Designation Example (Root Node = A, Max Layers = 4)

Note: When designating a root node, the root node should call `esp_mesh_set_parent()` in order to directly connect with the router. Likewise, all other nodes should call `esp_mesh_fix_root()` to forgo the election process.

Parent Node Selection

By default, ESP-WIFI-MESH is self organizing meaning that each node will autonomously select which potential parent node to form an upstream connection with. The autonomously selected parent node is known as the preferred parent node. The criteria used for selecting the preferred parent node is designed to reduce the number of layers in the ESP-WIFI-MESH network and to balance the number of downstream connections between potential parent nodes (see section on *Preferred Parent Node*).

However ESP-WIFI-MESH also allows users to disable self-organizing behavior which will allow users to define their own criteria for parent node selection, or to configure nodes to have designated parent nodes (see the Mesh Manual Networking Example).

Asynchronous Power-on Reset

ESP-WIFI-MESH network building can be affected by the order in which nodes power-on. If certain nodes within the network power-on asynchronously (i.e., separated by several minutes), **the final structure of the network could differ from the ideal case where all nodes are powered on synchronously**. Nodes that are delayed in powering on will adhere to the following rules:

Rule 1: If a root node already exists in the network, the delayed node will not attempt to elect a new root node, even if it has a stronger RSSI with the router. The delayed node will instead join the network like any other idle node by connecting with a preferred parent node. If the delayed node is the designated root node, all other nodes in the network will remain idle until the delayed node powers-on.

Rule 2: If a delayed node forms an upstream connection and becomes an intermediate parent node, it may also become the new preferred parent of other nodes (i.e., being a shallower node). This will cause the other nodes to switch their upstream connections to connect with the delayed node (see *Parent Node Switching*).

Rule 3: If an idle node has a designated parent node which is delayed in powering-on, the idle node will not attempt to form any upstream connections in the absence of its designated parent node. The idle node will remain idle indefinitely until its designated parent node powers-on.

The following example demonstrates the effects of asynchronous power-on with regards to network building.

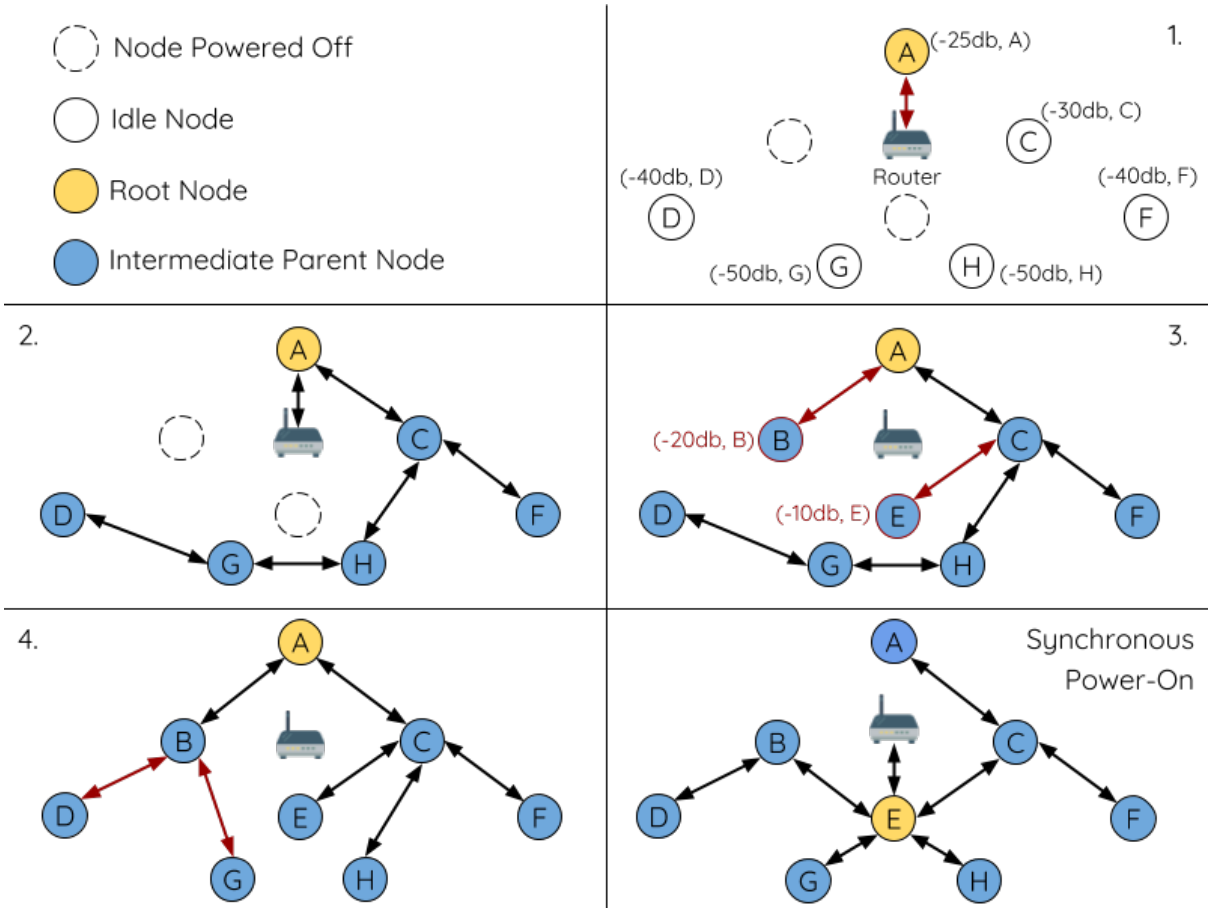

Fig. 35: Network Building with Asynchronous Power On Example

1. Nodes A/C/D/F/G/H are powered-on synchronously and begin the root node election process by broadcasting their MAC addresses and router RSSIs. Node A is elected as the root node as it has the strongest RSSI.

2. Once node A becomes the root node, the remaining nodes begin forming upstream connections layer by layer with their preferred parent nodes. The result is a network with five layers.

3. Node B/E are delayed in powering-on but neither attempt to become the root node even though they have stronger router RSSIs (-20 dB and -10 dB) compared to node A. Instead both delayed nodes form upstream connections with their preferred parent nodes A and C respectively. Both nodes B/E become intermediate parent nodes after connecting.

4. Nodes D/G switch their upstream connections as node B is the new preferred parent node due to it being on a shallower layer (second layer node). Due to the switch, the resultant network has three layers instead of the original five layers.

Synchronous Power-On: Had all nodes powered-on synchronously, node E would have become the root node as it has the strongest router RSSI (-10 dB). This would result in a significantly different network layout compared to the network formed under the conditions of asynchronous power-on. **However the synchronous power-on network layout can still be reached if the user manually switches the root node** (see `esp_mesh_waive_root()`).

Note: Differences in parent node selection caused by asynchronous power-on are autonomously corrected for to some extent in ESP-WIFI-MESH (see *Parent Node Switching*)

Loop-back Avoidance, Detection, and Handling

A loop-back is the situation where a particular node forms an upstream connection with one of its descendant nodes (a node within the particular node's subnetwork). This results in a circular connection path thereby breaking the tree topology. ESP-WIFI-MESH prevents loop-back during parent selection by excluding nodes already present in the selecting node's routing table (see *Routing Tables*) thus prevents a particular node from attempting to connect to any node within its subnetwork.

In the event that a loop-back occurs, ESP-WIFI-MESH utilizes a path verification mechanism and energy transfer mechanism to detect the loop-back occurrence. The parent node of the upstream connection that caused the loop-back will then inform the child node of the loop-back and initiate a disconnection.

4.16.5 Managing a Network

ESP-WIFI-MESH is a self healing network meaning it can detect and correct for failures in network routing. Failures occur when a parent node with one or more child nodes breaks down, or when the connection between a parent node and its child nodes becomes unstable. Child nodes in ESP-WIFI-MESH will autonomously select a new parent node and form an upstream connection with it to maintain network interconnectivity. ESP-WIFI-MESH can handle both Root Node Failures and Intermediate Parent Node Failures.

Root Node Failure

If the root node breaks down, the nodes connected with it (second layer nodes) will promptly detect the failure of the root node. The second layer nodes will initially attempt to reconnect with the root node. However after multiple failed attempts, the second layer nodes will initialize a new round of root node election. **The second layer node with the strongest router RSSI will be elected as the new root node** whilst the remaining second layer nodes will form an upstream connection with the new root node (or a neighboring parent node if not in range).

If the root node and multiple downstream layers simultaneously break down (e.g., root node, second layer, and third layer), the shallowest layer that is still functioning will initialize the root node election. The following example illustrates an example of self healing from a root node break down.

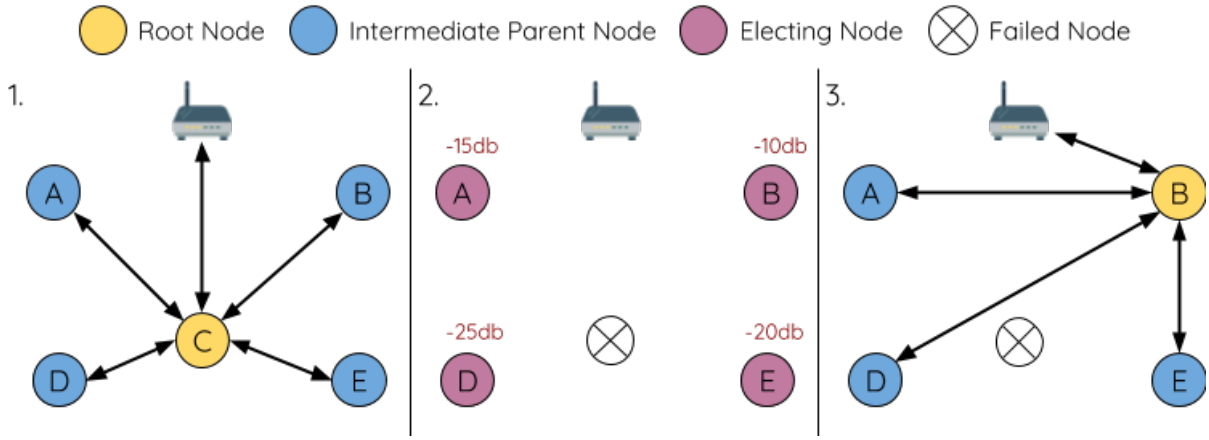

Fig. 36: Self Healing From Root Node Failure

1. Node C is the root node of the network. Nodes A/B/D/E are second layer nodes connected to node C.

2. Node C breaks down. After multiple failed attempts to reconnect, the second layer nodes begin the election process by broadcasting their router RSSIs. Node B has the strongest router RSSI.

3. Node B is elected as the root node and begins accepting downstream connections. The remaining second layer nodes A/D/E form upstream connections with node B thus the network is healed and can continue operating normally.

Note: If a designated root node breaks down, the remaining nodes **will not autonomously attempt to elect a new root node** as an election process will never be attempted whilst a designated root node is used.

Intermediate Parent Node Failure

If an intermediate parent node breaks down, the disconnected child nodes will initially attempt to reconnect with the parent node. After multiple failed attempts to reconnect, each child node will begin to scan for potential parent nodes (see *Beacon Frames & RSSI Thresholding*).

If other potential parent nodes are available, each child node will individually select a new preferred parent node (see *Preferred Parent Node*) and form an upstream connection with it. If there are no other potential parent nodes for a particular child node, it will remain idle indefinitely.

The following diagram illustrates an example of self healing from an Intermediate Parent Node break down.

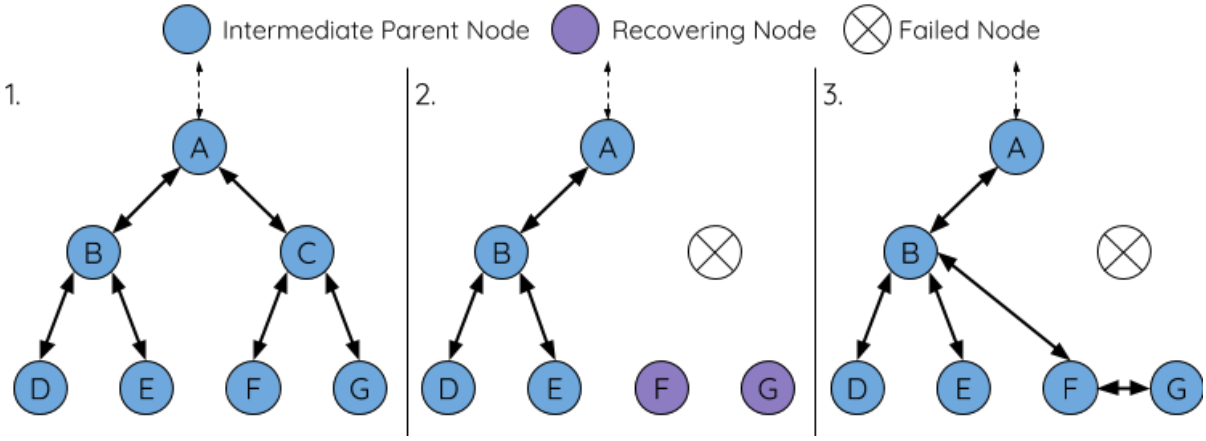

Fig. 37: Self Healing From Intermediate Parent Node Failure

1. The following branch of the network consists of nodes A to G.

2. Node C breaks down. Nodes F/G detect the break down and attempt to reconnect with node C. After multiple failed attempts to reconnect, nodes F/G begin to select a new preferred parent node.

3. Node G is out of range from any other parent node hence remains idle for the time being. Node F is in range of nodes B/E, however node B is selected as it is the shallower node. Node F becomes an intermediate parent node after connecting with Node B thus node G can connect with node F. The network is healed, however the network routing as been affected and an extra layer has been added.

Note: If a child node has a designated parent node that breaks down, the child node will make no attempt to connect with a new parent node. The child node will remain idle indefinitely.

Root Node Switching

ESP-WIFI-MESH does not automatically switch the root node unless the root node breaks down. Even if the root node's router RSSI degrades to the point of disconnection, the root node will remain unchanged. Root node switching is the act of explicitly starting a new election such that a node with a stronger router RSSI will be elected as the new root node. This can be a useful method of adapting to degrading root node performance.

To trigger a root node switch, the current root node must explicitly call `esp_mesh_waive_root()` to trigger a new election. The current root node will signal all nodes within the network to begin transmitting and scanning for beacon frames (see *Automatic Root Node Selection*) **whilst remaining connected to the network (i.e., not idle)**. If

another node receives more votes than the current root node, a root node switch will be initiated. **The root node will remain unchanged otherwise**.

A newly elected root node sends a **switch request** to the current root node which in turn will respond with an acknowledgment signifying both nodes are ready to switch. Once the acknowledgment is received, the newly elected root node will disconnect from its parent and promptly form an upstream connection with the router thereby becoming the new root node of the network. The previous root node will disconnect from the router **whilst maintaining all of its downstream connections** and enter the idle state. The previous root node will then begin scanning for potential parent nodes and selecting a preferred parent.

The following diagram illustrates an example of a root node switch.

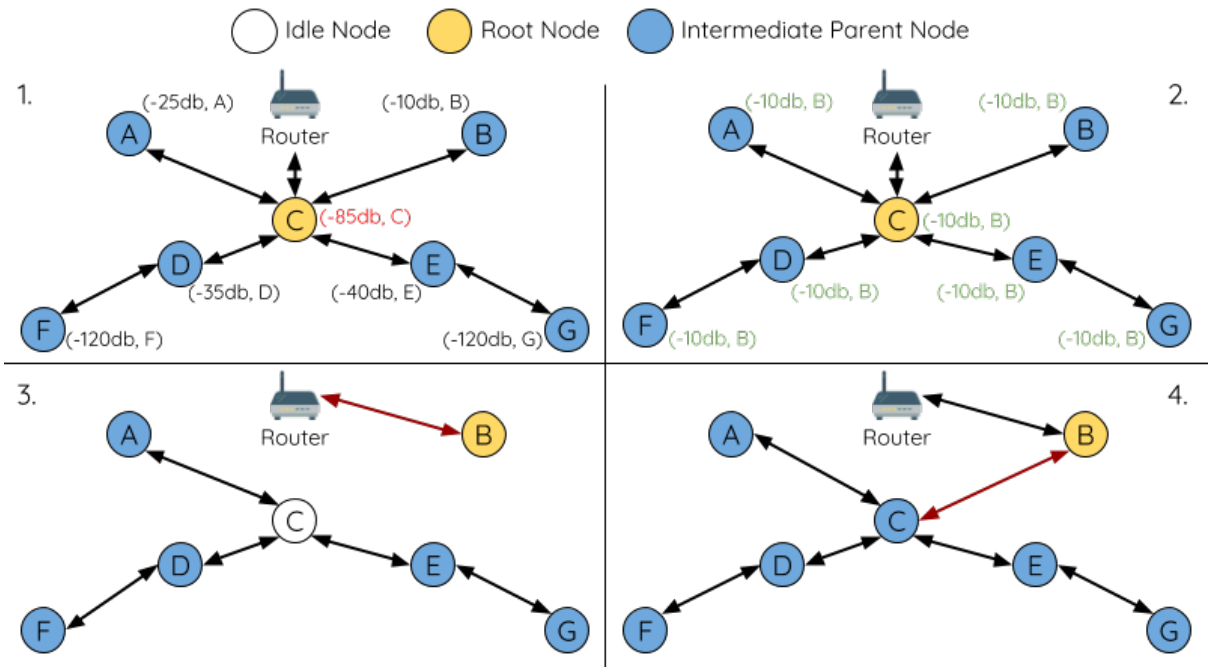

Fig. 38: Root Node Switch Example

1. Node C is the current root node but has degraded signal strength with the router (-85db). The node C triggers a new election and all nodes begin transmitting and scanning for beacon frames **whilst still being connected**.

2. After multiple rounds of transmission and scanning, node B is elected as the new root node. Node B sends node C a **switch request** and node C responds with an acknowledgment.

3. Node B disconnects from its parent and connects with the router becoming the network's new root node. Node C disconnects from the router, enters the idle state, and begins scanning for and selecting a new preferred parent node. **Node C maintains all its downstream connections throughout this process**.

4. Node C selects node B as its preferred parent node, forms an upstream connection, and becomes a second layer node. The network layout is similar after the switch as node C still maintains the same subnetwork. However each node in node C's subnetwork has been placed one layer deeper as a result of the switch. *Parent Node Switching* may adjust the network layout afterwards if any nodes have a new preferred parent node as a result of the root node switch.

Note: Root node switching must require an election hence is only supported when using a self-organized ESP-WIFI-MESH network. In other words, root node switching cannot occur if a designated root node is used.

Parent Node Switching

Parent Node Switching entails a child node switching its upstream connection to another parent node of a shallower layer. **Parent Node Switching occurs autonomously** meaning that a child node will change its upstream connection

automatically if a potential parent node of a shallower layer becomes available (i.e., due to a *Asynchronous Power-on Reset*).

All potential parent nodes periodically transmit beacon frames (see *Beacon Frames & RSSI Thresholding*) allowing for a child node to scan for the availability of a shallower parent node. Due to parent node switching, a self-organized ESP-WIFI-MESH network can dynamically adjust its network layout to ensure each connection has a good RSSI and that the number of layers in the network is minimized.

4.16.6 Data Transmission

ESP-WIFI-MESH Packet

ESP-WIFI-MESH network data transmissions use ESP-WIFI-MESH packets. ESP-WIFI-MESH packets are **entirely contained within the frame body of a Wi-Fi data frame**. A multi-hop data transmission in an ESP-WIFI-MESH network will involve a single ESP-WIFI-MESH packet being carried over each wireless hop by a different Wi-Fi data frame.

The following diagram shows the structure of an ESP-WIFI-MESH packet and its relation with a Wi-Fi data frame.

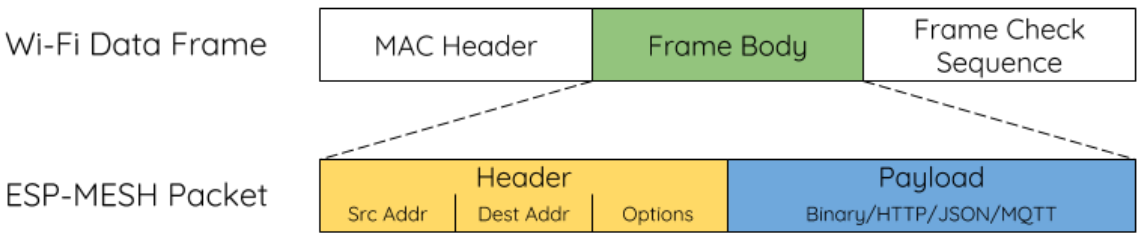

Fig. 39: ESP-WIFI-MESH Packet

The header of an ESP-WIFI-MESH packet contains the MAC addresses of the source and destination nodes. The options field contains information pertaining to the special types of ESP-WIFI-MESH packets such as a group transmission or a packet originating from the external IP network (see `MESH_OPT_SEND_GROUP` and `MESH_OPT_RECV_DS_ADDR`).

The payload of an ESP-WIFI-MESH packet contains the actual application data. This data can be raw binary data, or encoded under an application layer protocol such as HTTP, MQTT, and JSON (see `mesh_proto_t`).

Note: When sending an ESP-WIFI-MESH packet to the external IP network, the destination address field of the header will contain the IP address and port of the target server rather than the MAC address of a node (see `mesh_addr_t`). Furthermore the root node will handle the formation of the outgoing TCP/IP packet.

Group Control & Multicasting

Multicasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to multiple nodes within the network. Multicasting in ESP-WIFI-MESH can be achieved by either specifying a list of target nodes, or specifying a preconfigured group of nodes. Both methods of multicasting are called via `esp_mesh_send()`.

To multicast by specifying a list of target nodes, users must first set the ESP-WIFI-MESH packet's destination address to the **Multicast-Group Address** (`01:00:5E:xx:xx:xx`). This signifies that the ESP-WIFI-MESH packet is a multicast packet with a group of addresses, and that the address should be obtained from the header options. Users must then list the MAC addresses of the target nodes as options (see `mesh_opt_t` and `MESH_OPT_SEND_GROUP`). This method of multicasting requires no prior setup but can incur a large amount of overhead data as each target node's MAC address must be listed in the options field of the header.

Multicasting by group allows a ESP-WIFI-MESH packet to be transmitted to a preconfigured group of nodes. Each grouping is identified by a unique ID, and a node can be placed into a group via `esp_mesh_set_group_id()`. Multicasting to a group involves setting the destination address of the ESP-WIFI-MESH packet to the target group ID. Furthermore, the `MESH_DATA_GROUP` flag must set. Using groups to multicast incurs less overhead, but requires nodes to previously added into groups.

Note: During a multicast, all nodes within the network still receive the ESP-WIFI-MESH packet on the MAC layer. However, nodes not included in the MAC address list or the target group will simply filter out the packet.

Broadcasting

Broadcasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to all nodes within the network. Each node essentially forwards a broadcast packet to all of its upstream and downstream connections such that the packet propagates throughout the network as quickly as possible. However, ESP-WIFI-MESH utilizes the following methods to avoid wasting bandwidth during a broadcast.

1. When an intermediate parent node receives a broadcast packet from its parent, it will forward the packet to each of its child nodes whilst storing a copy of the packet for itself.

2. When an intermediate parent node is the source node of the broadcast, it will transmit the broadcast packet upstream to is parent node and downstream to each of its child nodes.

3. When an intermediate parent node receives a broadcast packet from one of its child nodes, it will forward the packet to its parent node and each of its remaining child nodes whilst storing a copy of the packet for itself.

4. When a leaf node is the source node of a broadcast, it will directly transmit the packet to its parent node.

5. When the root node is the source node of a broadcast, the root node will transmit the packet to all of its child nodes.

6. When the root node receives a broadcast packet from one of its child nodes, it will forward the packet to each of its remaining child nodes whilst storing a copy of the packet for itself.

7. When a node receives a broadcast packet with a source address matching its own MAC address, the node will discard the broadcast packet.

8. When an intermediate parent node receives a broadcast packet from its parent node which was originally transmitted from one of its child nodes, it will discard the broadcast packet

Upstream Flow Control

ESP-WIFI-MESH relies on parent nodes to control the upstream data flow of their immediate child nodes. To prevent a parent node's message buffer from overflowing due to an overload of upstream transmissions, a parent node will allocate a quota for upstream transmissions known as a **receiving window** for each of its child nodes. **Each child node must apply for a receiving window before it is permitted to transmit upstream**. The size of a receiving window can be dynamically adjusted. An upstream transmission from a child node to the parent node consists of the following steps:

1. Before each transmission, the child node sends a window request to its parent node. The window request consists of a sequence number which corresponds to the child node's data packet that is pending transmission.

2. The parent node receives the window request and compares the sequence number with the sequence number of the previous packet sent by the child node. The comparison is used to calculate the size of the receiving window which is transmitted back to the child node.

3. The child node transmits the data packet in accordance with the window size specified by the parent node. If the child node depletes its receiving window, it must obtain another receiving windows by sending a request before it is permitted to continue transmitting.

Note: ESP-WIFI-MESH does not support any downstream flow control.

Warning: Due to *Parent Node Switching*, packet loss may occur during upstream transmissions.

Due to the fact that the root node acts as the sole interface to an external IP network, it is critical that downstream nodes are aware of the root node's connection status with the external IP network. Failing to do so can lead to nodes attempting to pass data upstream to the root node whilst it is disconnected from the IP network. This results in unnecessary transmissions and packet loss. ESP-WIFI-MESH address this issue by providing a mechanism to stabilize the throughput of outgoing data based on the connection status between the root node and the external IP network. The root node can broadcast its external IP network connection status to all other nodes by calling `esp_mesh_post_toDS_state()`.

Bi-Directional Data Stream

The following diagram illustrates the various network layers involved in an ESP-WIFI-MESH Bidirectional Data Stream.

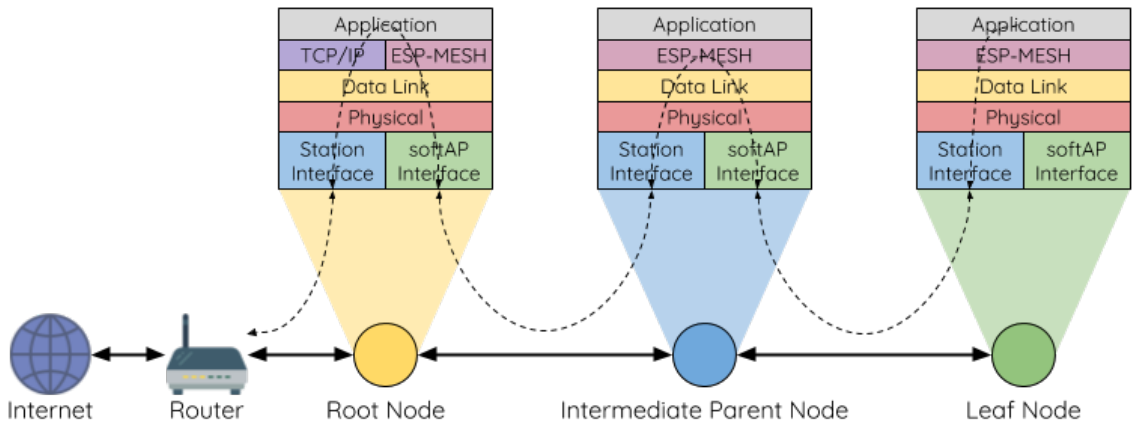

Fig. 40: ESP-WIFI-MESH Bidirectional Data Stream

Due to the use of *Routing Tables*, **ESP-WIFI-MESH is able to handle pack forwarding entirely on the mesh layer**. A TCP/IP layer is only required on the root node when it transmits/receives a packet to/from an external IP network.

4.16.7 Channel Switching

Background

In traditional Wi-Fi networks, **channels** are predetermined frequency ranges. In an infrastructure basic service set (BSS), the serving AP and its connected stations must be on the same operating channels (1 to 14) in which beacons are transmitted. Physically adjacent BSS (Basic Service Sets) operating on the same channel can lead to interference and degraded performance.

In order to allow a BSS adapt to changing physical layer conditions and maintain performance, Wi-Fi contains mechanisms for **network channel switching**. A network channel switch is an attempt to move a BSS to a new operating channel whilst minimizing disruption to the BSS during this process. However it should be recognized that a channel switch may be unsuccessful in moving all stations to the new operating channel.

In an infrastructure Wi-Fi network, network channel switches are triggered by the AP with the aim of having the AP and all connected stations synchronously switch to a new channel. Network channel switching is implemented

by embedding a **Channel Switch Announcement (CSA)** element within the AP's periodically transmitted beacon frames. The CSA element is used to advertise to all connected stations regarding an upcoming network channel switch and will be included in multiple beacon frames up until the switch occurs.

A CSA element contains information regarding the **New Channel Number** and a **Channel Switch Count** which indicates the number of beacon frame intervals (TBTTs) remaining until the network channel switch occurs. Therefore, the Channel Switch Count is decremented every beacon frame and allows connected stations to synchronize their channel switch with the AP.

ESP-WIFI-MESH Network Channel Switching

ESP-WIFI-MESH Network Channel Switching also utilize beacon frames that contain a CSA element. However, being a multi-hop network makes the switching process in ESP-WIFI-MESH is more complex due to the fact that a beacon frame might not be able to reach all nodes within the network (i.e., in a single hop). Therefore, an ESP-WIFI-MESH network relies on nodes to forward the CSA element so that it is propagated throughout the network.

When an intermediate parent node with one or more child nodes receives a beacon frame containing a CSA, the node will forward the CSA element by including the element in its next transmitted beacon frame (i.e., with the same **New Channel Number** and **Channel Switch Count**). Given that all nodes within an ESP-WIFI-MESH network receive the same CSA, the nodes can synchronize their channel switches using the Channel Switch Count, albeit with a short delay due to CSA element forwarding.

An ESP-WIFI-MESH network channel switch can be triggered by either the router or the root node.

Root Node Triggered **A root node triggered channel switch can only occur when the ESP-WIFI-MESH network is not connected to a router**. By calling `esp_mesh_switch_channel()`, the root node will set an initial Channel Switch Count value and begin including a CSA element in its beacon frames. Each CSA element is then received by second layer nodes, and forwarded downstream in their own beacon frames.

Router Triggered When an ESP-WIFI-MESH network is connected to a router, the entire network must use the same channel as the router. Therefore, **the root node will not be permitted to trigger a channel switch when it is connected to a router**.

When the root node receives beacon frame containing a CSA element from the router, **the root node will set Channel Switch Count value in the CSA element to a custom value before forwarding it downstream via beacon frames**. It will also decrement the Channel Switch Count of subsequent CSA elements relative to the custom value. This custom value can be based on factors such as the number of network layers, the current number of nodes etc.

The setting the Channel Switch Count value to a custom value is due to the fact that the ESP-WIFI-MESH network and its router may have a different and varying beacon intervals. Therefore, the Channel Switch Count value provided by the router is irrelevant to an ESP-WIFI-MESH network. By using a custom value, nodes within the ESP-WIFI-MESH network are able to switch channels synchronously relative to the ESP-WIFI-MESH network's beacon interval. However, this will also result in the ESP-WIFI-MESH network's channel switch being unsynchronized with the channel switch of the router and its connected stations.

Impact of Network Channel Switching

- **Due to the ESP-WIFI-MESH network channel switch being unsynchronized with the router's channel switch, there wil**
  - The ESP-WIFI-MESH network's channel switch time is dependent on the ESP-WIFI-MESH network's beacon interval and the root node's custom Channel Switch Count value.
  - The channel discrepancy prevents any data exchange between the root node and the router during that ESP-WIFI-MESH network's switch.
  - In the ESP-WIFI-MESH network, the root node and intermediate parent nodes will request their connected child nodes to stop transmissions until the channel switch takes place by setting the **Channel Switch Mode** field in the CSA element to 1.

  - Frequent router triggered network channel switches can degrade the ESP-WIFI-MESH network's performance. Note that this can be caused by the ESP-WIFI-MESH network itself (e.g., due to wireless medium contention with ESP-WIFI-MESH network). If this is the case, users should disable the automatic channel switching on the router and use a specified channel instead.
- **When there is a temporary channel discrepancy, the root node remains technically connected to the router.**
  - Disconnection occurs after the root node fails to receive any beacon frames or probe responses from the router over a fixed number of router beacon intervals.
  - Upon disconnection, the root node will automatically re-scan all channels for the presence of a router.
- **If the root node is unable to receive any of the router's CSA beacon frames (e.g., due to short switch time given by the r**
  - After the router switches channels, the root node will no longer be able to receive the router's beacon frames and probe responses and result in a disconnection after a fixed number of beacon intervals.
  - The root node will re-scan all channels for the router after disconnection.
  - The root node will maintain downstream connections throughout this process.

Note: Although ESP-WIFI-MESH network channel switching aims to move all nodes within the network to a new operating channel, it should be recognized that a channel switch might not successfully move all nodes (e.g., due to reasons such as node failures).

Channel and Router Switching Configuration

ESP-WIFI-MESH allows for autonomous channel switching to be enabled/disabled via configuration. Likewise, autonomous router switching (i.e., when a root node autonomously connects to another router) can also be enabled/disabled by configuration. Autonomous channel switching and router switching is dependent on the following configuration parameters and run-time conditions.

Allow Channel Switch: This parameter is set via the `allow_channel_switch` field of the *`mesh_cfg_t`* structure and permits an ESP-WIFI-MESH network to dynamically switch channels when set.

Preset Channel: An ESP-WIFI-MESH network can have a preset channel by setting the `channel` field of the *`mesh_cfg_t`* structure to the desired channel number. If this field is unset, the `allow_channel_switch` parameter is overridden such that channel switches are always permitted.

Allow Router Switch: This parameter is set via the `allow_router_switch` field of the *`mesh_router_t`* and permits an ESP-WIFI-MESH to dynamically switch to a different router when set.

Preset Router BSSID: An ESP-WIFI-MESH network can have a preset router by setting the `bssid` field of the *`mesh_router_t`* structure to the BSSID of the desired router. If this field is unset, the `allow_router_switch` parameter is overridden such that router switches are always permitted.

Root Node Present: The presence of a root node will can also affect whether or a channel or router switch is permitted.

The following table illustrates how the different combinations of parameters/conditions affect whether channel switching and/or router switching is permitted. Note that *X* represents a "do not care" for the parameter.

Preset Channel	Allow Channel Switch	Preset Router BSSID	Allow Router Switch	Root Node Present	Permitted Switches?
N	X	N	X	X	Channel and Router
N	X	Y	N	X	Channel Only
N	X	Y	Y	X	Channel and Router
Y	Y	N	X	X	Channel and Router
Y	N	N	X	N	Router Only
Y	N	N	X	Y	Channel and Router
Y	Y	Y	N	X	Channel Only
Y	N	Y	N	N	N
Y	N	Y	N	Y	Channel Only
Y	Y	Y	Y	X	Channel and Router
Y	N	Y	Y	N	Router Only
Y	N	Y	Y	Y	Channel and Router

4.16.8 Performance

The performance of an ESP-WIFI-MESH network can be evaluated based on multiple metrics such as the following:

Network Building Time: The amount of time taken to build an ESP-WIFI-MESH network from scratch.

Healing Time: The amount of time taken for the network to detect a node break down and carry out appropriate actions to heal the network (such as generating a new root node or forming new connections).

Per-hop latency: The latency of data transmission over one wireless hop. In other words, the time taken to transmit a data packet from a parent node to a child node or vice versa.

Network Node Capacity: The total number of nodes the ESP-WIFI-MESH network can simultaneously support. This number is determined by the maximum number of downstream connections a node can accept and the maximum number of layers permissible in the network.

The following table lists the common performance figures of an ESP-WIFI-MESH network:

- Network Building Time: < 60 seconds
- **Healing time:**
  - Root node break down: < 10 seconds
  - Child node break down: < 5 seconds
- Per-hop latency: 10 to 30 milliseconds

Note: The following test conditions were used to generate the performance figures above.

- Number of test devices: **100**
- Maximum Downstream Connections to Accept: **6**
- Maximum Permissible Layers: **6**

Note: Throughput depends on packet error rate and hop count.

Note: The throughput of root node's access to the external IP network is directly affected by the number of nodes in the ESP-WIFI-MESH network and the bandwidth of the router.

Note: The performance figures can vary greatly between installations based on network configuration and operating environment.

4.16.9 Further Notes

- Data transmission uses Wi-Fi WPA2-PSK encryption
- Mesh networking IE uses AES encryption

4.17 Fatal Errors

4.17.1 Overview

In certain situations, the execution of the program can not be continued in a well-defined way. In ESP-IDF, these situations include:

- CPU Exceptions: Illegal Instruction, Load/Store Alignment Error, Load/Store Prohibited error.
- System level checks and safeguards:
  - *Interrupt watchdog* timeout
  - *Task watchdog* timeout (only fatal if *CONFIG_ESP_TASK_WDT_PANIC* is set)
  - Cache access error
  - Memory protection fault
  - Brownout detection event
  - Stack overflow
  - Stack smashing protection check
  - Heap integrity check
  - Undefined behavior sanitizer (UBSAN) checks
- Failed assertions, via `assert`, `configASSERT` and similar macros.

This guide explains the procedure used in ESP-IDF for handling these errors, and provides suggestions on troubleshooting the errors.

4.17.2 Panic Handler

Every error cause listed in the *Overview* will be handled by the *panic handler*.

The panic handler will start by printing the cause of the error to the console. For CPU exceptions, the message will be similar to

```
Guru Meditation Error: Core 0 panic'ed (Illegal instruction). Exception␣
↪was unhandled.
```

For some of the system level checks (interrupt watchdog, cache access error), the message will be similar to

```
Guru Meditation Error: Core 0 panic'ed (Cache error). Exception was␣
↪unhandled.
```

In all cases, the error cause will be printed in parentheses. See *Guru Meditation Errors* for a list of possible error causes.

Subsequent behavior of the panic handler can be set using *CONFIG_ESP_SYSTEM_PANIC* configuration choice. The available options are:

- Print registers and reboot (`CONFIG_ESP_SYSTEM_PANIC_PRINT_REBOOT`) —default option.
  This will print register values at the point of the exception, print the backtrace, and restart the chip.
- Print registers and halt (`CONFIG_ESP_SYSTEM_PANIC_PRINT_HALT`)
  Similar to the above option, but halt instead of rebooting. External reset is required to restart the program.
- Silent reboot (`CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT`)
  Do not print registers or backtrace, restart the chip immediately.
- Invoke GDB Stub (`CONFIG_ESP_SYSTEM_PANIC_GDBSTUB`)
  Start GDB server which can communicate with GDB over console UART port. This option will only provide read-only debugging or post-mortem debugging. See *GDB Stub* for more details.

Note: The `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` choice in the configuration option *CONFIG_ESP_SYSTEM_PANIC* is only available when the component `esp_gdbstub` is included in the build.

The behavior of the panic handler is affected by three other configuration options.

- If *CONFIG_ESP_DEBUG_OCDAWARE* is enabled (which is the default), the panic handler will detect whether a JTAG debugger is connected. If it is, execution will be halted and control will be passed to the debugger. In this case, registers and backtrace are not dumped to the console, and GDBStub / Core Dump functions are not used.
- If the *Core Dump* feature is enabled, then the system state (task stacks and registers) will be dumped to either Flash or UART, for later analysis.
- If *CONFIG_ESP_PANIC_HANDLER_IRAM* is disabled (disabled by default), the panic handler code is placed in flash memory, not IRAM. This means that if ESP-IDF crashes while flash cache is disabled, the panic handler will automatically re-enable flash cache before running GDB Stub or Core Dump. This adds some minor risk, if the flash cache status is also corrupted during the crash.
  If this option is enabled, the panic handler code (including required UART functions) is placed in IRAM, and hence will decrease the usable memory space in SRAM. But this may be necessary to debug some complex issues with crashes while flash cache is disabled (for example, when writing to SPI flash) or when flash cache is corrupted when an exception is triggered.
- If *CONFIG_ESP_SYSTEM_PANIC_REBOOT_DELAY_SECONDS* is enabled (disabled by default) and set to a number higher than 0, the panic handler will delay the reboot for that amount of time in seconds. This can help if the tool used to monitor serial output does not provide a possibility to stop and examine the serial output. In that case, delaying the reboot will allow users to examine and debug the panic handler output (backtrace, etc.) for the duration of the delay. After the delay, the device will reboot. The reset reason is preserved.

The following diagram illustrates the panic handler behavior:

4.17.3 Register Dump and Backtrace

Unless the `CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT` option is enabled, the panic handler prints some of the CPU registers, and the backtrace, to the console

```

The register values printed are the register values in the exception frame, i.e., values at the moment when the CPU exception or another fatal error has occurred.

A Register dump is not printed if the panic handler has been executed as a result of an `abort()` call.

If *IDF Monitor* is used, Program Counter values will be converted to code locations (function name, file name, and line number), and the output will be annotated with additional lines:

```

Backtrace stopped: frame did not save the PC
```

While the backtrace above is very handy, it requires the user to use *IDF Monitor*. Thus, in order to generate and print a backtrace while using another monitor program, it is possible to activate *CONFIG_ESP_SYSTEM_USE_EH_FRAME* option from the menuconfig.

This option will let the compiler generate DWARF information for each function of the project. Then, when a CPU exception occurs, the panic handler will parse these data and determine the backtrace of the task that failed. The

output looks like this:

```
Backtrace: 0x42009e9a:0x3fc92120 0x42009ea6:0x3fc92120 0x42009ec2:0x3fc92130␣
↪0x42024620:0x3fc92150 0x40387d7c:0x3fc92160 0xfffffffe:0x3fc92170
```

These `PC:SP` pairs represent the PC (Program Counter) and SP (Stack Pointer) for each stack frame of the current task.

The main benefit of the *CONFIG_ESP_SYSTEM_USE_EH_FRAME* option is that the backtrace is generated by the board itself (without the need for *IDF Monitor*). However, the option's drawback is that it results in an increase of the compiled binary's size (ranging from 20% to 100% increase in size). Furthermore, this option causes debug information to be included within the compiled binary. Therefore, users are strongly advised not to enable this option in mass/final production builds.

To find the location where a fatal error has happened, look at the lines which follow the "Backtrace" line. Fatal error location is the top line, and subsequent lines show the call stack.

4.17.4 GDB Stub

If the `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` option is enabled, the panic handler will not reset the chip when a fatal error happens. Instead, it will start a GDB remote protocol server, commonly referred to as GDB Stub. When this happens, a GDB instance running on the host computer can be instructed to connect to the ESP32-C3 UART port.

If *IDF Monitor* is used, GDB is started automatically when a GDB Stub prompt is detected on the UART. The output looks like this:

```
Entering gdb stub now.
$T0b#e6GNU gdb (crosstool-NG crosstool-ng-1.22.0-80-gff1f415) 7.10
Copyright (C) 2015 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law.  Type "show copying"
and "show warranty" for details.
This GDB was configured as "--host=x86_64-build_apple-darwin16.3.0 --
↪target=riscv32-esp-elf".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
<http://www.gnu.org/software/gdb/bugs/>.
Find the GDB manual and other documentation resources online at:
<http://www.gnu.org/software/gdb/documentation/>.
For help, type "help".
Type "apropos word" to search for commands related to "word"...
Reading symbols from /Users/user/esp/example/build/example.elf...done.
Remote debugging using /dev/cu.usbserial-31301
0x400e1b41 in app_main ()
    at /Users/user/esp/example/main/main.cpp:36
36      *((int*) 0) = 0;
(gdb)
```

The GDB prompt can be used to inspect CPU registers, local and static variables, and arbitrary locations in memory. It is not possible to set breakpoints, change the PC, or continue execution. To reset the program, exit GDB and perform an external reset: Ctrl-T Ctrl-R in IDF Monitor, or using the external reset button on the development board.

4.17.5 RTC Watchdog Timeout

The RTC watchdog is used in the startup code to keep track of execution time and it also helps to prevent a lock-up caused by an unstable power source. It is enabled by default (see *CONFIG_BOOTLOADER_WDT_ENABLE*). If the execution time is exceeded, the RTC watchdog will restart the system. In this case, the ROM bootloader will print a message with the `RTC Watchdog Timeout` reason for the reboot.

```
rst:0x10 (RTCWDT_RTC_RST)
```

The RTC watchdog covers the execution time from the first stage bootloader (ROM bootloader) to application startup. It is initially set in the ROM bootloader, then configured in the bootloader with the *CONFIG_BOOTLOADER_WDT_TIME_MS* option (9000 ms by default). During the application initialization stage, it is reconfigured because the source of the slow clock may have changed, and finally disabled right before the `app_main()` call. There is an option *CONFIG_BOOTLOADER_WDT_DISABLE_IN_USER_CODE* which prevents the RTC watchdog from being disabled before `app_main`. Instead, the RTC watchdog remains active and must be fed periodically in your application's code.

4.17.6 Guru Meditation Errors

This section explains the meaning of different error causes, printed in parens after the `Guru Meditation Error: Core panic'ed` message.

Note: See the Guru Meditation Wikipedia article for historical origins of "Guru Meditation".

Illegal instruction

This CPU exception indicates that the instruction which was executed was not a valid instruction. The most common reasons for this error include:

- FreeRTOS task function has returned. In FreeRTOS, if a task function needs to terminate, it should call `vTaskDelete()` and delete itself, instead of returning.
- Failure to read next instruction from SPI flash. This usually happens if:
  - Application has reconfigured the SPI flash pins as some other function (GPIO, UART, etc.). Consult the Hardware Design Guidelines and the datasheet for the chip or module for details about the SPI flash pins.
  - Some external device has accidentally been connected to the SPI flash pins, and has interfered with communication between ESP32-C3 and SPI flash.
- In C++ code, exiting from a non-void function without returning a value is considered to be an undefined behavior. When optimizations are enabled, the compiler will often omit the epilogue in such functions. This most often results in an Illegal instruction exception. By default, ESP-IDF build system enables `-Werror=return-type` which means that missing return statements are treated as compile time errors. However if the application project disables compiler warnings, this issue might go undetected and the Illegal instruction exception will occur at run time.

Instruction Address Misaligned

This CPU exception indicates that the address of the instruction to execute is not 2-byte aligned.

Instruction Access Fault, Load Access Fault, Store Access Fault

This CPU exception happens when application attempts to execute, read from or write to an invalid memory location. The address which was written/read is found in `MTVAL` register in the register dump. If this address is zero, it usually means that application attempted to dereference a NULL pointer. If this address is close to zero, it usually means that application attempted to access member of a structure, but the pointer to the structure was NULL. If this address is something else (garbage value, not in `0x3fxxxxxx` - `0x6xxxxxxx` range), it likely means that the pointer used to access the data was either not initialized or was corrupted.

Breakpoint

This CPU exception happens when the instruction `EBREAK` is executed. See also *FreeRTOS End of Stack Watchpoint*.

Load Address Misaligned, Store Address Misaligned

Application has attempted to read or write memory location, and address alignment did not match load/store size. For example, 32-bit load can only be done from 4-byte aligned address, and 16-bit load can only be done from a 2-byte aligned address.

Interrupt Watchdog Timeout on CPU0/CPU1

Indicates that an interrupt watchdog timeout has occurred. See *Watchdogs* for more information.

Cache error

In some situations, ESP-IDF will temporarily disable access to external SPI Flash and SPI RAM via caches. For example, this happens when spi_flash APIs are used to read/write/erase/mmap regions of SPI Flash. In these situations, tasks are suspended, and interrupt handlers not registered with `ESP_INTR_FLAG_IRAM` are disabled. Make sure that any interrupt handlers registered with this flag have all the code and data in IRAM/DRAM. Refer to the *SPI flash API documentation* for more details.

Memory Protection Fault

ESP32-C3 Permission Control feature is used in ESP-IDF to prevent the following types of memory access:

- writing to instruction RAM after the program is loaded
- executing code from data RAM (areas used for heap and static .data and .bss)

Such operations are not necessary for most programs. Prohibiting such operations typically makes software vulnerabilities harder to exploit. Applications which rely on dynamic loading or self-modifying code may disable this protection using *CONFIG_ESP_SYSTEM_MEMPROT_FEATURE* Kconfig option.

When the fault occurs, the panic handler reports the address of the fault and the type of memory access that caused it.

4.17.7 Other Fatal Errors

Brownout

ESP32-C3 has a built-in brownout detector, which is enabled by default. The brownout detector can trigger a system reset if the supply voltage goes below a safe level. The brownout detector can be configured using *CONFIG_ESP_BROWNOUT_DET* and *CONFIG_ESP_BROWNOUT_DET_LVL_SEL* options.

When the brownout detector triggers, the following message is printed:

```
Brownout detector was triggered
```

The chip is reset after the message is printed.

Note that if the supply voltage is dropping at a fast rate, only part of the message may be seen on the console.

Corrupt Heap

ESP-IDF's heap implementation contains a number of run-time checks of the heap structure. Additional checks ("Heap Poisoning") can be enabled in menuconfig. If one of the checks fails, a message similar to the following will be printed:

```
CORRUPT HEAP: Bad tail at 0x3ffe270a. Expected 0xbaad5678 got 0xbaac5678
assertion "head != NULL" failed: file "/Users/user/esp/esp-idf/components/heap/
↪multi_heap_poisoning.c", line 201, function: multi_heap_free
abort() was called at PC 0x400dca43 on core 0
```

Consult *Heap Memory Debugging* documentation for further information.

Stack overflow

Hardware Stack Guard ESP32-C3 has an integrated assist-debug module that can watch the SP register to ensure that it is within the bounds of allocated stack memory. The assist-debug module needs to set new stack bounds on every interrupt handling and FreeRTOS context switch. This can have a small impact on performance.

Here are some additional details about the assist-debug module:

- Implemented in hardware
- Watches Stack Pointer register value
- Requires no additional CPU time or memory while watching stack bounds

When the assist-debug module detects a stack overflow, the panic handler will run and display a message that resembles the following:

```
Guru Meditation Error: Core 0 panic'ed (Stack protection fault).
```

Hardware stack guard can be disabled using *CONFIG_ESP_SYSTEM_HW_STACK_GUARD* options.

FreeRTOS End of Stack Watchpoint ESP-IDF provides a custom FreeRTOS stack overflow detecting mechanism based on watchpoints. Every time FreeRTOS switches task context, one of the watchpoints is set to watch the last 32 bytes of stack.

Generally, this may cause the watchpoint to be triggered up to 28 bytes earlier than expected. The value 32 is chosen because it is larger than the stack canary size in FreeRTOS (20 bytes). Adopting this approach ensures that the watchpoint triggers before the stack canary is corrupted, not after.

Note: Not every stack overflow is guaranteed to trigger the watchpoint. It is possible that the task writes to memory beyond the stack canary location, in which case the watchpoint will not be triggered.

If watchpoint triggers, the message will be similar to:

```
Guru Meditation Error: Core  0 panic'ed (Breakpoint). Exception was unhandled.
```

This feature can be enabled by using the *CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK* option.

FreeRTOS Stack Checks See *CONFIG_FREERTOS_CHECK_STACKOVERFLOW*

Stack Smashing

Stack smashing protection (based on GCC `-fstack-protector*` flags) can be enabled in ESP-IDF using *CONFIG_COMPILER_STACK_CHECK_MODE* option. If stack smashing is detected, message similar to the following will be printed:

```
Stack smashing protect failure!

abort() was called at PC 0x400d2138 on core 0
```

(continues on next page)

(continued from previous page)

```
Backtrace: 0x4008e6c0:0x3ffc1780 0x4008e8b7:0x3ffc17a0 0x400d2138:0x3ffc17c0␣
↪0x400e79d5:0x3ffc17e0 0x400e79a7:0x3ffc1840 0x400e79df:0x3ffc18a0␣
↪0x400e2235:0x3ffc18c0 0x400e1916:0x3ffc18f0 0x400e19cd:0x3ffc1910␣
↪0x400e1a11:0x3ffc1930 0x400e1bb2:0x3ffc1950 0x400d2c44:0x3ffc1a80
0
```

The backtrace should point to the function where stack smashing has occurred. Check the function code for unbounded access to local arrays.

Undefined Behavior Sanitizer (UBSAN) Checks

Undefined behavior sanitizer (UBSAN) is a compiler feature which adds run-time checks for potentially incorrect operations, such as:

- overflows (multiplication overflow, signed integer overflow)
- shift base or exponent errors (e.g., shift by more than 32 bits)
- integer conversion errors

See GCC documentation of `-fsanitize=undefined` option for the complete list of supported checks.

Enabling UBSAN UBSAN is disabled by default. It can be enabled at file, component, or project level by adding the `-fsanitize=undefined` compiler option in the build system.

When enabling UBSAN for code which uses the SOC hardware register header files (`soc/xxx_reg.h`), it is recommended to disable shift-base sanitizer using `-fno-sanitize=shift-base` option. This is due to the fact that ESP-IDF register header files currently contain patterns which cause false positives for this specific sanitizer option.

To enable UBSAN at project level, add the following code at the end of the project's `CMakeLists.txt` file:

```
idf_build_set_property(COMPILE_OPTIONS "-fsanitize=undefined" "-fno-sanitize=shift-
↪base" APPEND)
```

Alternatively, pass these options through the `EXTRA_CFLAGS` and `EXTRA_CXXFLAGS` environment variables.

Enabling UBSAN results in significant increase of code and data size. Most applications, except for the trivial ones, will not fit into the available RAM of the microcontroller when UBSAN is enabled for the whole application. Therefore it is recommended that UBSAN is instead enabled for specific components under test.

To enable UBSAN for a specific component (`component_name`) from the project's `CMakeLists.txt` file, add the following code at the end of the file:

```
idf_component_get_property(lib component_name COMPONENT_LIB)
target_compile_options(${lib} PRIVATE "-fsanitize=undefined" "-fno-sanitize=shift-
↪base")
```

Note: See the build system documentation for more information about *build properties* and *component properties*.

To enable UBSAN for a specific component (`component_name`) from `CMakeLists.txt` of the same component, add the following at the end of the file:

```
target_compile_options(${COMPONENT_LIB} PRIVATE "-fsanitize=undefined" "-fno-
↪sanitize=shift-base")
```

UBSAN Output When UBSAN detects an error, a message and the backtrace are printed, for example:

```
Undefined behavior of type out_of_bounds

Backtrace:0x4008b383:0x3ffcd8b0 0x4008c791:0x3ffcd8d0 0x4008c587:0x3ffcd8f0␣
↪0x4008c6be:0x3ffcd950 0x400db74f:0x3ffcd970 0x400db99c:0x3ffcd9a0
```

When using *IDF Monitor*, the backtrace will be decoded to function names and source code locations, pointing to the location where the issue has happened (here it is `main.c:128`):

```
0x4008b383: panic_abort at /path/to/esp-idf/components/esp_system/panic.c:367

0x4008c791: esp_system_abort at /path/to/esp-idf/components/esp_system/system_api.
↪c:106

0x4008c587: __ubsan_default_handler at /path/to/esp-idf/components/esp_system/
↪ubsan.c:152

0x4008c6be: __ubsan_handle_out_of_bounds at /path/to/esp-idf/components/esp_system/
↪ubsan.c:223

0x400db74f: test_ub at main.c:128

0x400db99c: app_main at main.c:56 (discriminator 1)
```

The types of errors reported by UBSAN can be as follows:

Name	Meaning
`type_mismatch`, `type_mismatch_v1`	Incorrect pointer value: null, unaligned, not compatible with the given type.
`add_overflow`, `sub_overflow`, `mul_overflow`, `negate_overflow`	Integer overflow during addition, subtraction, multiplication, negation.
`divrem_overflow`	Integer division by 0 or `INT_MIN`.
`shift_out_of_bounds`	Overflow in left or right shift operators.
`out_of_bounds`	Access outside of bounds of an array.
`unreachable`	Unreachable code executed.
`missing_return`	Non-void function has reached its end without returning a value (C++ only).
`vla_bound_not_positive`	Size of variable length array is not positive.
`load_invalid_value`	Value of `bool` or `enum` (C++ only) variable is invalid (out of bounds).
`nonnull_arg`	Null argument passed to a function which is declared with a `nonnull` attribute.
`nonnull_return`	Null value returned from a function which is declared with `returns_nonnull` attribute.
`builtin_unreachable`	`__builtin_unreachable` function called.
`pointer_overflow`	Overflow in pointer arithmetic.

4.18 Hardware Abstraction

ESP-IDF provides a group of APIs for hardware abstraction. These APIs allow you to control peripherals at different levels of abstraction, giving you more flexibility compared to using only the ESP-IDF drivers to interact with hardware. ESP-IDF Hardware abstraction is likely to be useful for writing high-performance bare-metal drivers, or for attempting to port an ESP chip to another platform.

This guide is split into the following sections:

1. *Architecture*

2. *LL (Low Level) Layer*
3. *HAL (Hardware Abstraction Layer)*

Warning: Hardware abstraction API (excluding the driver and `xxx_types.h`) should be considered an experimental feature, thus cannot be considered public API. The hardware abstraction API does not adhere to the API name changing restrictions of ESP-IDF's versioning scheme. In other words, it is possible that Hardware Abstraction API may change in between non-major release versions.

Note: Although this document mainly focuses on hardware abstraction of peripherals, e.g., UART, SPI, I2C, certain layers of hardware abstraction extend to other aspects of hardware as well, e.g., some of the CPU's features are partially abstracted.

4.18.1 Architecture

Hardware abstraction in ESP-IDF is comprised of the following layers, ordered from low level of abstraction that is closer to hardware, to high level of abstraction that is further away from hardware.

- Low Level (LL) Layer
- Hardware Abstraction Layer (HAL)
- Driver Layers

The LL Layer, and HAL are entirely contained within the `hal` component. Each layer is dependent on the layer below it, i.e, driver depends on HAL, HAL depends on LL, LL depends on the register header files.

For a particular peripheral `xxx`, its hardware abstraction generally consists of the header files described in the table below. Files that are **Target Specific** have a separate implementation for each target, i.e., a separate copy for each chip. However, the `#include` directive is still target-independent, i.e., is the same for different targets, as the build system automatically includes the correct version of the header and source files.

Table 22: Hardware Abstraction Header Files

Include Directive	Target Specific	Description
`#include 'soc/xxx_caps.h"`	Y	This header contains a list of C macros specifying the various capabilities of the ESP32-C3's peripheral `xxx`. Hardware capabilities of a peripheral include things such as the number of channels, DMA support, hardware FIFO/buffer lengths, etc.
`#include "soc/xxx_struct.h"` `#include "soc/xxx_reg.h"`	Y	The two headers contain a representation of a peripheral's registers in C structure and C macro format respectively, allowing you to operate a peripheral at the register level via either of these two header files.
`#include "soc/xxx_pins.h"`	Y	If certain signals of a peripheral are mapped to a particular pin of the ESP32-C3, their mappings are defined in this header as C macros.
`#include "soc/xxx_periph.h"`	N	This header is mainly used as a convenience header file to automatically include `xxx_caps.h`, `xxx_struct.h`, and `xxx_reg.h`.
`#include "hal/xxx_types.h`	N	This header contains type definitions and macros that are shared among the LL, HAL, and driver layers. Moreover, it is considered public API thus can be included by the application level. The shared types and definitions usually related to non-implementation specific concepts such as the following: • Protocol-related types/macros such a frames, modes, common bus speeds, etc. • Features/characteristics of an `xxx` peripheral that are likely to be present on any implementation (implementation-independent) such as channels, operating modes, signal amplification or attenuation intensities, etc.
`#include "hal/xxx_ll.h"`	Y	This header contains the Low Level (LL) Layer of hardware abstraction. LL Layer API are primarily used to abstract away register operations into readable functions.
`#include "hal/xxx_hal.h"`	Y	The Hardware Abstraction Layer (HAL) is used to abstract away peripheral operation steps into functions (e.g., reading a buffer, starting a transmission, handling an event, etc). The HAL is built on top of the LL Layer.
`#include "driver/xxx.h"`	N	The driver layer is the highest level of ESP-IDF's hardware abstraction. Driver layer API are meant to be called from ESP-IDF applications, and internally utilize OS primitives. Thus, driver layer API are event-driven, and can used in a multi-threaded environment.

4.18.2 LL (Low Level) Layer

The primary purpose of the LL Layer is to abstract away register field access into more easily understandable functions. LL functions essentially translate various in/out arguments into the register fields of a peripheral in the form of get/set functions. All the necessary bit shifting, masking, offsetting, and endianness of the register fields should be handled by the LL functions.

```
//Inside xxx_ll.h

static inline void xxx_ll_set_baud_rate(xxx_dev_t *hw,
                                        xxx_ll_clk_src_t clock_source,
                                        uint32_t baud_rate) {
    uint32_t src_clk_freq = (source_clk == XXX_SCLK_APB) ? APB_CLK_FREQ : REF_CLK_
↪FREQ;
    uint32_t clock_divider = src_clk_freq / baud;
    // Set clock select field
    hw->clk_div_reg.divider = clock_divider >> 4;
    // Set clock divider field
```

(continues on next page)

(continued from previous page)

```
    hw->config.clk_sel = (source_clk == XXX_SCLK_APB) ? 0 : 1;
}

static inline uint32_t xxx_ll_get_rx_byte_count(xxx_dev_t *hw) {
    return hw->status_reg.rx_cnt;
}
```

The code snippet above illustrates typical LL functions for a peripheral `xxx`. LL functions typically have the following characteristics:

- All LL functions are defined as `static inline` so that there is minimal overhead when calling these functions due to compiler optimization. These functions are not guaranteed to be inlined by the compiler, so any LL function that is called when the cache is disabled (e.g., from an IRAM ISR context) should be marked with `__attribute__((always_inline))`.
- The first argument should be a pointer to a `xxx_dev_t` type. The `xxx_dev_t` type is a structure representing the peripheral's registers, thus the first argument is always a pointer to the starting address of the peripheral's registers. Note that in some cases where the peripheral has multiple channels with identical register layouts, `xxx_dev_t *hw` may point to the registers of a particular channel instead.
- LL functions should be short, and in most cases are deterministic. In other words, in the worst case, runtime of the LL function can be determined at compile time. Thus, any loops in LL functions should be finite bounded; however, there are currently a few exceptions to this rule.
- LL functions are not thread-safe, it is the responsibility of the upper layers (driver layer) to ensure that registers or register fields are not accessed concurrently.

4.18.3 HAL (Hardware Abstraction Layer)

The HAL layer models the operational process of a peripheral as a set of general steps, where each step has an associated function. For each step, the details of a peripheral's register implementation (i.e., which registers need to be set/read) are hidden (abstracted away) by the HAL. By modeling peripheral operation as a set of functional steps, any minor hardware implementation differences of the peripheral between different targets or chip versions can be abstracted away by the HAL (i.e., handled transparently). In other words, the HAL API for a particular peripheral remains mostly the same across multiple targets/chip versions.

The following HAL function examples are selected from the Watchdog Timer HAL as each function maps to one of the steps in a WDT's operation life cycle, thus illustrating how a HAL abstracts a peripheral's operation into functional steps.

```
// Initialize one of the WDTs
void wdt_hal_init(wdt_hal_context_t *hal, wdt_inst_t wdt_inst, uint32_t prescaler,␣
↪bool enable_intr);

// Configure a particular timeout stage of the WDT
void wdt_hal_config_stage(wdt_hal_context_t *hal, wdt_stage_t stage, uint32_t␣
↪timeout, wdt_stage_action_t behavior);

// Start the WDT
void wdt_hal_enable(wdt_hal_context_t *hal);

// Feed (i.e., reset) the WDT
void wdt_hal_feed(wdt_hal_context_t *hal);

// Handle a WDT timeout
void wdt_hal_handle_intr(wdt_hal_context_t *hal);

// Stop the WDT
void wdt_hal_disable(wdt_hal_context_t *hal);

// De-initialize the WDT
void wdt_hal_deinit(wdt_hal_context_t *hal);
```

To Disable RTC_WDT

```
wdt_hal_context_t rtc_wdt_ctx = RWDT_HAL_CONTEXT_DEFAULT();
wdt_hal_write_protect_disable(&rtc_wdt_ctx);
wdt_hal_disable(&rtc_wdt_ctx);
wdt_hal_write_protect_enable(&rtc_wdt_ctx);
```

To Reset the RTC_WDT Counter

```
wdt_hal_context_t rtc_wdt_ctx = RWDT_HAL_CONTEXT_DEFAULT();
wdt_hal_write_protect_disable(&rtc_wdt_ctx);
wdt_hal_feed(&rtc_wdt_ctx);
wdt_hal_write_protect_enable(&rtc_wdt_ctx);
```

HAL functions generally have the following characteristics:

- The first argument to a HAL function has the `xxx_hal_context_t *` type. The HAL context type is used to store information about a particular instance of the peripheral (i.e., the context instance). A HAL context is initialized by the `xxx_hal_init()` function and can store information such as the following:
  - The channel number of this instance
  - Pointer to the peripheral's (or channel's) registers (i.e., a `xxx_dev_t *` type)
  - Information about an ongoing transaction (e.g., pointer to DMA descriptor list in use)
  - Some configuration values for the instance (e.g., channel configurations)
  - Variables to maintain state information regarding the instance (e.g., a flag to indicate if the instance is waiting for transaction to complete)
- HAL functions should not contain any OS primitives such as queues, semaphores, mutexes, etc. All synchronization/concurrency should be handled at higher layers (e.g., the driver).
- Some peripherals may have steps that cannot be further abstracted by the HAL, thus end up being a direct wrapper (or macro) for an LL function.
- Some HAL functions may be placed in IRAM thus may carry an `IRAM_ATTR` or be placed in a separate `xxx_hal_iram.c` source file.

4.19 JTAG Debugging

This document provides a guide to installing OpenOCD for ESP32-C3 and debugging using GDB.

Note: You can also debug your ESP32-C3 without needing to setup JTAG or OpenOCD by using `idf.py monitor`. See: *IDF Monitor* and *CONFIG_ESP_SYSTEM_GDBSTUB_RUNTIME*.

The document is structured as follows:

Introduction Introduction to the purpose of this guide.

How it Works? Description how ESP32-C3, JTAG interface, OpenOCD and GDB are interconnected and working together to enable debugging of ESP32-C3.

Selecting JTAG Adapter What are the criteria and options to select JTAG adapter hardware.

Setup of OpenOCD Procedure to install OpenOCD and verify that it is installed.

Configuring ESP32-C3 Target Configuration of OpenOCD software and setting up of JTAG adapter hardware, which together make up the debugging target.

Launching Debugger Steps to start up a debug session with GDB from *Eclipse* and from *Command Line*.

Debugging Examples If you are not familiar with GDB, check this section for debugging examples provided from *Eclipse* as well as from *Command Line*.

Building OpenOCD from Sources Procedure to build OpenOCD from sources for *Windows*, *Linux* and *macOS* operating systems.

Tips and Quirks This section provides collection of tips and quirks related to JTAG debugging of ESP32-C3 with OpenOCD and GDB.

4.19.1 Introduction

Espressif has ported OpenOCD to support the ESP32-C3 processor and the multi-core FreeRTOS (which is the foundation of most ESP32-C3 apps). Additionally, some extra tools have been written to provide extra features that OpenOCD does not support natively.

This document provides a guide to installing OpenOCD for ESP32-C3 and debugging using GDB under Linux, Windows and macOS. Except for OS specific installation procedures, the s/w user interface and use procedures are the same across all supported operating systems.

Note: Screenshots presented in this document have been made for Eclipse Neon 3 running on Ubuntu 16.04 LTS. There may be some small differences in what a particular user interface looks like, depending on whether you are using Windows, macOS or Linux and/or a different release of Eclipse.

4.19.2 How it Works?

The key software and hardware components that perform debugging of ESP32-C3 with OpenOCD over JTAG (Joint Test Action Group) interface is presented in the diagram below under the "Debugging With JTAG" label. These components include riscv32-esp-elf-gdb debugger, OpenOCD on chip debugger, and the JTAG adapter connected to ESP32-C3 target.

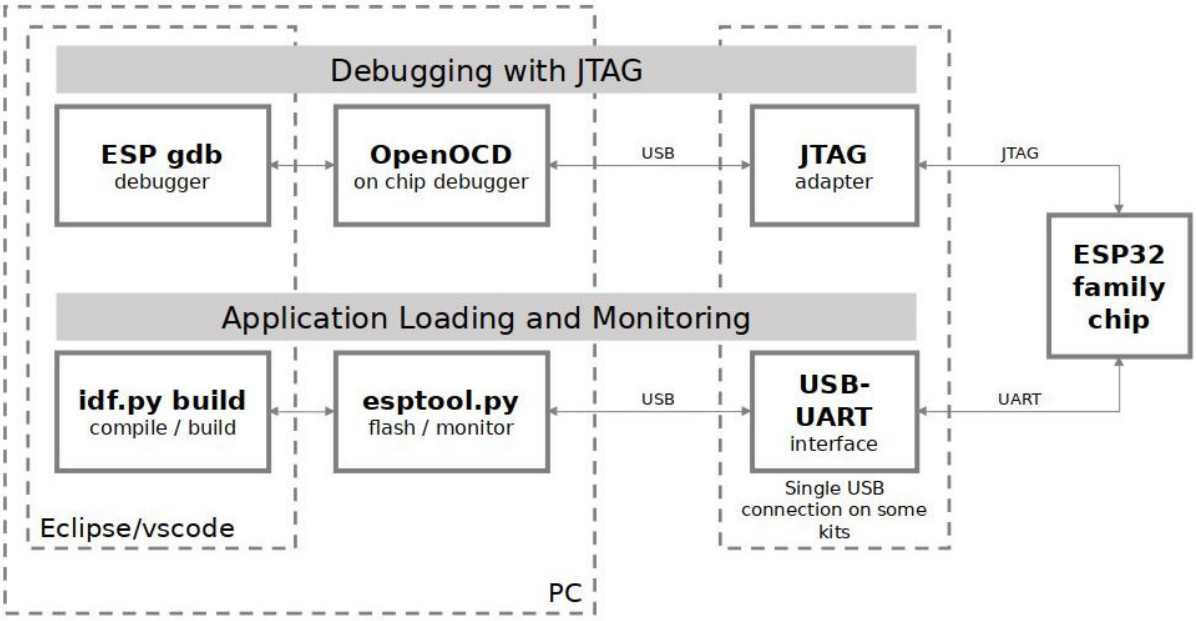

Fig. 42: JTAG debugging - overview diagram

Likewise, the "Application Loading and Monitoring" label indicates the key software and hardware components that allow an application to be compiled, built, and flashed to ESP32-C3, as well as to provide means to monitor diagnostic messages from ESP32-C3.

"Debugging With JTAG" and "Application Loading and Monitoring" is integrated under the Eclipse IDE in order to provide a quick and easy transition between writing/compiling/loading/debugging code. The Eclipse IDE (and the integrated debugging software) is available for Windows, Linux and macOS platforms. Depending on user preferences, both the debugger and `idf.py build` can also be used directly from terminal/command line, instead of Eclipse.

The connection from PC to ESP32-C3 is done effectively with a single USB cable. This is made possible by the ESP32-C3 chip itself, which provides two USB channels, one for JTAG and the other for the USB terminal connection. The USB cable should be connected to the D+/D- USB pins of ESP32-C3 and not to the serial RxD/TxD through a USB-to-UART chip. The proper connection is explained later in subsection *Configuring ESP32-C3 Target*.

Note: Debugging through the USB interface implemented in ESP32-C3 requires to have a chip with revision 0.3 or newer. Please use other debugging options (e.g., with ESP-Prog) for chip revisions 0.1 and 0.2. The easiest way to determine the chip revision is to look for the `boot: chip revision: v0.3` message at the beginning of the boot log. See SoC errata for more details.

4.19.3 Selecting JTAG Adapter

The quickest and most convenient way to start with JTAG debugging is through a USB cable connected to the D+/D- USB pins of ESP32-C3. No need for an external JTAG adapter and extra wiring/cable to connect JTAG to ESP32-C3.

If you decide to use separate JTAG adapter, look for one that is compatible with both the voltage levels on the ESP32-C3 as well as with the OpenOCD software. The JTAG port on the ESP32-C3 is an industry-standard JTAG port which lacks (and does not need) the TRST pin. The JTAG I/O pins all are powered from the VDD_3P3_RTC pin (which normally would be powered by a 3.3 V rail) so the JTAG adapter needs to be able to work with JTAG pins in that voltage range.

On the software side, OpenOCD supports a fair amount of JTAG adapters. See https://openocd.org/doc/html/Debug-Adapter-Hardware.html for an (unfortunately slightly incomplete) list of the adapters OpenOCD works with. This page lists SWD-compatible adapters as well; take note that the ESP32-C3 does not support SWD. JTAG adapters that are hardcoded to a specific product line, e.g., ST-LINK debugging adapters for STM32 families, will not work.

The minimal signalling to get a working JTAG connection are TDI, TDO, TCK, TMS and GND. Some JTAG debuggers also need a connection from the ESP32-C3 power line to a line called e.g., Vtar to set the working voltage. SRST can optionally be connected to the CH_PD of the ESP32-C3, although for now, support in OpenOCD for that line is pretty minimal.

ESP-Prog is an example for using an external board for debugging by connecting it to the JTAG pins of ESP32-C3.

4.19.4 Setup of OpenOCD

If you have already set up ESP-IDF with CMake build system according to the *Getting Started Guide*, then OpenOCD is already installed. After *setting up the environment* in your terminal, you should be able to run OpenOCD. Check this by executing the following command:

```
openocd --version
```

The output should be as follows (although the version may be more recent than listed here):

```
Open On-Chip Debugger v0.12.0-esp32-20240318 (2024-03-18-18:25)
Licensed under GNU GPL v2
For bug reports, read
        http://openocd.org/doc/doxygen/bugs.html
```

You may also verify that OpenOCD knows where its configuration scripts are located by printing the value of `OPENOCD_SCRIPTS` environment variable, by typing `echo $OPENOCD_SCRIPTS` (for Linux and macOS) or `echo %OPENOCD_SCRIPTS%` (for Windows). If a valid path is printed, then OpenOCD is set up correctly.

If any of these steps do not work, please go back to the *setting up the tools* section (for Linux and macOS) or *ESP-IDF Tools Installer* (for Windows) section of the Getting Started Guide.

Note: It is also possible to build OpenOCD from source. Please refer to *Building OpenOCD from Sources* section for details.

4.19.5 Configuring ESP32-C3 Target

Once OpenOCD is installed, you can proceed to configuring the ESP32-C3 target (i.e ESP32-C3 board with JTAG interface). Configuring the target is split into the following three steps:

- *Configure and Connect JTAG Interface*
- *Run OpenOCD*
- *Upload Application for Debugging*

Configure and Connect JTAG Interface

This step depends on the JTAG and ESP32-C3 board you are using (see the two cases described below).

Configure ESP32-C3 Built-in JTAG Interface

ESP32-C3 has a built-in JTAG circuitry and can be debugged without any additional chip. Only an USB cable connected to the D+/D- pins is necessary. The necessary connections are shown in the following section.

Configure Hardware

Table 23: ESP32-C3 pins and USB signals

ESP32-C3 Pin	USB Signal
GPIO18	D-
GPIO19	D+
5V	V_BUS
GND	Ground

Please verify that the ESP32-C3 pins used for USB communication are not connected to some other HW that may disturb the JTAG operation.

Configure USB Drivers JTAG communication should work on all supported platforms. Windows users might get *LIBUSB_ERROR_NOT_FOUND* errors. Please use version 2.8 (or newer) of the *ESP-IDF Tools Installer* and select the driver "Espressif - WinUSB support for JTAG (ESP32-C3/S3)" in order to resolve this issue. If you do not want to re-run the installer then the same can be achieved with idf-env by running the following command from PowerShell:

```
Invoke-WebRequest 'https://dl.espressif.com/dl/idf-env/idf-env.exe' -OutFile .\idf-
↪env.exe; .\idf-env.exe driver install --espressif
```

On Linux adding OpenOCD udev rules is required and is done by placing the following udev rules file in the `/etc/udev/rules.d` folder.

Configure Other JTAG Interfaces

For guidance about which JTAG interface to select when using OpenOCD with ESP32-C3, refer to the section *Selecting JTAG Adapter*. Then follow the configuration steps below to get it working.

Configure eFuses By default, ESP32-C3 JTAG interface is connected to the *built-in USB_SERIAL_JTAG peripheral*. To use an external JTAG adapter instead, you need to switch the JTAG interface to the GPIO pins. This can be done by burning eFuses using `idf.py` tool.

Burning `DIS_USB_JTAG` eFuse will permanently disable the connection between USB_SERIAL_JTAG and the JTAG port of the ESP32-C3. JTAG interface can then be connected to GPIO4-GPIO7. Note that USB CDC functionality of USB_SERIAL_JTAG will still be usable, i.e., flashing and monitoring over USB CDC will still work.

Warning: Burning eFuses is an irreversible operation, so please consider the above option before starting the process.

Configure Hardware

1. Identify all pins/signals on JTAG interface and ESP32-C3 board that should be connected to establish communication.

Table 24: ESP32-C3 pins and JTAG signals

ESP32-C3 Pin	JTAG Signal
MTDO / GPIO7	TDO
MTDI / GPIO5	TDI
MTCK / GPIO6	TCK
MTMS / GPIO4	TMS

2. Verify if ESP32-C3 pins used for JTAG communication are not connected to some other hardware that may disturb JTAG operation.
3. Connect identified pin/signals of ESP32-C3 and JTAG interface.

Configure Drivers You may need to install driver software to make JTAG work with computer. Refer to documentation of your JTAG adapter for related details.

On Linux, adding OpenOCD udev rules is required and is done by copying the udev rules file into the `/etc/udev/rules.d` directory.

Connect Connect JTAG interface to the computer. Power on ESP32-C3 and JTAG interface boards. Check if the JTAG interface is visible on the computer.

To carry on with debugging environment setup, proceed to section *Run OpenOCD*.

Run OpenOCD

Once target is configured and connected to computer, you are ready to launch OpenOCD.

Open a terminal and set it up for using the ESP-IDF as described in the *setting up the environment* section of the Getting Started Guide. Then run OpenOCD (this command works on Windows, Linux, and macOS):

```
openocd -f board/esp32c3-builtin.cfg
```

Note: The files provided after `-f` above are specific for ESP32-C3 through built-in USB connection. You may need to provide different files depending on the hardware that is used. For guidance see *Configuration of OpenOCD for Specific Target*.

For example, `board/esp32c6-ftdi.cfg` can be used for a custom board with an FT2232H or FT232H chip used for JTAG connection, or with ESP-Prog.

You should now see similar output (this log is for ESP32-C3 through built-in USB connection):

```
user-name@computer-name:~/esp/esp-idf$ openocd -f board/esp32c3-builtin.cfg
Open On-Chip Debugger v0.10.0-esp32-20201202-26-g05a036c2 (2021-03-15-17:18)
Licensed under GNU GPL v2
For bug reports, read
    https://openocd.org/doc/doxygen/bugs.html
Info : only one transport option; autoselect 'jtag'
Warn : Transport "jtag" was already selected
```

(continues on next page)

(continued from previous page)

```
force hard breakpoints
Info : Listening on port 6666 for tcl connections
Info : Listening on port 4444 for telnet connections
Info : esp_usb_jtag: Device found. Base speed 40000KHz, div range 1 to 255
Info : clock speed 40000 kHz
Info : JTAG tap: esp32c3.cpu tap/device found: 0x00005c25 (mfg: 0x612 (Espressif␣
↪Systems), part: 0x0005, ver: 0x0)
Info : datacount=2 progbufsize=16
Info : Examined RISC-V core; found 1 harts
Info :  hart 0: XLEN=32, misa=0x40101104
Info : Listening on port 3333 for gdb connections
```

- If there is an error indicating permission problems, please see section on "Permissions delegation" in the OpenOCD README file located in the `~/esp/openocd-esp32` directory.
- In case there is an error in finding the configuration files, e.g., `Can't find board/esp32c3-builtin.cfg`, check if the `OPENOCD_SCRIPTS` environment variable is set correctly. This variable is used by OpenOCD to look for the files specified after the `-f` option. See *Setup of OpenOCD* section for details. Also check if the file is indeed under the provided path.
- If you see JTAG errors (e.g., `...all ones` or `...all zeroes`), please check your JTAG connections, whether other signals are connected to JTAG besides ESP32-C3's pins, and see if everything is powered on correctly.

Upload Application for Debugging

Build and upload your application to ESP32-C3 as usual, see *Step 5. First Steps on ESP-IDF*.

Another option is to write application image to flash using OpenOCD via JTAG with commands like this:

```
openocd -f board/esp32c3-builtin.cfg -c "program_esp filename.bin 0x10000 verify␣
↪exit"
```

OpenOCD flashing command `program_esp` has the following format:

`program_esp <image_file> <offset> [verify] [reset] [exit] [compress] [encrypt]`

- `image_file` - Path to program image file.
- `offset` - Offset in flash bank to write image.
- `verify` - Optional. Verify flash contents after writing.
- `reset` - Optional. Reset target after programming.
- `exit` - Optional. Finally exit OpenOCD.
- `compress` - Optional. Compress image file before programming.
- `encrypt` - Optional. Encrypt binary before writing to flash. Same functionality with `idf.py encrypted-flash`

You are now ready to start application debugging. Follow the steps described in the section below.

4.19.6 Launching Debugger

The toolchain for ESP32-C3 features GNU Debugger, in short GDB. It is available with other toolchain programs under filename: riscv32-esp-elf-gdb. GDB can be called and operated directly from command line in a terminal. Another option is to call it from within IDE (like Eclipse, Visual Studio Code, etc.) and operate indirectly with help of GUI instead of typing commands in a terminal.

The options of using debugger are discussed under links below.

- *Eclipse*
- *Command Line*
- Configuration for Visual Studio Code Debug

It is recommended to first check if debugger works from *Command Line* and then move to using *Eclipse*.

4.19.7 Debugging Examples

This section is intended for users not familiar with GDB. It presents example debugging session from *Eclipse* using simple application available under get-started/blink and covers the following debugging actions:

1. *Navigating Through the Code, Call Stack and Threads*
2. *Setting and Clearing Breakpoints*
3. *Halting the Target Manually*
4. *Stepping Through the Code*
5. *Checking and Setting Memory*
6. *Watching and Setting Program Variables*
7. *Setting Conditional Breakpoints*

Similar debugging actions are provided using GDB from *Command Line*.

Note: *Debugging FreeRTOS Objects* is currently only available for command line debugging.

Before proceeding to examples, set up your ESP32-C3 target and load it with get-started/blink.

4.19.8 Building OpenOCD from Sources

Please refer to separate documents listed below, that describe build process.

Building OpenOCD from Sources for Windows

Note: This document outlines how to build a binary of OpenOCD from its source files instead of downloading the pre-built binary. For a quick setup, users can download a pre-built binary of OpenOCD from Espressif GitHub instead of compiling it themselves (see *Setup of OpenOCD* for more details).

Note: All code snippets in this document are assumed to be running in an MSYS2 shell with the MINGW32 subsystem.

Install Dependencies Install packages that are required to compile OpenOCD:

```
pacman -S --noconfirm --needed autoconf automake git make \
mingw-w64-i686-gcc \
mingw-w64-i686-toolchain \
mingw-w64-i686-libtool \
mingw-w64-i686-pkg-config \
mingw-w64-cross-winpthreads-git \
p7zip
```

Download Sources of OpenOCD The sources for the ESP32-C3-enabled variant of OpenOCD are available from Espressif's GitHub under https://github.com/espressif/openocd-esp32. These source files can be pulled via Git using the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in `~/esp/openocd-esp32` directory.

Downloading libusb The libusb library is also required when building OpenOCD. The following commands will download a particular release of libusb and uncompress it to the current directory.

```
wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z
```

We now need to export the following variables such that the libusb library gets linked into the OpenOCD build.

```
export CPPFLAGS="$CPPFLAGS -I${PWD}/libusb/include/libusb-1.0"
export LDFLAGS="$LDFLAGS -L${PWD}/libusb/MinGW32/.libs/dll"
```

Build OpenOCD The following commands will configure OpenOCD then build it.

```
cd ~/esp/openocd-esp32
export CPPFLAGS="$CPPFLAGS -D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="
↪$CFLAGS -Wno-error"
./bootstrap
./configure --disable-doxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --
↪build=i686-w64-mingw32 --host=i686-w64-mingw32
make
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src
cp /opt/i686-w64-mingw32/bin/libwinpthread-1.dll ./src
```

Once the build is completed, the OpenOCD binary will be placed in `~/esp/openocd-esp32/src/`.

You can then optionally call `make install`. This will copy the OpenOCD binary to a user specified location.

- This location can be specified when OpenOCD is configured, or by setting `export DESTDIR="/custom/install/dir"` before calling `make install`.
- If you have an existing OpenOCD (from e.g., another development platform), you may want to skip this call as your existing OpenOCD may get overwritten.

Note:

- Should an error occur, resolve it and try again until the command `make` works.
- If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under `OpenOCD configuration summary`.
- If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
- For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.Windows`.
- Don't forget to copy *libusb-1.0.dll* and *libwinpthread-1.dll* into *OOCD_INSTALLDIR/bin* from `~/esp/openocd-esp32/src`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src` directory.

Full Listing For greater convenience, all of commands called throughout the OpenOCD build process have been listed in the code snippet below. Users can copy this code snippet into a shell script then execute it:

```
pacman -S --noconfirm --needed autoconf automake git make mingw-w64-i686-gcc mingw-
↪w64-i686-toolchain mingw-w64-i686-libtool mingw-w64-i686-pkg-config mingw-w64-
↪cross-winpthreads-git p7zip
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git

wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z
export CPPFLAGS="$CPPFLAGS -I${PWD}/libusb/include/libusb-1.0"; export LDFLAGS="
↪$LDFLAGS -L${PWD}/libusb/MinGW32/.libs/dll"

export CPPFLAGS="$CPPFLAGS -D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="
↪$CFLAGS -Wno-error"
cd ~/esp/openocd-esp32
./bootstrap
./configure --disable-doxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --
↪build=i686-w64-mingw32 --host=i686-w64-mingw32
make
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src
cp /opt/i686-w64-mingw32/bin/libwinpthread-1.dll ./src

# # optional
# export DESTDIR="$PWD"
# make install
# cp ./src/libusb-1.0.dll $DESTDIR/mingw32/bin
# cp ./src/libwinpthread-1.dll $DESTDIR/mingw32/bin
```

Next Steps To carry on with debugging environment setup, proceed to section *Configuring ESP32-C3 Target*.

Building OpenOCD from Sources for Linux

The following instructions are alternative to downloading binary OpenOCD from Espressif GitHub. To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section *Setup of OpenOCD*.

Download Sources of OpenOCD The sources for the ESP32-C3-enabled variant of OpenOCD are available from Espressif GitHub under https://github.com/espressif/openocd-esp32. To download the sources, use the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in `~/esp/openocd-esp32` directory.

Install Dependencies Install packages that are required to compile OpenOCD.

Note: Install the following packages one by one, check if installation was successful and then proceed to the next package. Resolve reported problems before moving to the next step.

```
sudo apt-get install make
sudo apt-get install libtool
sudo apt-get install pkg-config
sudo apt-get install autoconf
sudo apt-get install automake
```

(continues on next page)

(continued from previous page)

```
sudo apt-get install texinfo
sudo apt-get install libusb-1.0
```

Note:

- Version of pkg-config should be 0.2.3 or above.
- Version of autoconf should be 2.6.4 or above.
- Version of automake should be 1.9 or above.
- When using USB-Blaster, ASIX Presto, OpenJTAG and FT2232 as adapters, drivers libFTDI and FTD2XX need to be downloaded and installed.
- When using CMSIS-DAP, HIDAPI is needed.

Build OpenOCD Proceed with configuring and building OpenOCD:

```
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g., another development platform), as it may get overwritten.

Note:

- Should an error occur, resolve it and try again until the command `make` works.
- If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under `OpenOCD configuration summary`.
- If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
- For details concerning compiling OpenOCD, please refer to `openocd-esp32/README`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/openocd-esp32/bin` directory.

Next Steps To carry on with debugging environment setup, proceed to section *Configuring ESP32-C3 Target*.

Building OpenOCD from Sources for MacOS

The following instructions are alternative to downloading binary OpenOCD from Espressif GitHub. To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section *Setup of OpenOCD*.

Download Sources of OpenOCD The sources for the ESP32-C3-enabled variant of OpenOCD are available from Espressif GitHub under https://github.com/espressif/openocd-esp32. To download the sources, use the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in `~/esp/openocd-esp32` directory.

Install Dependencies Install packages that are required to compile OpenOCD using Homebrew:

```
brew install automake libtool libusb wget gcc@4.9 pkg-config
```

Build OpenOCD Proceed with configuring and building OpenOCD:

```
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g., another development platform), as it may get overwritten.

Note:

- Should an error occur, resolve it and try again until the command `make` works.
- Error `Unknown command 'raggedright'` may indicate that the required version of `texinfo` was not installed on your computer or installed but was not linked to your PATH. To resolve this issue make sure `texinfo` is installed and PATH is adjusted prior to the `./bootstrap` by running:

```
brew install texinfo
export PATH=/usr/local/opt/texinfo/bin:$PATH
```

- If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under `OpenOCD configuration summary`.
- If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
- For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.OSX`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src/openocd` directory.

Next Steps To carry on with debugging environment setup, proceed to section *Configuring ESP32-C3 Target*.

The examples of invoking OpenOCD in this document assume using pre-built binary distribution described in section *Setup of OpenOCD*.

To use binaries build locally from sources, change the path to OpenOCD executable to `src/openocd` and set the `OPENOCD_SCRIPTS` environment variable so that OpenOCD can find the configuration files. For Linux and macOS:

```
cd ~/esp/openocd-esp32
export OPENOCD_SCRIPTS=$PWD/tcl
```

For Windows:

```
cd %USERPROFILE%\esp\openocd-esp32
set "OPENOCD_SCRIPTS=%CD%\tcl"
```

Example of invoking OpenOCD build locally from sources, for Linux and macOS:

```
src/openocd -f board/esp32c3-builtin.cfg
```

and Windows:

```
src\openocd -f board/esp32c3-builtin.cfg
```

4.19.9 Tips and Quirks

This section provides collection of links to all tips and quirks referred to from various parts of this guide.

Tips and Quirks

This section provides collection of all tips and quirks referred to from various parts of this guide.

Breakpoints and Watchpoints Available ESP32-C3 debugger supports 8 hardware implemented breakpoints and 64 software ones. Hardware breakpoints are implemented by ESP32-C3 chip's logic and can be set anywhere in the code: either in flash or IRAM program's regions. Additionally there are 2 types of software breakpoints implemented by OpenOCD: flash (up to 32) and IRAM (up to 32) breakpoints. Currently GDB can not set software breakpoints in flash. So until this limitation is removed those breakpoints have to be emulated by OpenOCD as hardware ones (see *below* for details). ESP32-C3 also supports 8 watchpoints, so 8 variables can be watched for change or read by the GDB command `watch myVariable`. Note that menuconfig option *CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK* uses the last watchpoint and will not provide expected results, if you also try to use it within OpenOCD/GDB. See menuconfig's help for detailed description.

What Else Should I Know About Breakpoints? Emulating part of hardware breakpoints using software flash ones means that the GDB command `hb myFunction` which is invoked for function in flash will use pure hardware breakpoint if it is available otherwise one of the 32 software flash breakpoints is used. The same rule applies to `b myFunction`-like commands. In this case GDB will decide what type of breakpoint to set itself. If `myFunction` is resided in writable region (IRAM) software IRAM breakpoint will be used otherwise hardware or software flash breakpoint is used as it is done for `hb` command.

Flash Mappings vs SW Flash Breakpoints In order to set/clear software breakpoints in flash, OpenOCD needs to know their flash addresses. To accomplish conversion from the ESP32-C3 address space to the flash one, OpenOCD uses mappings of program's code regions resided in flash. Those mappings are kept in the image header which is prepended to program binary data (code and data segments) and is specific to every application image written to the flash. So to support software flash breakpoints OpenOCD should know where application image under debugging is resided in the flash. By default OpenOCD reads partition table at 0x8000 and uses mappings from the first found application image, but there can be the cases when it will not work, e.g., partition table is not at standard flash location or even there can be multiple images: one factory and two OTA and you may want to debug any of them. To cover all possible debugging scenarios OpenOCD supports special command which can be used to set arbitrary location of application image to debug. The command has the following format:

```
esp appimage_offset <offset>
```

Offset should be in hex format. To reset to the default behaviour you can specify `-1` as offset.

Note: Since GDB requests memory map from OpenOCD only once when connecting to it, this command should be specified in one of the TCL configuration files, or passed to OpenOCD via its command line. In the latter case command line should look like below:

```
openocd -f board/esp32c3-builtin.cfg -c "init; halt; esp appimage_offset 0x210000"
```

Another option is to execute that command via OpenOCD telnet session and then connect GDB, but it seems to be less handy.

Why Stepping with "next" Does Not Bypass Subroutine Calls? When stepping through the code with `next` command, GDB is internally setting a breakpoint ahead in the code to bypass the subroutine calls. If all 8 breakpoints are already set, this functionality will not work. If this is the case, delete breakpoints to have one "spare". With all breakpoints already used, stepping through the code with `next` command will work as like with `step` command and debugger will step inside subroutine calls.

Support Options for OpenOCD at Compile Time ESP-IDF has some support options for OpenOCD debugging which can be set at compile time:

- *CONFIG_ESP_DEBUG_OCDAWARE* is enabled by default. If a panic or unhandled exception is thrown and a JTAG debugger is connected (ie OpenOCD is running), ESP-IDF will break into the debugger.
- *CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK* (disabled by default) sets watchpoint index 1 (the second of two) at the end of any task stack. This is the most accurate way to debug task stack overflows. Click the link for more details.

Please see the *project configuration menu* menu for more details on setting compile-time options.

FreeRTOS Support OpenOCD has explicit support for the ESP-IDF FreeRTOS. GDB can see FreeRTOS tasks as threads. Viewing them all can be done using the GDB `i threads` command, changing to a certain task is done with `thread n`, with `n` being the number of the thread. FreeRTOS detection can be disabled in target's configuration. For more details see *Configuration of OpenOCD for Specific Target*.

GDB has a Python extension for FreeRTOS support. ESP-IDF automatically loads this module into GDB with the `idf.py gdb` command when the system requirements are met. See more details in *Debugging FreeRTOS Objects*.

Optimize JTAG Speed In order to achieve higher data rates and minimize number of dropped packets it is recommended to optimize setting of JTAG clock frequency, so it is at maximum and still provides stable operation of JTAG. To do so use the following tips.

1. The upper limit of JTAG clock frequency is 20 MHz if CPU runs at 80 MHz, or 26 MHz if CPU runs at 160 MHz or 240 MHz.
2. Depending on particular JTAG adapter and the length of connecting cables, you may need to reduce JTAG frequency below 20 MHz or 26 MHz.
3. In particular reduce frequency, if you get DSR/DIR errors (and they do not relate to OpenOCD trying to read from a memory range without physical memory being present there).
4. ESP-WROVER-KIT operates stable at 20 MHz or 26 MHz.

What Is the Meaning of Debugger's Startup Commands? On startup, debugger is issuing sequence of commands to reset the chip and halt it at specific line of code. This sequence (shown below) is user defined to pick up at most convenient/appropriate line and start debugging.

- `set remote hardware-watchpoint-limit 8` —Restrict GDB to using available hardware watchpoints supported by the chip, 8 for ESP32-C3. For more information see https://sourceware.org/gdb/onlinedocs/gdb/Remote-Configuration.html.
- `mon reset halt` —reset the chip and keep the CPUs halted
- `maintenance flush register-cache` —monitor (`mon`) command can not inform GDB that the target state has changed. GDB will assume that whatever stack the target had before `mon reset halt` will still be valid. In fact, after reset the target state will change, and executing `maintenance flush register-cache` is a way to force GDB to get new state from the target.
- `thb app_main` —insert a temporary hardware breakpoint at `app_main`, put here another function name if required
- `c` —resume the program. It will then stop at breakpoint inserted at `app_main`.

Configuration of OpenOCD for Specific Target There are several kinds of OpenOCD configuration files (`*.cfg`). All configuration files are located in subdirectories of `share/openocd/scripts` directory of OpenOCD distribution (or `tcl/scripts` directory of the source repository). For the purposes of this guide, the most important ones are `board`, `interface` and `target`.

- `interface` configuration files describe the JTAG adapter. Examples of JTAG adapters are ESP-Prog and J-Link.
- `target` configuration files describe specific chips, or in some cases, modules.
- `board` configuration files are provided for development boards with a built-in JTAG adapter. Such files include an `interface` configuration file to choose the adapter, and `target` configuration file to choose the chip/module.

The following configuration files are available for ESP32-C3:

Table 25: OpenOCD configuration files for ESP32-C3

Name	Description
`board/esp32c3-builtin.cfg`	Board configuration file for ESP32-C3 through built-in USB, includes target and adapter configuration.
`board/esp32c3-ftdi.cfg`	Board configuration file for ESP32-C3 debug through an ESP-Prog compatible FTDI, includes target and adapter configuration.
`target/esp32c3.cfg`	ESP32-C3 target configuration file. Can be used together with one of the `interface/` configuration files.
`interface/esp_usb_jtag.cfg`	JTAG adapter configuration file for ESP32-C3.
`interface/ftdi/esp32_devkitj_v1.cfg`	JTAG adapter configuration file for ESP-Prog boards.

If you are using one of the boards which have a pre-defined configuration file, you only need to pass one `-f` argument to OpenOCD, specifying that file.

If you are using a board not listed here, you need to specify both the interface configuration file and target configuration file.

Custom Configuration Files OpenOCD configuration files are written in TCL, and include a variety of choices for customization and scripting. This can be useful for non-standard debugging situations. Please refer to OpenOCD Manual for the TCL scripting reference.

OpenOCD Configuration Variables The following variables can be optionally set before including the ESP-specific target configuration file. This can be done either in a custom configuration file, or from the command line.

The syntax for setting a variable in TCL is:

```
set VARIABLE_NAME value
```

To set a variable from the command line (replace the name of .cfg file with the correct file for your board):

```
openocd -c 'set VARIABLE_NAME value' -f board/esp-xxxxx-kit.cfg
```

It is important to set the variable before including the ESP-specific configuration file, otherwise the variable will not have effect. You can set multiple variables by repeating the `-c` option.

Table 26: Common ESP-related OpenOCD variables

Variable	Description
`ESP_RTOS`	Set to `none` to disable RTOS support. In this case, thread list will not be available in GDB. Can be useful when debugging FreeRTOS itself, and stepping through the scheduler code.
`ESP_FLASH_SIZE`	Set to `0` to disable Flash breakpoints support.
`ESP_SEMIHOST_BASEDIR`	Set to the path (on the host) which will be the default directory for semihosting functions.

How Debugger Resets ESP32-C3? The board can be reset by entering `mon reset` or `mon reset halt` into GDB.

Can JTAG Pins Be Used for Other Purposes? ESP32-C3 contains a USB Serial/JTAG Controller which can be used for debugging. By default, ESP32-C3 JTAG interface is connected to the built-in USB SERIAL/JTAG peripheral. For details, please refer to *Configure ESP32-C3 built-in JTAG Interface*.

When you use USB Serial/JTAG Controller for debugging, GPIO4-GPIO7 can be used for other purposes.

However, if you switch the USB JTAG interface to the GPIOs by burning eFuses, GPIO4-GPIO7 can be used for JTAG debugging. When they perform this function, they cannot be used for other purposes.

Operation of JTAG may be disturbed, if some other hardware is connected to JTAG pins besides ESP32-C3 module and JTAG adapter. ESP32-C3 JTAG is using the following pins:

Table 27: ESP32-C3 pins and JTAG signals

ESP32-C3 Pin	JTAG Signal
MTDO / GPIO7	TDO
MTDI / GPIO5	TDI
MTCK / GPIO6	TCK
MTMS / GPIO4	TMS

JTAG communication will likely fail, if configuration of JTAG pins is changed by a user application. If OpenOCD initializes correctly (detects all the CPU cores in the SOC), but loses sync and spews out a lot of DTR/DIR errors when the program is running, it is likely that the application reconfigures the JTAG pins to something else, or the user forgot to connect Vtar to a JTAG adapter that requires it.

JTAG with Flash Encryption or Secure Boot By default, enabling Flash Encryption and/or Secure Boot will disable JTAG debugging. On first boot, the bootloader will burn an eFuse bit to permanently disable JTAG at the same time it enables the other features.

Please note that once JTAG is permanently disabled, it cannot be re-enabled for JTAG access. However, we do have the option of disabling JTAG softly. For more details on soft disabling and re-enabling soft-disabled JTAG, please refer to the *HMAC for Enabling JTAG*.

The project configuration option *CONFIG_SECURE_BOOT_ALLOW_JTAG* will keep JTAG enabled at this time, removing all physical security but allowing debugging. (Although the name suggests Secure Boot, this option can be applied even when only Flash Encryption is enabled).

However, OpenOCD may attempt to automatically read and write the flash in order to set *software breakpoints*. This has two problems:

- Software breakpoints are incompatible with Flash Encryption, OpenOCD currently has no support for encrypting or decrypting flash contents.
- If Secure Boot is enabled, setting a software breakpoint will change the digest of a signed app and make the signature invalid. This means if a software breakpoint is set and then a reset occurs, the signature verification will fail on boot.

To disable software breakpoints while using JTAG, add an extra argument `-c 'set ESP_FLASH_SIZE 0'` to the start of the OpenOCD command line, see *OpenOCD Configuration Variables*.

Note: For the same reason, the ESP-IDF app may fail bootloader verification of app signatures, when this option is enabled and a software breakpoint is set.

Reporting Issues with OpenOCD/GDB In case you encounter a problem with OpenOCD or GDB programs itself and do not find a solution searching available resources on the web, open an issue in the OpenOCD issue tracker under https://github.com/espressif/openocd-esp32/issues.

1. In issue report provide details of your configuration:
   a. JTAG adapter type, and the chip/module being debugged.
   b. Release of ESP-IDF used to compile and load application that is being debugged.
   c. Details of OS used for debugging.
   d. Is OS running natively on a PC or on a virtual machine?
2. Create a simple example that is representative to observed issue. Describe steps how to reproduce it. In such an example debugging should not be affected by non-deterministic behaviour introduced by the Wi-Fi stack, so problems will likely be easier to reproduce, if encountered once.
3. Prepare logs from debugging session by adding additional parameters to start up commands.
   OpenOCD:

   ```
   openocd -l openocd_log.txt -d3 -f board/esp32c3-builtin.cfg
   ```

   Logging to a file this way will prevent information displayed on the terminal. This may be a good thing taken amount of information provided, when increased debug level `-d3` is set. If you still like to see the log on the screen, then use another command instead:

   ```
   openocd -d3 -f board/esp32c3-builtin.cfg 2>&1 | tee openocd.log
   ```

   Debugger:

   ```
   riscv32-esp-elf-gdb -ex "set remotelogfile gdb_log.txt" <all other options>
   ```

   Optionally add command `remotelogfile gdb_log.txt` to the `gdbinit` file.
4. Attach both `openocd_log.txt` and `gdb_log.txt` files to your issue report.

Using Debugger

This section covers the steps to configure and run a debugger using various methods, including:

- *Eclipse*
- *Command Line*
- *Idf.py Debug Targets*

For how to run a debugger from VS Code, see Configuration for Visual Studio Code Debug.

Eclipse

Note: It is recommended to first check if debugger works using *Idf.py Debug Targets* or from *Command Line* and then move to using Eclipse.

Eclipse is an integrated development environment (IDE) that provides a powerful set of tools for developing and debugging software applications. For ESP-IDF applications, IDF Eclipse plugin provides two ways of debugging:

1. ESP-IDF GDB OpenOCD Debugging
2. GDB Hardware Debugging

By default, Eclipse supports OpenOCD Debugging via the GDB Hardware Debugging plugin, which requires starting the OpenOCD server from the command line and configuring the GDB client from Eclipse to start with the debugging. This approach can be time-consuming and error-prone.

To make the debugging process easier, the IDF Eclipse plugin has a customized ESP-IDF GDB OpenOCD Debugging functionality. This functionality supports configuring the OpenOCD server and GDB client from within Eclipse. All the required configuration parameters will be pre-filled by the plugin, and you can start debugging with just a click of a button.

Therefore, it is recommended to use the ESP-IDF GDB OpenOCD Debugging via the IDF Eclipse plugin.

GDB Hardware Debugging

Note: This approach is recommended only if you are unable to debug using ESP-IDF GDB OpenOCD Debugging for some reason.

To install the `GDB Hardware Debugging` plugin, open Eclipse and select `Help` > `Install` New Software.

After installation is complete, follow these steps to configure the debugging session. Please note that some configuration parameters are generic, while others are project-specific. This will be shown below by configuring debugging for "blink" example project. If not done already, add this project to Eclipse workspace following Eclipse Plugin. The source of get-started/blink application is available in examples directory of ESP-IDF repository.

1. In Eclipse, go to `Run` > `Debug Configuration`. A new window will open. In the left pane of the window, double-click `GDB Hardware Debugging` (or select `GDB Hardware Debugging` and press the `New` button) to create a new configuration.
2. In a form that will show up on the right, enter the `Name:` of this configuration, e.g., "Blink checking".
3. On the `Main` tab below, under `Project:`, press the `Browse` button and select the `blink` project.
4. In the next line under `C/C++ Application:`, press the `Browse` button and select the `blink.elf` file. If `blink.elf` is not there, it is likely that this project has not been built yet. Refer to the Eclipse Plugin for instructions.
5. Finally, under `Build (if required) before launching` click `Disable auto build`. A sample window with settings entered in points 1 - 5 is shown below.

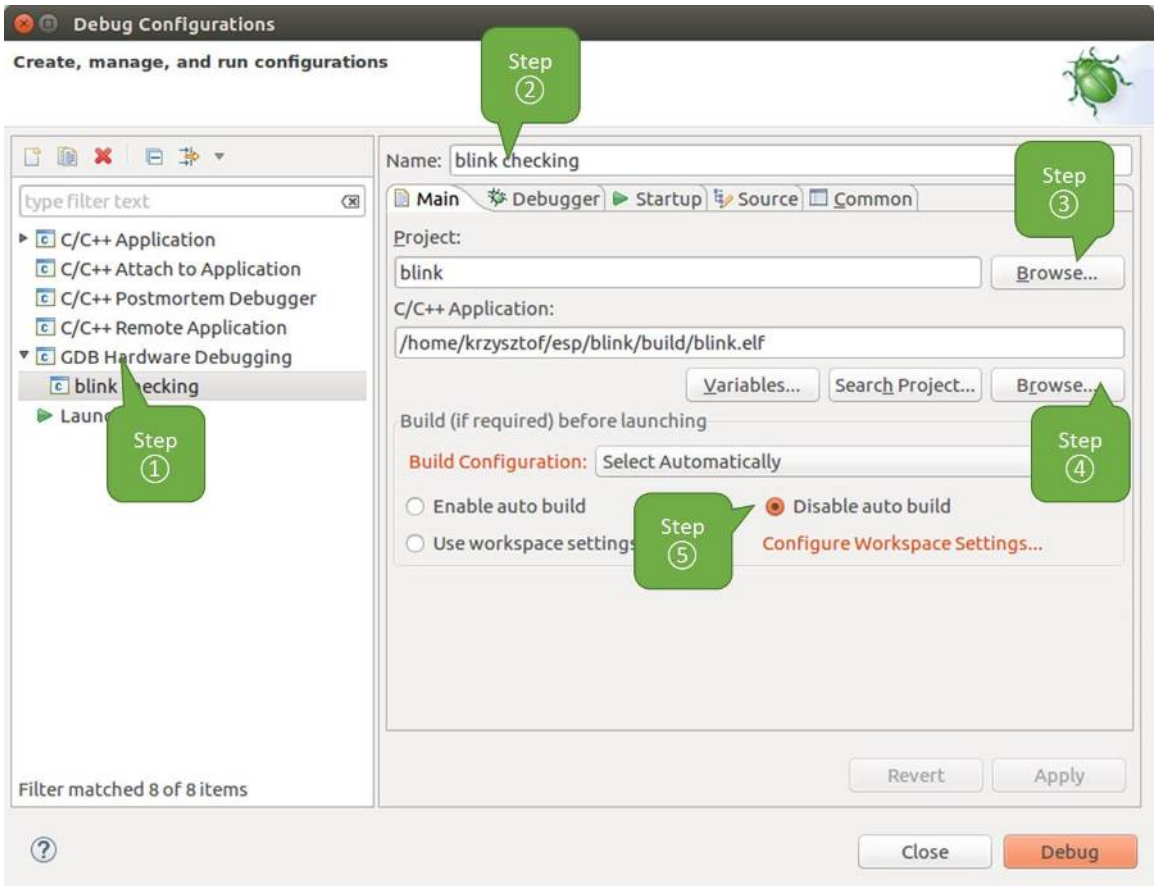

Fig. 43: Configuration of GDB Hardware Debugging - Main tab

6. Click the `Debugger` tab. In field `GDB Command`, enter `riscv32-esp-elf-gdb` to invoke the debugger.
7. Change the default configuration of the `Remote host` by entering `3333` under the `Port number`. Configuration entered in points 6 and 7 is shown on the following picture.
8. The last tab that requires changing the default configuration is `Startup`. Under `Initialization Commands` uncheck `Reset and Delay (seconds)` and `Halt`. Then, in the entry field below, enter the following lines:

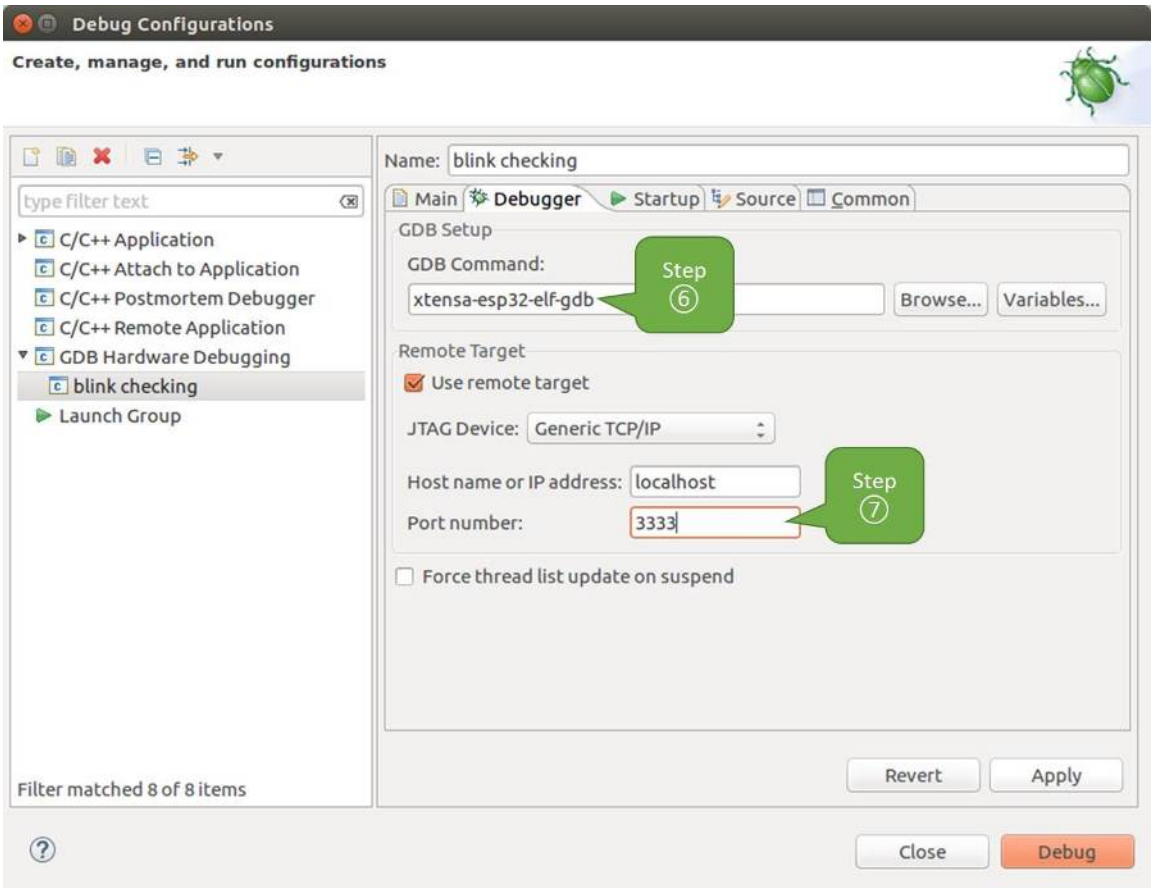

Fig. 44: Configuration of GDB Hardware Debugging - Debugger tab

```
mon reset halt
maintenance flush register-cache
set remote hardware-watchpoint-limit 2
```

Note: To automatically update the image in the flash before starting a new debug session, add the following command lines to the beginning of the `Initialization Commands` textbox:

```
mon reset halt
mon program_esp ${workspace_loc:blink/build/blink.bin} 0x10000 verify
```

For description of `program_esp` command, see *Upload Application for Debugging*.

9. Uncheck the `Load image` option under `Load Image and Symbols`.
10. Further down on the same tab, establish an initial breakpoint to halt CPUs after they are reset by debugger. The plugin will set this breakpoint at the beginning of the function entered under `Set break point at:`. Checkout this option and enter `app_main` in provided field.
11. Checkout `Resume` option. This will make the program to resume after `mon reset halt` is invoked per point 8. The program will then stop at breakpoint inserted at `app_main`.
    Configuration described in points 8 - 11 is shown below.

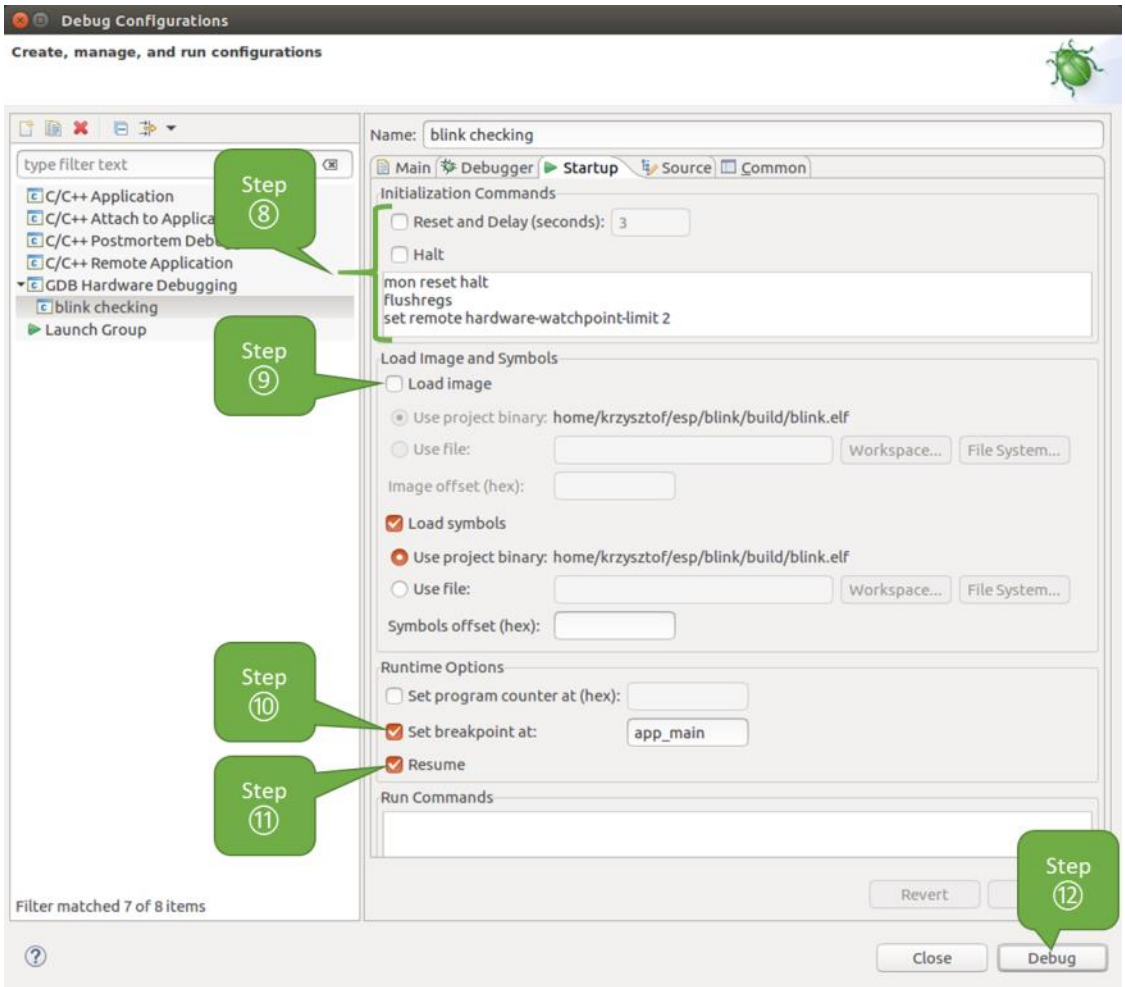

Fig. 45: Configuration of GDB Hardware Debugging - Startup tab

If the `Startup` sequence looks convoluted and respective `Initialization Commands` are unclear, check *What Is the Meaning of Debugger's Startup Commands?* for additional explanation.

12. If you have completed the *Configuring ESP32-C3 Target* steps described above, so the target is running and ready to talk to debugger, go right to debugging by pressing `Debug` button. Otherwise press `Apply` to save changes, go back to *Configuring ESP32-C3 Target* and return here to start debugging.

Once all configuration steps 1-12 are satisfied, the new Eclipse perspective called "Debug" will open, as shown in the example picture below.

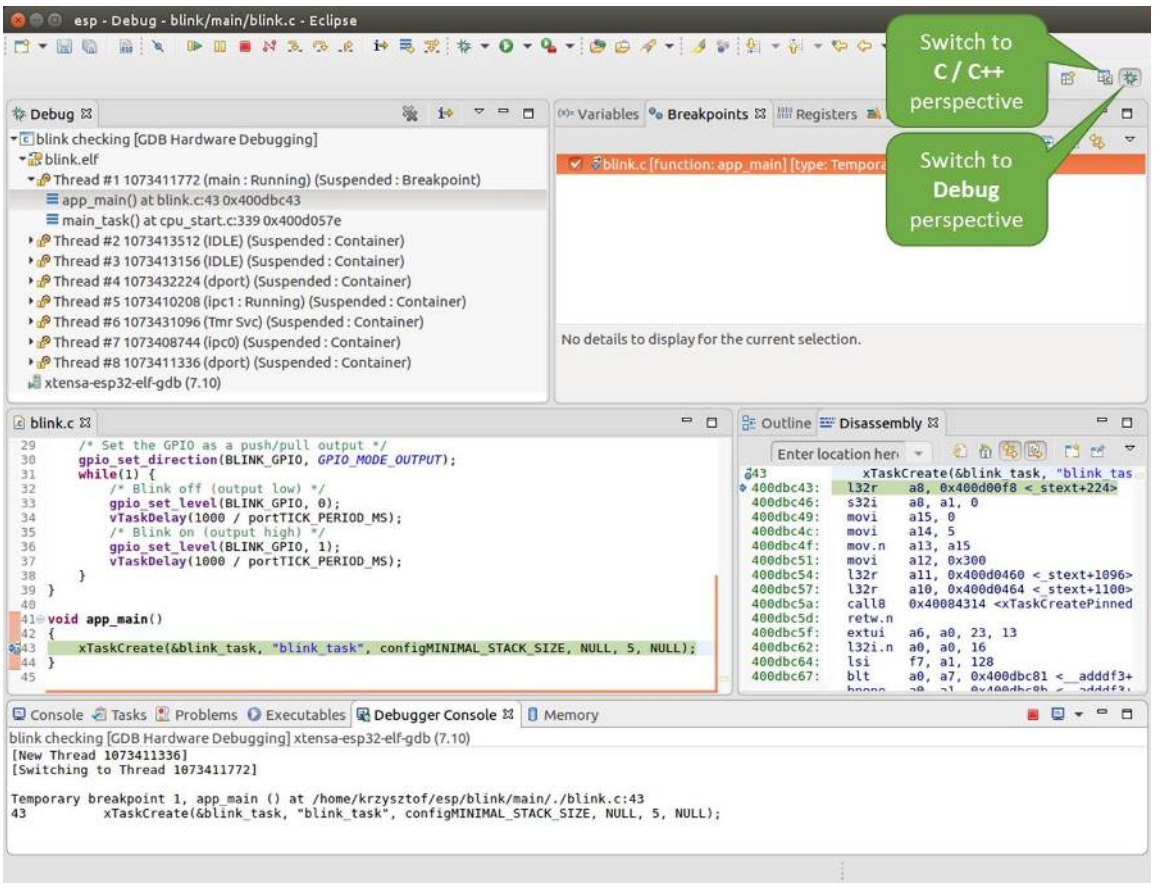

Fig. 46: Debug Perspective in Eclipse

If you are not quite sure how to use GDB, check *Eclipse* example debugging session in section *Debugging Examples*.

Command Line

1. Begin by completing the steps described under *Configuring ESP32-C3 Target*. This is prerequisite to start a debugging session.
2. Open a new terminal session and go to the directory that contains the project for debugging, e.g.,

```
cd ~/esp/blink
```

3. When launching a debugger, you will need to provide a couple of configuration parameters and commands. Instead of entering them one by one in the command line, create a configuration file and name it `gdbinit`:

```
target remote :3333
set remote hardware-watchpoint-limit 2
mon reset halt
maintenance flush register-cache
thb app_main
c
```

   Save this file in the current directory.
   For more details on what is inside `gdbinit` file, see *What Is the Meaning of Debugger's Startup Commands?*

4. Now you are ready to launch GDB. Type the following in terminal:

```
riscv32-esp-elf-gdb -x gdbinit build/blink.elf
```

5. If the previous steps have been done correctly, you will see a similar log concluded with the `(gdb)` prompt:

```
user-name@computer-name:~/esp/blink$ riscv32-esp-elf-gdb -x gdbinit build/
↪blink.elf

(gdb)
```

Note the third-to-last line, which shows debugger halting at breakpoint established in `gdbinit` file at function `app_main()`. Since the processor is halted, the LED should not be blinking. If this is what you see as well, you are ready to start debugging.

If you are not sure how to use GDB, check *Command Line* example debugging session in section *Debugging Examples*.

Idf.py Debug Targets It is also possible to execute the described debugging tools conveniently from `idf.py`. These commands are supported:

1. `idf.py openocd`
   Runs OpenOCD in a console with configuration defined in the environment or via command line. It uses default script directory defined as `OPENOCD_SCRIPTS` environmental variable, which is automatically added from an Export script (`export.sh` or `export.bat`). It is possible to override the script location using command line argument `--openocd-scripts`.
   To configure the JTAG configuration for the current board, please use the environmental variable `OPENOCD_COMMANDS` or `--openocd-commands` command line argument. If none of the above is defined, OpenOCD is started with `-f board/esp32c3-builtin.cfg` board definition.
2. `idf.py gdb`
   Starts the GDB the same way as the *Command Line*, but generates the initial GDB scripts referring to the current project elf file.
3. `idf.py gdbtui`
   The same as *2*, but starts the gdb with `tui` argument, allowing for a simple source code view.
4. `idf.py gdbgui`
   Starts gdbgui debugger frontend enabling out-of-the-box debugging in a browser window. To enable this option, run the install script with the "--enable-gdbgui" argument, e.g., `install.sh --enable-gdbgui`.
   You can combine these debugging actions on a single command line, allowing for convenient setup of blocking and non-blocking actions in one step. `idf.py` implements a simple logic to move the background actions (such as openocd) to the beginning and the interactive ones (such as gdb, monitor) to the end of the action list. An example of a very useful combination is:

   ```
   idf.py openocd gdbgui monitor
   ```

   The above command runs OpenOCD in the background, starts gdbgui to open a browser window with active debugger frontend and opens a serial monitor in the active console.

Debugging Examples

This section describes debugging with GDB from *Eclipse* as well as from *Command Line*.

Eclipse Verify if your target is ready and loaded with get-started/blink example. Configure and start debugger following steps in section *Eclipse*. Pick up where target was left by debugger, i.e., having the application halted at breakpoint established at `app_main()`.

Examples in This Section

1. *Navigating Through the Code, Call Stack and Threads*
2. *Setting and Clearing Breakpoints*
3. *Halting the Target Manually*
4. *Stepping Through the Code*
5. *Checking and Setting Memory*
6. *Watching and Setting Program Variables*
7. *Setting Conditional Breakpoints*

Navigating Through the Code, Call Stack and Threads When the target is halted, debugger shows the list of threads in "Debug" window. The line of code where program halted is highlighted in another window below, as shown on the following picture. The LED stops blinking.

Specific thread where the program halted is expanded showing the call stack. It represents function calls that lead up to the highlighted line of code, where the target halted. The first line of call stack under Thread #1 contains the last called function `app_main()`, that in turn was called from function `main_task()` shown in a line below. Each line of the stack also contains the file name and line number where the function was called. By clicking/highlighting the stack entries, in window below, you will see contents of this file.

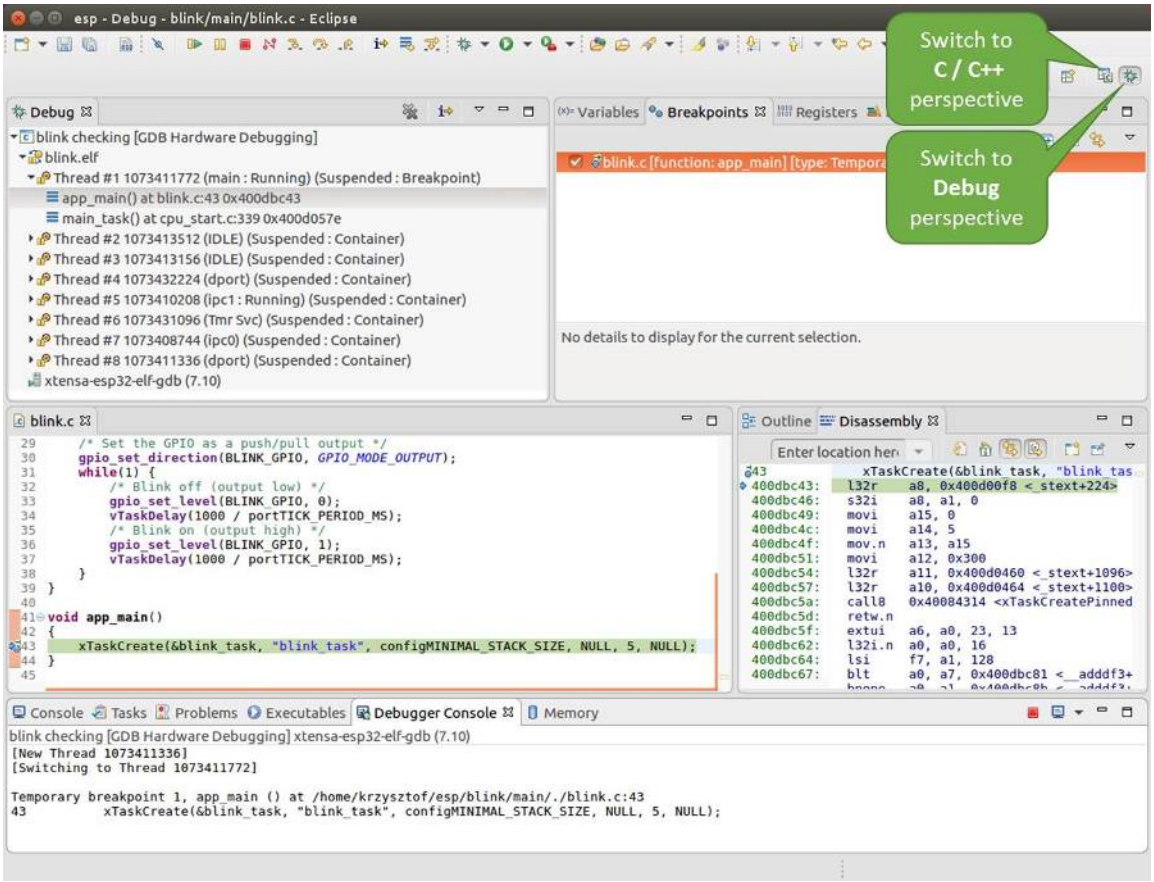

Fig. 47: Debug Perspective in Eclipse

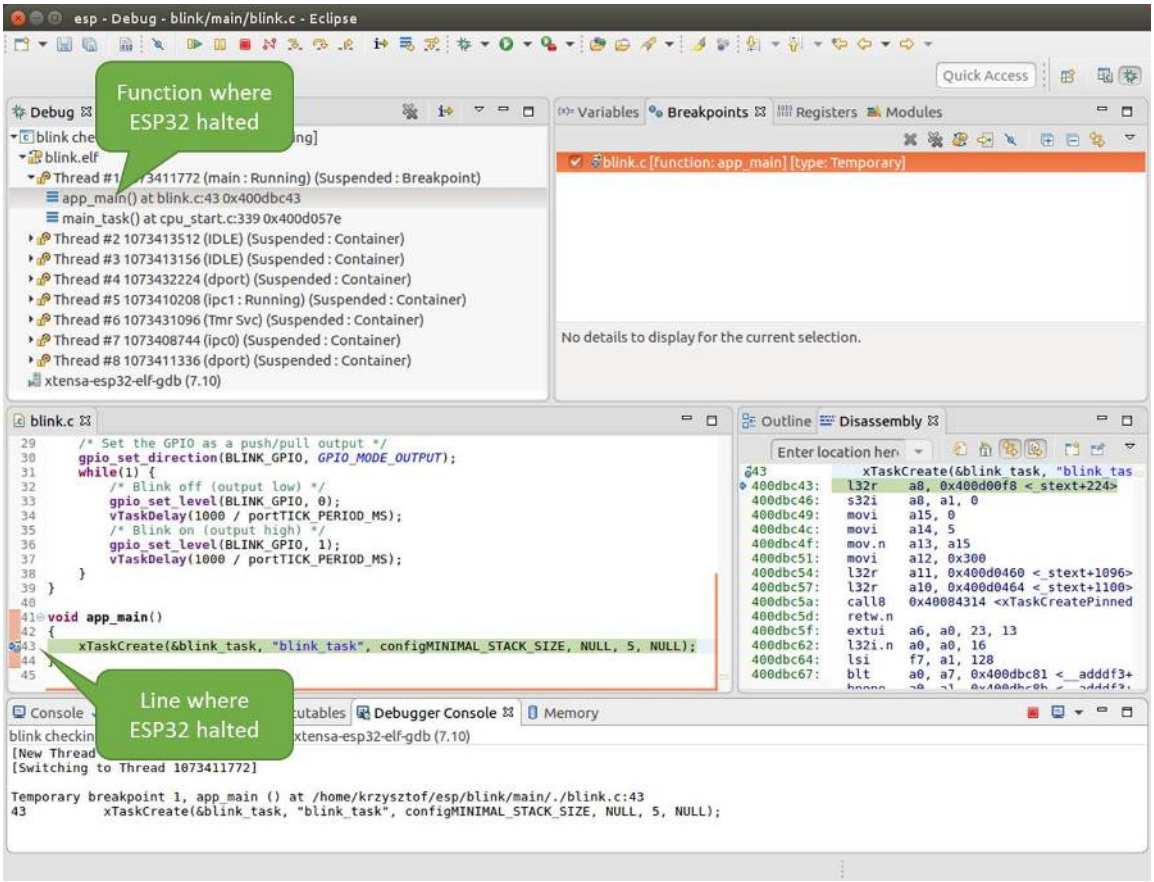

Fig. 48: Target halted during debugging

By expanding threads you can navigate throughout the application. Expand Thread #5 that contains much longer call stack. You will see there, besides function calls, numbers like `0x4000000c`. They represent addresses of binary code not provided in source form.

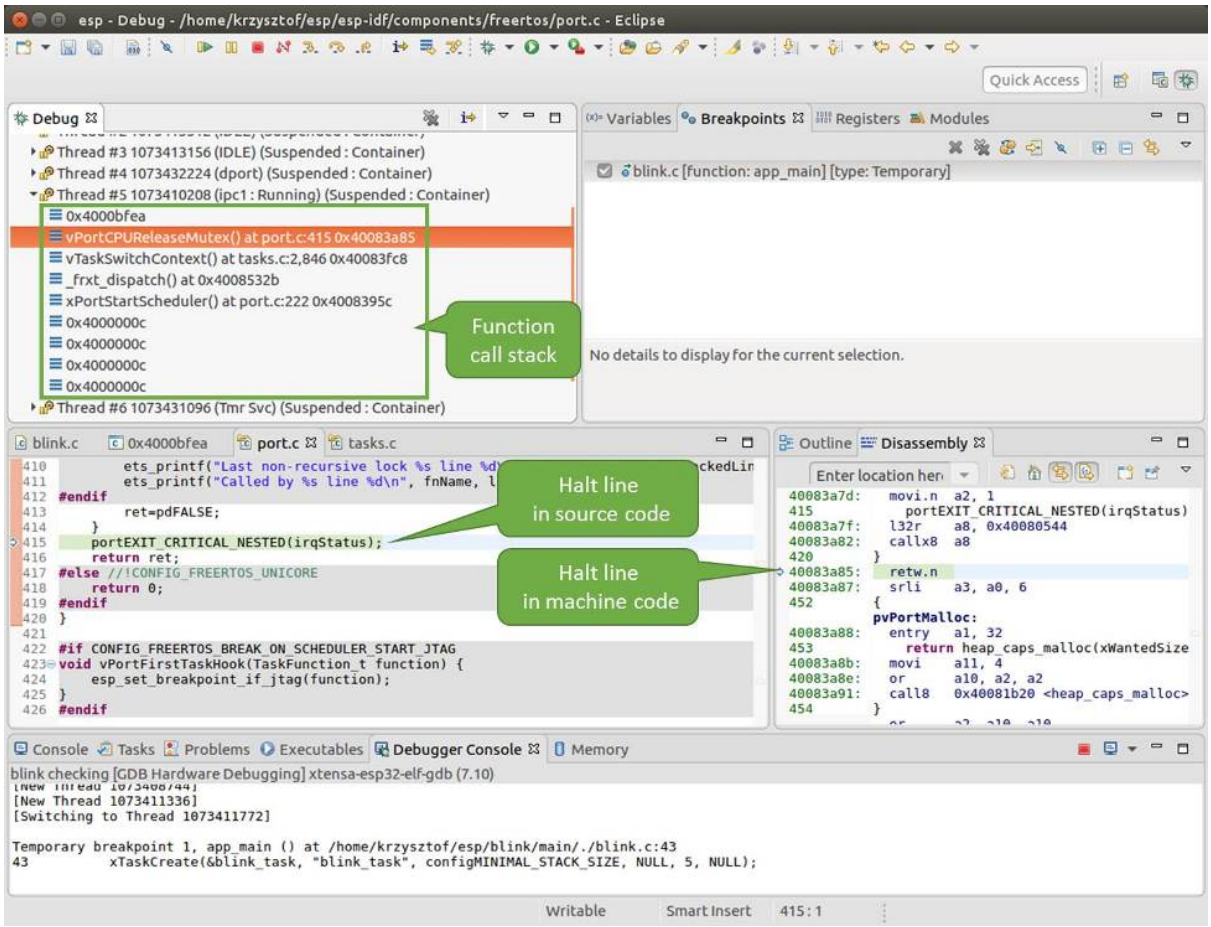

Fig. 49: Navigate through the call stack

In another window on right, you can see the disassembled machine code no matter if your project provides it in source or only the binary form.

Go back to the `app_main()` in Thread #1 to familiar code of `blink.c` file that will be examined in more details in the following examples. Debugger makes it easy to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

Setting and Clearing Breakpoints When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers/peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let's establish two breakpoints when the state of LED changes. Basing on code listing above, this happens at lines 33 and 36. To do so, hold the "Control" on the keyboard and double clink on number `33` in file `blink.c` file. A dialog will open where you can confirm your selection by pressing "OK" button. If you do not like to see the dialog just double click the line number. Set another breakpoint in line 36.

Information how many breakpoints are set and where is shown in window "Breakpoints" on top right. Click "Show Breakpoints Supported by Selected Target" to refresh this list. Besides the two just set breakpoints the list may contain temporary breakpoint at function `app_main()` established at debugger start. As maximum two breakpoints are allowed (see *Breakpoints and Watchpoints Available*), you need to delete it, or debugging will fail.

If you now click "Resume" (click `blink_task()` under "Thread #8", if "Resume" button is grayed out), the processor will run and halt at a breakpoint. Clicking "Resume" another time will make it run again, halt on second breakpoint, and so on.

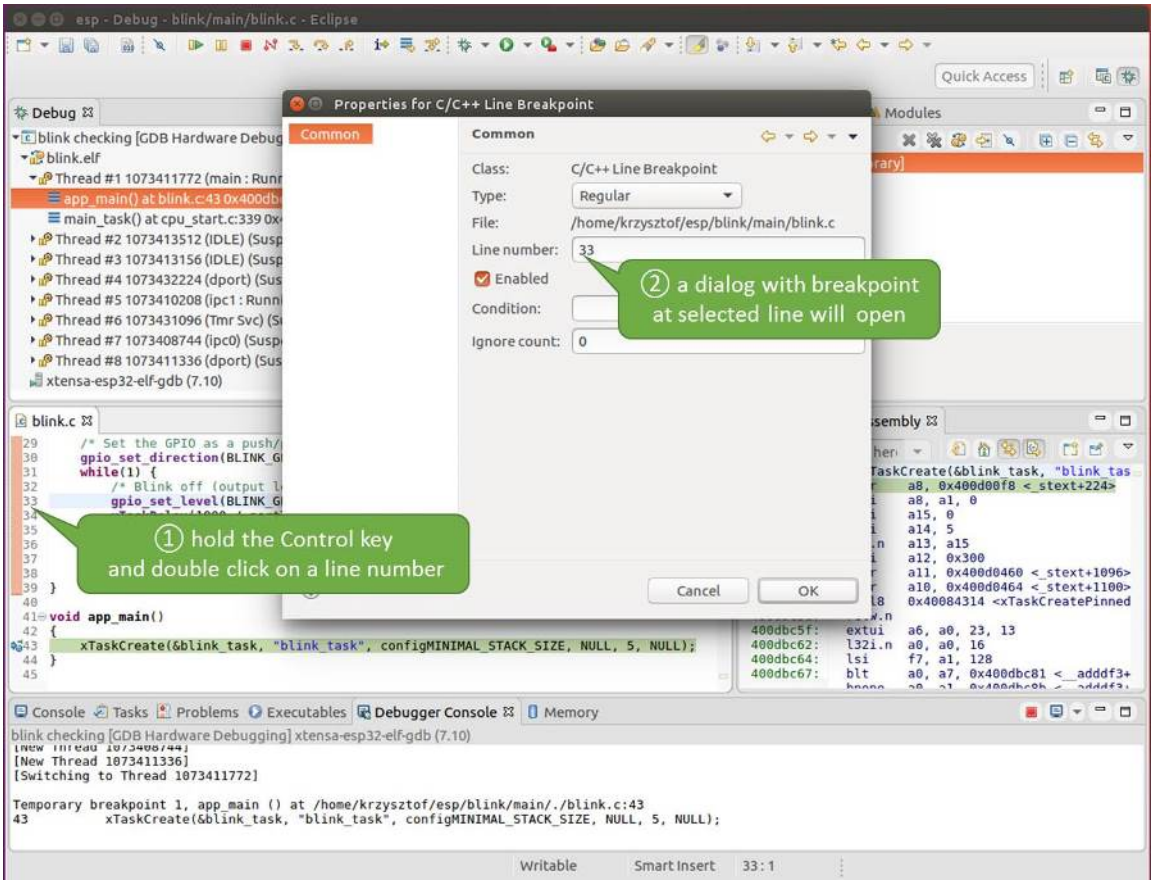

Fig. 50: Setting a breakpoint

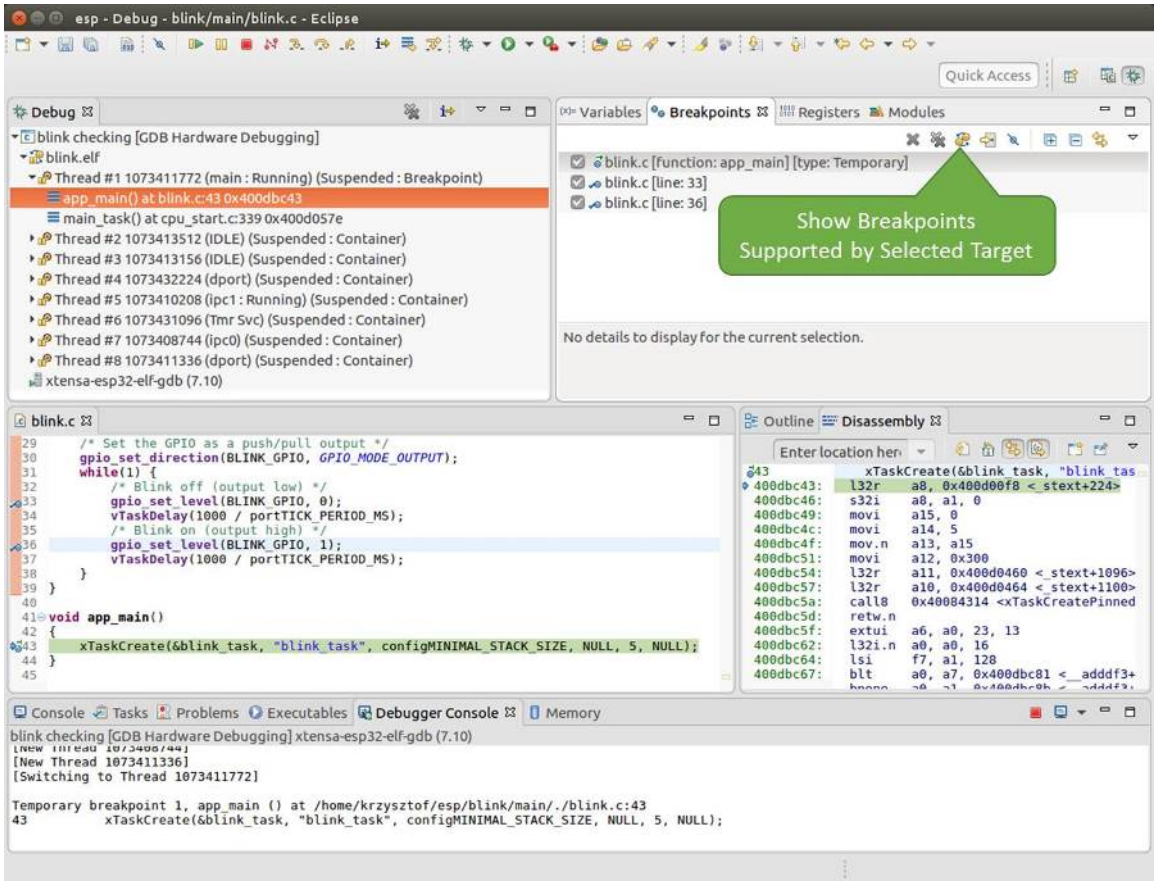

Fig. 51: Three breakpoints are set / maximum two are allowed

You will be also able to see that LED is changing the state after each click to "Resume" program execution.

Read more about breakpoints under *Breakpoints and Watchpoints Available* and *What Else Should I Know About Breakpoints?*

Halting the Target Manually When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any break points defined. In such case, to go back to debugging mode, you can break program execution manually by pressing "Suspend" button.

To check it, delete all breakpoints and click "Resume". Then click "Suspend". Application will be halted at some random point and LED will stop blinking. Debugger will expand thread and highlight the line of code where application halted.

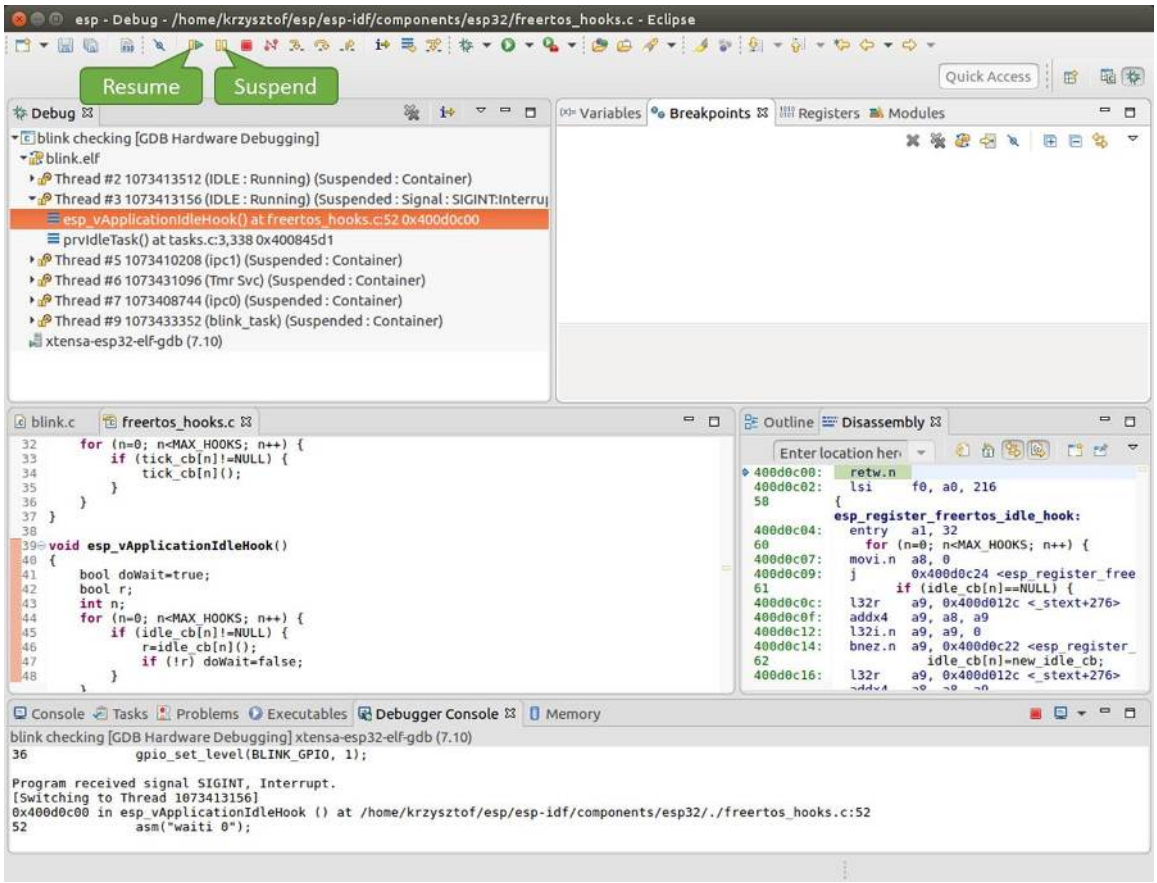

Fig. 52: Target halted manually

In particular case above, the application has been halted in line 52 of code in file `freertos_hooks.c` Now you can resume it again by pressing "Resume" button or do some debugging as discussed below.

Stepping Through the Code It is also possible to step through the code using "Step Into (F5)" and "Step Over (F6)" commands. The difference is that "Step Into (F5)" is entering inside subroutines calls, while "Step Over (F6)" steps over the call, treating it as a single source line.

Before being able to demonstrate this functionality, using information discussed in previous paragraph, make sure that you have only one breakpoint defined at line `36` of `blink.c`.

Resume program by entering pressing F8 and let it halt. Now press "Step Over (F6)", one by one couple of times, to see how debugger is stepping one program line at a time.

If you press "Step Into (F5)" instead, then debugger will step inside subroutine calls.

In this particular case debugger stepped inside `gpio_set_level(BLINK_GPIO, 0)` and effectively moved to `gpio.c` driver code.

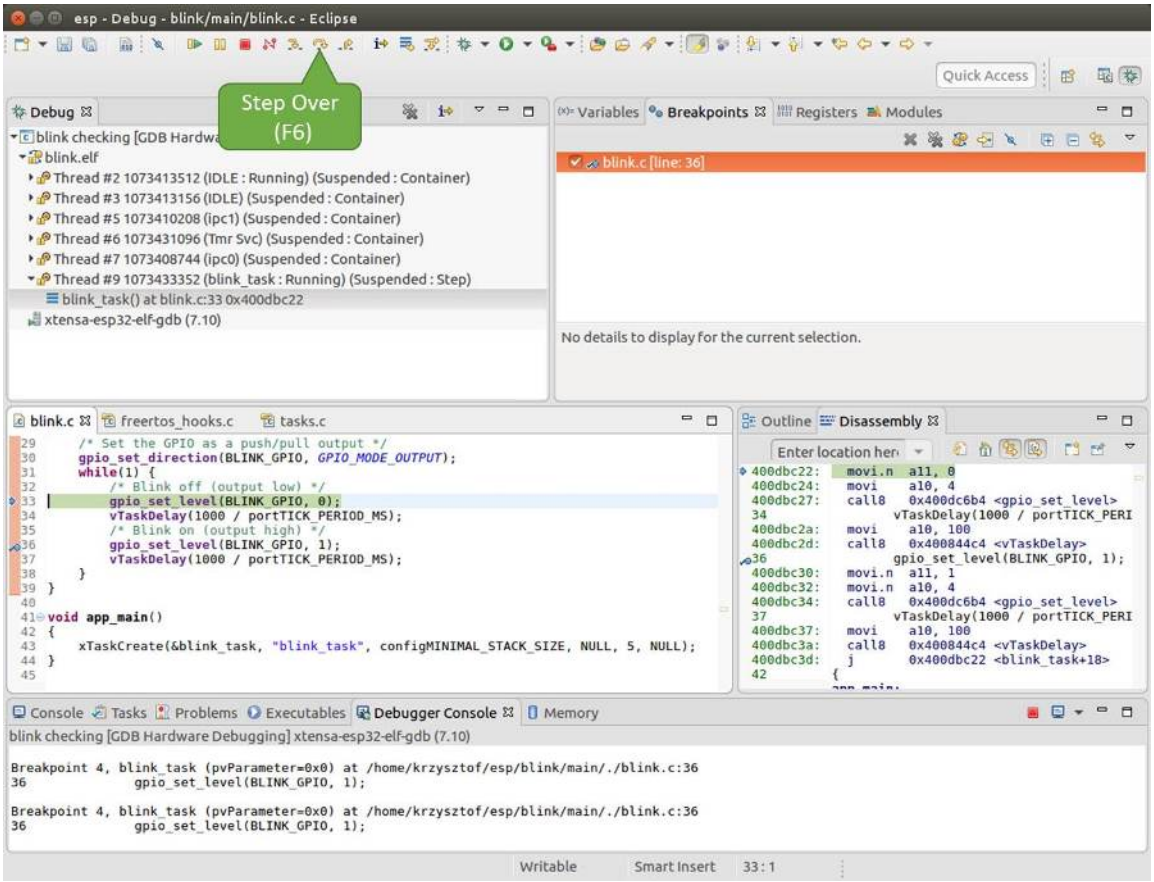

Fig. 53: Stepping through the code with "Step Over (F6)"

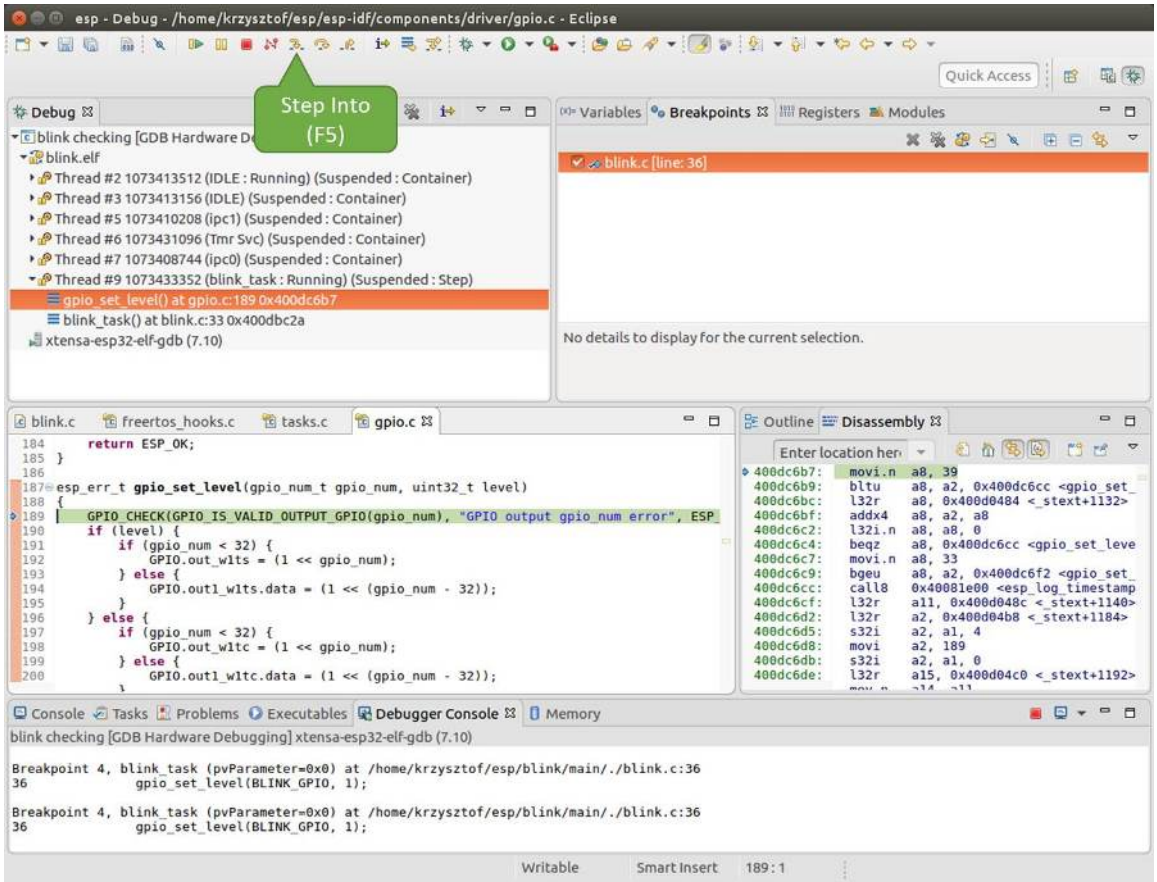

Fig. 54: Stepping through the code with "Step Into (F5)"

See *Why Stepping with "next" Does Not Bypass Subroutine Calls?* for potential limitation of using `next` command.

Checking and Setting Memory To display or set contents of memory use "Memory" tab at the bottom of "Debug" perspective.

With the "Memory" tab, we will read from and write to the memory location `0x3FF44004` labeled as `GPIO_OUT_REG` used to set and clear individual GPIO's.

For more information, see *ESP32-C3 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO_MUX)* [PDF].

Being in the same `blink.c` project as before, set two breakpoints right after `gpio_set_level` instruction. Click "Memory" tab and then "Add Memory Monitor" button. Enter `0x3FF44004` in provided dialog.

Now resume program by pressing F8 and observe "Monitor" tab.

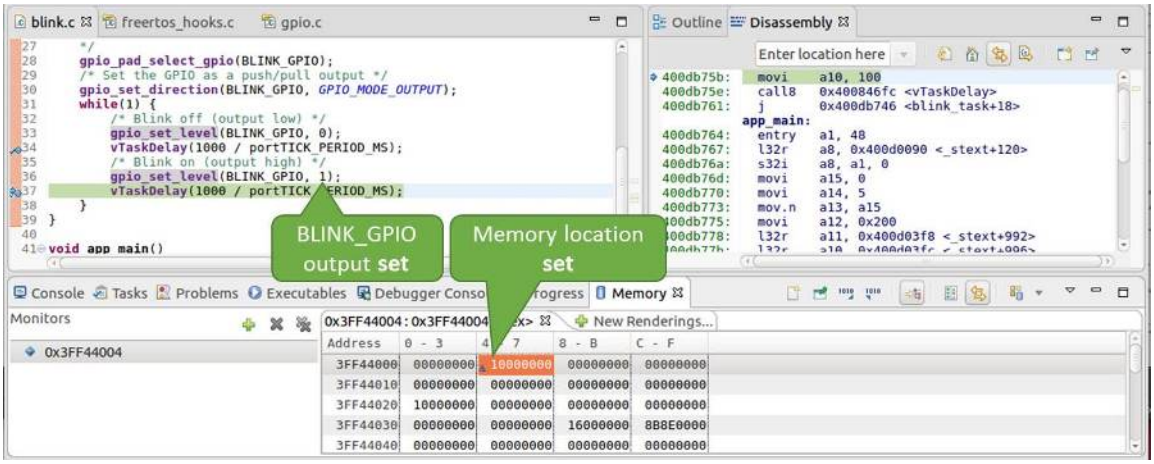

Fig. 55: Observing memory location 0x3FF44004 changing one bit to "ON"

You should see one bit being flipped over at memory location `0x3FF44004` (and LED changing the state) each time F8 is pressed.

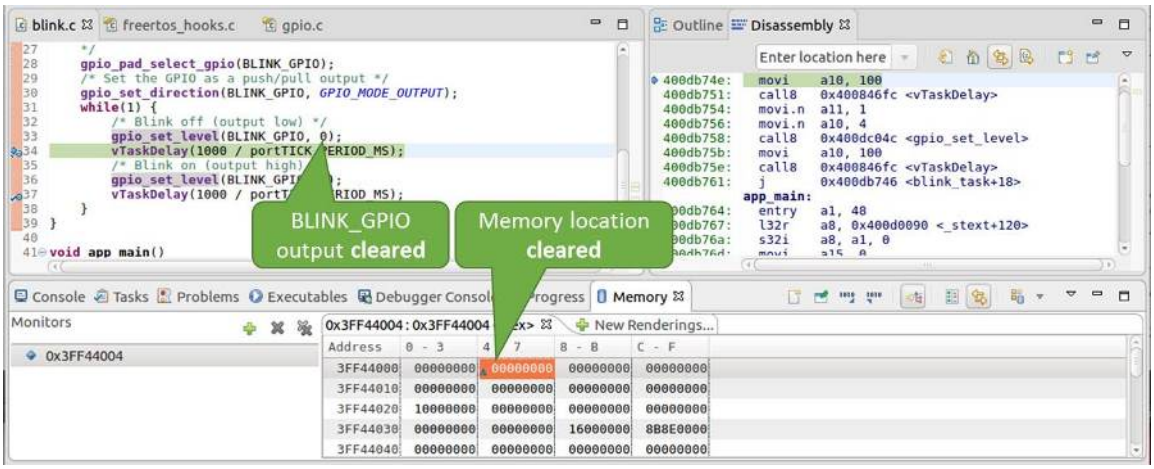

Fig. 56: Observing memory location 0x3FF44004 changing one bit to "OFF"

To set memory use the same "Monitor" tab and the same memory location. Type in alternate bit pattern as previously observed. Immediately after pressing enter you will see LED changing the state.

Watching and Setting Program Variables A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file `blink.c` by adding a declaration of

a global variable `int i` above definition of function `blink_task`. Then add `i++` inside `while(1)` of this function to get `i` incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter a breakpoint in the line where you put `i++`.

In next step, in the window with "Breakpoints", click the "Expressions" tab. If this tab is not visible, then add it by going to the top menu Window > Show View > Expressions. Then click "Add new expression" and enter `i`.

Resume program execution by pressing F8. Each time the program is halted you will see `i` value being incremented.

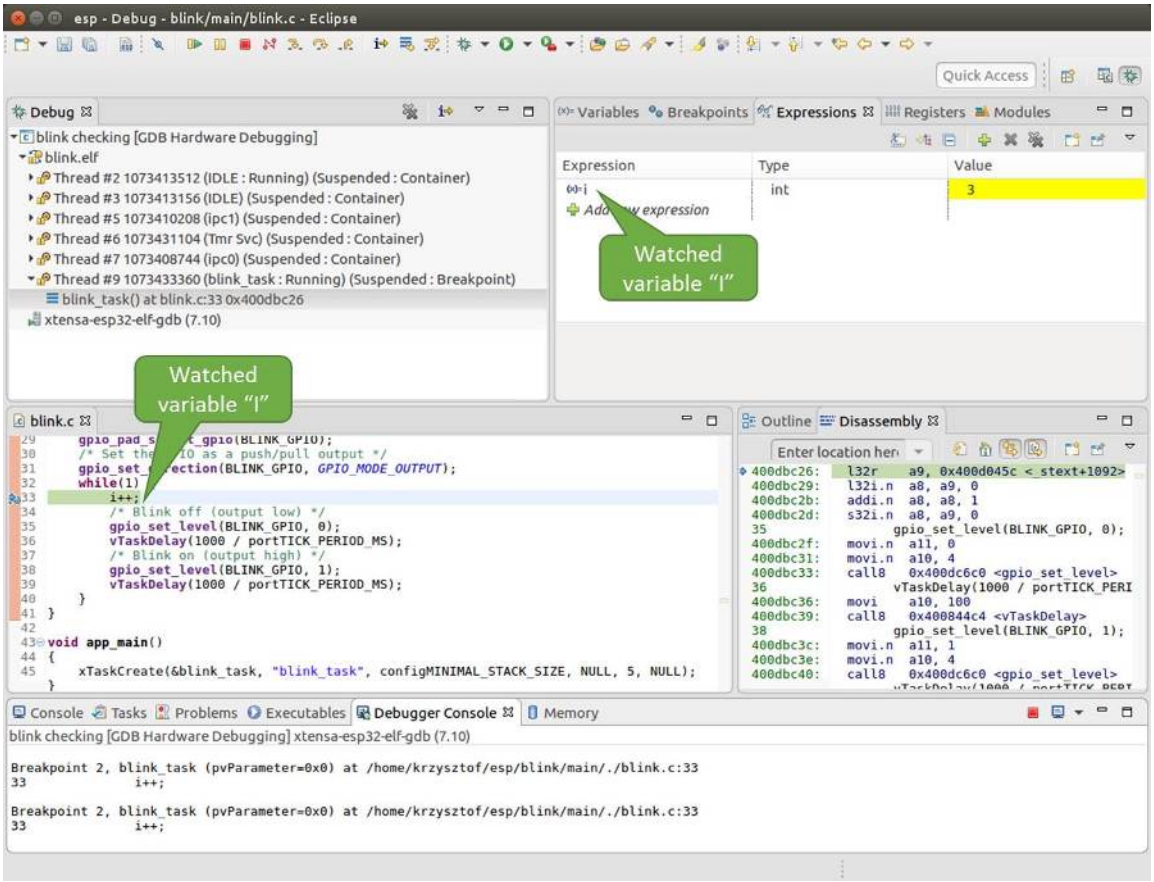

Fig. 57: Watching program variable "i"

To modify `i` enter a new number in "Value" column. After pressing "Resume (F8)" the program will keep incrementing `i` starting from the new entered number.

Setting Conditional Breakpoints Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Right click on the breakpoint to open a context menu and select "Breakpoint Properties". Change the selection under "Type:" to "Hardware" and enter a "Condition:" like `i == 2`.

If current value of `i` is less than `2` (change it if required) and program is resumed, it will blink LED in a loop until condition `i == 2` gets true and then finally halt.

Command Line Verify if your target is ready and loaded with get-started/blink example. Configure and start debugger following steps in section *Command Line*. Pick up where target was left by debugger, i.e. having the application halted at breakpoint established at `app_main()`:

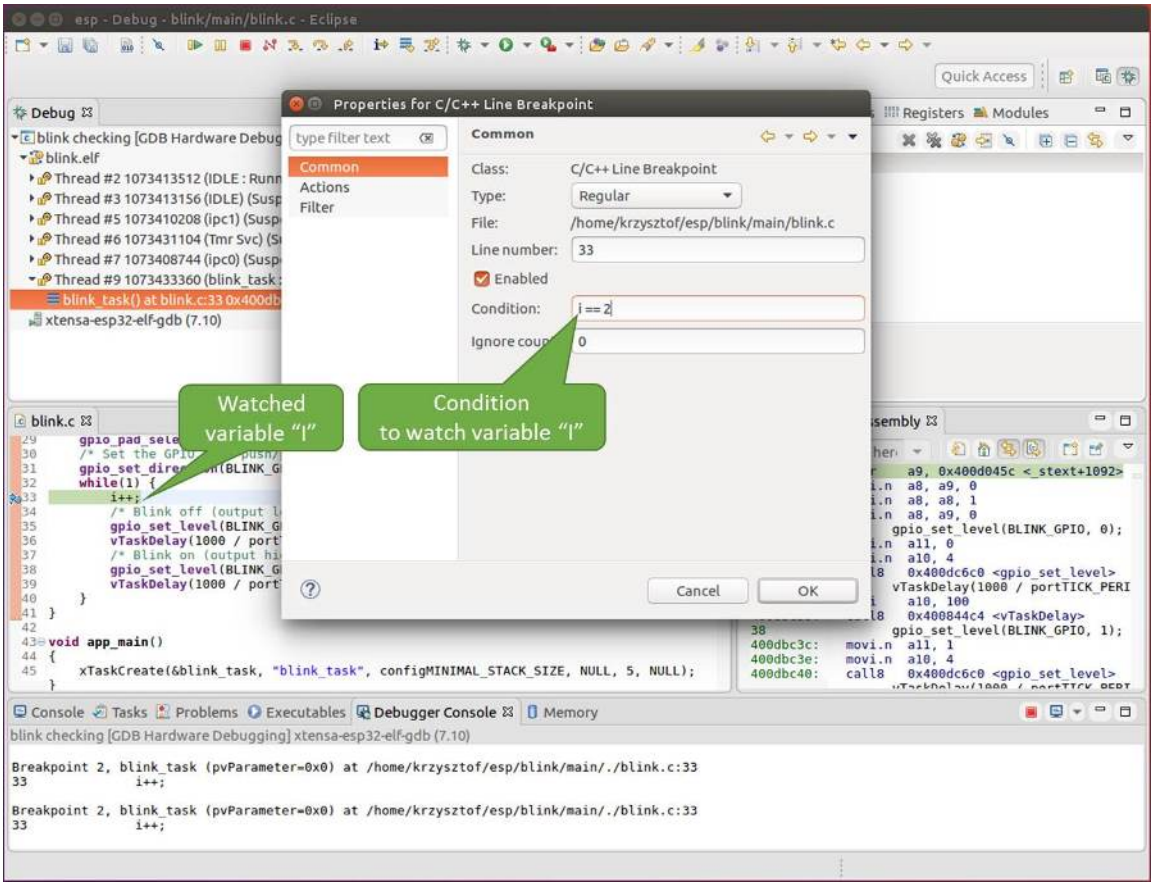

Fig. 58: Setting a conditional breakpoint

```
Temporary breakpoint 1, app_main () at /home/user-name/esp/blink/main/./blink.c:43
43      xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5,␣
↪NULL);
(gdb)
```

Examples in This Section

2. *Setting and Clearing Breakpoints*
3. *Halting and Resuming the Application*
4. *Stepping Through the Code*
5. *Checking and Setting Memory*
6. *Watching and Setting Program Variables*
7. *Setting Conditional Breakpoints*
8. *Debugging FreeRTOS Objects*

Navigating Through the Code, Call Stack and Threads When you see the `(gdb)` prompt, the application is halted. LED should not be blinking.

To find out where exactly the code is halted, enter `l` or `list`, and debugger will show couple of lines of code around the halt point (line 43 of code in file `blink.c`)

```
(gdb) l
38      }
39  }
40
41  void app_main()
42  {
43      xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5,␣
↪NULL);
44  }
(gdb)
```

Check how code listing works by entering, e.g., `l 30, 40` to see particular range of lines of code.

You can use `bt` or `backtrace` to see what function calls lead up to this code:

```
(gdb) bt
#0  app_main () at /home/user-name/esp/blink/main/./blink.c:43
#1  0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/
↪esp32c3/./cpu_start.c:339
(gdb)
```

Line #0 of output provides the last function call before the application halted, i.e., `app_main ()` we have listed previously. The `app_main ()` was in turn called by function `main_task` from line 339 of code located in file `cpu_start.c`.

To get to the context of `main_task` in file `cpu_start.c`, enter `frame N`, where N = 1, because the `main_task` is listed under #1):

```
(gdb) frame 1
#1  0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/
↪esp32c3/./cpu_start.c:339
339     app_main();
(gdb)
```

Enter `l` and this will reveal the piece of code that called `app_main()` (in line 339):

```
(gdb) l
334         ;
335     }
336 #endif
337     //Enable allocation in region where the startup stacks were located.
338     heap_caps_enable_nonos_stack_heaps();
339     app_main();
340     vTaskDelete(NULL);
341 }
342
(gdb)
```

By listing some lines before, you will see the function name `main_task` we have been looking for:

```
(gdb) l 326, 341
326 static void main_task(void* args)
327 {
328     // Now that the application is about to start, disable boot watchdogs
329     REG_CLR_BIT(TIMG_WDTCONFIG0_REG(0), TIMG_WDT_FLASHBOOT_MOD_EN_S);
330     REG_CLR_BIT(RTC_CNTL_WDTCONFIG0_REG, RTC_CNTL_WDT_FLASHBOOT_MOD_EN);
331 #if !CONFIG_FREERTOS_UNICORE
332     // Wait for FreeRTOS initialization to finish on APP CPU, before replacing␣
↪its startup stack
333     while (port_xSchedulerRunning[1] == 0) {
334         ;
335     }
336 #endif
337     //Enable allocation in region where the startup stacks were located.
338     heap_caps_enable_nonos_stack_heaps();
339     app_main();
340     vTaskDelete(NULL);
341 }
(gdb)
```

To see the other code, enter `i threads`. This will show the list of threads running on target:

```
(gdb) i threads
  Id   Target Id         Frame
  8    Thread 1073411336 (dport) 0x400d0848 in dport_access_init_core (arg=
↪<optimized out>)
    at /home/user-name/esp/esp-idf/components/esp32c3/./dport_access.c:170
  7    Thread 1073408744 (ipc0) xQueueGenericReceive (xQueue=0x3ffae694,␣
↪pvBuffer=0x0, xTicksToWait=1644638200,
    xJustPeeking=0) at /home/user-name/esp/esp-idf/components/freertos/./queue.
↪c:1452
  6    Thread 1073431096 (Tmr Svc) prvTimerTask (pvParameters=0x0)
    at /home/user-name/esp/esp-idf/components/freertos/./timers.c:445
  5    Thread 1073410208 (ipc1 : Running) 0x4000bfea in ?? ()
  4    Thread 1073432224 (dport) dport_access_init_core (arg=0x0)
    at /home/user-name/esp/esp-idf/components/esp32c3/./dport_access.c:150
  3    Thread 1073413156 (IDLE) prvIdleTask (pvParameters=0x0)
    at /home/user-name/esp/esp-idf/components/freertos/./tasks.c:3282
  2    Thread 1073413512 (IDLE) prvIdleTask (pvParameters=0x0)
    at /home/user-name/esp/esp-idf/components/freertos/./tasks.c:3282
* 1    Thread 1073411772 (main : Running) app_main () at /home/user-name/esp/blink/
↪main/./blink.c:43
(gdb)
```

The thread list shows the last function calls per each thread together with the name of C source file if available.

You can navigate to specific thread by entering `thread N`, where `N` is the thread Id. To see how it works go to thread thread 5:

```
(gdb) thread 5
[Switching to thread 5 (Thread 1073410208)]
#0  0x4000bfea in ?? ()
(gdb)
```

Then check the backtrace:

```
(gdb) bt
#0  0x4000bfea in ?? ()
#1  0x40083a85 in vPortCPUReleaseMutex (mux=<optimized out>) at /home/user-name/
↪esp/esp-idf/components/freertos/./port.c:415
#2  0x40083fc8 in vTaskSwitchContext () at /home/user-name/esp/esp-idf/components/
↪freertos/./tasks.c:2846
#3  0x4008532b in _frxt_dispatch ()
#4  0x4008395c in xPortStartScheduler () at /home/user-name/esp/esp-idf/components/
↪freertos/./port.c:222
#5  0x4000000c in ?? ()
#6  0x4000000c in ?? ()
#7  0x4000000c in ?? ()
#8  0x4000000c in ?? ()
(gdb)
```

As you see, the backtrace may contain several entries. This will let you check what exact sequence of function calls lead to the code where the target halted. Question marks `??` instead of a function name indicate that application is available only in binary format, without any source file in C language. The value like `0x4000bfea` is the memory address of the function call.

Using `bt`, `i threads`, `thread N` and `list` commands we are now able to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

Setting and Clearing Breakpoints When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers/peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let's establish two breakpoints when the state of LED changes. Basing on code listing above this happens at lines 33 and 36. Breakpoints may be established using command `break M` where M is the code line number:

```
(gdb) break 33
Breakpoint 2 at 0x400db6f6: file /home/user-name/esp/blink/main/./blink.c, line 33.
(gdb) break 36
Breakpoint 3 at 0x400db704: file /home/user-name/esp/blink/main/./blink.c, line 36.
```

If you new enter `c`, the processor will run and halt at a breakpoint. Entering `c` another time will make it run again, halt on second breakpoint, and so on:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F6 (active)    APP_CPU: PC=0x400D10D8

Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:33
33          gpio_set_level(BLINK_GPIO, 0);
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F8 (active)    APP_CPU: PC=0x400D10D8
Target halted. PRO_CPU: PC=0x400DB704 (active)    APP_CPU: PC=0x400D10D8

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:36
36          gpio_set_level(BLINK_GPIO, 1);
```

(continues on next page)

(continued from previous page)

```
(gdb)
```

You will be also able to see that LED is changing the state only if you resume program execution by entering `c`.

To examine how many breakpoints are set and where, use command `info break`:

```
(gdb) info break
Num     Type           Disp Enb Address    What
2       breakpoint     keep y   0x400db6f6 in blink_task at /home/user-name/esp/
↪blink/main/./blink.c:33
    breakpoint already hit 1 time
3       breakpoint     keep y   0x400db704 in blink_task at /home/user-name/esp/
↪blink/main/./blink.c:36
    breakpoint already hit 1 time
(gdb)
```

Please note that breakpoint numbers (listed under `Num`) start with `2`. This is because first breakpoint has been already established at function `app_main()` by running command `thb app_main` on debugger launch. As it was a temporary breakpoint, it has been automatically deleted and now is not listed anymore.

To remove breakpoints enter `delete N` command (in short `d N`), where `N` is the breakpoint number:

```
(gdb) delete 1
No breakpoint number 1.
(gdb) delete 2
(gdb)
```

Read more about breakpoints under *Breakpoints and Watchpoints Available* and *What Else Should I Know About Breakpoints?*

Halting and Resuming the Application When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any break points defined. In such case, to go back to debugging mode, you can break program execution manually by entering Ctrl+C.

To check it delete all breakpoints and enter `c` to resume application. Then enter Ctrl+C. Application will be halted at some random point and LED will stop blinking. Debugger will print the following:

```
(gdb) c
Continuing.
^CTarget halted. PRO_CPU: PC=0x400D0C00            APP_CPU: PC=0x400D0C00 (active)
[New Thread 1073433352]

Program received signal SIGINT, Interrupt.
[Switching to Thread 1073413512]
0x400d0c00 in esp_vApplicationIdleHook () at /home/user-name/esp/esp-idf/
↪components/esp32c3/./freertos_hooks.c:52
52          asm("waiti 0");
(gdb)
```

In particular case above, the application has been halted in line 52 of code in file `freertos_hooks.c`. Now you can resume it again by enter `c` or do some debugging as discussed below.

Stepping Through the Code It is also possible to step through the code using `step` and `next` commands (in short `s` and `n`). The difference is that `step` is entering inside subroutines calls, while `next` steps over the call, treating it as a single source line.

To demonstrate this functionality, using command `break` and `delete` discussed in previous paragraph, make sure that you have only one breakpoint defined at line `36` of `blink.c`:

```
(gdb) info break
Num     Type           Disp Enb Address    What
3       breakpoint     keep y   0x400db704 in blink_task at /home/user-name/esp/
↪blink/main/./blink.c:36
    breakpoint already hit 1 time
(gdb)
```

Resume program by entering `c` and let it halt:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB754 (active)    APP_CPU: PC=0x400D1128

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:36
36          gpio_set_level(BLINK_GPIO, 1);
(gdb)
```

Then enter `n` couple of times to see how debugger is stepping one program line at a time:

```
(gdb) n
Target halted. PRO_CPU: PC=0x400DB756 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB758 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DC04C (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB75B (active)    APP_CPU: PC=0x400D1128
37          vTaskDelay(1000 / portTICK_PERIOD_MS);
(gdb) n
Target halted. PRO_CPU: PC=0x400DB75E (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400846FC (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB761 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB746 (active)    APP_CPU: PC=0x400D1128
33          gpio_set_level(BLINK_GPIO, 0);
(gdb)
```

If you enter `s` instead, then debugger will step inside subroutine calls:

```
(gdb) s
Target halted. PRO_CPU: PC=0x400DB748 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB74B (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DC04C (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DC04F (active)    APP_CPU: PC=0x400D1128
gpio_set_level (gpio_num=GPIO_NUM_4, level=0) at /home/user-name/esp/esp-idf/
↪components/esp_driver_gpio/src/gpio.c:183
183     GPIO_CHECK(GPIO_IS_VALID_OUTPUT_GPIO(gpio_num), "GPIO output gpio_num error
↪", ESP_ERR_INVALID_ARG);
(gdb)
```

In this particular case debugger stepped inside `gpio_set_level(BLINK_GPIO, 0)` and effectively moved to `gpio.c` driver code.

See *Why Stepping with "next" Does Not Bypass Subroutine Calls?* for potential limitation of using `next` command.

Checking and Setting Memory Displaying the contents of memory is done with command `x`. With additional parameters you may vary the format and count of memory locations displayed. Run `help x` to see more details. Companion command to `x` is `set` that let you write values to the memory.

We will demonstrate how `x` and `set` work by reading from and writing to the memory location `0x3FF44004` labeled as `GPIO_OUT_REG` used to set and clear individual GPIO's.

For more information, see *ESP32-C3 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO_MUX)* [PDF].

Being in the same `blink.c` project as before, set two breakpoints right after `gpio_set_level` instruction. Enter two times `c` to get to the break point followed by `x /1wx 0x3FF44004` to display contents of `GPIO_OUT_REG` memory location:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB75E (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB74E (active)    APP_CPU: PC=0x400D1128

Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:34
34          vTaskDelay(1000 / portTICK_PERIOD_MS);
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000000
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB751 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB75B (active)    APP_CPU: PC=0x400D1128

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:37
37          vTaskDelay(1000 / portTICK_PERIOD_MS);
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000010
(gdb)
```

If your are blinking LED connected to GPIO4, then you should see fourth bit being flipped each time the LED changes the state:

```
0x3ff44004: 0x00000000
...
0x3ff44004: 0x00000010
```

Now, when the LED is off, that corresponds to `0x3ff44004: 0x00000000` being displayed, try using `set` command to set this bit by writing `0x00000010` to the same memory location:

```
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000000
(gdb) set {unsigned int}0x3FF44004=0x000010
```

You should see the LED to turn on immediately after entering `set {unsigned int}0x3FF44004=0x000010` command.

Watching and Setting Program Variables A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file `blink.c` by adding a declaration of a global variable `int i` above definition of function `blink_task`. Then add `i++` inside `while(1)` of this function to get `i` incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter the command `watch i`:

```
(gdb) watch i
Hardware watchpoint 2: i
(gdb)
```

This will insert so called "watchpoint" in each place of code where variable `i` is being modified. Now enter `continue` to resume the application and observe it being halted:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB751 (active)    APP_CPU: PC=0x400D0811
[New Thread 1073432196]

Program received signal SIGTRAP, Trace/breakpoint trap.
[Switching to Thread 1073432196]
0x400db751 in blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:33
33          i++;
(gdb)
```

Resume application couple more times so `i` gets incremented. Now you can enter `print i` (in short `p i`) to check the current value of `i`:

```
(gdb) p i
$1 = 3
(gdb)
```

To modify the value of `i` use `set` command as below (you can then print it out to check if it has been indeed changed):

```
(gdb) set var i = 0
(gdb) p i
$3 = 0
(gdb)
```

You may have up to two watchpoints, see *Breakpoints and Watchpoints Available*.

Setting Conditional Breakpoints Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Delete existing breakpoints and try this:

```
(gdb) break blink.c:34 if (i == 2)
Breakpoint 3 at 0x400db753: file /home/user-name/esp/blink/main/./blink.c, line 34.
(gdb)
```

Above command sets conditional breakpoint to halt program execution in line `34` of `blink.c` if `i == 2`.

If current value of `i` is less than `2` and program is resumed, it will blink LED in a loop until condition `i == 2` gets true and then finally halt:

```
(gdb) set var i = 0
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB755 (active)    APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB753 (active)    APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB755 (active)    APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB753 (active)    APP_CPU: PC=0x400D112C

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↪blink.c:34
34          gpio_set_level(BLINK_GPIO, 0);
(gdb)
```

Debugging FreeRTOS Objects This part might be interesting when you are debugging FreeRTOS tasks interactions.

Users that need to use the FreeRTOS task interactions can use the GDB `freertos` command. The `freertos` command is not native to GDB and comes from the freertos-gdb Python extension module. The `freertos` command contains a series of sub-commands as demonstrated in the code snippet:

```
(gdb) freertos
"freertos" must be followed by the name of a subcommand.
List of freertos subcommands:

freertos queue --  Generate a print out of the current queues info.
freertos semaphore --  Generate a print out of the current semaphores info.
freertos task --  Generate a print out of the current tasks and their states.
freertos timer --  Generate a print out of the current timers info.
```

For a more detailed description of this extension, please refer to https://pypi.org/project/freertos-gdb.

Note: The freertos-gdb Python module is included as a Python package requirement by ESP-IDF, thus should be automatically installed (see *Step 3. Set up the Tools* for more details).

The FreeRTOS extension automatically loads in case GDB is executed with command via `idf.py gdb`. Otherwise, the module could be enabled via the `python import freertos_gdb` command inside GDB.

Users only need to have Python 3.6 (or above) that contains a Python shared library.

Obtaining Help on Commands Commands presented so for should provide are very basis and intended to let you quickly get started with JTAG debugging. Check help what are the other commands at you disposal. To obtain help on syntax and functionality of particular command, being at `(gdb)` prompt type `help` and command name:

```
(gdb) help next
Step program, proceeding through subroutine calls.
Usage: next [N]
Unlike "step", if the current source line calls a subroutine,
this command does not enter the subroutine, but instead steps over
the call, in effect treating it as a single source line.
(gdb)
```

By typing just `help`, you will get top level list of command classes, to aid you drilling down to more details. Optionally refer to available GDB cheat sheets, for instance https://darkdust.net/files/GDB%20Cheat%20Sheet.pdf. Good to have as a reference (even if not all commands are applicable in an embedded environment).

Ending Debugger Session To quit debugger enter `q`:

```
(gdb) q
A debugging session is active.

    Inferior 1 [Remote target] will be detached.

Quit anyway? (y or n) y
Detaching from program: /home/user-name/esp/blink/build/blink.elf, Remote target
Ending remote debugging.
user-name@computer-name:~/esp/blink$
```

4.20 Linker Script Generation

4.20.1 Overview

There are several *memory regions* where code and data can be placed. Code and read-only data are placed by default in flash, writable data in RAM, etc. However, it is sometimes necessary to change these default placements.

For example, it may be necessary to place:

- critical code in RAM for performance reasons.
- executable code in IRAM so that it can be ran while cache is disabled.
- code in RTC memory for use in a wake stub.

With the linker script generation mechanism, it is possible to specify these placements at the component level within ESP-IDF. The component presents information on how it would like to place its symbols, objects or the entire archive. During build, the information presented by the components are collected, parsed and processed; and the placement rules generated is used to link the app.

4.20.2 Quick Start

This section presents a guide for quickly placing code/data to RAM and RTC memory - placements ESP-IDF provides out-of-the-box.

For this guide, suppose we have the following:

```
components
└── my_component
    ├── CMakeLists.txt
    ├── Kconfig
    ├── src/
    │   ├── my_src1.c
    │   ├── my_src2.c
    │   └── my_src3.c
    └── my_linker_fragment_file.lf
```

- a component named `my_component` that is archived as library `libmy_component.a` during build
- three source files archived under the library, `my_src1.c`, `my_src2.c` and `my_src3.c` which are compiled as `my_src1.o`, `my_src2.o` and `my_src3.o`, respectively
- under `my_src1.o`, the function `my_function1` is defined; under `my_src2.o`, the function `my_function2` is defined
- there is bool-type config `PERFORMANCE_MODE` (y/n) and int type config `PERFORMANCE_LEVEL` (with range 0-3) in `my_component`'s Kconfig

Creating and Specifying a Linker Fragment File

Before anything else, a linker fragment file needs to be created. A linker fragment file is simply a text file with a `.lf` extension upon which the desired placements will be written. After creating the file, it is then necessary to present it to the build system. The instructions for the build systems supported by ESP-IDF are as follows:

In the component's `CMakeLists.txt` file, specify argument `LDFRAGMENTS` in the `idf_component_register` call. The value of `LDFRAGMENTS` can either be an absolute path or a relative path from the component directory to the created linker fragment file.

```
# file paths relative to CMakeLists.txt
idf_component_register(...
                       LDFRAGMENTS "path/to/linker_fragment_file.lf" "path/to/
↪another_linker_fragment_file.lf"
                       ...
                       )
```

Specifying Placements

It is possible to specify placements at the following levels of granularity:

- object file (`.obj` or `.o` files)
- symbol (function/variable)
- archive (`.a` files)

Placing Object Files Suppose the entirety of `my_src1.o` is performance-critical, so it is desirable to place it in RAM. On the other hand, the entirety of `my_src2.o` contains symbols needed coming out of deep sleep, so it needs to be put under RTC memory.

In the linker fragment file, we can write:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    my_src1 (noflash)      # places all my_src1 code/read-only data under IRAM/DRAM
    my_src2 (rtc)          # places all my_src2 code/ data and read-only data under␣
↪RTC fast memory/RTC slow memory
```

What happens to `my_src3.o`? Since it is not specified, default placements are used for `my_src3.o`. More on default placements *here*.

Placing Symbols Continuing our example, suppose that among functions defined under `object1.o`, only `my_function1` is performance-critical; and under `object2.o`, only `my_function2` needs to execute after the chip comes out of deep sleep. This could be accomplished by writing:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    my_src1:my_function1 (noflash)
    my_src2:my_function2 (rtc)
```

The default placements are used for the rest of the functions in `my_src1.o` and `my_src2.o` and the entire `object3.o`. Something similar can be achieved for placing data by writing the variable name instead of the function name, like so:

```
my_src1:my_variable (noflash)
```

> **Warning:** There are *limitations* in placing code/data at symbol granularity. In order to ensure proper placements, an alternative would be to group relevant code and data into source files, and *use object-granularity placements*.

Placing Entire Archive In this example, suppose that the entire component archive needs to be placed in RAM. This can be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    * (noflash)
```

Similarly, this places the entire component in RTC memory:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    * (rtc)
```

Configuration-Dependent Placements Suppose that the entire component library should only have special placement when a certain condition is true; for example, when `CONFIG_PERFORMANCE_MODE == y`. This could be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    if PERFORMANCE_MODE = y:
        * (noflash)
    else:
        * (default)
```

For a more complex config-dependent placement, suppose the following requirements: when `CONFIG_PERFORMANCE_LEVEL == 1`, only `object1.o` is put in RAM; when `CONFIG_PERFORMANCE_LEVEL == 2`, `object1.o` and `object2.o`; and when `CONFIG_PERFORMANCE_LEVEL == 3` all object files under the archive are to be put into RAM. When these three are false however, put entire library in RTC memory. This scenario is a bit contrived, but, it can be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    if PERFORMANCE_LEVEL = 1:
        my_src1 (noflash)
    elif PERFORMANCE_LEVEL = 2:
        my_src1 (noflash)
        my_src2 (noflash)
    elif PERFORMANCE_LEVEL = 3:
        my_src1 (noflash)
        my_src2 (noflash)
        my_src3 (noflash)
    else:
        * (rtc)
```

Nesting condition-checking is also possible. The following is equivalent to the snippet above:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    if PERFORMANCE_LEVEL <= 3 && PERFORMANCE_LEVEL > 0:
        if PERFORMANCE_LEVEL >= 1:
            object1 (noflash)
            if PERFORMANCE_LEVEL >= 2:
                object2 (noflash)
                if PERFORMANCE_LEVEL >= 3:
                    object2 (noflash)
    else:
        * (rtc)
```

The 'default' Placements

Up until this point, the term 'default placements' has been mentioned as fallback placements when the placement rules `rtc` and `noflash` are not specified. It is important to note that the tokens `noflash` or `rtc` are not merely keywords, but are actually entities called fragments, specifically *schemes*.

In the same manner as `rtc` and `noflash` are schemes, there exists a `default` scheme which defines what the default placement rules should be. As the name suggests, it is where code and data are usually placed, i.e., code/constants is placed in flash, variables placed in RAM, etc. More on the default scheme *here*.

Note: For an example of an ESP-IDF component using the linker script generation mechanism, see freer-

tos/CMakeLists.txt. `freertos` uses this to place its object files to the instruction RAM for performance reasons.

This marks the end of the quick start guide. The following text discusses the internals of the mechanism in a little bit more detail. The following sections should be helpful in creating custom placements or modifying default behavior.

4.20.3 Linker Script Generation Internals

Linking is the last step in the process of turning C/C++ source files into an executable. It is performed by the toolchain's linker, and accepts linker scripts which specify code/data placements, among other things. With the linker script generation mechanism, this process is no different, except that the linker script passed to the linker is dynamically generated from: (1) the collected *linker fragment files* and (2) *linker script template*.

Note: The tool that implements the linker script generation mechanism lives under tools/ldgen.

Linker Fragment Files

As mentioned in the quick start guide, fragment files are simple text files with the `.lf` extension containing the desired placements. This is a simplified description of what fragment files contain, however. What fragment files actually contain are 'fragments'. Fragments are entities which contain pieces of information which, when put together, form placement rules that tell where to place sections of object files in the output binary. There are three types of fragments: *sections*, *scheme* and *mapping*.

Grammar The three fragment types share a common grammar:

```
[type:name]
key: value
key:
    value
    value
    value
    ...
```

- type: Corresponds to the fragment type, can either be `sections`, `scheme` or `mapping`.
- name: The name of the fragment, should be unique for the specified fragment type.
- key, value: Contents of the fragment; each fragment type may support different keys and different grammars for the key values.
  - For *sections* and *scheme*, the only supported key is `entries`
  - For *mappings*, both `archive` and `entries` are supported.

Note: In cases where multiple fragments of the same type and name are encountered, an exception is thrown.

Note: The only valid characters for fragment names and keys are alphanumeric characters and underscore.

Condition Checking

Condition checking enable the linker script generation to be configuration-aware. Depending on whether expressions involving configuration values are true or not, a particular set of values for a key can be used. The evaluation uses `eval_string` from kconfiglib package and adheres to its required syntax and limitations. Supported operators are as follows:

- **comparison**
  - LessThan <
  - LessThanOrEqualTo <=

  - MoreThan >
  - MoreThanOrEqualTo >=
  - Equal =
  - NotEqual `!=`
- **logical**
  - Or `||`
  - And `&&`
  - Negation `!`
- **grouping**
  - Parenthesis `()`

Condition checking behaves as you would expect an `if...elseif/elif...else` block in other languages. Condition-checking is possible for both key values and entire fragments. The two sample fragments below are equivalent:

```
# Value for keys is dependent on config
[type:name]
key_1:
    if CONDITION = y:
        value_1
    else:
        value_2
key_2:
    if CONDITION = y:
        value_a
    else:
        value_b
```

```
# Entire fragment definition is dependent on config
if CONDITION = y:
    [type:name]
    key_1:
        value_1
    key_2:
        value_a
else:
    [type:name]
    key_1:
        value_2
    key_2:
        value_b
```

Comments

Comment in linker fragment files begin with `#`. Like in other languages, comment are used to provide helpful descriptions and documentation and are ignored during processing.

Types Sections

Sections fragments defines a list of object file sections that the GCC compiler emits. It may be a default section (e.g., `.text`, `.data`) or it may be user defined section through the `__attribute__` keyword.

The use of an optional '+' indicates the inclusion of the section in the list, as well as sections that start with it. This is the preferred method over listing both explicitly.

```
[sections:name]
entries:
    .section+
    .section
    ...
```

Example:

```
# Non-preferred
[sections:text]
entries:
    .text
    .text.*
    .literal
    .literal.*

# Preferred, equivalent to the one above
[sections:text]
entries:
    .text+              # means .text and .text.*
    .literal+           # means .literal and .literal.*
```

Scheme

Scheme fragments define what `target` a sections fragment is assigned to.

```
[scheme:name]
entries:
    sections -> target
    sections -> target
    ...
```

Example:

```
[scheme:noflash]
entries:
    text -> iram0_text          # the entries under the sections fragment named␣
↪text will go to iram0_text
    rodata -> dram0_data        # the entries under the sections fragment named␣
↪rodata will go to dram0_data
```

The `default` scheme

There exists a special scheme with the name `default`. This scheme is special because catch-all placement rules are generated from its entries. This means that, if one of its entries is `text -> flash_text`, the placement rule will be generated for the target `flash_text`.

```
*(.literal .literal.* .text .text.*)
```

These catch-all rules then effectively serve as fallback rules for those whose mappings were not specified.

The `default scheme` is defined in esp_system/app.lf. The `noflash` and `rtc` scheme fragments which are built-in schemes referenced in the quick start guide are also defined in this file.

Mapping

Mapping fragments define what scheme fragment to use for mappable entities, i.e., object files, function names, variable names, archives.

```
[mapping:name]
archive: archive                # output archive file name, as built (i.e., libxxx.
↪a)
entries:
    object:symbol (scheme)      # symbol granularity
    object (scheme)             # object granularity
    * (scheme)                  # archive granularity
```

There are three levels of placement granularity:

- symbol: The object file name and symbol name are specified. The symbol name can be a function name or a variable name.
- object: Only the object file name is specified.

- archive: `*` is specified, which is a short-hand for all the object files under the archive.

To know what an entry means, let us expand a sample object-granularity placement:

```
object (scheme)
```

Then expanding the scheme fragment from its entries definitions, we have:

```
object (sections -> target,
        sections -> target,
        ...)
```

Expanding the sections fragment with its entries definition:

```
object (.section,      # given this object file
        .section,      # put its sections listed here at this
        ... -> target, # target

        .section,
        .section,      # same should be done for these sections
        ... -> target,

        ...)           # and so on
```

Example:

```
[mapping:map]
archive: libfreertos.a
entries:
    * (noflash)
```

Aside from the entity and scheme, flags can also be specified in an entry. The following flags are supported (note: <> = argument name, [] = optional):

1. ALIGN(<alignment>[, pre, post])
   Align the placement by the amount specified in `alignment`. Generates
2. SORT([<sort_by_first>, <sort_by_second>])
   Emits `SORT_BY_NAME`, `SORT_BY_ALIGNMENT`, `SORT_BY_INIT_PRIORITY` or `SORT` in the input section description.
   Possible values for `sort_by_first` and `sort_by_second` are: `name`, `alignment`, `init_priority`.
   If both `sort_by_first` and `sort_by_second` are not specified, the input sections are sorted by name. If both are specified, then the nested sorting follows the same rules discussed in https://sourceware.org/binutils/docs/ld/Input-Section-Wildcards.html.
3. KEEP()
   Prevent the linker from discarding the placement by surrounding the input section description with KEEP command. See https://sourceware.org/binutils/docs/ld/Input-Section-Keep.html for more details.

4.SURROUND(<name>)

Generate symbols before and after the placement. The generated symbols follow the naming `_<name>_start` and `_<name>_end`. For example, if `name` == sym1,

When adding flags, the specific `section -> target` in the scheme needs to be specified. For multiple `section -> target`, use a comma as a separator. For example,

```
# Notes:
# A. semicolon after entity-scheme
# B. comma before section2 -> target2
# C. section1 -> target1 and section2 -> target2 should be defined in entries of␣
↪scheme1
```

(continues on next page)

(continued from previous page)

```
entity1 (scheme1);
    section1 -> target1 KEEP() ALIGN(4, pre, post),
    section2 -> target2 SURROUND(sym) ALIGN(4, post) SORT()
```

Putting it all together, the following mapping fragment, for example,

```
[mapping:name]
archive: lib1.a
entries:
    obj1 (noflash);
        rodata -> dram0_data KEEP() SORT() ALIGN(8) SURROUND(my_sym)
```

generates an output on the linker script:

```
. = ALIGN(8)
_my_sym_start = ABSOLUTE(.)
KEEP(lib1.a:obj1.*( SORT(.rodata) SORT(.rodata.*) ))
_my_sym_end = ABSOLUTE(.)
```

Note that ALIGN and SURROUND, as mentioned in the flag descriptions, are order sensitive. Therefore, if for the same mapping fragment these two are switched, the following is generated instead:

```
_my_sym_start = ABSOLUTE(.)
. = ALIGN(8)
KEEP(lib1.a:obj1.*( SORT(.rodata) SORT(.rodata.*) ))
_my_sym_end = ABSOLUTE(.)
```

On Symbol-Granularity Placements Symbol granularity placements is possible due to compiler flags `-ffunction-sections` and `-ffdata-sections`. ESP-IDF compiles with these flags by default. If the user opts to remove these flags, then the symbol-granularity placements will not work. Furthermore, even with the presence of these flags, there are still other limitations to keep in mind due to the dependence on the compiler's emitted output sections.

For example, with `-ffunction-sections`, separate sections are emitted for each function; with section names predictably constructed i.e., `.text.{func_name}` and `.literal.{func_name}`. This is not the case for string literals within the function, as they go to pooled or generated section names.

With `-fdata-sections`, for global scope data the compiler predictably emits either `.data.{var_name}`, `.rodata.{var_name}` or `.bss.{var_name}`; and so `Type I` mapping entry works for these. However, this is not the case for static data declared in function scope, as the generated section name is a result of mangling the variable name with some other information.

Linker Script Template

The linker script template is the skeleton in which the generated placement rules are put into. It is an otherwise ordinary linker script, with a specific marker syntax that indicates where the generated placement rules are placed.

To reference the placement rules collected under a `target` token, the following syntax is used:

```
mapping[target]
```

Example:

The example below is an excerpt from a possible linker script template. It defines an output section `.iram0.text`, and inside is a marker referencing the target `iram0_text`.

```
.iram0.text :
{
    /* Code marked as running out of IRAM */
```

(continues on next page)

(continued from previous page)

```
    _iram_text_start = ABSOLUTE(.);

    /* Marker referencing iram0_text */
    mapping[iram0_text]

    _iram_text_end = ABSOLUTE(.);
} > iram0_0_seg
```

Suppose the generator collected the fragment definitions below:

```
[sections:text]
    .text+
    .literal+

[sections:iram]
    .iram1+

[scheme:default]
entries:
    text -> flash_text
    iram -> iram0_text

[scheme:noflash]
entries:
    text -> iram0_text

[mapping:freertos]
archive: libfreertos.a
entries:
    * (noflash)
```

Then the corresponding excerpt from the generated linker script will be as follows:

```
.iram0.text :
{
    /* Code marked as running out of IRAM */
    _iram_text_start = ABSOLUTE(.);

    /* Placement rules generated from the processed fragments, placed where the␣
↪marker was in the template */
    *(.iram1 .iram1.*)
    *libfreertos.a:(.literal .text .literal.* .text.*)

    _iram_text_end = ABSOLUTE(.);
} > iram0_0_seg
```

`*libfreertos.a:(.literal .text .literal.* .text.*)`

Rule generated from the entry `* (noflash)` of the `freertos` mapping fragment. All `text` sections of all object files under the archive `libfreertos.a` will be collected under the target `iram0_text` (as per the `noflash` scheme) and placed wherever in the template `iram0_text` is referenced by a marker.

`*(.iram1 .iram1.*)`

Rule generated from the default scheme entry `iram -> iram0_text`. Since the default scheme specifies an `iram -> iram0_text` entry, it too is placed wherever `iram0_text` is referenced by a marker. Since it is a rule generated from the default scheme, it comes first among all other rules collected under the same target name.

The linker script template currently used is esp_system/ld/esp32c3/sections.ld.in; the generated output script `sections.ld` is put under its build directory.

4.21 Low Power Modes

4.21.1 Overview

The standby power consumption plays an important role in embedded IoT application scenarios. This guide aims to introduce the basic principles of low power consumption of the ESP32-C3 and the low power modes supported by the ESP32-C3. Besides, it also covers recommended configurations, configuration steps, and power consumption performance of each mode to help users quickly configure the appropriate low power mode according to the needs at hand.

Introduction to Low Power Mode for Systemic Power Management

The ESP32-C3 supports various low power modes. From a systemic perspective on power management, the typical modes include DFS, Light-sleep mode, and Deep-sleep mode. These modes reduce power consumption by lowering clock frequencies (DFS) or entering sleep states without affecting system functionality. During sleep, unnecessary power domains are shut down, or clock gating is applied to peripherals not in use. Sleep modes are further classified into Light-sleep mode and Deep-sleep mode based on whether powering down domains would disrupt program execution context.

Furthermore, for common use cases of the ESP32-C3 such as Wi-Fi/Bluetooth operation, ESP-IDF segment the modes above and optimize them specifically, which will be introduced in subsequent sections.

This section will first introduce low power modes from a systemic perspective, without considering specific use cases.

DFS Dynamic Frequency Scaling (DFS) is a fundamental feature of the power management mechanism integrated into ESP-IDF. DFS adjusts the Advanced Peripheral Bus (APB) frequency and CPU frequency based on the application's holding of power locks. When holding a high-performance lock, it utilizes high frequency, while in idle states without holding power locks, it switches to low frequency to reduce power consumption, thereby minimizing the power consumption of running applications as much as possible.

The frequency adjustment mechanism of DFS operates based on the maximum frequency demand dictated by held power locks. Additionally, the values of *CONFIG_FREERTOS_HZ* also influence the frequency adjustments of DFS. Higher values lead to a higher frequency of task scheduling, then the system can also more quickly re-adjust the clock frequencies according to the system requirements. For further details regarding the frequency adjustment mechanism, please refer to *Power Management*.

The following graph illustrates the ideal current situation during the operation of the DFS mechanism.

```
          Hold CPU and APB MAX lock
                    |
                    |    Release CPU MAX lock
          ▲         |      /
Current   |         ▼     /
          |   ────────┐       Release APB MAX lock
          |           |           /
          |           |          /
          |           └─────────┐
          |           ▲         |
          |           |         |
          |   m-th tick |       └──────────
          |                     ▲
          |                     |
          |           n-th tick |
          └──────────────────────────────────►
```

Ideal DFS Mechanism Frequency Adjustment Current Graph
```

DFS is suitable for scenarios where the CPU must remain active but low power consumption is required. Therefore, DFS is often activated with other low power modes, as will be detailed in the following sections.

Light-sleep Mode Light-sleep mode is a low power mode preset in the ESP32-C3. Users can switch to Light-sleep mode by calling `esp_light_sleep_start()` interface. Upon entering sleep, the chip will shut down unnecessary power domains and apply clock gating to modules not in use, based on the current operational states of peripherals. The ESP32-C3 supports various wake-up sources. Please refer to *Sleep Modes* for more information. When the chip wakes up from Light-sleep mode, the CPU continues running from the context it was in before entering sleep, and the operational states of peripherals remain unaffected. To effectively reduce chip power consumption under Light-sleep mode, it is highly recommended that users utilize Auto Light-sleep mode described below.

Auto Light-sleep mode is a low power mode provided by ESP-IDF *Power Management* component that leverages FreeRTOS's Tickless IDLE feature. When the application releases all power locks and all FreeRTOS tasks are in a blocked or suspended state, the system automatically calculates the next time point when an event will wake the operating system. If this calculated time point exceeds a set duration (*CONFIG_FREERTOS_IDLE_TIME_BEFORE_SLEEP*), the `esp_pm` component automatically configures the timer wake-up source and enters light sleep to reduce power consumption. To enable this mode, users need to set the `light_sleep_enable` field to true in `esp_pm_config_t` when configuring DFS. For more details, please refer to *DFS Configuration*.

  Ideal Current Graph of Auto Light-sleep Mode
```

Note:

- To better illustrate the main changes of Auto Light-sleep mode, the DFS frequency reduction process is omitted from the graph above.
- Auto Light-sleep mode is suitable for scenarios where real-time response to external demands is not required.
- Auto Light-sleep mode operates based on timer wake-up sources. Therefore, users should not manually configure timer wake-up sources in their application.

Deep-sleep Mode Deep-sleep mode is designed to achieve better power performance by retaining only RTC/LP memory and peripherals during sleep, while all other modules are shut down. Similar to Light-sleep mode, Deep-sleep mode is entered through API calls and requires configuration of wake-up sources for awakening. Users can switch to Deep-sleep mode by calling `esp_deep_sleep_start()` interface.

Deep-sleep mode requires the configuration of wake-up sources. The ESP32-C3 supports multiple wake-up sources. For a complete list of wake-up sources, please refer to *Sleep Modes*. These wake-up sources can also be combined so that any wake-up source can trigger the awakening. If no wake-up source is configured when entering deep sleep, the chip will remain in sleep state until an external reset occurs. Unlike Light-sleep mode, Deep-sleep mode upon awakening will lose the CPU's running context before, so the bootloader needs to be run again to enter the user program.

The workflow of Deep-sleep mode is shown as below:

```
┌──────┐   call API   ┌──────┐
│      │──────────────►│ deep │
│active│               │ sleep│
│      │               │      │
└──────┘               └──────┘
    ▲                     │
    └─────────────────────┘
   wake-up source wakes up
  Deep-sleep Mode Workflow
```

The primary application scenario of Deep-sleep mode determines that the system will awaken only after a long period and will return to deep sleep state after completing its task. The ideal current graph is as follows.

```
        ▲
Current |
        |                call API
        |                   |
        |                   ▼
        |                ┌────┐
        |                │    │
        | wake-up source │    │
        |  wakes up  \   │    │
        |             \  │    │
        |     ___________┘    └_________________
        |

                                            Time
       Ideal Current Graph of Deep-sleep Mode
```

Deep-sleep mode can be utilized in low power sensor applications or situations where data transmission is not required for most of the time, commonly referred to as standby mode.

Devices can wake up periodically from deep sleep to measure and upload data, and then return to deep sleep. Alternatively, it can store multiple data sets in RTC memory and transmit them all at once upon the next wake-up. This feature can be implemented using the deep-sleep-stub functionality. For details, please refer to *Deep-sleep Wake Stubs*.

Low Power Mode Configuration on Pure System After introducing low power modes from a systemic perspective, this section will present common configuration options, recommended configuration options for each mode, and configurations steps.

Common Configuration Options

Note: The configuration options below are briefly introduced. For more detailed information, please click the link behind each option.

DFS Configuration DFS offers the following configurable options:

- **`max_freq_mhz`** This parameter denotes the maximum CPU frequency (MHz), i.e., the frequency at which the CPU operates at its highest performance level. It is typically set to the maximum value specified by the chip parameters.
- **`min_freq_mhz`** This parameter denotes the minimum CPU frequency (MHz), i.e., the CPU's operating frequency when the system is in an idle state. This field can be set to the crystal oscillator (XTAL) frequency value or the XTAL frequency value divided by an integer.
- **`light_sleep_enable`** Enabling this option allows the system to automatically enter the light sleep during idle periods, i.e., enabling Auto Light-sleep mode, as detailed earlier.

Specific configuration steps are as follows:

1. Enable *CONFIG_PM_ENABLE*
2. Configure `max_freq_mhz` and `min_freq_mhz` as follows:

```
esp_pm_config_t pm_config = {
        .max_freq_mhz = CONFIG_EXAMPLE_MAX_CPU_FREQ_MHZ,
        .min_freq_mhz = CONFIG_EXAMPLE_MIN_CPU_FREQ_MHZ,
        .light_sleep_enable = false
};
ESP_ERROR_CHECK(esp_pm_configure(&pm_config));
```

Recommended Configuration

Configuration Name	Configuration Status
Enable power management component (*CONFIG_PM_ENABLE*)	ON
RTOS Tick rate (Hz) (*CONFIG_FREERTOS_HZ*)	1000
`max_freq_mhz`	160
`min_freq_mhz`	40
`light_sleep_enable`	false

Note: Configurations not mentioned in the above table are set to default.

Light-sleep Mode Configuration This section introduces the recommended configuration and configuration steps for Auto Light-sleep mode.

Note: The configuration options below are briefly introduced. For more detailed information, please click the link behind each option.

- Minimum IDLE Tick count before entering sleep state (*CONFIG_FREERTOS_IDLE_TIME_BEFORE_SLEEP*)
- Put light sleep related codes in IRAM (*CONFIG_PM_SLP_IRAM_OPT*)
- Put RTOS IDLE related codes in IRAM (*CONFIG_PM_RTOS_IDLE_OPT*)

- RTC slow clock source (*CONFIG_RTC_CLK_SRC*)

Clock Source	Timer Accuracy	Frequency Offset
RTC_CLK_SRC_INT_RC	High	Large
RTC_CLK_SRC_EXT_CRYS	Low	Small

- Disable all GPIO when chip at sleep (*CONFIG_PM_SLP_DISABLE_GPIO*)
- Power down MAC and baseband (*CONFIG_ESP_PHY_MAC_BB_PD*)
- Power down CPU (*CONFIG_PM_POWER_DOWN_CPU_IN_LIGHT_SLEEP*)
- Power down flash in light sleep (*CONFIG_ESP_SLEEP_POWER_DOWN_FLASH*)

Configuration Steps:

1. Configure wake-up sources (refer to *Sleep Modes* for details)
2. Enable *CONFIG_PM_ENABLE*
3. Enable *CONFIG_FREERTOS_USE_TICKLESS_IDLE*
4. Configure DFS parameters
5. `light_sleep_enable` = true, detailed as follows:

```
esp_pm_config_t pm_config = {
  .max_freq_mhz = CONFIG_EXAMPLE_MAX_CPU_FREQ_MHZ,
  .min_freq_mhz = CONFIG_EXAMPLE_MIN_CPU_FREQ_MHZ,
  #if CONFIG_FREERTOS_USE_TICKLESS_IDLE
  .light_sleep_enable = true
  #endif
};
ESP_ERROR_CHECK(esp_pm_configure(&pm_config));
```

6. Additional relevant parameters for configuration introduction

Recommended Configuration

Configuration Name	Configuration Status
Enable power management component (*CONFIG_PM_ENABLE*)	ON
Enable RTOS Tickless IDLE mode (*CONFIG_FREERTOS_USE_TICKLESS_IDLE*)	ON
RTOS Tick rate (Hz) (*CONFIG_FREERTOS_HZ*)	1000
Minimum IDLE Tick count before entering sleep mode (*CONFIG_FREERTOS_IDLE_TIME_BEFORE_SLEEP*)	3
Put light sleep related codes in IRAM (*CONFIG_PM_SLP_IRAM_OPT*)	OFF
Put RTOS IDLE related codes in IRAM (*CONFIG_PM_RTOS_IDLE_OPT*)	OFF
RTC slow clock source (*CONFIG_RTC_CLK_SRC*)	Internal 150 kHz OSC
Disable all GPIO when chip at sleep (*CONFIG_PM_SLP_DISABLE_GPIO*)	ON
Power down MAC and baseband (*CONFIG_ESP_PHY_MAC_BB_PD*)	ON
Power down CPU (*CONFIG_PM_POWER_DOWN_CPU_IN_LIGHT_SLEEP*)	ON

Deep-sleep Mode Configuration For Deep-sleep mode, other configurations are of minimal significance except wake-up source-related configurations.

Configuration Steps:

1. Configure wake-up sources (refer to *Sleep Modes* for details)
2. Call the API, as follows

```
/* Enter deep sleep */
esp_deep_sleep_start();
```

Users can keep specific modules powered on during sleep using the following configuration options:

- **Power up External 40 MHz XTAL** In some special applications, certain modules require high clock accuracy and stability during sleep (e.g., BT). In such cases, it is recommended to enable the External 40 MHz XTAL during sleep. Code to enable and disable, as follows:

```
ESP_ERROR_CHECK(esp_sleep_pd_config(ESP_PD_DOMAIN_XTAL, ESP_PD_OPTION_ON));
ESP_ERROR_CHECK(esp_sleep_pd_config(ESP_PD_DOMAIN_XTAL, ESP_PD_OPTION_
↪OFF));
```

- **Power up Internal 8 MHz OSC** In some special applications, certain modules (e.g., LEDC) use the Internal 8 MHz OSC as a clock source and need to function normally during light sleep. In such cases, it is recommended to enable the Internal 8 MHz OSC during sleep. Code to enable and disable, as follows:

```
ESP_ERROR_CHECK(esp_sleep_pd_config(ESP_PD_DOMAIN_RTC8M, ESP_PD_OPTION_
↪ON));
ESP_ERROR_CHECK(esp_sleep_pd_config(ESP_PD_DOMAIN_RTC8M, ESP_PD_OPTION_
↪OFF));
```

Introduction to Low Power Mode in Wi-Fi Scenarios

After the previous introduction to low power mode from a systemic perspective, this section delves into low power mode in Wi-Fi scenarios. Due to the complexity of Wi-Fi scenarios, basic principles of Wi-Fi power saving will be introduced before specific low power mode. This section is focused on station mode.

Choosing Low Power Mode in Wi-Fi Scenarios To help users select appropriate low power mode, a summary table of low power modes in Wi-Fi scenarios is provided before detailed introduction.

Item	Modem-sleep	Modem-sleep+DFS	Auto Ligh-sleep	Deep-sleep
Sleep	Automatic	Automatic	Automatic	Manual
Wake-up	Automatic	Automatic	Automatic	Configure Wake-up Source
Wi-Fi Connection	Maintain	Maintain	Maintain	Disconnect
CPU	On	On/Throttled	Paused	Off
System Clock	On	On	Off	Off
Peripherals	On	On	On	Off
DTIM1	21.47 mA	11.35 mA	1.4 mA	/
DTIM3	20.82 mA	10.71 mA	0.62 mA	/
DTIM10	20.67 mA	10.32 mA	0.31 mA	/
Average Current	/	/	/	4.8 μA

Note: All currents in the table are average currents, and the terms in the table are explained in the following text. Users can refer to them as needed.

Basic Principles of Wi-Fi Power Saving Firstly, during the operation of a station, prolonged channel monitoring is required to avoid conflicts during transmission and reception. It leads to significant energy consumption as the RF module remains active, thus wasting power. Therefore, Wi-Fi protocols introduce power-saving modes.

The basic principle of power-saving mode is to reduce energy consumption by minimizing unnecessary monitoring time. Access points (APs) will cache packets for a station that has entered power-saving mode. At the same time, it will periodically send beacon frames containing Traffic Indication Map (TIM) information. TIM indicates the unicast packets cached by the AP. Within TIM, the Delivery Traffic Indication Message (DTIM) is special as it caches broadcast packets and sends them out periodically every n TIM intervals (determined by the AP). For stations,

TIM is optional listening, while DTIM is mandatory listening. Therefore, station can choose to wake up only before each DTIM frame to power up Wi-Fi-related modules (RF modules) instead of constantly being in listening state. This effectively reduces power consumption.

```
                        DTIM                DTIM
        TIM               |                   |
         |    |    |    |    |    |    |    |    |    |    |
         |    |    |    |    |    |    |    |    |    |    |
AP    ___|____|____|____|____|____|____|____|____|____|____|____

                        ┌────┐              ┌────┐
                        |    |              |    |
                        |    |              |    |
                        |    |              |    |
Sta   ------------------|----|--------------|----|-------------------

                   DTIM4 Power Saving Mode Diagram
```

Second, the time from powering up to powering down Wi-Fi related modules in a station also affects power consumption. Apart from the necessary time for data transmission processing, there are four configurations mainly affecting the duration:

- Time offset caused by clock accuracy. The main reason is that clocks may deviate from ideal time to some extent, and the deviation can be positive or negative.
- Time spent processing missed beacon frames, such as the duration of continuous listening after a missed beacon, the maximum allowable number of missed beacons, etc. The existence and duration of this period are uncertain but can be configured within a range.
- Active time added to ensure the reception of burst data packets, which can be determined by configuration.
- ILDE time is required for specific power-saving modes to meet entry conditions. Therefore, reducing the working time can improve power performance while meeting communication requirements.

```
┌──────────┬──────────┬──────────┬──────────┬──────────┐
|          |          | time spent |          |          |
|time offset |  necessary | processing | active time| IDLE time |
|          | processing |  missed  |          |          |
|          |   time   |  beacon  |          |          |
└──────────┴──────────┴──────────┴──────────┴──────────┘

                Chip Operation Time Overview
```

Furthermore, when the station is not in a Wi-Fi transmission or reception state, other modules begin to affect the chip's power consumption. Different power-saving modes will configure different clock sources or dynamically adjust the operating frequencies of certain modules such as the CPU, while also shutting down varying numbers of functional modules, which effectively reduces the power consumption. Users can select suitable configurations according to their needs.

If time is plotted on the horizontal axis and current on the vertical axis, then the ideal current consumption graph of the chip under low power mode can be simplified as shown below:

```
         ▲
Current  |
         |
         |            interval                period
         |        | ◄──────────► |           | ◄─► |
         |      ┌────┐         ┌────┐         ┌────┐
         |      |    |         |    |         |    |
         |      |    |         |    |         |    | base current
         |      |    |         |    |         |    |   |
         |      |    |         |    |         |    |   ▼
         |  ────┘    └─────────┘    └─────────┘    └──────
         |
         └──────────────────────────────────────────────►
```

(continues on next page)

(continued from previous page)

```
                                                        Time
     Ideal Current Graph of the Chip Under Low Power Mode
```

When the station needs to engage in Wi-Fi communication, the Wi-Fi-related modules (PHY) are activated, causing a significant increase in current. The current remains at a relatively high level until the task is completed. After that, the chip will deactivate the Wi-Fi-related modules, causing the current to decrease to a lower level.

Three main factors affect power consumption performance: interval, period, and base current.

- **Interval** refers to the interval at which the station's Wi-Fi-related modules operate. It can be customized by low power mode or determined by the DTIM interval according to Wi-Fi protocol power-saving mechanisms (see first part in *Basic Principles of Wi-Fi Power Saving*). Generally, a larger interval leads to better power performance under the same conditions. But it also results in slower response times, affecting communication timeliness.
- **Period** can be seen as the duration of each time the station's Wi-Fi operates, which also affects power performance. The period is not fixed (see second part in *Basic Principles of Wi-Fi Power Saving*). In ensuring normal Wi-Fi communication, a shorter period leads to better power performance. However, reducing the period will inevitably affect communication reliability.
- **Base current** refers to the current of the chip when the Wi-Fi-related modules are not active. It is influenced by various factors. Different power-saving modes have different sleep strategies. Therefore, optimizing the configuration to reduce the base current can improve power performance. But closing other modules will affect related functions and the wake-up time of the chip.

Therefore, power consumption can be reduced by considering the three aspects. Next, Modem-sleep mode and Auto Light-sleep mode will be introduced. The main difference between the two modes lies in the optimization of these three factors.

Modem-sleep Mode The main principle of Modem-sleep mode is based on the DTIM mechanism. In this mode, the chip periodically wakes up for Wi-Fi-related tasks, and enters sleep state between intervals to power down PHY (RF module) to reduce power consumption. Besides, through the DTIM mechanism, the station can maintain Wi-Fi connection and data transmission with the AP.

Modem-sleep mode automatically enters sleep after the Wi-Fi task ends without the need to call an API. During sleep, only the Wi-Fi-related modules (PHY) are closed, while other modules remain in power-up state.

Modem-sleep mode will wake up according to the DTIM interval or listen interval (as introduced below in *Modem-sleep Mode Configuration*), acting as if the system has automatically set a Wi-Fi wake-up source. Therefore, users do not need to configure a wake-up source. The system can also wake up when actively sending packets.

Modem-sleep mode is a toggle mode that automatically runs after calling the API to activate it. Its workflow is very clear, as shown in the diagram below.

```
┌──────────────┐        Wi-Fi task finished        ┌──────────────┐
│              ├──────────────────────────────────►│   modem      │
│   active     │                                   │   sleep      │
│              │◄──────────────────────────────────┤              │
└──────────────┘    DTIM interval activated        └──────────────┘
                        / sending packets

                    Modem-sleep Mode Workflow
```

Based on the base current graph provided above and combined with the operating principle of Modem-sleep mode, an ideal current graph can be derived, taking Min Modem-sleep mode (as introduced below in *Modem-sleep Mode Configuration*) as an example.

```
        ▲
Current |
        |                DTIM interval
        |              | ◄──────────► |
        |            ┌────┐         ┌────┐         ┌────┐
```

(continues on next page)

(continued from previous page)

        |   DTIM   |      |         |      |         |      |  Wi-Fi task
        |  interval|      |         |      |         |      | finished
        |activated |      |         |      |         |      | /
        |        \ |      |         |      |         |      |/
        |  ________|      |_________|      |_________|      |______
        |
        |____________________________________________________________►
                                                            Time
              Ideal Current Graph of Min Modem-sleep Mode
```

Modem-sleep mode is generally used in scenarios where the CPU needs to remain active and maintain a Wi-Fi connection. For example, it is utilized to realize local voice wake-up by the ESP32-C3, where the CPU continuously collects and processes audio data.

DFS + Modem-sleep Mode In Modem-sleep mode, the CPU remains active while the DFS mechanism primarily adjusts the CPU and APB operating frequencies to reduce power consumption. Therefore, combining DFS with Modem sleep mode can further optimize power performance. Additionally, as the Wi-Fi task requests the *ESP_PM_CPU_FREQ_MAX* power lock to ensure the rapid execution of Wi-Fi tasks, frequency adjustment by DFS and Modem-sleep mode only occurs during the base current phase, which is after the Wi-Fi task ends.

In Wi-Fi scenarios, to help users understand main changes, the state of DFS can be simplified. Specifically, although DFS primarily adjusts frequencies based on the maximum demands of the CPU and APB locks, in Wi-Fi scenarios, the CPU frequency needs to be maximized for operation. Besides, after the Wi-Fi task ends, it can be ideally assumed that no other tasks need to be completed, and that after some time, both locks are released to enter IDLE state. This simplified situation also ignores any current variations caused by changes in the locks during this time.

In Wi-Fi scenarios, the flowchart of DFS csn be simplified as follows:

```
                                  ┌──────────┐
                                  │          │
                                  │   DFS    │
                                  │          │
                                  └──────────┘
                                       |
                                       ▼
  ┌──────────┐    when IDLE     ┌──────────┐
  │          │ ────────────►    │          │
  │          │                  │          │
  │  active  │                  │   IDLE   │
  │          │                  │          │
  │          │ ◄────────────    │          │
  └──────────┘    not IDLE      └──────────┘

Simplified Flowchart of DFS in the Wi-Fi Scenario
```

The system transitions between active state and IDLE state in Wi-Fi scenarios. After the Wi-Fi task is completed, the system releases all locks after a period of time and enters the IDLE state. At this point, the DFS mechanism reduces the frequency to the set minimum value, ignoring the frequency adjustment actions during the state transition, which facilitates understanding.

The DFS + Modem-sleep mode's ideal current graph is simplified as below:

```
        ▲                Wi-Fi task finished
Current |                   /  modem sleep
        |                  /
        |           ┌──────┐                  ┌──────┐
        |           |      |                  |      |
        |           |      |                  |      |   lock released
        |           |      |                  |      |   DFS frequency

            DFS + Modem-sleep Mode's Ideal Current Graph
```

Auto Light-sleep Mode + Wi-Fi Scenario Auto Light-sleep mode combines the ESP-IDF power management mechanism, the DTIM mechanism, and Light-sleep mode in Wi-Fi scenarios. Enabling power management is a prerequisite of this mode, and its auto aspect is demonstrated by the system automatically entering Light-sleep after being in the IDLE state for a set duration. Additionally, auto Auto Light-sleep mode adheres to the DTIM mechanism. The system will automatically wake up to maintain Wi-Fi connection with AP.

In the Wi-Fi environment, the sleep mechanism of Auto Light-sleep mode remains consistent with that of the pure system. It still relies on the power management mechanism, where the condition for entering sleep is when the system has been IDLE for a duration exceeding the set time. The system will assess if the IDLE time meets the conditions, and if so, it will directly enter sleep. This process is automatic. During sleep, RF, the 8 MHz oscillator, the 40 MHz high-speed crystal oscillator, PLL, and gated digital core clock are automatically turned off, and CPU operation is suspended.

In the Wi-Fi environment, the Auto Light-sleep mode follows the DTIM mechanism. The system will automatically wake up before the arrival of DTIM frames, as if a Wi-Fi wake-up source has been set. Therefore, there is no need for configuration. Additionally, the system can be awakened when actively sending packets.

The operation workflow of Auto Light-sleep mode in the Wi-Fi environment is relatively complex, but it is entirely automated throughout. Specific details are illustrated in the diagram.

    Ideal Current Graph of Modem + Auto Light-sleep Mode
```

In the Wi-Fi environment, Auto Light-sleep mode can be utilized to maintain Wi-Fi connection and respond promptly to data sent by AP. Additionally, the CPU can remain IDLE when no commands are received. For example, in applications such as Wi-Fi switches, the CPU is mostly IDLE until it receives a control command to operate on GPIO.

Deep-sleep Mode + Wi-Fi Scenario The Deep-sleep mode in Wi-Fi scenarios is essentially the same as in a pure system. For details, please refer to *Deep-sleep Mode*. Here, it will not be further discussed.

Low Power Mode Configuration in Wi-Fi Scenarios After introducing the low power mode in Wi-Fi scenarios, this section will cover common configuration options, unique configuration options for each mode, and instructions for using the corresponding low power mode APIs. Additionally, recommendations for the respective modes' configurations (including recommended configurations for pure systems) will be provided, along with specific performance details.

Note: The configuration options below are briefly introduced. For more detailed information, please click the link behind each option.

Common Configuration Options

- Power consumption related:
  - Max Wi-Fi TX power (dBm) (*CONFIG_ESP_PHY_MAX_WIFI_TX_POWER*)
- Speed optimization related:
  - Wi-Fi IRAM speed optimization (*CONFIG_ESP_WIFI_IRAM_OPT*)
  - Wi-Fi RX IRAM speed optimization (*CONFIG_ESP_WIFI_RX_IRAM_OPT*)
  - Wi-Fi Sleep IRAM speed optimization (*CONFIG_ESP_WIFI_SLP_IRAM_OPT*)
- Wi-Fi Protocol related:
  - Minimum active time (*CONFIG_ESP_WIFI_SLP_DEFAULT_MIN_ACTIVE_TIME*)
  - Maximum keep alive time (*CONFIG_ESP_WIFI_SLP_DEFAULT_MAX_ACTIVE_TIME*)
  - Send gratuitous ARP periodically (*CONFIG_LWIP_ESP_GRATUITOUS_ARP*)
  - Wi-Fi sleep optimize when beacon lost (*CONFIG_ESP_WIFI_SLP_BEACON_LOST_OPT*)

Modem-sleep Mode Configuration

- Configurable Options
  - **Min Modem** This parameter indicates that the station operates according to the DTIM cycle. It wakes up before each DTIM to receive beacon frames, which ensures that broadcast information is not missed. However, the DTIM cycle is determined by the AP. If the DTIM cycle is short, the power saving effect will be reduced.
  - **Max Modem** This parameter indicates that the station customizes a listen interval and wakes up to receive beacon frames at intervals defined by the listen interval. This approach saves power when the listen interval is large but may lead to missed DTIMs and broadcast data.
- Configuration Steps

– Call the API and select the mode parameters

```
    typedef enum {
        WIFI_PS_NONE,
        WIFI_PS_MIN_MODEM,
        WIFI_PS_MAX_MODEM,
    } wifi_ps_type_t;
    esp_err_t esp_wifi_set_ps(wifi_ps_type_t type);

If WIFI_PS_MAX_MODEM is selected, the listen interval also needs to be␣
↪configured. An example is provided below::

      #define LISTEN_INTERVAL 3
      wifi_config_t wifi_config = {
          .sta = {
          .ssid = "SSID",
          .password = "Password",
          .listen_interval = LISTEN_INTERVAL,
        },
      };
      ESP_ERROR_CHECK(esp_wifi_set_mode(WIFI_MODE_STA));
      ESP_ERROR_CHECK(esp_wifi_set_config(ESP_IF_WIFI_STA, &wifi_config));
      ESP_ERROR_CHECK(esp_wifi_start());
```

- Recommended Configuration

  The recommended configuration provided here is for Min Modem-sleep mode + DFS.

Configuration Name	Configuration Status
WIFI_PS_MIN_MODEM	ON
CONFIG_PM_ENABLE	ON
RTOS Tick rate (Hz)	1000
`max_freq_mhz`	160
`min_freq_mhz`	40
`light_sleep_enable`	false

- Configuration Performance

CPU frequency	DFS	DTIM	Average current (mA)	Max current (mA)	Min current (mA)
160 MHz	ON	1	11.35	83.31	5.03
160 MHz	OFF	1	21.47	191.53	20.58
160 MHz	ON	3	10.71	82.82	5.09
160 MHz	OFF	3	20.82	82.98	20.48
160 MHz	ON	10	10.32	81.05	5.74
160 MHz	OFF	10	20.67	229.83	20.48

Auto Light-sleep Mode + Wi-Fi Scenario Configuration Auto Light-sleep mode in Wi-Fi scenarios does not require wake-up source configuration compared with a pure system. But the remaining part of configuration is basically the same in the two operation scenarios. Therefore, detailed introduction of configurable options, configuration steps, and recommended configurations can be found in the previous section *Deep-sleep Mode*, with the Wi-Fi-related configurations set to default.

- Configuration Performance

  The configuration performance mirrors that of the recommended Auto Light-sleep mode configuration in a pure system, combined with the default Wi-Fi-related configurations in the Wi-Fi environment.

CPU frequency	DTIM	Average current (mA)	Max current (mA)	Min current (mA)
160 MHz	1	1.4	87.26	0.14
160 MHz	3	0.62	86.33	0.14
160 MHz	10	0.31	86.11	0.14

Deep-sleep Mode + Wi-Fi Scenario Configuration Deep-sleep mode configuration in Wi-Fi scenarios is essentially the same as in a pure system. Therefore, detailed introduction of configurable options, configuration steps, and recommended configurations can be found in the previous section *Deep-sleep Mode*, with the Wi-Fi-related configurations set to default.

- Configuration Performance
  The performance of this configuration mirrors that of the recommended Deep-sleep mode configuration in a pure system, combined with the default Wi-Fi-related configurations in the Wi-Fi environment.
  Average current approximately 4.8 µA

4.22 lwIP

ESP-IDF uses the open source lwIP lightweight TCP/IP stack. The ESP-IDF version of lwIP (esp-lwip) has some modifications and additions compared to the upstream project.

4.22.1 Supported APIs

ESP-IDF supports the following lwIP TCP/IP stack functions:

- *BSD Sockets API*
- *Netconn API* is enabled but not officially supported for ESP-IDF applications

Adapted APIs

> **Warning:** When using any lwIP API other than the *BSD Sockets API*, please make sure that the API is thread-safe. To check if a given API call is thread-safe, enable the *CONFIG_LWIP_CHECK_THREAD_SAFETY* configuration option and run the application. This enables lwIP to assert the correct access of the TCP/IP core functionality. If the API is not accessed or locked properly from the appropriate *lwIP FreeRTOS Task*, the execution will be aborted. The general recommendation is to use the *ESP-NETIF* component to interact with lwIP.

Some common lwIP app APIs are supported indirectly by ESP-IDF:

- Dynamic Host Configuration Protocol (DHCP) Server & Client are supported indirectly via the *ESP-NETIF* functionality.
- Domain Name System (DNS) is supported in lwIP; DNS servers could be assigned automatically when acquiring a DHCP address, or manually configured using the *ESP-NETIF* API.

Note: DNS server configuration in lwIP is global, not interface-specific. If you are using multiple network interfaces with distinct DNS servers, exercise caution to prevent inadvertent overwrites of one interface's DNS settings when acquiring a DHCP lease from another interface.

- Simple Network Time Protocol (SNTP) is also supported via the *ESP-NETIF*, or directly via the lwip/include/apps/esp_sntp.h functions, which also provide thread-safe API to lwip/lwip/src/include/lwip/apps/sntp.h functions, see also *SNTP Time Synchronization*.
- ICMP Ping is supported using a variation on the lwIP ping API, see *ICMP Echo*.
- ICMPv6 Ping, supported by lwIP's ICMPv6 Echo API, is used to test IPv6 network connectivity. For more information, see protocols/sockets/icmpv6_ping.
- NetBIOS lookup is available using the standard lwIP API. protocols/http_server/restful_server has the option to demonstrate using NetBIOS to look up a host on the LAN.
- mDNS uses a different implementation to the lwIP default mDNS, see *mDNS Service*. But lwIP can look up mDNS hosts using standard APIs such as `gethostbyname()` and the convention `hostname.local`, provided the *CONFIG_LWIP_DNS_SUPPORT_MDNS_QUERIES* setting is enabled.
- The PPP implementation in lwIP can be used to create PPPoS (PPP over serial) interface in ESP-IDF. Please refer to the documentation of the *ESP-NETIF* component to create and configure a PPP network interface, by means of the `ESP_NETIF_DEFAULT_PPP()` macro defined in esp_netif/include/esp_netif_defaults.h. Additional runtime settings are provided via esp_netif/include/esp_netif_ppp.h. PPPoS interfaces are typically used to interact with NBIoT/GSM/LTE modems. More application-level friendly API is supported by the esp_modem library, which uses this PPP lwIP module behind the scenes.

4.22.2 BSD Sockets API

The BSD Sockets API is a common cross-platform TCP/IP sockets API that originated in the Berkeley Standard Distribution of UNIX but is now standardized in a section of the POSIX specification. BSD Sockets are sometimes called POSIX Sockets or Berkeley Sockets.

As implemented in ESP-IDF, lwIP supports all of the common usages of the BSD Sockets API.

References

A wide range of BSD Sockets reference materials are available, including:

- Single UNIX Specification - BSD Sockets page
- Berkeley Sockets - Wikipedia page

Examples

A number of ESP-IDF examples show how to use the BSD Sockets APIs:

- protocols/sockets/tcp_server
- protocols/sockets/tcp_client
- protocols/sockets/udp_server
- protocols/sockets/udp_client
- protocols/sockets/udp_multicast
- protocols/http_request: this simplified example uses a TCP socket to send an HTTP request, but *ESP HTTP Client* is a much better option for sending HTTP requests

Supported Functions

The following BSD socket API functions are supported. For full details, see lwip/lwip/src/include/lwip/sockets.h.

- `socket()`
- `bind()`
- `accept()`
- `shutdown()`
- `getpeername()`
- `getsockopt()` & `setsockopt()`: see *Socket Options*
- `close()`: via *Virtual Filesystem Component*
- `read()`, `readv()`, `write()`, `writev()`: via *Virtual Filesystem Component*

- `recv()`, `recvmsg()`, `recvfrom()`
- `send()`, `sendmsg()`, `sendto()`
- `select()`: via *Virtual Filesystem Component*
- `poll()` : on ESP-IDF, `poll()` is implemented by calling `select()` internally, so using `select()` directly is recommended, if a choice of methods is available
- `fcntl()`: see *fcntl()*

Non-standard functions:

- `ioctl()`: see *ioctl()*

Note: Some lwIP application sample code uses prefixed versions of BSD APIs, e.g., `lwip_socket()`, instead of the standard `socket()`. Both forms can be used with ESP-IDF, but using standard names is recommended.

Socket Error Handling

BSD Socket error handling code is very important for robust socket applications. Normally, socket error handling involves the following aspects:

- Detecting the error
- Getting the error reason code
- Handling the error according to the reason code

In lwIP, we have two different scenarios for handling socket errors:

- Socket API returns an error. For more information, see *Socket API Errors*.
- `select(int maxfdp1, fd_set *readset, fd_set *writeset, fd_set *exceptset, struct timeval *timeout)` has an exception descriptor indicating that the socket has an error. For more information, see *select() Errors*.

Socket API Errors Error detection

- We can know that the socket API fails according to its return value.

Get the error reason code

- When socket API fails, the return value does not contain the failure reason and the application can get the error reason code by accessing `errno`. Different values indicate different meanings. For more information, see *Socket Error Reason Code*.

Example:

```
int err;
int sockfd;

if (sockfd = socket(AF_INET,SOCK_STREAM,0) < 0) {
    // the error code is obtained from errno
    err = errno;
    return err;
}
```

`select()` Errors Error detection

- Socket error when `select()` has exception descriptor.

Get the error reason code

- If the `select()` indicates that the socket fails, we can not get the error reason code by accessing `errno`, instead we should call `getsockopt()` to get the failure reason code. Since `select()` has exception descriptor, the error code is not given to `errno`.

Note: The `getsockopt()` function has the following prototype: `int getsockopt(int s, int level, int optname, void *optval, socklen_t *optlen)`. Its purpose is to get the current value of the option of any type, any state socket, and store the result in `optval`. For example, when you get the error code on a socket, you can get it by `getsockopt(sockfd, SOL_SOCKET, SO_ERROR, &err, &optlen)`.

Example:

```
int err;

if (select(sockfd + 1, NULL, NULL, &exfds, &tval) <= 0) {
    err = errno;
    return err;
} else {
    if (FD_ISSET(sockfd, &exfds)) {
        // select() exception set using getsockopt()
        int optlen = sizeof(int);
        getsockopt(sockfd, SOL_SOCKET, SO_ERROR, &err, &optlen);
        return err;
    }
}
```

Socket Error Reason Code Below is a list of common error codes. For a more detailed list of standard POSIX/C error codes, please see newlib errno.h and the platform-specific extensions newlib/platform_include/errno.h.

Error code	Description
ECONNREFUSED	Connection refused
EADDRINUSE	Address already in use
ECONNABORTED	Software caused connection abort
ENETUNREACH	Network is unreachable
ENETDOWN	Network interface is not configured
ETIMEDOUT	Connection timed out
EHOSTDOWN	Host is down
EHOSTUNREACH	Host is unreachable
EINPROGRESS	Connection already in progress
EALREADY	Socket already connected
EDESTADDRREQ	Destination address required
EPROTONOSUPPORT	Unknown protocol

Socket Options

The `getsockopt()` and `setsockopt()` functions allow getting and setting per-socket options respectively.

Not all standard socket options are supported by lwIP in ESP-IDF. The following socket options are supported:

Common Options Used with level argument `SOL_SOCKET`.

- `SO_REUSEADDR`: available if *CONFIG_LWIP_SO_REUSE* is set, whose behavior can be customized by setting *CONFIG_LWIP_SO_REUSE_RXTOALL*
- `SO_KEEPALIVE`
- `SO_BROADCAST`
- `SO_ACCEPTCONN`
- `SO_RCVBUF`: available if *CONFIG_LWIP_SO_RCVBUF* is set
- `SO_SNDTIMEO` / `SO_RCVTIMEO`
- `SO_ERROR`: only used with `select()`, see *Socket Error Handling*
- `SO_TYPE`

- `SO_NO_CHECK`: for UDP sockets only

IP Options Used with level argument `IPPROTO_IP`.

- `IP_TOS`
- `IP_TTL`
- `IP_PKTINFO`: available if *CONFIG_LWIP_NETBUF_RECVINFO* is set

For multicast UDP sockets:

- `IP_MULTICAST_IF`
- `IP_MULTICAST_LOOP`
- `IP_MULTICAST_TTL`
- `IP_ADD_MEMBERSHIP`
- `IP_DROP_MEMBERSHIP`

TCP Options TCP sockets only. Used with level argument `IPPROTO_TCP`.

- `TCP_NODELAY`

Options relating to TCP keepalive probes:

- `TCP_KEEPALIVE`: int value, TCP keepalive period in milliseconds
- `TCP_KEEPIDLE`: same as `TCP_KEEPALIVE`, but the value is in seconds
- `TCP_KEEPINTVL`: int value, the interval between keepalive probes in seconds
- `TCP_KEEPCNT`: int value, number of keepalive probes before timing out

IPv6 Options IPv6 sockets only. Used with level argument `IPPROTO_IPV6`.

- `IPV6_CHECKSUM`
- `IPV6_V6ONLY`

For multicast IPv6 UDP sockets:

- `IPV6_JOIN_GROUP` / `IPV6_ADD_MEMBERSHIP`
- `IPV6_LEAVE_GROUP` / `IPV6_DROP_MEMBERSHIP`
- `IPV6_MULTICAST_IF`
- `IPV6_MULTICAST_HOPS`
- `IPV6_MULTICAST_LOOP`

`fcntl()`

The `fcntl()` function is a standard API for manipulating options related to a file descriptor. In ESP-IDF, the *Virtual Filesystem Component* layer is used to implement this function.

When the file descriptor is a socket, only the following `fcntl()` values are supported:

- `O_NONBLOCK` to set or clear non-blocking I/O mode. Also supports `O_NDELAY`, which is identical to `O_NONBLOCK`.
- `O_RDONLY`, `O_WRONLY`, `O_RDWR` flags for different read or write modes. These flags can only be read using `F_GETFL`, and cannot be set using `F_SETFL`. A TCP socket returns a different mode depending on whether the connection has been closed at either end or is still open at both ends. UDP sockets always return `O_RDWR`.

`ioctl()`

The `ioctl()` function provides a semi-standard way to access some internal features of the TCP/IP stack. In ESP-IDF, the *Virtual Filesystem Component* layer is used to implement this function.

When the file descriptor is a socket, only the following `ioctl()` values are supported:

- `FIONREAD` returns the number of bytes of the pending data already received in the socket's network buffer.

- `FIONBIO` is an alternative way to set/clear non-blocking I/O status for a socket, equivalent to `fcntl(fd, F_SETFL, O_NONBLOCK, ...)`.

4.22.3 Netconn API

lwIP supports two lower-level APIs as well as the BSD Sockets API: the Netconn API and the Raw API.

The lwIP Raw API is designed for single-threaded devices and is not supported in ESP-IDF.

The Netconn API is used to implement the BSD Sockets API inside lwIP, and it can also be called directly from ESP-IDF apps. This API has lower resource usage than the BSD Sockets API. In particular, it can send and receive data without firstly copying it into internal lwIP buffers.

Important: Espressif does not test the Netconn API in ESP-IDF. As such, this functionality is **enabled but not supported**. Some functionality may only work correctly when used from the BSD Sockets API.

For more information about the Netconn API, consult lwip/lwip/src/include/lwip/api.h and part of the **unofficial** lwIP Application Developers Manual.

4.22.4 lwIP FreeRTOS Task

lwIP creates a dedicated TCP/IP FreeRTOS task to handle socket API requests from other tasks.

A number of configuration items are available to modify the task and the queues (mailboxes) used to send data to/from the TCP/IP task:

- *CONFIG_LWIP_TCPIP_RECVMBOX_SIZE*
- *CONFIG_LWIP_TCPIP_TASK_STACK_SIZE*
- *CONFIG_LWIP_TCPIP_TASK_AFFINITY*

4.22.5 IPv6 Support

Both IPv4 and IPv6 are supported in a dual-stack configuration and are enabled by default. Both IPv6 and IPv4 may be disabled separately if they are not needed, see *Minimum RAM Usage*.

IPv6 support is limited to **Stateless Autoconfiguration** only. **Stateful configuration** is not supported in ESP-IDF, nor in upstream lwIP.

IPv6 Address configuration is defined by means of these protocols or services:

- **SLAAC** IPv6 Stateless Address Autoconfiguration (RFC-2462)
- **DHCPv6** Dynamic Host Configuration Protocol for IPv6 (RFC-8415)

None of these two types of address configuration is enabled by default, so the device uses only Link Local addresses or statically-defined addresses.

Stateless Autoconfiguration Process

To enable address autoconfiguration using the Router Advertisement protocol, please enable:

- *CONFIG_LWIP_IPV6_AUTOCONFIG*

This configuration option enables IPv6 autoconfiguration for all network interfaces, which differs from the upstream lwIP behavior, where the autoconfiguration needs to be explicitly enabled for each `netif` with `netif->ip6_autoconfig_enabled=1`.

DHCPv6

DHCPv6 in lwIP is very simple and supports only stateless configuration. It could be enabled using:

- *CONFIG_LWIP_IPV6_DHCP6*

Since the DHCPv6 works only in its stateless configuration, the *Stateless Autoconfiguration Process* has to be enabled as well via *CONFIG_LWIP_IPV6_AUTOCONFIG*.

Moreover, the DHCPv6 needs to be explicitly enabled from the application code using:

```
dhcp6_enable_stateless(netif);
```

DNS Servers in IPv6 Autoconfiguration

In order to autoconfigure DNS server(s), especially in IPv6-only networks, we have these two options:

- Recursive Domain Name System (DNS): this belongs to the Neighbor Discovery Protocol (NDP) and uses *Stateless Autoconfiguration Process*.
  The number of servers must be set *CONFIG_LWIP_IPV6_RDNSS_MAX_DNS_SERVERS*, this option is disabled by default, i.e., set to 0.
- DHCPv6 stateless configuration, uses *DHCPv6* to configure DNS servers. Note that this configuration assumes IPv6 Router Advertisement Flags (RFC-5175) to be set to
  - Managed Address Configuration Flag = 0
  - Other Configuration Flag = 1

4.22.6 ESP-lwIP Custom Modifications

Additions

The following code is added, which is not present in the upstream lwIP release:

Thread-Safe Sockets It is possible to `close()` a socket from a different thread than the one that created it. The `close()` call blocks, until any function calls currently using that socket from other tasks have returned.

It is, however, not possible to delete a task while it is actively waiting on `select()` or `poll()` APIs. It is always necessary that these APIs exit before destroying the task, as this might corrupt internal structures and cause subsequent crashes of the lwIP. These APIs allocate globally referenced callback pointers on the stack so that when the task gets destroyed before unrolling the stack, the lwIP could still hold pointers to the deleted stack.

On-Demand Timers lwIP IGMP and MLD6 feature both initialize a timer in order to trigger timeout events at certain times.

The default lwIP implementation is to have these timers enabled all the time, even if no timeout events are active. This increases CPU usage and power consumption when using automatic Light-sleep mode. `ESP-lwIP` default behavior is to set each timer `on demand`, so it is only enabled when an event is pending.

To return to the default lwIP behavior, which is always-on timers, disable *CONFIG_LWIP_TIMERS_ONDEMAND*.

lwIP Timers API When not using Wi-Fi, the lwIP timer can be turned off via the API to reduce power consumption.

The following API functions are supported. For full details, see lwip/lwip/src/include/lwip/timeouts.h.

- `sys_timeouts_init()`
- `sys_timeouts_deinit()`

Additional Socket Options

- Some standard IPV4 and IPV6 multicast socket options are implemented, see *Socket Options*.
- Possible to set IPV6-only UDP and TCP sockets with `IPV6_V6ONLY` socket option, while normal lwIP is TCP-only.

IP Layer Features

- IPV4-source-based routing implementation is different
- IPV4-mapped IPV6 addresses are supported

NAPT and Port Forwarding IPV4 network address port translation (NAPT) and port forwarding are supported. However, the enabling of NAPT is limited to a single interface.

- To use NAPT for forwarding packets between two interfaces, it needs to be enabled on the interface connecting to the target network. For example, to enable internet access for Ethernet traffic through the Wi-Fi interface, NAPT must be enabled on the Ethernet interface.
- Usage of NAPT is demonstrated in network/vlan_support.

Customized lwIP Hooks The original lwIP supports implementing custom compile-time modifications via `LWIP_HOOK_FILENAME`. This file is already used by the ESP-IDF port layer, but ESP-IDF users could still include and implement any custom additions via a header file defined by the macro `ESP_IDF_LWIP_HOOK_FILENAME`. Here is an example of adding a custom hook file to the build process, and the hook is called `my_hook.h`, located in the project's `main` folder:

```
idf_component_get_property(lwip lwip COMPONENT_LIB)
target_compile_options(${lwip} PRIVATE "-I${PROJECT_DIR}/main")
target_compile_definitions(${lwip} PRIVATE "-DESP_IDF_LWIP_HOOK_FILENAME=\"my_hook.
↪h\"")
```

Customized lwIP Options From ESP-IDF Build System The most common lwIP options are configurable through the component configuration menu. However, certain definitions need to be injected from the command line. The CMake function `target_compile_definitions()` can be employed to define macros, as illustrated below:

```
idf_component_get_property(lwip lwip COMPONENT_LIB)
target_compile_definitions(${lwip} PRIVATE "-DETHARP_SUPPORT_VLAN=1")
```

This approach may not work for function-like macros, as there is no guarantee that the definition will be accepted by all compilers, although it is supported in GCC. To address this limitation, the `add_definitions()` function can be utilized to define the macro for the entire project, for example: `add_definitions("-DFALLBACK_DNS_SERVER_ADDRESS(addr)=\"IP_ADDR4((addr), 8, 8,8,8)\"")`.

Alternatively, you can define your function-like macro in a header file which will be pre-included as an lwIP hook file, see *Customized lwIP Hooks*.

Limitations

ESP-IDF additions to lwIP still suffer from the global DNS limitation, described in *Adapted APIs*. To address this limitation from application code, the `FALLBACK_DNS_SERVER_ADDRESS()` macro can be utilized to define a global DNS fallback server accessible from all interfaces. Alternatively, you have the option to maintain per-interface DNS servers and reconfigure them whenever the default interface changes.

The number of IP addresses returned by network database APIs such as `getaddrinfo()` and `gethostbyname()` is restricted by the macro `DNS_MAX_HOST_IP`. By default, the value of this macro is set to 1.

In the implementation of `getaddrinfo()`, the canonical name is not available. Therefore, the `ai_canonname` field of the first returned `addrinfo` structure will always refer to the `nodename` argument or a string with the same contents.

Calling `send()` or `sendto()` repeatedly on a UDP socket may eventually fail with `errno` equal to `ENOMEM`. This failure occurs due to the limitations of buffer sizes in the lower-layer network interface drivers. If all driver transmit buffers are full, the UDP transmission will fail. For applications that transmit a high volume of UDP datagrams and aim to avoid any dropped datagrams by the sender, it is advisable to implement error code checking and employ a retransmission mechanism with a short delay.

Increasing the number of TX buffers in the *Wi-Fi* project configuration may also help.

4.22.7 Performance Optimization

TCP/IP performance is a complex subject, and performance can be optimized toward multiple goals. The default settings of ESP-IDF are tuned for a compromise between throughput, latency, and moderate memory usage.

Maximum Throughput

Espressif tests ESP-IDF TCP/IP throughput using the iperf test application: https://iperf.fr/, please refer to *Improving Network Speed* for more details about the actual testing and using the optimized configuration.

Important: Suggest applying changes a few at a time and checking the performance each time with a particular application workload.

- If a lot of tasks are competing for CPU time on the system, consider that the lwIP task has configurable CPU affinity (*CONFIG_LWIP_TCPIP_TASK_AFFINITY*) and runs at fixed priority (18, `ESP_TASK_TCPIP_PRIO`). To optimize CPU utilization, consider assigning competing tasks to different cores or adjusting their priorities to lower values. For additional details on built-in task priorities, please refer to *Built-in Task Priorities*.
- If using `select()` function with socket arguments only, disabling *CONFIG_VFS_SUPPORT_SELECT* will make `select()` calls faster.
- If there is enough free IRAM, select *CONFIG_LWIP_IRAM_OPTIMIZATION* and *CONFIG_LWIP_EXTRA_IRAM_OPTIMIZATION* to improve TX/RX throughput.

If using a Wi-Fi network interface, please also refer to *Wi-Fi Buffer Usage*.

Minimum Latency

Except for increasing buffer sizes, most changes that increase throughput also decrease latency by reducing the amount of CPU time spent in lwIP functions.

- For TCP sockets, lwIP supports setting the standard `TCP_NODELAY` flag to disable Nagle's algorithm.

Minimum RAM Usage

Most lwIP RAM usage is on-demand, as RAM is allocated from the heap as needed. Therefore, changing lwIP settings to reduce RAM usage may not change RAM usage at idle, but can change it at peak.

- Reducing *CONFIG_LWIP_MAX_SOCKETS* reduces the maximum number of sockets in the system. This also causes TCP sockets in the `WAIT_CLOSE` state to be closed and recycled more rapidly when needed to open a new socket, further reducing peak RAM usage.
- Reducing *CONFIG_LWIP_TCPIP_RECVMBOX_SIZE*, *CONFIG_LWIP_TCP_RECVMBOX_SIZE* and *CONFIG_LWIP_UDP_RECVMBOX_SIZE* reduce RAM usage at the expense of throughput, depending on usage.
- Reducing *CONFIG_LWIP_TCP_ACCEPTMBOX_SIZE* reduce RAM usage by limiting concurrent accepted connections.

- Reducing *CONFIG_LWIP_TCP_MSL* and *CONFIG_LWIP_TCP_FIN_WAIT_TIMEOUT* reduces the maximum segment lifetime in the system. This also causes TCP sockets in the `TIME_WAIT` and `FIN_WAIT_2` states to be closed and recycled more rapidly.
- Disabling *CONFIG_LWIP_IPV6* can save about 39 KB for firmware size and 2 KB RAM when the system is powered up and 7 KB RAM when the TCP/IP stack is running. If there is no requirement for supporting IPV6, it can be disabled to save flash and RAM footprint.
- Disabling *CONFIG_LWIP_IPV4* can save about 26 KB of firmware size and 600 B RAM on power up and 6 KB RAM when the TCP/IP stack is running. If the local network supports IPv6-only configuration, IPv4 can be disabled to save flash and RAM footprint.

If using Wi-Fi, please also refer to *Wi-Fi Buffer Usage*.

Peak Buffer Usage The peak heap memory that lwIP consumes is the **theoretically-maximum memory** that the lwIP driver consumes. Generally, the peak heap memory that lwIP consumes depends on:

- the memory required to create a UDP connection: `lwip_udp_conn`
- the memory required to create a TCP connection: `lwip_tcp_conn`
- the number of UDP connections that the application has: `lwip_udp_con_num`
- the number of TCP connections that the application has: `lwip_tcp_con_num`
- the TCP TX window size: `lwip_tcp_tx_win_size`
- the TCP RX window size: `lwip_tcp_rx_win_size`

So, the peak heap memory that the lwIP consumes can be calculated with the following formula:

lwip_dynamic_peek_memory = (lwip_udp_con_num * lwip_udp_conn) + (lwip_tcp_con_num * (lwip_tcp_tx_win_size + lwip_tcp_rx_win_size + lwip_tcp_conn))

Some TCP-based applications need only one TCP connection. However, they may choose to close this TCP connection and create a new one when an error occurs (e.g., a sending failure). This may result in multiple TCP connections existing in the system simultaneously, because it may take a long time for a TCP connection to close, according to the TCP state machine, refer to RFC793.

4.23 Memory Types

ESP32-C3 chip has multiple memory types and flexible memory mapping features. This section describes how ESP-IDF uses these features by default.

ESP-IDF distinguishes between instruction memory bus (IRAM, IROM, RTC FAST memory) and data memory bus (DRAM, DROM). Instruction memory is executable, and can only be read or written via 4-byte aligned words. Data memory is not executable and can be accessed via individual byte operations. For more information about the different memory buses consult the *ESP32-C3 Technical Reference Manual > System and Memory* [PDF].

4.23.1 DRAM (Data RAM)

Non-constant static data (.data) and zero-initialized data (.bss) is placed by the linker into Internal SRAM as data memory. The remaining space in this region is used for the runtime heap.

Note: The maximum statically allocated DRAM size is reduced by the *IRAM (Instruction RAM)* size of the compiled application. The available heap memory at runtime is reduced by the total static IRAM and DRAM usage of the application.

Constant data may also be placed into DRAM, for example if it is used in an non-flash-safe ISR (see explanation under *How to Place Code in IRAM*).

"noinit" DRAM

The macro `__NOINIT_ATTR` can be used as attribute to place data into `.noinit` section. The values placed into this section will not be initialized at startup and should keep its value after software restart.

Example:

```
__NOINIT_ATTR uint32_t noinit_data;
```

4.23.2 IRAM (Instruction RAM)

Note: Any internal SRAM which is not used for Instruction RAM will be made available as *DRAM (Data RAM)* for static data and dynamic allocation (heap).

When to Place Code in IRAM

Cases when parts of the application should be placed into IRAM:

- Interrupt handlers must be placed into IRAM if `ESP_INTR_FLAG_IRAM` is used when registering the interrupt handler. For more information, see *IRAM-Safe Interrupt Handlers*.
- Some timing critical code may be placed into IRAM to reduce the penalty associated with loading the code from flash. ESP32-C3 reads code and data from flash via the MMU cache. In some cases, placing a function into IRAM may reduce delays caused by a cache miss and significantly improve that function's performance.

How to Place Code in IRAM

Some code is automatically placed into the IRAM region using the linker script.

If some specific application code needs to be placed into IRAM, it can be done by using the *Linker Script Generation* feature and adding a linker script fragment file to your component that targets at the entire source files or functions with the `noflash` placement. See the *Linker Script Generation* docs for more information.

Alternatively, it is possible to specify IRAM placement in the source code using the `IRAM_ATTR` macro:

```
#include "esp_attr.h"

void IRAM_ATTR gpio_isr_handler(void* arg)
{
    // ...
}
```

There are some possible issues with placement in IRAM, that may cause problems with IRAM-safe interrupt handlers:

- Strings or constants inside an `IRAM_ATTR` function may not be placed in RAM automatically. It is possible to use `DRAM_ATTR` attributes to mark these, or using the linker script method will cause these to be automatically placed correctly.

```
void IRAM_ATTR gpio_isr_handler(void* arg)
{
   const static DRAM_ATTR uint8_t INDEX_DATA[] = { 45, 33, 12, 0 };
   const static char *MSG = DRAM_STR("I am a string stored in RAM");
}
```

Note that knowing which data should be marked with `DRAM_ATTR` can be hard, the compiler will sometimes recognize that a variable or expression is constant (even if it is not marked `const`) and optimize it into flash, unless it is marked with `DRAM_ATTR`.

- GCC optimizations that automatically generate jump tables or switch/case lookup tables place these tables in flash. IDF by default builds all files with `-fno-jump-tables -fno-tree-switch-conversion` flags to avoid this.

Jump table optimizations can be re-enabled for individual source files that do not need to be placed in IRAM. For instructions on how to add the `-fno-jump-tables -fno-tree-switch-conversion` options when compiling individual source files, see *Controlling Component Compilation*.

4.23.3 IROM (Code Executed from flash)

If a function is not explicitly placed into *IRAM (Instruction RAM)* or RTC memory, it is placed into flash. As IRAM is limited, most of an application's binary code must be placed into IROM instead.

During *Application Startup Flow*, the bootloader (which runs from IRAM) configures the MMU flash cache to map the app's instruction code region to the instruction space. Flash accessed via the MMU is cached using some internal SRAM and accessing cached flash data is as fast as accessing other types of internal memory.

4.23.4 DROM (Data Stored in flash)

By default, constant data is placed by the linker into a region mapped to the MMU flash cache. This is the same as the *IROM (Code Executed from flash)* section, but is for read-only data not executable code.

The only constant data not placed into this memory type by default are literal constants which are embedded by the compiler into application code. These are placed as the surrounding function's executable instructions.

The `DRAM_ATTR` attribute can be used to force constants from DROM into the *DRAM (Data RAM)* section (see above).

4.23.5 RTC FAST Memory

The same region of RTC FAST memory can be accessed as both instruction and data memory. Code which has to run after wake-up from deep sleep mode has to be placed into RTC memory. Please check detailed description in *deep sleep* documentation.

Remaining RTC FAST memory is added to the heap unless the option *CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP* is disabled. This memory can be used interchangeably with *DRAM (Data RAM)*, but is slightly slower to access.

4.23.6 DMA-Capable Requirement

Most peripheral DMA controllers (e.g., SPI, sdmmc, etc.) have requirements that sending/receiving buffers should be placed in DRAM and word-aligned. We suggest to place DMA buffers in static variables rather than in the stack. Use macro `DMA_ATTR` to declare global/local static variables like:

```
DMA_ATTR uint8_t buffer[]="I want to send something";

void app_main()
{
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

Or:

```
void app_main()
{
    DMA_ATTR static uint8_t buffer[] = "I want to send something";
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

It is also possible to allocate DMA-capable memory buffers dynamically by using the *MALLOC_CAP_DMA* capabilities flag.

4.23.7 DMA Buffer in the Stack

Placing DMA buffers in the stack is possible but discouraged. If doing so, pay attention to the following:

- Use macro `WORD_ALIGNED_ATTR` in functions before variables to place them in proper positions like:

```
void app_main()
{
    uint8_t stuff;
    WORD_ALIGNED_ATTR uint8_t buffer[] = "I want to send something";   //or␣
↪the buffer will be placed right after stuff.
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

4.24 OpenThread

OpenThread is an IP stack running on the 802.15.4 MAC layer which features mesh network and low power consumption.

4.24.1 Modes of the OpenThread Stack

OpenThread can run under the following modes on Espressif chips:

Standalone Node

The full OpenThread stack and the application layer run on the same chip. This mode is available on chips with 15.4 radio such as ESP32-H2 and ESP32-C6.

Radio Co-Processor (RCP)

The chip is connected to another host running the OpenThread IP stack. It sends and receives 15.4 packets on behalf of the host. This mode is available on chips with 15.4 radio such as ESP32-H2 and ESP32-C6. The underlying transport between the chip and the host can be SPI or UART. For the sake of latency, we recommend using SPI as the underlying transport.

OpenThread Host

For chips without a 15.4 radio, it can be connected to an RCP and run OpenThread under host mode. This mode enables OpenThread on Wi-Fi chips such as ESP32, ESP32-S2, ESP32-S3, and ESP32-C3. The following diagram shows how devices work under different modes:

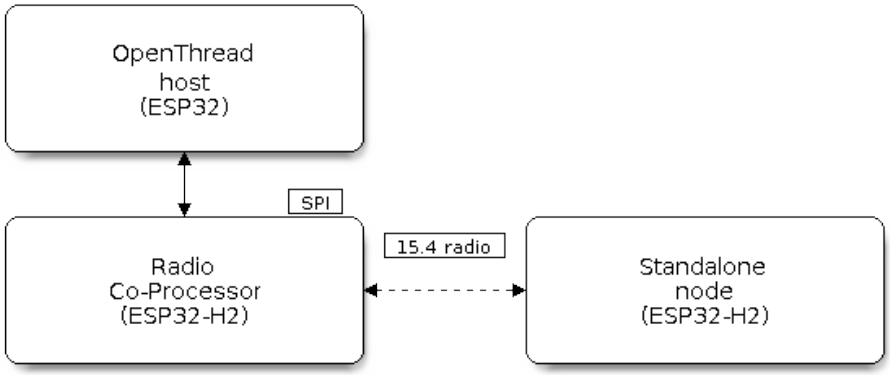

Fig. 59: OpenThread device modes

4.24.2 How to Write an OpenThread Application

The OpenThread openthread/ot_cli example is a good place to start at. It demonstrates basic OpenThread initialization and simple socket-based server and client.

Before OpenThread Initialization

- s1.1: The main task calls `esp_vfs_eventfd_register()` to initialize the eventfd virtual file system. The eventfd file system is used for task notification in the OpenThread driver.
- s1.2: The main task calls `nvs_flash_init()` to initialize the NVS where the Thread network data is stored.
- s1.3: **Optional**. The main task calls `esp_netif_init()` only when it wants to create the network interface for Thread.
- s1.4: The main task calls `esp_event_loop_create()` to create the system Event task and initialize an application event's callback function.

OpenThread Stack Initialization

- s2.1: Call `esp_openthread_init()` to initialize the OpenThread stack.

OpenThread Network Interface Initialization

The whole stage is **optional** and only required if the application wants to create the network interface for Thread.

- s3.1: Call `esp_netif_new()` with `ESP_NETIF_DEFAULT_OPENTHREAD` to create the interface.
- s3.2: Call `esp_openthread_netif_glue_init()` to create the OpenThread interface handlers.
- s3.3: Call `esp_netif_attach()` to attach the handlers to the interface.

The OpenThread Main Loop

- s4.3: Call `esp_openthread_launch_mainloop()` to launch the OpenThread main loop. Note that this is a busy loop and does not return until the OpenThread stack is terminated.

Calling OpenThread APIs

The OpenThread APIs are not thread-safe. When calling OpenThread APIs from other tasks, make sure to hold the lock with `esp_openthread_lock_acquire()` and release the lock with `esp_openthread_lock_release()` afterwards.

Deinitialization

The following steps are required to deinitialize the OpenThread stack:

- Call `esp_netif_destroy()` and `esp_openthread_netif_glue_deinit()` to deinitialize the OpenThread network interface if you have created one.
- Call `esp_openthread_deinit()` to deinitialize the OpenThread stack.

4.24.3 The OpenThread Border Router

The OpenThread border router connects the Thread network with other IP networks. It provides IPv6 connectivity, service registration, and commission functionality.

To launch an OpenThread border router on an ESP chip, you need to connect an RCP to a Wi-Fi capable chip such as ESP32.

Calling `esp_openthread_border_router_init()` during the initialization launches all the border routing functionalities.

You may refer to the openthread/ot_br example and the README for further border router details.

4.25 Partition Tables

4.25.1 Overview

A single ESP32-C3's flash can contain multiple apps, as well as many different kinds of data (calibration data, filesystems, parameter storage, etc). For this reason a partition table is flashed to (*default offset*) 0x8000 in the flash.

The partition table length is 0xC00 bytes, as we allow a maximum of 95 entries. An MD5 checksum, used for checking the integrity of the partition table at runtime, is appended after the table data. Thus, the partition table occupies an entire flash sector, which size is 0x1000 (4 KB). As a result, any partition following it must be at least located at (*default offset*) + 0x1000.

Each entry in the partition table has a name (label), type (app, data, or something else), subtype and the offset in flash where the partition is loaded.

The simplest way to use the partition table is to open the project configuration menu (`idf.py menuconfig`) and choose one of the simple predefined partition tables under *CONFIG_PARTITION_TABLE_TYPE*:

- "Single factory app, no OTA"
- "Factory app, two OTA definitions"

In both cases the factory app is flashed at offset 0x10000. If you execute *idf.py partition-table* then it will print a summary of the partition table.

4.25.2 Built-in Partition Tables

Here is the summary printed for the "Single factory app, no OTA" configuration:

```
# ESP-IDF Partition Table
# Name,   Type, SubType, Offset,  Size, Flags
nvs,      data, nvs,     0x9000,  0x6000,
phy_init, data, phy,     0xf000,  0x1000,
factory,  app,  factory, 0x10000, 1M,
```

- At a 0x10000 (64 KB) offset in the flash is the app labelled "factory". The bootloader will run this app by default.
- There are also two data regions defined in the partition table for storing NVS library partition and PHY init data.

Here is the summary printed for the "Factory app, two OTA definitions" configuration:

```
# ESP-IDF Partition Table
# Name,   Type, SubType, Offset,  Size, Flags
nvs,      data, nvs,     0x9000,  0x4000,
otadata,  data, ota,     0xd000,  0x2000,
phy_init, data, phy,     0xf000,  0x1000,
factory,  app,  factory, 0x10000,  1M,
ota_0,    app,  ota_0,   0x110000, 1M,
ota_1,    app,  ota_1,   0x210000, 1M,
```

- There are now three app partition definitions. The type of the factory app (at 0x10000) and the next two "OTA" apps are all set to "app", but their subtypes are different.
- There is also a new "otadata" slot, which holds the data for OTA updates. The bootloader consults this data in order to know which app to execute. If "ota data" is empty, it will execute the factory app.

4.25.3 Creating Custom Tables

If you choose "Custom partition table CSV" in menuconfig then you can also enter the name of a CSV file (in the project directory) to use for your partition table. The CSV file can describe any number of definitions for the table you need.

The CSV format is the same format as printed in the summaries shown above. However, not all fields are required in the CSV. For example, here is the "input" CSV for the OTA partition table:

```
# Name,   Type, SubType,  Offset,   Size,  Flags
nvs,      data, nvs,      0x9000,  0x4000
otadata,  data, ota,      0xd000,  0x2000
phy_init, data, phy,      0xf000,  0x1000
factory,  app,  factory,  0x10000,  1M
ota_0,    app,  ota_0,    ,         1M
ota_1,    app,  ota_1,    ,         1M
nvs_key,  data, nvs_keys, ,        0x1000
```

- Whitespace between fields is ignored, and so is any line starting with # (comments).
- Each non-comment line in the CSV file is a partition definition.

- The "Offset" field for each partition is empty. The gen_esp32part.py tool fills in each blank offset, starting after the partition table and making sure each partition is aligned correctly.

Name Field

Name field can be any meaningful name. It is not significant to the ESP32-C3. The maximum length of names is 16 bytes, including one null terminator. Names longer than the maximum length will be truncated.

Type Field

Partition type field can be specified as `app` (0x00) or `data` (0x01). Or it can be a number 0-254 (or as hex 0x00-0xFE). Types 0x00-0x3F are reserved for ESP-IDF core functions.

If your app needs to store data in a format not already supported by ESP-IDF, then please add a custom partition type value in the range 0x40-0xFE.

See *`esp_partition_type_t`* for the enum definitions for `app` and `data` partitions.

If writing in C++ then specifying a application-defined partition type requires casting an integer to *`esp_partition_type_t`* in order to use it with the *partition API*. For example:

```
static const esp_partition_type_t APP_PARTITION_TYPE_A = (esp_partition_type_
↪t)0x40;
```

The ESP-IDF bootloader ignores any partition types other than `app` (0x00) and `data` (0x01).

SubType

The 8-bit SubType field is specific to a given partition type. ESP-IDF currently only specifies the meaning of the subtype field for `app` and `data` partition types.

See enum *`esp_partition_subtype_t`* for the full list of subtypes defined by ESP-IDF, including the following:

- When type is `app`, the SubType field can be specified as `factory` (0x00), `ota_0` (0x10) ... `ota_15` (0x1F) or `test` (0x20).
  - `factory` (0x00) is the default app partition. The bootloader will execute the factory app unless there it sees a partition of type data/ota, in which case it reads this partition to determine which OTA image to boot.
    - OTA never updates the factory partition.
    - If you want to conserve flash usage in an OTA project, you can remove the factory partition and use `ota_0` instead.
  - `ota_0` (0x10) ... `ota_15` (0x1F) are the OTA app slots. When *OTA* is in use, the OTA data partition configures which app slot the bootloader should boot. When using OTA, an application should have at least two OTA application slots (`ota_0` & `ota_1`). Refer to the *OTA documentation* for more details.
  - `test` (0x20) is a reserved subtype for factory test procedures. It will be used as the fallback boot partition if no other valid app partition is found. It is also possible to configure the bootloader to read a GPIO input during each boot, and boot this partition if the GPIO is held low, see *Boot from Test Firmware*.
- When type is `data`, the subtype field can be specified as `ota` (0x00), `phy` (0x01), `nvs` (0x02), nvs_keys (0x04), or a range of other component-specific subtypes (see *`subtype enum`*).
  - `ota` (0) is the *OTA data partition* which stores information about the currently selected OTA app slot. This partition should be 0x2000 bytes in size. Refer to the *OTA documentation* for more details.
  - `phy` (1) is for storing PHY initialisation data. This allows PHY to be configured per-device, instead of in firmware.
    - In the default configuration, the phy partition is not used and PHY initialisation data is compiled into the app itself. As such, this partition can be removed from the partition table to save space.
    - To load PHY data from this partition, open the project configuration menu (`idf.py menuconfig`) and enable *CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION* option. You will also need to flash your devices with phy init data as the esp-idf build system does not do this automatically.
  - `nvs` (2) is for the *Non-Volatile Storage (NVS) API*.

    * NVS is used to store per-device PHY calibration data (different to initialisation data).
    * NVS is used to store Wi-Fi data if the *esp_wifi_set_storage(WIFI_STORAGE_FLASH)* initialization function is used.
    * The NVS API can also be used for other application data.
    * It is strongly recommended that you include an NVS partition of at least 0x3000 bytes in your project.
    * If using NVS API to store a lot of data, increase the NVS partition size from the default 0x6000 bytes.
  - `nvs_keys` (4) is for the NVS key partition. See *Non-Volatile Storage (NVS) API* for more details.
    * It is used to store NVS encryption keys when *NVS Encryption* feature is enabled.
    * The size of this partition should be 4096 bytes (minimum partition size).
  - There are other predefined data subtypes for data storage supported by ESP-IDF. These include:
    * `coredump` (0x03) is for storing core dumps while using a custom partition table CSV file. See *Core Dump* for more details.
    * `efuse` (0x05) is for emulating eFuse bits using *Virtual eFuses*.
    * `undefined` (0x06) is implicitly used for data partitions with unspecified (empty) subtype, but it is possible to explicitly mark them as undefined as well.
    * `fat` (0x81) is for *FAT Filesystem Support*.
    * `spiffs` (0x82) is for *SPIFFS Filesystem*.
    * `littlefs` (0x83) is for LittleFS filesystem. See storage/littlefs example for more details.

- If the partition type is any application-defined value (range 0x40-0xFE), then `subtype` field can be any value chosen by the application (range 0x00-0xFE).
  Note that when writing in C++, an application-defined subtype value requires casting to type `esp_partition_subtype_t` in order to use it with the *partition API*.

Extra Partition SubTypes

A component can define a new partition subtype by setting the `EXTRA_PARTITION_SUBTYPES` property. This property is a CMake list, each entry of which is a comma separated string with `<type>, <subtype>, <value>` format. The build system uses this property to add extra subtypes and creates fields named `ESP_PARTITION_SUBTYPE_<type>_<subtype>` in `esp_partition_subtype_t`. The project can use this subtype to define partitions in the partitions table CSV file and use the new fields in `esp_partition_subtype_t`.

Offset & Size

- The offset represents the partition address in the SPI flash, which sector size is 0x1000 (4 KB). Thus, the offset must be a multiple of 4 KB.
- Partitions with blank offsets in the CSV file will start after the previous partition, or after the partition table in the case of the first partition.
- Partitions of type `app` have to be placed at offsets aligned to 0x10000 (64 KB). If you leave the offset field blank, `gen_esp32part.py` will automatically align the partition. If you specify an unaligned offset for an `app` partition, the tool will return an error.
- Partitions of type `app` should have the size aligned to the flash sector size (4 KB). If you specify an unaligned size for an `app` partition, the tool will return an error.
- Sizes and offsets can be specified as decimal numbers, hex numbers with the prefix 0x, or size multipliers K or M (1024 and 1024*1024 bytes).

If you want the partitions in the partition table to work relative to any placement (*CONFIG_PARTITION_TABLE_OFFSET*) of the table itself, leave the offset field (in CSV file) for all partitions blank. Similarly, if changing the partition table offset then be aware that all blank partition offsets may change to match, and that any fixed offsets may now collide with the partition table (causing an error).

Flags

Two flags are currently supported, `encrypted` and `readonly`:

- If `encrypted` flag is set, the partition will be encrypted if *Flash Encryption* is enabled.

Note: `app` type partitions will always be encrypted, regardless of whether this flag is set or not.

- If `readonly` flag is set, the partition will be read-only. This flag is only supported for `data` type partitions except `ota` and `coredump` subtypes. This flag can help to protect against accidental writes to a partition that contains critical device-specific configuration data, e.g., factory data partition.

Note: Using C file I/O API to open a file (`fopen`) in any write mode (`w`, `w+`, `a`, `a+`, `r+`) will fail and return `NULL`. Using `open` with any other flag than `O_RDONLY` will fail and return `-1` while `errno` global variable will be set to `EROFS`. This is also true for any other POSIX syscall function performing write or erase operations. Opening a handle in read-write mode for NVS on a read-only partition will fail and return *`ESP_ERR_NOT_ALLOWED`* error code. Using a lower level API like `esp_partition`, `spi_flash`, etc. to write to a read-only partition will result in *`ESP_ERR_NOT_ALLOWED`* error code.

You can specify multiple flags by separating them with a colon. For example, `encrypted:readonly`.

4.25.4 Generating Binary Partition Table

The partition table which is flashed to the ESP32-C3 is in a binary format, not CSV. The tool partition_table/gen_esp32part.py is used to convert between CSV and binary formats.

If you configure the partition table CSV name in the project configuration (`idf.py menuconfig`) and then build the project or run `idf.py partition-table`, this conversion is done as part of the build process.

To convert CSV to Binary manually:

```
python gen_esp32part.py input_partitions.csv binary_partitions.bin
```

To convert binary format back to CSV manually:

```
python gen_esp32part.py binary_partitions.bin input_partitions.csv
```

To display the contents of a binary partition table on stdout (this is how the summaries displayed when running `idf.py partition-table` are generated:

```
python gen_esp32part.py binary_partitions.bin
```

4.25.5 Partition Size Checks

The ESP-IDF build system will automatically check if generated binaries fit in the available partition space, and will fail with an error if a binary is too large.

Currently these checks are performed for the following binaries:

- Bootloader binary must fit in space before partition table (see *Bootloader Size*).
- App binary should fit in at least one partition of type "app". If the app binary does not fit in any app partition, the build will fail. If it only fits in some of the app partitions, a warning is printed about this.

Note: Although the build process will fail if the size check returns an error, the binary files are still generated and can be flashed (although they may not work if they are too large for the available space.)

MD5 Checksum

The binary format of the partition table contains an MD5 checksum computed based on the partition table. This checksum is used for checking the integrity of the partition table during the boot.

The MD5 checksum generation can be disabled by the `--disable-md5sum` option of `gen_esp32part.py` or by the *CONFIG_PARTITION_TABLE_MD5* option.

4.25.6 Flashing the Partition Table

- `idf.py partition-table-flash`: will flash the partition table with esptool.py.
- `idf.py flash`: Will flash everything including the partition table.

A manual flashing command is also printed as part of `idf.py partition-table` output.

Note: Note that updating the partition table does not erase data that may have been stored according to the old partition table. You can use `idf.py erase-flash` (or `esptool.py erase_flash`) to erase the entire flash contents.

4.25.7 Partition Tool (`parttool.py`)

The component *partition_table* provides a tool parttool.py for performing partition-related operations on a target device. The following operations can be performed using the tool:

- reading a partition and saving the contents to a file (read_partition)
- writing the contents of a file to a partition (write_partition)
- erasing a partition (erase_partition)
- retrieving info such as name, offset, size and flag ("encrypted") of a given partition (get_partition_info)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool's Python API and command-line interface, respectively.

Python API

Before anything else, make sure that the *parttool* module is imported.

```
import sys
import os

idf_path = os.environ["IDF_PATH"]  # get value of IDF_PATH from environment
parttool_dir = os.path.join(idf_path, "components", "partition_table")  # parttool.
↪py lives in $IDF_PATH/components/partition_table

sys.path.append(parttool_dir)  # this enables Python to find parttool module
from parttool import *  # import all names inside parttool module
```

The starting point for using the tool's Python API to do is create a *ParttoolTarget* object:

```
# Create a parttool.py target device connected on serial port /dev/ttyUSB1
target = ParttoolTarget("/dev/ttyUSB1")
```

The created object can now be used to perform operations on the target device:

```
# Erase partition with name 'storage'
target.erase_partition(PartitionName("storage"))

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin
↪'
target.read_partition(PartitionType("data", "spiffs"), "spiffs.bin")

# Write to partition 'factory' the contents of a file named 'factory.bin'
target.write_partition(PartitionName("factory"), "factory.bin")

# Print the size of default boot partition
storage = target.get_partition_info(PARTITION_BOOT_DEFAULT)
print(storage.size)
```

The partition to operate on is specified using *PartitionName* or *PartitionType* or PARTITION_BOOT_DEFAULT. As the name implies, these can be used to refer to partitions of a particular name, type-subtype combination, or the default boot partition.

More information on the Python API is available in the docstrings for the tool.

Command-line Interface

The command-line interface of *parttool.py* has the following structure:

```
parttool.py [command-args] [subcommand] [subcommand-args]

- command-args - These are arguments that are needed for executing the main␣
↪command (parttool.py), mostly pertaining to the target device
- subcommand - This is the operation to be performed
- subcommand-args - These are arguments that are specific to the chosen operation
```

```
# Erase partition with name 'storage'
parttool.py --port "/dev/ttyUSB1" erase_partition --partition-name=storage

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin
↪'
parttool.py --port "/dev/ttyUSB1" read_partition --partition-type=data --partition-
↪subtype=spiffs --output "spiffs.bin"

# Write to partition 'factory' the contents of a file named 'factory.bin'
parttool.py --port "/dev/ttyUSB1" write_partition --partition-name=factory --input
↪"factory.bin"

# Print the size of default boot partition
parttool.py --port "/dev/ttyUSB1" get_partition_info --partition-boot-default --
↪info size
```

Note: If the device has already enabled `Flash Encryption` or `Secure Boot`, attempting to use commands that modify the flash content, such as `erase_partition` or `write_partition`, will result in an error. This error is generated by the erase command of `esptool.py`, which is called first before writing. This error is done as a safety measure to prevent bricking your device.

:: A fatal error occurred: Active security features detected, erasing flash is disabled as a safety measure. Use --force to override, please use with caution, otherwise it may brick your device!

To work around this, you need use the `--force` flag with `esptool.py`. Specifically, the `parttool.py` provides the `--esptool-erase-args` argument that help to pass this flag to `esptool.py`.

```
# Erase partition with name 'storage'
# If Flash Encryption or Secure Boot are enabled then add "--esptool-erase-
↪args=force"
parttool.py --port "/dev/ttyUSB1" --esptool-erase-args=force erase_partition --
↪partition-name=storage

# Write to partition 'factory' the contents of a file named 'factory.bin'
# If Flash Encryption or Secure Boot are enabled then add "--esptool-erase-
↪args=force"
parttool.py --port "/dev/ttyUSB1" --esptool-erase-args=force write_partition --
↪partition-name=factory --input "factory.bin"
```

More information can be obtained by specifying *--help* as argument:

```
# Display possible subcommands and show main command argument descriptions
parttool.py --help

# Show descriptions for specific subcommand arguments
parttool.py [subcommand] --help
```

4.26 Performance

ESP-IDF ships with default settings that are designed for a trade-off between performance, resource usage, and available functionality.

These guides describe how to optimize a firmware application for a particular aspect of performance. Usually this involves some trade-off in terms of limiting available functions, or swapping one aspect of performance (such as execution speed) for another (such as RAM usage).

4.26.1 How to Optimize Performance

1. Decide the performance-critical aspects of your application, such as achieving a particular response time for a certain network operation, meeting a particular startup time limit, or maintaining a certain level of peripheral data throughput.
2. Find a way to measure this performance (some methods are outlined in the guides below).
3. Modify the code and project configuration and compare the new measurement to the old measurement.
4. Repeat step 3 until the performance meets the requirements set out in step 1.

4.26.2 Guides

Speed Optimization

Overview Optimizing execution speed is a key element of software performance. Code that executes faster can also have other positive effects, e.g., reducing overall power consumption. However, improving execution speed may have trade-offs with other aspects of performance such as *Minimizing Binary Size*.

Choose What to Optimize If a function in the application firmware is executed once per week in the background, it may not matter if that function takes 10 ms or 100 ms to execute. If a function is executed constantly at 10 Hz, it matters greatly if it takes 10 ms or 100 ms to execute.

Most kinds of application firmware only have a small set of functions that require optimal performance. Perhaps those functions are executed very often, or have to meet some application requirements for latency or throughput. Optimization efforts should be targeted at these particular functions.

Measuring Performance The first step to improving something is to measure it.

Basic Performance Measurements You may be able to measure directly the performance relative to an external interaction with the world, e.g., see the examples wifi/iperf and ethernet/iperf for measuring general network performance. Or you can use an oscilloscope or logic analyzer to measure the timing of an interaction with a device peripheral.

Otherwise, one way to measure performance is to augment the code to take timing measurements:

```
#include "esp_timer.h"

void measure_important_function(void) {
    const unsigned MEASUREMENTS = 5000;
    uint64_t start = esp_timer_get_time();

    for (int retries = 0; retries < MEASUREMENTS; retries++) {
        important_function(); // This is the thing you need to measure
    }

    uint64_t end = esp_timer_get_time();

    printf("%u iterations took %llu milliseconds (%llu microseconds per␣
↪invocation)\n",
           MEASUREMENTS, (end - start)/1000, (end - start)/MEASUREMENTS);
}
```

Executing the target multiple times can help average out factors, e.g., RTOS context switches, overhead of measurements, etc.

- Using `esp_timer_get_time()` generates "wall clock" timestamps with microsecond precision, but has moderate overhead each time the timing functions are called.
- It is also possible to use the standard Unix `gettimeofday()` and `utime()` functions, although the overhead is slightly higher.
- Otherwise, including `hal/cpu_hal.h` and calling the HAL function `cpu_hal_get_cycle_count()` returns the number of CPU cycles executed. This function has lower overhead than the others, which is good for measuring very short execution times with high precision.
- While performing "microbenchmarks" (i.e., benchmarking only a very small routine of code that runs in less than 1-2 milliseconds), the flash cache performance can sometimes cause big variations in timing measurements depending on the binary. This happens because binary layout can cause different patterns of cache misses in a particular sequence of execution. If the test code is larger, then this effect usually averages out. Executing a small function multiple times when benchmarking can help reduce the impact of flash cache misses. Alternatively, move this code to IRAM (see *Targeted Optimizations*).

External Tracing The *Application Level Tracing Library* allows measuring code execution with minimal impact on the code itself.

Tasks If the option *CONFIG_FREERTOS_GENERATE_RUN_TIME_STATS* is enabled, then the FreeRTOS API `vTaskGetRunTimeStats()` can be used to retrieve runtime information about the processor time used by each FreeRTOS task.

SEGGER SystemView is an excellent tool for visualizing task execution and looking for performance issues or improvements in the system as a whole.

Improving Overall Speed The following optimizations improve the execution of nearly all code, including boot times, throughput, latency, etc:

- Set *CONFIG_ESPTOOLPY_FLASHMODE* to QIO or QOUT mode (Quad I/O). Both almost double the speed at which code is loaded or executed from flash compared to the default DIO mode. QIO is slightly faster than QOUT if both are supported. Note that both the flash chip model, and the electrical connections between the ESP32-C3 and the flash chip must support quad I/O modes or the SoC will not work correctly.
- Set *CONFIG_COMPILER_OPTIMIZATION* to `Optimize for performance (-O2)`. This may slightly increase binary size compared to the default setting, but almost certainly increases the performance of some code. Note that if your code contains C or C++ Undefined Behavior, then increasing the compiler optimization level may expose bugs that otherwise are not seen.
- Set *CONFIG_ESP_SYSTEM_HW_STACK_GUARD* to disabled. This may slightly increase the performance of some code, especially in cases where a lot of interrupts occur on the device.
- Avoid using floating point arithmetic `float`. On ESP32-C3 these calculations are emulated in software and are very slow. If possible, use fixed point representations, a different method of integer representation, or convert part of the calculation to be integer only before switching to floating point.
- Avoid using double precision floating point arithmetic `double`. These calculations are emulated in software and are very slow. If possible then use an integer-based representation, or single-precision floating point.

Reduce Logging Overhead Although standard output is buffered, it is possible for an application to be limited by the rate at which it can print data to log output once buffers are full. This is particularly relevant for startup time if a lot of output is logged, but such problem can happen at other times as well. There are multiple ways to solve this problem:

- Reduce the volume of log output by lowering the app *CONFIG_LOG_DEFAULT_LEVEL* (the equivalent bootloader setting is *CONFIG_BOOTLOADER_LOG_LEVEL*). This also reduces the binary size, and saves some CPU time spent on string formatting.
- Increase the speed of logging output by increasing the *CONFIG_ESP_CONSOLE_UART_BAUDRATE*.
- If your application does not require dynamic log level changes and you do not need to control logs per module using tags, consider disabling *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL* and changing *CONFIG_LOG_TAG_LEVEL_IMPL*. It helps to reduce memory usage and also contributes to speeding up log operations in your application about 10 times.

Not Recommended The following options also increase execution speed, but are not recommended as they also reduce the debuggability of the firmware application and may increase the severity of any bugs.

- Set *CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL* to disabled. This also reduces firmware binary size by a small amount. However, it may increase the severity of bugs in the firmware including security-related bugs. If it is necessary to do this to optimize a particular function, consider adding `#define NDEBUG` at the top of that single source file instead.

Targeted Optimizations The following changes increase the speed of a chosen part of the firmware application:

- Move frequently executed code to IRAM. By default, all code in the app is executed from flash cache. This means that it is possible for the CPU to have to wait on a "cache miss" while the next instructions are loaded from flash. Functions which are copied into IRAM are loaded once at boot time, and then always execute at full speed.
  IRAM is a limited resource, and using more IRAM may reduce available DRAM, so a strategic approach is needed when moving code to IRAM. See *IRAM (Instruction RAM)* for more information.
- Jump table optimizations can be re-enabled for individual source files that do not need to be placed in IRAM. For hot paths in large `switch cases`, this improves performance. For instructions on how to add the

`-fjump-tables` and `-ftree-switch-conversion` options when compiling individual source files, see *Controlling Component Compilation*

Improving Startup Time In addition to the overall performance improvements shown above, the following options can be tweaked to specifically reduce startup time:

- Minimizing the *CONFIG_LOG_DEFAULT_LEVEL* and *CONFIG_BOOTLOADER_LOG_LEVEL* has a large impact on startup time. To enable more logging after the app starts up, set the *CONFIG_LOG_MAXIMUM_LEVEL* as well, and then call `esp_log_level_set()` to restore higher level logs. The system/startup_time main function shows how to do this.
- If using Deep-sleep mode, setting *CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP* allows a faster wake from sleep. Note that if using Secure Boot, this represents a security compromise, as Secure Boot validation are not be performed on wake.
- Setting *CONFIG_BOOTLOADER_SKIP_VALIDATE_ON_POWER_ON* skips verifying the binary on every boot from the power-on reset. How much time this saves depends on the binary size and the flash settings. Note that this setting carries some risk if the flash becomes corrupt unexpectedly. Read the help text of the *config item* for an explanation and recommendations if using this option.
- It is possible to save a small amount of time during boot by disabling RTC slow clock calibration. To do so, set *CONFIG_RTC_CLK_CAL_CYCLES* to 0. Any part of the firmware that uses RTC slow clock as a timing source will be less accurate as a result.

The example project system/startup_time is pre-configured to optimize startup time. The file system/startup_time/sdkconfig.defaults contain all of these settings. You can append these to the end of your project's own `sdkconfig` file to merge the settings, but please read the documentation for each setting first.

Task Priorities As ESP-IDF FreeRTOS is a real-time operating system, it is necessary to ensure that high-throughput or low-slatency tasks are granted a high priority in order to run immediately. Priority is set when calling `xTaskCreate()` or `xTaskCreatePinnedToCore()` and can be changed at runtime by calling `vTaskPrioritySet()`.

It is also necessary to ensure that tasks yield CPU (by calling `vTaskDelay()`, `sleep()`, or by blocking on semaphores, queues, task notifications, etc) in order to not starve lower-priority tasks and cause problems for the overall system. The *Task Watchdog Timer (TWDT)* provides a mechanism to automatically detect if task starvation happens. However, note that a TWDT timeout does not always indicate a problem, because sometimes the correct operation of the firmware requires some long-running computation. In these cases, tweaking the TWDT timeout or even disabling the TWDT may be necessary.

Built-in Task Priorities ESP-IDF starts a number of system tasks at fixed priority levels. Some are automatically started during the boot process, while some are started only if the application firmware initializes a particular feature. To optimize performance, structure the task priorities of your application properly to ensure the tasks are not delayed by the system tasks, while also not starving system tasks and impacting other functions of the system.

This may require splitting up a particular task. For example, perform a time-critical operation in a high-priority task or an interrupt handler and do the non-time-critical part in a lower-priority task.

Header components/esp_system/include/esp_task.h contains macros for the priority levels used for built-in ESP-IDF tasks system. See *Background Tasks* for more details about the system tasks.

Common priorities are:

- *Running the Main Task* that executes app_main function has minimum priority (1).
- *ESP Timer (High Resolution Timer)* system task to manage timer events and execute callbacks has high priority (22, `ESP_TASK_TIMER_PRIO`)
- FreeRTOS Timer Task to handle FreeRTOS timer callbacks is created when the scheduler initializes and has minimum task priority (1, *configurable*).

- *Event Loop Library* system task to manage the default system event loop and execute callbacks has high priority (20, `ESP_TASK_EVENT_PRIO`). This configuration is only used if the application calls `esp_event_loop_create_default()`. It is possible to call `esp_event_loop_create()` with a custom task configuration instead.
- *lwIP* TCP/IP task has high priority (18, `ESP_TASK_TCPIP_PRIO`).
- *Wi-Fi Driver* task has high priority (23).
- Wi-Fi wpa_supplicant component may create dedicated tasks while the Wi-Fi Protected Setup (WPS), WPA2 EAP-TLS, Device Provisioning Protocol (DPP) or BSS Transition Management (BTM) features are in use. These tasks all have low priority (2).
- *Controller && VHCI* task has high priority (23, `ESP_TASK_BT_CONTROLLER_PRIO`). The Bluetooth Controller needs to respond to requests with low latency, so it should always be among the highest priority task in the system.
- *NimBLE-based Host APIs* task has high priority (21).
- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the priority is medium-high (15). This setting can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
- If using the *ESP-MQTT* component, it creates a task with default priority 5 (*configurable*), depending on *CONFIG_MQTT_USE_CUSTOM_CONFIG*, and also configurable at runtime by `task_prio` field in the `esp_mqtt_client_config_t`)
- To see what is the task priority for `mDNS` service, please check Performance Optimization.

Choosing Task Priorities of the Application In general, it is not recommended to set task priorities higher than the built-in Wi-Fi/Bluetooth operations as starving them of CPU may make the system unstable.

For very short timing-critical operations that do not use the network, use an ISR or a very restricted task (with very short bursts of runtime only) at the highest priority (24).

Choosing priority 19 allows lower-layer Wi-Fi/Bluetooth functionality to run without delays, but still preempts the lwIP TCP/IP stack and other less time-critical internal functionality - this is the best option for time-critical tasks that do not perform network operations.

Any task that does TCP/IP network operations should run at a lower priority than the lwIP TCP/IP task (18) to avoid priority-inversion issues.

With a few exceptions, most importantly the lwIP TCP/IP task, in the default configuration most built-in tasks are pinned to Core 0. This makes it quite easy for the application to place high priority tasks on Core 1. Using priority 19 or higher guarantees that an application task can run on Core 1 without being preempted by any built-in task. To further isolate the tasks running on each CPU, configure the *lwIP task* to only run on Core 0 instead of either core, which may reduce total TCP/IP throughput depending on what other tasks are running.

In general, it is not recommended to set task priorities on Core 0 higher than the built-in Wi-Fi/Bluetooth operations as starving them of CPU may make the system unstable. Choosing priority 19 and Core 0 allows lower-layer Wi-Fi/Bluetooth functionality to run without delays, but still pre-empts the lwIP TCP/IP stack and other less time-critical internal functionality. This is an option for time-critical tasks that do not perform network operations. Any task that does TCP/IP network operations should run at lower priority than the lwIP TCP/IP task (18) to avoid priority-inversion issues.

Note: Setting a task to always run in preference to built-in ESP-IDF tasks does not require pinning the task to Core 1. Instead, the task can be left unpinned and assigned a priority of 17 or lower. This allows the task to optionally run on Core 0 if there are no higher-priority built-in tasks running on that core. Using unpinned tasks can improve the overall CPU utilization, however it makes reasoning about task scheduling more complex.

Note: Task execution is always completely suspended when writing to the built-in SPI flash chip. Only *IRAM-Safe Interrupt Handlers* continues executing.

Improving Interrupt Performance ESP-IDF supports dynamic *Interrupt Allocation* with interrupt preemption. Each interrupt in the system has a priority, and higher-priority interrupts preempts lower priority ones.

Interrupt handlers execute in preference to any task, provided the task is not inside a critical section. For this reason, it is important to minimize the amount of time spent in executing an interrupt handler.

To obtain the best performance for a particular interrupt handler:

- Assign more important interrupts a higher priority using a flag such as `ESP_INTR_FLAG_LEVEL2` or `ESP_INTR_FLAG_LEVEL3` when calling `esp_intr_alloc()`.
- If you are sure the entire interrupt handler can run from IRAM (see *IRAM-Safe Interrupt Handlers*) then set the `ESP_INTR_FLAG_IRAM` flag when calling `esp_intr_alloc()` to assign the interrupt. This prevents it being temporarily disabled if the application firmware writes to the internal SPI flash.
- Even if the interrupt handler is not IRAM-safe, if it is going to be executed frequently then consider moving the handler function to IRAM anyhow. This minimizes the chance of a flash cache miss when the interrupt code is executed (see *Targeted Optimizations*). It is possible to do this without adding the `ESP_INTR_FLAG_IRAM` flag to mark the interrupt as IRAM-safe, if only part of the handler is guaranteed to be in IRAM.

Improving Network Speed

- For Wi-Fi, see *How to Improve Wi-Fi Performance* and *Wi-Fi Buffer Usage*
- For lwIP TCP/IP, see *Performance Optimization*
- The wifi/iperf example contains a configuration that is heavily optimized for Wi-Fi TCP/IP throughput, usually at the expense of higher RAM usage. Append the contents of the files wifi/iperf/sdkconfig.defaults, wifi/iperf/sdkconfig.defaults.esp32c3 and wifi/iperf/sdkconfig.ci.99 to the `sdkconfig` file in your project in order to add all of these options. Note that some of these options may have trade-offs in terms of reduced debuggability, increased firmware size, increased memory usage, or reduced performance of other features. To get the best result, read the documentation pages linked above and use related information to determine exactly which options are best suited for your app.

Improving I/O Performance Using standard C library functions like `fread` and `fwrite` instead of platform specific unbuffered syscalls such as `read` and `write` can be slow.These functions are designed to be portable, so they are not necessarily optimized for speed, have a certain overhead and are buffered.

FAT Filesystem Support specific information and tips:

- Maximum size of the R/W request = FatFS cluster size (allocation unit size).
- Use `read` and `write` instead of `fread` and `fwrite`.
- To increase speed of buffered reading functions like `fread` and `fgets`, you can increase a size of the file buffer (Newlib's default is 128 bytes) to a higher number like 4096, 8192 or 16384. This can be done locally via the `setvbuf` function used on a certain file pointer or globally applied to all files via modifying *CONFIG_FATFS_VFS_FSTAT_BLKSIZE*.

> **Note:** Setting a bigger buffer size also increases the heap memory usage.

Minimizing Binary Size

The ESP-IDF build system compiles all source files in the project and ESP-IDF, but only functions and variables that are actually referenced by the program are linked into the final binary. In some cases, it is necessary to reduce the total size of the firmware binary, e.g., in order to fit it into the available flash partition size.

The first step to reducing the total firmware binary size is measuring what is causing the size to increase.

Measuring Static Sizes To optimize both the firmware binary size and the memory usage, it is necessary to measure statically-allocated RAM (`data`, `bss`), code (`text`), and read-only data (`rodata`) in your project. The *idf.py* sub-commands `size`, `size-components`, and `size-files` can be used to examine statically-allocated RAM usage at different levels of detail. For more information, please see the *IDF Size* tool.

Linker Map File

Note: This is an advanced analysis method, but it can be very useful. Feel free to skip ahead to *Reducing Overall Size* and possibly come back to this later.

The `idf.py size` analysis tools all work by parsing the GNU binutils `linker map file`, which is a summary of everything the linker did when it created (i.e., linked) the final firmware binary file.

Linker map files themselves are plain text files, so it is possible to read them and find out exactly what the linker did. However, they are also very complex and long, often exceeding 100,000 lines.

The map file itself is broken into parts and each part has a heading. The parts are:

- `Archive member included to satisfy reference by file (symbol)`
  - This shows you: for each object file included in the link, what symbol (function or variable) was the linker searching for when it included that object file.
  - If you are wondering why some object file in particular was included in the binary, this part may give a clue. This part can be used in conjunction with the `Cross Reference Table` at the end of the file.

  Note: Not every object file shown in this list ends up included in the final binary, some end up in the `Discarded input sections` list instead.

- `Allocating common symbols`
  - This is a list of some global variables along with their sizes. Common symbols have a particular meaning in ELF binary files, but ESP-IDF does not make much use of them.
- `Discarded input sections`
  - These sections were read by the linker as part of an object file to be linked into the final binary, but then nothing else referred to them, so they were discarded from the final binary.
  - For ESP-IDF, this list can be very long, as we compile each function and static variable to a unique section in order to minimize the final binary size. Specifically, ESP-IDF uses compiler options `-ffunction-sections -fdata-sections` and linker option `--gc-sections`.
  - Items mentioned in this list **do not** contribute to the final binary.
- `Memory Configuration`, `Linker script and memory map`
  - These two parts go together. Some of the output comes directly from the linker command line and the Linker Script, both provided by *Build System*. The linker script is partially generated from the ESP-IDF project using the *Linker Script Generation* feature.
  - As the output of the `Linker script and memory map` part of the map unfolds, you can see each symbol (function or static variable) linked into the final binary along with its address (as a 16 digit hex number), its length (also in hex), and the library and object file it was linked from (which can be used to determine the component and the source file).
  - Following all of the output sections that take up space in the final `.bin` file, the `memory map` also includes some sections in the ELF file that are only used for debugging, e.g., ELF sections `.debug_*`, etc. These do not contribute to the final binary size. You can notice the address of these symbols is a very small number, starting from `0x0000000000000000` and counting up.
- `Cross Reference Table`
  - This table shows the symbol (function or static variable) that the list of object file(s) refers to. If you are wondering why a particular thing is included in the binary, this will help determine what included it.

  Note: Unfortunately, the `Cross Reference Table` does not only include symbols that made it into the final binary. It also includes symbols in discarded sections. Therefore, just because something is shown here does not mean that it was included in the final binary - this needs to be

checked separately.

Note: Linker map files are generated by the GNU binutils linker `ld`, not ESP-IDF. You can find additional information online about the linker map file format. This quick summary is written from the perspective of ESP-IDF build system in particular.

Reducing Overall Size The following configuration options reduces the final binary size of almost any ESP-IDF project:

- Set *CONFIG_COMPILER_OPTIMIZATION* to `Optimize for size (-Os)`. In some cases, `Optimize for performance (-O2)` will also reduce the binary size compared to the default. Note that if your code contains C or C++ Undefined Behavior then increasing the compiler optimization level may expose bugs that otherwise do not happen.
- Reduce the compiled-in log output by lowering the app *CONFIG_LOG_DEFAULT_LEVEL*. If the *CONFIG_LOG_MAXIMUM_LEVEL* is changed from the default then this setting controls the binary size instead. Reducing compiled-in logging reduces the number of strings in the binary, and also the code size of the calls to logging functions.
- If your application does not require dynamic log level changes and you do not need to control logs per module using tags, consider disabling *CONFIG_LOG_DYNAMIC_LEVEL_CONTROL* and changing *CONFIG_LOG_TAG_LEVEL_IMPL*. It reduces IRAM usage by approximately 260 bytes, DRAM usage by approximately 264 bytes, and flash usage by approximately 1 KB compared to the default option, it also speeds up logging.
- Set the *CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL* to `Silent`. This avoids compiling in a dedicated assertion string and source file name for each assert that may fail. It is still possible to find the failed assert in the code by looking at the memory address where the assertion failed.
- Besides the *CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL*, you can disable or silent the assertion for the HAL component separately by setting *CONFIG_HAL_DEFAULT_ASSERTION_LEVEL*. It is to notice that ESP-IDF lowers the HAL assertion level in bootloader to be silent even if *CONFIG_HAL_DEFAULT_ASSERTION_LEVEL* is set to full-assertion level. This is to reduce the bootloader size.
- Setting *CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT* removes specific error messages for particular internal ESP-IDF error check macros. This may make it harder to debug some error conditions by reading the log output.
- If the binary needs to run on only certain revision(s) of ESP32-C3, increasing *CONFIG_ESP32C3_REV_MIN* to match can result in a reduced binary size. This is particularly true if setting ESP32-C3 minimum revision 3 and using Wi-Fi, as some functionality was moved to ROM code.
- Do not enable *CONFIG_COMPILER_CXX_EXCEPTIONS*, *CONFIG_COMPILER_CXX_RTTI*, or set the *CONFIG_COMPILER_STACK_CHECK_MODE* to Overall. All of these options are already disabled by default, but they have a large impact on binary size.
- Disabling *CONFIG_ESP_ERR_TO_NAME_LOOKUP* removes the lookup table to translate user-friendly names for error values (see *Error Handling*) in error logs, etc. This saves some binary size, but error values will be printed as integers only.
- Setting *CONFIG_ESP_SYSTEM_PANIC* to `Silent reboot` saves a small amount of binary size, however this is **only** recommended if no one will use UART output to debug the device.
- Setting *CONFIG_COMPILER_SAVE_RESTORE_LIBCALLS* reduces binary size by replacing inlined prologues/epilogues with library calls.
- If the application binary uses only one of the security versions of the protocomm component, then the support for others can be disabled to save some code size. The support can be disabled through *CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_0*, *CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_1* or *CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_2* respectively.

Note: In addition to the many configuration items shown here, there are a number of configuration options where changing the option from the default increases binary size. These are not noted here. Where the increase is significant

is usually noted in the configuration item help text.

Targeted Optimizations The following binary size optimizations apply to a particular component or a function:

Wi-Fi

- Disabling *CONFIG_ESP_WIFI_ENABLE_WPA3_SAE* will save some Wi-Fi binary size if WPA3 support is not needed. Note that WPA3 is mandatory for new Wi-Fi device certifications.
- Disabling *CONFIG_ESP_WIFI_SOFTAP_SUPPORT* will save some Wi-Fi binary size if soft-AP support is not needed.
- Disabling *CONFIG_ESP_WIFI_ENTERPRISE_SUPPORT* will save some Wi-Fi binary size if enterprise support is not needed.

Bluetooth NimBLE If using *NimBLE-based Host APIs* then the following modifications can reduce binary size:

- Set *CONFIG_BT_NIMBLE_MAX_CONNECTIONS* to 1 if only one Bluetooth LE connection is needed.
- Disable either *CONFIG_BT_NIMBLE_ROLE_CENTRAL* or *CONFIG_BT_NIMBLE_ROLE_OBSERVER* if these roles are not needed.
- Reducing *CONFIG_BT_NIMBLE_LOG_LEVEL* can reduce binary size. Note that if the overall log level has been reduced as described above in *Reducing Overall Size* then this also reduces the NimBLE log level.

lwIP IPv6

- Setting *CONFIG_LWIP_IPV6* to `false` will reduce the size of the lwIP TCP/IP stack, at the cost of only supporting IPv4.

  Note: IPv6 is required by some components such as *ASIO Port*. These components will not be available if IPV6 is disabled.

lwIP IPv4

- If IPv4 connectivity is not required, setting *CONFIG_LWIP_IPV4* to `false` will reduce the size of the lwIP, supporting IPv6-only TCP/IP stack.

  Note: Before disabling IPv4 support, please note that IPv6 only network environments are not ubiquitous and must be supported in the local network, e.g., by your internet service provider or using constrained local network settings.

Newlib Nano Formatting By default, ESP-IDF uses Newlib "full" formatting for I/O functions (`printf()`, `scanf()`, etc.)

Enabling the config option *CONFIG_NEWLIB_NANO_FORMAT* will switch Newlib to the "Nano" formatting mode. This is smaller in code size, and a large part of the implementation is compiled into the ESP32-C3 ROM, so it does not need to be included in the binary at all.

The exact difference in binary size depends on which features the firmware uses, but 25 KB ~ 50 KB is typical.

Enabling "Nano" formatting reduces the stack usage of each function that calls `printf()` or another string formatting function, see *Determining Stack Size*.

"Nano" formatting does not support 64-bit integers, or C99 formatting features. For a full list of restrictions, search for `--enable-newlib-nano-formatted-io` in the Newlib README file.

MbedTLS Features Under **Component Config > mbedTLS**, there are multiple mbedTLS features enabled default, some of which can be disabled if not needed to save code size.

These include:

- *CONFIG_MBEDTLS_HAVE_TIME*
- *CONFIG_MBEDTLS_ECDSA_DETERMINISTIC*
- *CONFIG_MBEDTLS_SHA512_C*
- *CONFIG_MBEDTLS_CLIENT_SSL_SESSION_TICKETS*
- *CONFIG_MBEDTLS_SERVER_SSL_SESSION_TICKETS*
- *CONFIG_MBEDTLS_SSL_CONTEXT_SERIALIZATION*
- *CONFIG_MBEDTLS_SSL_ALPN*
- *CONFIG_MBEDTLS_SSL_RENEGOTIATION*
- *CONFIG_MBEDTLS_CCM_C*
- *CONFIG_MBEDTLS_GCM_C*
- *CONFIG_MBEDTLS_ECP_C* (Alternatively: Leave this option enabled but disable some of the elliptic curves listed in the sub-menu.)
- *CONFIG_MBEDTLS_ECP_NIST_OPTIM*
- *CONFIG_MBEDTLS_ECP_FIXED_POINT_OPTIM*
- Change *CONFIG_MBEDTLS_TLS_MODE* if both server & client functionalities are not needed.
- Consider disabling some cipher suites listed in the `TLS Key Exchange Methods` sub-menu (i.e., *CONFIG_MBEDTLS_KEY_EXCHANGE_RSA*).
- Consider disabling *CONFIG_MBEDTLS_ERROR_STRINGS* if the application is already pulling in mbedTLS error strings through using `mbedtls_strerror()`.

The help text for each option has some more information for reference.

Important: It is **strongly not recommended to disable all these mbedTLS options**. Only disable options of which you understand the functionality and are certain that it is not needed in the application. In particular:

- Ensure that any TLS server(s) the device connects to can still be used. If the server is controlled by a third party or a cloud service, it is recommended to ensure that the firmware supports at least two of the supported cipher suites in case one is disabled in a future update.
- Ensure that any TLS client(s) that connect to the device can still connect with supported/recommended cipher suites. Note that future versions of client operating systems may remove support for some features, so it is recommended to enable multiple supported cipher suites, or algorithms for redundancy.

If depending on third party clients or servers, always pay attention to announcements about future changes to supported TLS features. If not, the ESP32-C3 device may become inaccessible if support changes.

Note: Not every combination of mbedTLS compile-time config is tested in ESP-IDF. If you find a combination that fails to compile or function as expected, please report the details on GitHub.

VFS *Virtual Filesystem Component* feature in ESP-IDF allows multiple filesystem drivers and file-like peripheral drivers to be accessed using standard I/O functions (`open`, `read`, `write`, etc.) and C library functions (`fopen`, `fread`, `fwrite`, etc.). When filesystem or file-like peripheral driver functionality is not used in the application, this feature can be fully or partially disabled. VFS component provides the following configuration options:

- *CONFIG_VFS_SUPPORT_TERMIOS* —can be disabled if the application does not use `termios` family of functions. Currently, these functions are implemented only for UART VFS driver. Most applications can disable this option. Disabling this option reduces the code size by about 1.8 KB.
- *CONFIG_VFS_SUPPORT_SELECT* — can be disabled if the application does not use the `select` function with file descriptors. Currently, only the UART and eventfd VFS drivers implement `select` support. Note that when this option is disabled, `select` can still be used for socket file descriptors. Disabling this option reduces the code size by about 2.7 KB.
- *CONFIG_VFS_SUPPORT_DIR* —can be disabled if the application does not use directory-related functions, such as `readdir` (see the description of this option for the complete list). Applications that only open, read

and write specific files and do not need to enumerate or create directories can disable this option, reducing the code size by 0.5 KB or more, depending on the filesystem drivers in use.
- *CONFIG_VFS_SUPPORT_IO* —can be disabled if the application does not use filesystems or file-like peripheral drivers. This disables all VFS functionality, including the three options mentioned above. When this option is disabled, *Console* can not be used. Note that the application can still use standard I/O functions with socket file descriptors when this option is disabled. Compared to the default configuration, disabling this option reduces code size by about 9.4 KB.

Bootloader Size This document deals with the size of an ESP-IDF app binary only, and not the ESP-IDF *Second Stage Bootloader*.

For a discussion of ESP-IDF bootloader binary size, see *Bootloader Size*.

IRAM Binary Size If the IRAM section of a binary is too large, this issue can be resolved by reducing IRAM memory usage. See *Optimizing IRAM Usage*.

Minimizing RAM Usage

In some cases, a firmware application's available RAM may run low or run out entirely. In these cases, it is necessary to tune the memory usage of the firmware application.

In general, firmware should aim to leave some headroom of free internal RAM to deal with extraordinary situations or changes in RAM usage in future updates.

Background Before optimizing ESP-IDF RAM usage, it is necessary to understand the basics of ESP32-C3 memory types, the difference between static and dynamic memory usage in C, and the way ESP-IDF uses stack and heap. This information can all be found in *Heap Memory Allocation*.

Measuring Static Memory Usage The *idf.py* tool can be used to generate reports about the static memory usage of an application, see *Measuring Static Sizes*.

Measuring Dynamic Memory Usage ESP-IDF contains a range of heap APIs for measuring free heap at runtime, see *Heap Memory Debugging*.

Note: In embedded systems, heap fragmentation can be a significant issue alongside total RAM usage. The heap measurement APIs provide ways to measure the largest free block. Monitoring this value along with the total number of free bytes can give a quick indication of whether heap fragmentation is becoming an issue.

Reducing Static Memory Usage

- Reducing the static memory usage of the application increases the amount of RAM available for heap at runtime, and vice versa.
- Generally speaking, minimizing static memory usage requires monitoring the `.data` and `.bss` sizes. For tools to do this, see *Measuring Static Sizes*.
- Internal ESP-IDF functions do not make heavy use of static RAM in C. In many instances (such as Wi-Fi library, Bluetooth controller), static buffers are still allocated from the heap. However, the allocation is performed only once during feature initialization and will be freed if the feature is deinitialized. This approach is adopted to optimize the availability of free memory at various stages of the application's life cycle.

To minimize static memory use:

- Constant data can be stored in flash memory instead of RAM, thus it is recommended to declare structures, buffers, or other variables as `const`. This approach may require modifying firmware functions to accept `const *` arguments instead of mutable pointer arguments. These changes can also help reduce the stack usage of certain functions.
- If using Bluedroid, setting the option *CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY* will cause Bluedroid to allocate memory on initialization and free it on deinitialization. This does not necessarily reduce the peak memory usage, but changes it from static memory usage to runtime memory usage.
- If using OpenThread, enabling the option *CONFIG_OPENTHREAD_PLATFORM_MSGPOOL_MANAGEMENT* will cause OpenThread to allocate message pool buffers from PSRAM, which will reduce static memory use.

Determining Stack Size In FreeRTOS, task stacks are usually allocated from the heap. The stack size for each task is fixed and passed as an argument to `xTaskCreate()`. Each task can use up to its allocated stack size, but using more than this will cause an otherwise valid program to crash, with a stack overflow or heap corruption.

Therefore, determining the optimum sizes of each task stack, minimizing the required size of each task stack, and minimizing the number of task stacks as whole, can all substantially reduce RAM usage.

Configuration Options for Stack Overflow Detection

Hardware Stack Guard The Hardware Stack Guard is a reliable method for detecting stack overflow. This method uses the hardware's Debug Assistant module to monitor the CPU's stack pointer register. A panic is immediately triggered if the stack pointer register goes beyond the bounds of the current stack (see *Hardware Stack Guard* for more details). The Hardware Stack Guard can be enabled via the *CONFIG_ESP_SYSTEM_HW_STACK_GUARD* option.

End of Stack Watchpoint The End of Stack Watchpoint feature places a CPU watchpoint at the end of the current stack. If that word is overwritten (such as in a stack overflow), a panic is triggered immediately. End of Stack Watchpoints can be enabled via the *CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK* option, but can only be used if debugger watchpoints are not already being used.

Stack Canary Bytes The Stack Canary Bytes feature adds a set of magic bytes at the end of each task's stack, and checks if those magic bytes have changed on every context switch. If those magic bytes are overwritten, a panic is triggered. Stack Canary Bytes can be enabled via the *CONFIG_FREERTOS_CHECK_STACKOVERFLOW* option.

Note: When using the End of Stack Watchpoint or Stack Canary Bytes, it is possible that a stack pointer skips over the watchpoint or canary bytes on a stack overflow and corrupts another region of RAM instead. Thus, these methods cannot detect all stack overflows.

Recommended and default option is *CONFIG_ESP_SYSTEM_HW_STACK_GUARD* which avoids this disadvantage.

Run-time Methods to Determine Stack Size

- The `uxTaskGetStackHighWaterMark()` returns the minimum free stack memory of a task throughout the task's lifetime, which gives a good indication of how much stack memory is left unused by a task.
  - The easiest time to call `uxTaskGetStackHighWaterMark()` is from the task itself: call `uxTaskGetStackHighWaterMark(NULL)` to get the current task's high water mark after the time that the task has achieved its peak stack usage, i.e., if there is a main loop, execute the main loop a number of times with all possible states, and then call `uxTaskGetStackHighWaterMark()`.
  - Often, it is possible to subtract almost the entire value returned here from the total stack size of a task, but allow some safety margin to account for unexpected small increases in stack usage at runtime.
- Call `uxTaskGetSystemState()` to get a summary of all tasks in the system. This includes their individual stack high watermark values.

Reducing Stack Sizes

- Avoid stack heavy functions. String formatting functions (like `printf()`) are particularly heavy users of the stack, so any task which does not ever call these can usually have its stack size reduced.
  - Enabling *Newlib Nano Formatting* reduces the stack usage of any task that calls `printf()` or other C string formatting functions.
- Avoid allocating large variables on the stack. In C, any large structures or arrays allocated as an automatic variable (i.e., default scope of a C declaration) uses space on the stack. To minimize the sizes of these, allocate them statically and/or see if you can save memory by dynamically allocating them from the heap only when they are needed.
- Avoid deep recursive function calls. Individual recursive function calls do not always add a lot of stack usage each time they are called, but if each function includes large stack-based variables then the overhead can get quite high.

Reducing Task Count Combine tasks. If a particular task is never created, the task's stack is never allocated, thus reducing RAM usage significantly. Unnecessary tasks can typically be removed if those tasks can be combined with another task. In an application, tasks can typically be combined or removed if:

- The work done by the tasks can be structured into multiple functions that are called sequentially.
- The work done by the tasks can be structured into smaller jobs that are serialized (via a FreeRTOS queue or similar) for execution by a worker task.

Internal Task Stack Sizes ESP-IDF allocates a number of internal tasks for housekeeping purposes or operating system functions. Some are created during the startup process, and some are created at runtime when particular features are initialized.

The default stack sizes for these tasks are usually set conservatively high to allow all common usage patterns. Many of the stack sizes are configurable, and it may be possible to reduce them to match the real runtime stack usage of the task.

Important: If internal task stack sizes are set too small, ESP-IDF will crash unpredictably. Even if the root cause is task stack overflow, this is not always clear when debugging. It is recommended that internal stack sizes are only reduced carefully (if at all), with close attention to high water mark free space under load. If reporting an issue that occurs when internal task stack sizes have been reduced, please always include the following information and the specific configuration that is being used.

- *Running the Main Task* has stack size *CONFIG_ESP_MAIN_TASK_STACK_SIZE*.
- *ESP Timer (High Resolution Timer)* system task which executes callbacks has stack size *CONFIG_ESP_TIMER_TASK_STACK_SIZE*.
- FreeRTOS Timer Task to handle FreeRTOS timer callbacks has stack size *CONFIG_FREERTOS_TIMER_TASK_STACK_DEPTH*.
- *Event Loop Library* system task to execute callbacks for the default system event loop has stack size *CONFIG_ESP_SYSTEM_EVENT_TASK_STACK_SIZE*.
- *lwIP* TCP/IP task has stack size *CONFIG_LWIP_TCPIP_TASK_STACK_SIZE*.
- *Bluetooth® API* have task stack sizes *CONFIG_BT_BTC_TASK_STACK_SIZE*, *CONFIG_BT_BTU_TASK_STACK_SIZE*.
- *NimBLE-based Host APIs* has task stack size *CONFIG_BT_NIMBLE_HOST_TASK_STACK_SIZE*.
- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the task stack size is 4 KB. This setting can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
- FreeRTOS idle task stack size is configured by *CONFIG_FREERTOS_IDLE_TASK_STACKSIZE*.
- If using the *ESP-MQTT* component, it creates a task with stack size configured by *CONFIG_MQTT_TASK_STACK_SIZE*. MQTT stack size can also be configured using `task_stack` field of `esp_mqtt_client_config_t`.
- To see how to optimize RAM usage when using `mDNS`, please check Minimizing RAM Usage.

Note: Aside from built-in system features such as ESP-timer, if an ESP-IDF feature is not initialized by the firmware, then no associated task is created. In those cases, the stack usage is zero, and the stack-size configuration for the task is not relevant.

Reducing Heap Usage For functions that assist in analyzing heap usage at runtime, see *Heap Memory Debugging*.

Normally, optimizing heap usage consists of analyzing the usage and removing calls to `malloc()` that are not being used, reducing the corresponding sizes, or freeing previously allocated buffers earlier.

There are some ESP-IDF configuration options that can reduce heap usage at runtime:

- lwIP documentation has a section to configure *Minimum RAM Usage*.
- *Wi-Fi Buffer Usage* describes options to either reduce the number of static buffers or reduce the maximum number of dynamic buffers in use, so as to minimize memory usage at a possible cost of performance. Note that static Wi-Fi buffers are still allocated from the heap when Wi-Fi is initialized, and will be freed if Wi-Fi is deinitialized.
- Several Mbed TLS configuration options can be used to reduce heap memory usage. See the *Reducing Heap Usage* docs for details.

Note: There are other configuration options that increases heap usage at runtime if changed from the defaults. These options are not listed above, but the help text for the configuration item will mention if there is some memory impact.

Optimizing IRAM Usage The available DRAM at runtime for heap usage is also reduced by the static IRAM usage. Therefore, one way to increase available DRAM is to reduce IRAM usage.

If the app allocates more static IRAM than available, then the app will fail to build, and linker errors such as `section '.iram0.text' will not fit in region 'iram0_0_seg'`, `IRAM0 segment data does not fit`, and `region 'iram0_0_seg' overflowed by 84-bytes` will be seen. If this happens, it is necessary to find ways to reduce static IRAM usage in order to link the application.

To analyze the IRAM usage in the firmware binary, use *Measuring Static Sizes*. If the firmware failed to link, steps to analyze are shown at *Showing Size When Linker Fails*.

The following options will reduce IRAM usage of some ESP-IDF features:

- Enable *CONFIG_FREERTOS_PLACE_FUNCTIONS_INTO_FLASH*. Provided these functions are not incorrectly used from ISRs, this option is safe to enable in all configurations.
- Enable *CONFIG_RINGBUF_PLACE_FUNCTIONS_INTO_FLASH*. Provided these functions are not incorrectly used from ISRs, this option is safe to enable in all configurations.
- Enable *CONFIG_RINGBUF_PLACE_ISR_FUNCTIONS_INTO_FLASH*. This option is not safe to use if the ISR ringbuf functions are used from an IRAM interrupt context, e.g., if *CONFIG_UART_ISR_IN_IRAM* is enabled. For the ESP-IDF drivers where this is the case, you can get an error at run-time when installing the driver in question.
- Disabling Wi-Fi options *CONFIG_ESP_WIFI_IRAM_OPT* and/or *CONFIG_ESP_WIFI_RX_IRAM_OPT* options frees available IRAM at the cost of Wi-Fi performance.
- Enabling *CONFIG_SPI_FLASH_ROM_IMPL* frees some IRAM but means that esp_flash bugfixes and new flash chip support are not available, see *SPI Flash API ESP-IDF Version vs Chip-ROM Version* for details.
- Disabling *CONFIG_ESP_EVENT_POST_FROM_IRAM_ISR* prevents posting `esp_event` events from *IRAM-Safe Interrupt Handlers* but saves some IRAM.
- Disabling *CONFIG_SPI_MASTER_ISR_IN_IRAM* prevents spi_master interrupts from being serviced while writing to flash, and may otherwise reduce spi_master performance, but saves some IRAM.
- Disabling *CONFIG_SPI_SLAVE_ISR_IN_IRAM* prevents spi_slave interrupts from being serviced while writing to flash, which saves some IRAM.

- Setting *CONFIG_HAL_DEFAULT_ASSERTION_LEVEL* to disable assertion for HAL component saves some IRAM, especially for HAL code who calls `HAL_ASSERT` a lot and resides in IRAM.
- Refer to the sdkconfig menu `Auto-detect Flash chips`, and you can disable flash drivers which you do not need to save some IRAM.
- Enable *CONFIG_HEAP_PLACE_FUNCTION_INTO_FLASH*. Provided that *CONFIG_SPI_MASTER_ISR_IN_IRAM* is not enabled and the heap functions are not incorrectly used from ISRs, this option is safe to enable in all configurations.

Flash Suspend Feature When using SPI flash driver API and other APIs based on the former (NVS, Partition APIs, etc.), the Cache will be disabled. During this period, any code executed must reside in internal RAM, see *Concurrency Constraints for Flash on SPI1*. Hence, interrupt handlers that are not in internal RAM will not be executed.

To achieve this, ESP-IDF drivers usually have the following two options:

- Place the driver's internal ISR handler in the internal RAM.
- Place some control functions in the internal RAM.

User ISR callbacks and involved variables have to be in internal RAM if they are also used in interrupt contexts.

Placing additional code into IRAM will exacerbate IRAM usage. For this reason, there is *CONFIG_SPI_FLASH_AUTO_SUSPEND*, which can alleviate the aforementioned kinds of IRAM usage. By enabling this feature, the Cache will not be disabled when SPI flash driver APIs and SPI flash driver-based APIs are used. Therefore, code and data in flash can be executed or accessed normally, but with some minor delay. See *Flash Auto Suspend Feature* for more details about this feature.

Regarding the flash suspend feature usage, and corresponding response time delay, please also see this example system/flash_suspend.

Note: Moving frequently-called functions from IRAM to flash may increase their execution time.

Note: Other configuration options exist that will increase IRAM usage by moving some functionality into IRAM, usually for performance, but the default option is not to do this. These are not listed here. The IRAM size impact of enabling these options is usually noted in the configuration item help text.

4.27 Reproducible Builds

4.27.1 Introduction

ESP-IDF build system has support for reproducible builds.

When reproducible builds are enabled, the application built with ESP-IDF does not depend on the build environment. Both the `.elf` file and `.bin` files of the application remains exactly the same, even if the following variables change:

- Directory where the project is located
- Directory where ESP-IDF is located (`IDF_PATH`)
- Build time

4.27.2 Reasons for Non-Reproducible Builds

There are several reasons why an application may depend on the build environment, even when the same source code and tools versions are used.

- In C code, `__FILE__` preprocessor macro is expanded to the full path of the source file.
- `__DATE__` and `__TIME__` preprocessor macros are expanded to compilation date and time.
- When the compiler generates object files, it adds sections with debug information. These sections help debuggers, like GDB, to locate the source code which corresponds to a particular location in the machine code. These sections typically contain paths of relevant source files. These paths may be absolute, and will include the path to ESP-IDF or to the project.

There are also other possible reasons, such as unstable order of inputs and non-determinism in the build system.

4.27.3 Enabling Reproducible Builds in ESP-IDF

Reproducible builds can be enabled in ESP-IDF using *CONFIG_APP_REPRODUCIBLE_BUILD* option.

This option is disabled by default. It can be enabled in `menuconfig`.

The option may also be added into `sdkconfig.defaults`. If adding the option into `sdkconfig.defaults`, delete the `sdkconfig` file and run the build again. See *Custom Sdkconfig Defaults* for more information.

4.27.4 How Reproducible Builds Are Achieved

ESP-IDF achieves reproducible builds using the following measures:

- In ESP-IDF source code, `__DATE__` and `__TIME__` macros are not used when reproducible builds are enabled. Note, if the application source code uses these macros, the build will not be reproducible.
- ESP-IDF build system passes a set of `-fmacro-prefix-map` and `-fdebug-prefix-map` flags to replace base paths with placeholders:
  - Path to ESP-IDF is replaced with `/IDF`
  - Path to the project is replaced with `/IDF_PROJECT`
  - Path to the build directory is replaced with `/IDF_BUILD`
  - Paths to components are replaced with `/COMPONENT_NAME_DIR` (where `NAME` is the name of the component)
- Build date and time are not included into the *application metadata structure* and *bootloader metadata structure* if *CONFIG_APP_REPRODUCIBLE_BUILD* is enabled.
- ESP-IDF build system ensures that source file lists, component lists and other sequences are sorted before passing them to CMake. Various other parts of the build system, such as the linker script generator also perform sorting to ensure that same output is produced regardless of the environment.

4.27.5 Reproducible Builds and Debugging

When reproducible builds are enabled, file names included in debug information sections are altered as shown in the previous section. Due to this fact, the debugger (GDB) is not able to locate the source files for the given code location.

This issue can be solved using GDB `set substitute-path` command. For example, by adding the following command to GDB init script, the altered paths can be reverted to the original ones.

```
set substitute-path /COMPONENT_FREERTOS_DIR /home/user/esp/esp-idf/components/
↪freertos
```

ESP-IDF build system generates a file with the list of such `set substitute-path` commands automatically during the build process. The file is called `prefix_map_gdbinit` and is located in the project `build` directory.

When *idf.py gdb* is used to start debugging, this additional `gdbinit` file is automatically passed to GDB. When launching GDB manually or from IDE, please pass this additional `gdbinit` script to GDB using `-x build/prefix_map_gdbinit` argument.

4.27.6 Factors Which Still Affect Reproducible Builds

Note that the built application still depends on:

- ESP-IDF version
- Versions of the build tools (CMake, Ninja) and the cross-compiler

IDF Docker Image can be used to ensure that these factors do not affect the build.

4.28 RF Calibration

ESP32-C3 supports three RF calibration methods during RF initialization:

1. Partial calibration
2. Full calibration
3. No calibration

4.28.1 Partial Calibration

During RF initialization, the partial calibration method is used by default for RF calibration. It is done based on the full calibration data which is stored in the NVS. To use this method, please go to `menuconfig` and enable *CONFIG_ESP_PHY_CALIBRATION_AND_DATA_STORAGE*.

4.28.2 Full Calibration

Full calibration is triggered in the following conditions:

1. NVS does not exist.
2. The NVS partition to store calibration data has been erased.
3. Hardware MAC address has changed.
4. PHY library version has changed.
5. The RF calibration data loaded from the NVS partition is broken.

Full calibration takes 100 ms longer than the partial calibration method. If boot duration is not of critical importance to the application, the full calibration method is recommended. To switch to the full calibration method, go to `menuconfig` and disable *CONFIG_ESP_PHY_CALIBRATION_AND_DATA_STORAGE*. If you use the default method of RF calibration, there are two ways to add the function of triggering full calibration as a last-resort remedy.

1. Erase the NVS partition if you do not mind all of the data stored in the NVS partition is erased. That is indeed the easiest way.
2. Call API `esp_phy_erase_cal_data_in_nvs()` before initializing Wi-Fi and Bluetooth®/Bluetooth Low Energy based on some conditions (e.g., an option provided in some diagnostic mode). In this case, only the PHY namespace of the NVS partition is erased.

4.28.3 No Calibration

The no calibration method is only used when the device wakes up from Deep-sleep mode.

4.28.4 PHY Initialization Data

The PHY initialization data is used for RF calibration. There are two ways to get the PHY initialization data.

One is to use the default initialization data which is located in the header file components/esp_phy/esp32c3/include/phy_init_data.h. It is embedded into the application binary after compiling and then stored into read-only memory (DROM). To use the default initialization data, please go to `menuconfig` and disable *CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION*.

An alternative is to store the initialization data in a PHY data partition. A PHY data partition is included in the default partition table. However, when using a custom partition table, please ensure that a PHY data partition (type:

`data`, subtype: `phy`) is included in the custom partition table. Whether you are using a custom partition table or the default partition table, if initialization data is stored in a partition, it has to be flashed there, otherwise a runtime error occurs. If you want to use initialization data stored in a partition, go to `menuconfig` and enable the option *CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION*.

4.28.5 API Reference

Header File

- components/esp_phy/include/esp_phy_init.h
- This header file can be included with:

```
#include "esp_phy_init.h"
```

- This header file is a part of the API provided by the `esp_phy` component. To declare that your component depends on `esp_phy`, add the following to your CMakeLists.txt:

```
REQUIRES esp_phy
```

or

```
PRIV_REQUIRES esp_phy
```

Functions

const *esp_phy_init_data_t* ***esp_phy_get_init_data*** (void)

Get PHY init data.

If "Use a partition to store PHY init data" option is set in menuconfig, This function will load PHY init data from a partition. Otherwise, PHY init data will be compiled into the application itself, and this function will return a pointer to PHY init data located in read-only memory (DROM).

If "Use a partition to store PHY init data" option is enabled, this function may return NULL if the data loaded from flash is not valid.

Note: Call esp_phy_release_init_data to release the pointer obtained using this function after the call to esp_wifi_init.

Returns pointer to PHY init data structure

void ***esp_phy_release_init_data*** (const *esp_phy_init_data_t* *data)

Release PHY init data.

Parameters **data** -- pointer to PHY init data structure obtained from esp_phy_get_init_data function

esp_err_t ***esp_phy_load_cal_data_from_nvs*** (*esp_phy_calibration_data_t* *out_cal_data)

Function called by esp_phy_load_cal_and_init to load PHY calibration data.

This is a convenience function which can be used to load PHY calibration data from NVS. Data can be stored to NVS using esp_phy_store_cal_data_to_nvs function.

If calibration data is not present in the NVS, or data is not valid (was obtained for a chip with a different MAC address, or obtained for a different version of software), this function will return an error.

Parameters **out_cal_data** -- pointer to calibration data structure to be filled with loaded data.
Returns ESP_OK on success

esp_err_t **esp_phy_store_cal_data_to_nvs** (const *esp_phy_calibration_data_t* *cal_data)

Function called by esp_phy_load_cal_and_init to store PHY calibration data.

This is a convenience function which can be used to store PHY calibration data to the NVS. Calibration data is returned by esp_phy_load_cal_and_init function. Data saved using this function to the NVS can later be loaded using esp_phy_store_cal_data_to_nvs function.

Parameters **cal_data** -- pointer to calibration data which has to be saved.
Returns ESP_OK on success

esp_err_t **esp_phy_erase_cal_data_in_nvs** (void)

Erase PHY calibration data which is stored in the NVS.

This is a function which can be used to trigger full calibration as a last-resort remedy if partial calibration is used. It can be called in the application based on some conditions (e.g. an option provided in some diagnostic mode).

Returns ESP_OK on success
Returns others on fail. Please refer to NVS API return value error number.

void **esp_phy_enable** (*esp_phy_modem_t* modem)

Enable PHY and RF module.

PHY and RF module should be enabled in order to use WiFi or BT. Now PHY and RF enabling job is done automatically when start WiFi or BT. Users should not call this API in their application.

Parameters **modem** -- the modem to call the phy enable.

void **esp_phy_disable** (*esp_phy_modem_t* modem)

Disable PHY and RF module.

PHY module should be disabled in order to shutdown WiFi or BT. Now PHY and RF disabling job is done automatically when stop WiFi or BT. Users should not call this API in their application.

Parameters **modem** -- the modem to call the phy disable.

void **esp_btbb_enable** (void)

Enable BTBB module.

BTBB module should be enabled in order to use IEEE802154 or BT. Now BTBB enabling job is done automatically when start IEEE802154 or BT. Users should not call this API in their application.

void **esp_btbb_disable** (void)

Disable BTBB module.

Disable BTBB module, used by IEEE802154 or Bluetooth. Users should not call this API in their application.

void **esp_phy_load_cal_and_init** (void)

Load calibration data from NVS and initialize PHY and RF module.

void **esp_phy_modem_init** (void)

Initialize backup memory for Phy power up/down.

void **esp_phy_modem_deinit** (void)

Deinitialize backup memory for Phy power up/down Set phy_init_flag if all modems deinit on ESP32C3.

void **esp_phy_common_clock_enable** (void)

Enable WiFi/BT common clock.

void **esp_phy_common_clock_disable** (void)

Disable WiFi/BT common clock.

int64_t **esp_phy_rf_get_on_ts** (void)

Get the time stamp when PHY/RF was switched on.

Returns return 0 if PHY/RF is never switched on. Otherwise return time in microsecond since boot when phy/rf was last switched on

esp_err_t **esp_phy_update_country_info**(const char *country)

Update the corresponding PHY init type according to the country code of Wi-Fi.

Parameters **country** -- country code
Returns ESP_OK on success.
Returns esp_err_t code describing the error on fail

char ***get_phy_version_str**(void)

Get PHY lib version.

Returns PHY lib version.

void **phy_init_param_set**(uint8_t param)

Set PHY init parameters.

Parameters **param** -- is 1 means combo module

void **phy_wifi_enable_set**(uint8_t enable)

Wi-Fi RX enable.

Parameters **enable** -- True for enable wifi receiving mode as default, false for closing wifi receiving mode as default.

Structures

struct **esp_phy_init_data_t**

Structure holding PHY init parameters.

Public Members

uint8_t **params**[128]

opaque PHY initialization parameters

struct **esp_phy_calibration_data_t**

Opaque PHY calibration data.

Public Members

uint8_t **version**[4]

PHY version

uint8_t **mac**[6]

The MAC address of the station

uint8_t **opaque**[1894]

calibration data

Enumerations

enum **esp_phy_modem_t**

PHY enable or disable modem.

Values:

enumerator **PHY_MODEM_WIFI**

PHY modem WIFI

enumerator **PHY_MODEM_BT**

PHY modem BT

enumerator **PHY_MODEM_IEEE802154**

PHY modem IEEE802154

enum **esp_phy_calibration_mode_t**

PHY calibration mode.

Values:

enumerator **PHY_RF_CAL_PARTIAL**

Do part of RF calibration. This should be used after power-on reset.

enumerator **PHY_RF_CAL_NONE**

Don't do any RF calibration. This mode is only suggested to be used after deep sleep reset.

enumerator **PHY_RF_CAL_FULL**

Do full RF calibration. Produces best results, but also consumes a lot of time and current. Suggested to be used once.

Header File

- components/esp_phy/include/esp_phy_cert_test.h
- This header file can be included with:

```
#include "esp_phy_cert_test.h"
```

- This header file is a part of the API provided by the `esp_phy` component. To declare that your component depends on `esp_phy`, add the following to your CMakeLists.txt:

```
REQUIRES esp_phy
```

or

```
PRIV_REQUIRES esp_phy
```

Functions

void **esp_wifi_power_domain_on**(void)

Wifi power domain power on.

void **esp_wifi_power_domain_off**(void)

Wifi power domain power off.

void **esp_phy_rftest_config**(uint8_t conf)

Environment variable configuration.

Parameters **conf** -- Set to 1 to enter RF test mode.

void **esp_phy_rftest_init**(void)

RF initialization configuration.

void **esp_phy_tx_contin_en** (bool contin_en)

TX Continuous mode.

Parameters **contin_en** -- Set to true for continuous packet sending, which can be used for certification testing; Set to false to cancel continuous mode, which is the default mode and can be used for WLAN tester.

void **esp_phy_cbw40m_en** (bool en)

HT40/HT20 mode selection.

Parameters **en** -- Set to false to enter 11n HT20 mode; Set to true to enter 11n HT40 mode;

void **esp_phy_wifi_tx** (uint32_t chan, *esp_phy_wifi_rate_t* rate, int8_t backoff, uint32_t length_byte, uint32_t packet_delay, uint32_t packet_num)

Wi-Fi TX command.

Parameters

- **chan** -- channel setting, 1~14;
- **rate** -- rate setting;
- **backoff** -- Transmit power attenuation, unit is 0.25dB. For example, 4 means that the power is attenuated by 1dB;
- **length_byte** -- TX packet length configuration, indicating PSDU Length, unit is byte;
- **packet_delay** -- TX packet interval configuration, unit is us;
- **packet_num** -- The number of packets sent, 0 means sending packets continuously, other values represent the number of packets to send.

void **esp_phy_test_start_stop** (uint8_t value)

Test start/stop command, used to stop transmitting or reciving state.

Parameters **value** -- Value should be set to 3 before TX/RX. Set value to 0 to end TX/RX state.

void **esp_phy_wifi_rx** (uint32_t chan, *esp_phy_wifi_rate_t* rate)

Wi-Fi RX command.

Parameters

- **chan** -- channel setting, 1~14;
- **rate** -- rate setting;

void **esp_phy_wifi_tx_tone** (uint32_t start, uint32_t chan, uint32_t backoff)

Wi-Fi Carrier Wave(CW) TX command.

Parameters

- **start** -- enable CW, 1 means transmit, 0 means stop transmitting;
- **chan** -- CW channel setting, 1~14;
- **backoff** -- CW power attenuation parameter, unit is 0.25dB. 4 indicates the power is attenuated by 1dB.

void **esp_phy_ble_tx** (uint32_t txpwr, uint32_t chan, uint32_t len, *esp_phy_ble_type_t* data_type, uint32_t syncw, *esp_phy_ble_rate_t* rate, uint32_t tx_num_in)

BLE TX command.

Parameters

- **txpwr** -- Transmit power level. Tx power is about (level-8)*3 dBm, step is 3dB. Level 8 is around 0 dBm;
- **chan** -- channel setting, range is 0~39, corresponding frequency = 2402+chan*2;
- **len** -- Payload length setting, range is 0-255, unit is byte, 37 bytes is employed generally;
- **data_type** -- Data type setting;
- **syncw** -- Packet identification (need to be provided by the packet generator or instrument manufacturer), 0x71764129 is employed generally;
- **rate** -- rate setting;
- **tx_num_in** -- The number of packets sent, 0 means sending packets continuously, other values represent the number of packets to send.

void **esp_phy_ble_rx** (uint32_t chan, uint32_t syncw, *esp_phy_ble_rate_t* rate)

BLE RX command.

Parameters

- **chan** -- channel selection, range is 0-39; Channels 0, 1, 2~10 correspond to 2404MHz, 2406MHz, 2408MHz~2424MHz respectively; Channels 11, 12, 13~36 correspond to 2428MHz, 2430MHz, 2432MHz~2478MHz respectively; Channel 37: 2402MHz, Channel 38: 2426MHz, Channel 39: 2480MHz;
- **syncw** -- Packet identification (need to be provided by the packet generator or instrument manufacturer), 0x71764129 is employed generally;
- **rate** -- rate setting;

void **esp_phy_bt_tx_tone** (uint32_t start, uint32_t chan, uint32_t power)

BLE Carrier Wave(CW) TX command.

Parameters

- **start** -- enable CW, 1 means transmit, 0 means stop transmitting;
- **chan** -- Single carrier transmission channel selection, range is 0~39, corresponding frequency freq = 2402+chan*2;
- **power** -- CW power attenuation parameter, unit is 0.25dB. 4 indicates the power is attenuated by 1dB.

void **esp_phy_get_rx_result** (*esp_phy_rx_result_t* *rx_result)

Get some RX information.

Parameters **rx_result** -- This struct for storing RX information;

Structures

struct **esp_phy_rx_result_t**

Structure holding PHY RX result.

Public Members

uint32_t **phy_rx_correct_count**

The number of desired packets received

int **phy_rx_rssi**

Average RSSI of desired packets

uint32_t **phy_rx_total_count**

The number of total packets received

uint32_t **phy_rx_result_flag**

0 means no RX info; 1 means the lastest Wi-Fi RX info; 2 means the lastest BLE RX info.

Enumerations

enum **esp_phy_wifi_rate_t**

Values:

enumerator **PHY_RATE_1M**

enumerator **PHY_RATE_2M**

enumerator **PHY_RATE_5M5**

enumerator **PHY_RATE_11M**

enumerator **PHY_RATE_6M**

enumerator **PHY_RATE_9M**

enumerator **PHY_RATE_12M**

enumerator **PHY_RATE_18M**

enumerator **PHY_RATE_24M**

enumerator **PHY_RATE_36M**

enumerator **PHY_RATE_48M**

enumerator **PHY_RATE_54M**

enumerator **PHY_RATE_MCS0**

enumerator **PHY_RATE_MCS1**

enumerator **PHY_RATE_MCS2**

enumerator **PHY_RATE_MCS3**

enumerator **PHY_RATE_MCS4**

enumerator **PHY_RATE_MCS5**

enumerator **PHY_RATE_MCS6**

enumerator **PHY_RATE_MCS7**

enumerator **PHY_WIFI_RATE_MAX**

enum **esp_phy_ble_rate_t**

Values:

enumerator **PHY_BLE_RATE_1M**

enumerator **PHY_BLE_RATE_2M**

enumerator **PHY_BLE_RATE_125K**

enumerator **PHY_BLE_RATE_500k**

enumerator **PHY_BLE_RATE_MAX**

enum **esp_phy_ble_type_t**

Values:

enumerator **PHY_BLE_TYPE_1010**

enumerator **PHY_BLE_TYPE_00001111**

enumerator **PHY_BLE_TYPE_prbs9**

enumerator **PHY_BLE_TYPE_00111100**

enumerator **PHY_BLE_TYPE_MAX**

4.29 Standard I/O and Console Output

ESP-IDF provides C standard I/O facilities, such as `stdin`, `stdout`, and `stderr` streams, as well as C standard library functions such as `printf()` which operate on these streams.

As common in POSIX systems, these streams are buffering wrappers around file descriptors:

- `stdin` is a buffered stream for reading input from the user, wrapping file descriptor `STDIN_FILENO` (0).
- `stdout` is a buffered stream for writing output to the user, wrapping `STDOUT_FILENO` (1).
- `stderr` is a buffered stream for writing error messages to the user, wrapping `STDERR_FILENO` (2).

In ESP-IDF, there is no practical distinction between `stdout` and `stderr`, as both streams are sent to the same physical interface. Most applications will use only `stdout`. For example, ESP-IDF logging functions always write to `stdout` regardless of the log level.

The underlying stdin, stdout, and stderr file descriptors are implemented based on *VFS drivers*.

On ESP32-C3, ESP-IDF provides implementations of VFS drivers for I/O over:

- UART
- USB Serial/JTAG
- "Null" (no output)

Standard I/O is not limited to these options, though. See below on enabling custom destinations for standard I/O.

4.29.1 Configuration

Built-in implementations of standard I/O can be selected using several Kconfig options:

- *CONFIG_ESP_CONSOLE_UART_DEFAULT* —Enables UART with default options (pin numbers, baud rate) for standard I/O.
- *CONFIG_ESP_CONSOLE_UART_CUSTOM* —Enables UART for standard I/O, with TX/RX pin numbers and baud rate configurable via Kconfig.
- *CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG* —Enables USB Serial/JTAG for standard I/O. See *USB Serial/JTAG Controller Console* for details about hardware connections required.
- *CONFIG_ESP_CONSOLE_NONE* —Disables standard I/O. If this option is selected, `stdin`, `stdout`, and `stderr` will be mapped to `/dev/null` and won't produce any output or generate any input.

Enabling one of these option will cause the corresponding VFS driver to be built into the application and used to open `stdin`, `stdout`, and `stderr` streams. Data written to `stdout` and `stderr` will be sent over the selected interface, and input from the selected interface will be available on `stdin`.

Secondary output

ESP-IDF has built-in support for sending standard output to a secondary destination. This option makes the application output visible on two interfaces at once, for example on both UART and USB Serial/JTAG.

Note that secondary console is output-only:

- data written to `stdout` and `stderr` by the application will be sent to both primary and secondary consoles
- `stdin` will only contain data sent by the host to the primary console.

The following secondary console options are available:

- *CONFIG_ESP_CONSOLE_SECONDARY_USB_SERIAL_JTAG*

4.29.2 Standard Streams and FreeRTOS Tasks

In ESP-IDF, to save RAM, `FILE` objects for `stdin`, `stdout`, and `stderr` are shared between all FreeRTOS tasks, but the pointers to these objects are unique for every task. This means that:

- It is possible to change `stdin`, `stdout`, and `stderr` for any given task without affecting other tasks, e.g., by doing `stdin = fopen("/dev/uart/1", "r")`.
- To change the default `stdin`, `stdout`, `stderr` streams for new tasks, modify `_GLOBAL_REENT->_stdin` (`_stdout`, `_stderr`) before creating the task.
- Closing default `stdin`, `stdout`, or `stderr` using `fclose` closes the `FILE` stream object, which will affect all other tasks.

Each stream (`stdin`, `stdout`, `stderr`) has a mutex associated with it. This mutex is used to protect the stream from concurrent access by multiple tasks. For example, if two tasks are writing to `stdout` at the same time, the mutex will ensure that the outputs from each task are not mixed together.

4.29.3 Blocking and non-blocking I/O

UART

By default, UART VFS uses simplified functions for reading from and writing to UART. Writes busy-wait until all data is put into UART FIFO, and reads are non-blocking, returning only the data present in the FIFO. Due to this non-blocking read behavior, higher level C library calls, such as `fscanf("%d\n", &var);`, might not have desired results.

Applications which use the UART driver can instruct VFS to use the driver's interrupt driven, blocking read and write functions instead. This can be done using a call to the *`uart_vfs_dev_use_driver()`* function. It is also possible to revert to the basic non-blocking functions using a call to *`uart_vfs_dev_use_nonblocking()`*.

When the interrupt-driven driver is installed, it is also possible to enable/disable non-blocking behavior using `fcntl` function with `O_NONBLOCK` flag.

USB Serial/JTAG

Similar to UART, the VFS driver for USB Serial/JTAG defaults to a simplified implementation: writes are blocking (busy-wait until all the data has been sent) and reads are non-blocking, returning only the data present in the FIFO. This behavior can be changed to use the interrupt driven, blocking read and write functions of USB Serial/JTAG driver using a call to the `usb_serial_jtag_vfs_use_nonblocking()` function. Note that the USB Serial/JTAG driver has to be initialized using `usb_serial_jtag_driver_install()` beforehand. It is also possible to revert to the basic non-blocking functions using a call to `usb_serial_jtag_vfs_use_nonblocking()`.

When the interrupt-driven driver is installed, it is also possible to enable/disable non-blocking behavior using `fcntl` function with `O_NONBLOCK` flag.

4.29.4 Newline conversion

VFS drivers provide an optional newline conversion feature for input and output. Internally, most applications send and receive lines terminated by the LF (`\n`) character. Different terminal programs may require different line termination, such as CR or CRLF.

Applications can configure this behavior globally using the following Kconfig options:

- *CONFIG_NEWLIB_STDOUT_LINE_ENDING_CRLF*, *CONFIG_NEWLIB_STDOUT_LINE_ENDING_CR*, *CONFIG_NEWLIB_STDOUT_LINE_ENDING_LF* - for output
- *CONFIG_NEWLIB_STDIN_LINE_ENDING_CRLF*, *CONFIG_NEWLIB_STDIN_LINE_ENDING_CR*, *CONFIG_NEWLIB_STDIN_LINE_ENDING_LF* - for input

It is also possible to configure line ending conversion for the specific VFS driver:

- For UART: *`uart_vfs_dev_port_set_rx_line_endings()`* and *`uart_vfs_dev_port_set_tx_line_endings()`*
- For USB Serial/JTAG: `usb_serial_jtag_vfs_set_rx_line_endings()` and `usb_serial_jtag_vfs_set_tx_line_endings()`

4.29.5 Buffering

By default, standard I/O streams are line buffered. This means that data written to the stream is not sent to the underlying device until a newline character is written, or the buffer is full. This means, for example, that if you call `printf("Hello")`, the text will not be sent to the UART until you call `printf("\n")` or the stream buffer fills up due to other prints.

This behavior can be changed using the `setvbuf()` function. For example, to disable buffering for `stdout`:

```
setvbuf(stdout, NULL, _IONBF, 0);
```

You can also use `setvbuf()` to increase the buffer size, or switch to fully buffered mode.

4.29.6 Custom channels for standard I/O

To send application output to a custom channel (for example, a WebSocket connection), it is possible to create a custom VFS driver. See the *VFS documentation* for details. The VFS driver has to implement at least the following functions:

- `open()` and `close()`
- `write()`
- `read()` —only if the custom channel is also used for input
- `fstat()` —recommended, to provide correct buffering behavior for the I/O streams
- `fcntl()` —only if non-blocking I/O has to be supported

Once you have created a custom VFS driver, use `esp_vfs_register()` to register it with VFS. Then, use `fopen()` to redirect `stdout` and `stderr` to the custom channel. For example:

```
FILE *f = fopen("/dev/mychannel", "w");
if (f == NULL) {
    // handle the error here
}
stdout = f;
stderr = f;
```

Note that logging functions (`ESP_LOGE()`, etc.) write their output to `stdout`. Keep this in mind when using logging within the implementation of your custom VFS (or any components which it calls). For example, if the custom VFS driver's `write()` operation fails and uses `ESP_LOGE()` to log the error, this will cause the output to be sent to `stdout`, which would again call the custom VFS driver's `write()` operation. This would result in an infinite loop. It is recommended to keep track of this re-entry condition in the VFS driver's `write()` implementation, and return immediately if the write operation is still in progress.

4.30 Thread Local Storage

4.30.1 Overview

Thread-local storage (TLS) is a mechanism by which variables are allocated such that there is one instance of the variable per extant thread. ESP-IDF provides three ways to make use of such variables:

- *FreeRTOS Native APIs*: ESP-IDF FreeRTOS native APIs.
- *Pthread APIs*: ESP-IDF pthread APIs.
- *C11 Standard*: C11 standard introduces special keywords to declare variables as thread local.

4.30.2 FreeRTOS Native APIs

The ESP-IDF FreeRTOS provides the following APIs to manage thread local variables:

- *`vTaskSetThreadLocalStoragePointer()`*
- *`pvTaskGetThreadLocalStoragePointer()`*
- *`vTaskSetThreadLocalStoragePointerAndDelCallback()`*

In this case, the maximum number of variables that can be allocated is limited by *CONFIG_FREERTOS_THREAD_LOCAL_STORAGE_POINTERS*. Variables are kept in the task control block (TCB) and accessed by their index. Note that index 0 is reserved for ESP-IDF internal uses.

Using the APIs above, you can allocate thread local variables of an arbitrary size, and assign them to any number of tasks. Different tasks can have different sets of TLS variables.

If size of the variable is more than 4 bytes, then you need to allocate/deallocate memory for it. Variable's deallocation is initiated by FreeRTOS when task is deleted, but user must provide callback function to do proper cleanup.

4.30.3 Pthread APIs

The ESP-IDF provides the following *POSIX Support (Including POSIX Threads Support)* to manage thread local variables:

- `pthread_key_create()`
- `pthread_key_delete()`
- `pthread_getspecific()`
- `pthread_setspecific()`

These APIs have all benefits of the ones above, but eliminates some their limits. The number of variables is limited only by size of available memory on the heap. Due to the dynamic nature, this API introduces additional performance overhead compared to the native one.

4.30.4 C11 Standard

The ESP-IDF FreeRTOS supports thread local variables according to C11 standard, ones specified with `__thread` keyword. For details on this feature, please refer to the GCC documentation.

Storage for that kind of variables is allocated on the task stack. Note that area for all such variables in the program is allocated on the stack of every task in the system even if that task does not use such variables at all. For example, ESP-IDF system tasks (e.g., `ipc`, `timer` tasks etc.) will also have that extra stack space allocated. Thus feature should be used with care.

Using C11 thread local variables comes at a trade-off. On one hand, they are quite handy to use in programming and can be accessed using minimal CPU instructions. However, this benefit comes at the cost of additional stack usage for all tasks in the system. Due to static nature of variables allocation, all tasks in the system have the same sets of C11 thread local variables.

4.31 Tools

4.31.1 IDF Frontend - `idf.py`

The `idf.py` command-line tool provides a front-end for easily managing your project builds, deployment and debugging, and more. It manages several tools, for example:

- CMake, which configures the project to be built.
- Ninja, which builds the project.
- esptool.py, which flashes the target.

The *Step 5. First Steps on ESP-IDF* contains a brief introduction on how to set up `idf.py` to configure, build, and flash projects.

Important: `idf.py` should be run in an ESP-IDF project directory, i.e., a directory containing a `CMakeLists.txt` file. Older style projects that contain a `Makefile` will not work with `idf.py`.

Commands

Start a New Project: `create-project`

```
idf.py create-project <project name>
```

This command creates a new ESP-IDF project. Additionally, the folder where the project will be created in can be specified by the `--path` option.

Create a New Component: `create-component`

```
idf.py create-component <component name>
```

This command creates a new component, which will have a minimum set of files necessary for building. The `-C` option can be used to specify the directory the component will be created in. For more information about components see the *Component CMakeLists Files*.

Select the Target Chip: `set-target` ESP-IDF supports multiple targets (chips). A full list of supported targets in your version of ESP-IDF can be seen by running `idf.py --list-targets`.

```
idf.py set-target <target>
```

This command sets the current project target.

Important: `idf.py set-target` will clear the build directory and re-generate the `sdkconfig` file from scratch. The old `sdkconfig` file will be saved as `sdkconfig.old`.

Note: The behavior of the `idf.py set-target` command is equivalent to:

1. clearing the build directory (`idf.py fullclean`)
2. removing the sdkconfig file (`mv sdkconfig sdkconfig.old`)
3. configuring the project with the new target (`idf.py -DIDF_TARGET=esp32 reconfigure`)

It is also possible to pass the desired `IDF_TARGET` as an environment variable (e.g., `export IDF_TARGET=esp32s2`) or as a CMake variable (e.g., `-DIDF_TARGET=esp32s2` argument to CMake or `idf.py`). Setting the environment variable is a convenient method if you mostly work with one type of the chip.

To specify the default value of `IDF_TARGET` for a given project, please add the `CONFIG_IDF_TARGET` option to the project's `sdkconfig.defaults` file, e.g., `CONFIG_IDF_TARGET="esp32s2"`. This value of the option will be used if `IDF_TARGET` is not specified by other methods, such as using an environment variable, a CMake variable, or the `idf.py set-target` command.

If the target has not been set by any of these methods, the build system will default to `esp32` target.

Start the Graphical Configuration Tool: `menuconfig`

```
idf.py menuconfig
```

Build the Project: `build`

```
idf.py build
```

This command builds the project found in the current directory. This can involve multiple steps:

- Create the build directory if needed. The sub-directory "build" is used to hold build output, although this can be changed with the `-B` option.
- Run CMake as necessary to configure the project and generate build files for the main build tool.
- Run the main build tool (Ninja or *GNU Make*). By default, the build tool is automatically detected but it can be explicitly set by passing the `-G` option to `idf.py`.

Building is incremental, so if no source files or configuration has changed since the last build, nothing will be done.

Additionally, the command can be run with `app`, `bootloader` and `partition-table` arguments to build only the app, bootloader or partition table as applicable.

Remove the Build Output: `clean`

```
idf.py clean
```

This command removes the project build output files from the build directory, and the project will be fully rebuilt on next build. Using this command does not remove the CMake configuration output inside the build folder.

Delete the Entire Build Contents: `fullclean`

```
idf.py fullclean
```

This command deletes the entire build directory contents, which includes all CMake configuration output. The next time the project is built, CMake will configure it from scratch. Note that this option recursively deletes **all** files in the build directory, so use with care. Project configuration is not deleted.

Flash the Project: `flash`

```
idf.py flash
```

This command automatically builds the project if necessary, and then flash it to the target. You can use `-p` and `-b` options to set serial port name and flasher baud rate, respectively.

Note: The environment variables `ESPPORT` and `ESPBAUD` can be used to set default values for the `-p` and `-b` options, respectively. Providing these options on the command line overrides the default.

`idf.py` uses the `write_flash` command of `esptool.py` under the hood to flash the target. You can pass additional arguments to configure the flash writing process using the `--extra-args` option. For example, to write to an external SPI flash chip, use the following command: `idf.py flash --extra-args="--spi-connection <CLK>,<Q>,<D>,<HD>,<CS>"`. To see the full list of available arguments, run `esptool.py write_flash --help` or see the esptool.py documentation.

Similarly to the `build` command, the command can be run with `app`, `bootloader` and `partition-table` arguments to flash only the app, bootloader or partition table as applicable.

Merge binaries: `merge-bin`

```
idf.py merge-bin [-o output-file] [-f format] [<format-specific-options>]
```

There are some situations, e.g. transferring the file to another machine and flashing it without ESP-IDF, where it is convenient to have only one file for flashing instead the several file output of `idf.py build`.

The command `idf.py merge-bin` will merge the bootloader, partition table, the application itself, and other partitions (if there are any) according to the project configuration and create a single binary file `merged-binary.[bin|hex]` in the build folder, which can then be flashed later.

It is possible to output merged file in binary (raw), IntelHex (hex) and UF2 (uf2) formats.

The uf2 binary can also be generated by *idf.py uf2*. The `idf.py uf2` is functionally equivalent to `idf.py merge-bin -f uf2`. However, the `idf.py merge-bin` command provides more flexibility and options for merging binaries into various formats described above.

Example usage:

```
idf.py merge-bin -o my-merged-binary.bin -f raw
```

There are also some format specific options, which are listed below:

- Only for raw format:
  - `--flash-offset`: This option will create a merged binary that should be flashed at the specified offset, instead of at the standard offset of 0x0.
  - `--fill-flash-size`: If set, the final binary file will be padded with FF bytes up to this flash size in order to fill the full flash content with the image and re-write the whole flash chip upon flashing.
- Only for uf2 format:
  - `--md5-disable`: This option will disable MD5 checksums at the end of each block. This can be useful for integration with e.g. tinyuf2.

Hints on How to Resolve Errors

`idf.py` will try to suggest hints on how to resolve errors. It works with a database of hints stored in tools/idf_py_actions/hints.yml and the hints will be printed if a match is found for the given error. The menuconfig target is not supported at the moment by automatic hints on resolving errors.

The `--no-hints` argument of `idf.py` can be used to turn the hints off in case they are not desired.

Important Notes

Multiple `idf.py` commands can be combined into one. For example, `idf.py -p COM4 clean flash monitor` will clean the source tree, then build the project and flash it to the target before running the serial monitor.

The order of multiple `idf.py` commands on the same invocation is not important, as they will automatically be executed in the correct order for everything to take effect (e.g., building before flashing, erasing before flashing).

For commands that are not known to `idf.py`, an attempt to execute them as a build system target will be made.

The command `idf.py` supports shell autocompletion for bash, zsh and fish shells.

To enable autocompletion for `idf.py`, use the `export` command (*Step 4. Set up the environment variables*). Autocompletion is initiated by pressing the TAB key. Type `idf.py -` and press the TAB key to autocomplete options.

The autocomplete support for PowerShell is planned in the future.

Advanced Commands

Open the Documentation: `docs`

```
idf.py docs
```

This command opens the documentation for the projects target and ESP-IDF version in the browser.

Show Size: `size`

```
idf.py size
```

This command prints app size information including the occupied RAM and flash and section (i.e., .bss) sizes.

```
idf.py size-components
```

Similarly, this command prints the same information for each component used in the project.

```
idf.py size-files
```

This command prints size information per source file in the project.

Options

- `--format` specifies the output format with available options: `text`, `csv`, `json`, default being `text`.
- `--output-file` optionally specifies the name of the file to print the command output to instead of the standard output.

Reconfigure the Project: `reconfigure`

```
idf.py reconfigure
```

This command forces CMake to be rerun regardless of whether it is necessary. It is unnecessary during normal usage, but can be useful after adding/removing files from the source tree, or when modifying CMake cache variables. For example, `idf.py -DNAME='VALUE' reconfigure` can be used to set variable `NAME` in CMake cache to value `VALUE`.

Clean the Python Byte Code: `python-clean`

```
idf.py python-clean
```

This command deletes generated python byte code from the ESP-IDF directory. The byte code may cause issues when switching between ESP-IDF and Python versions. It is advised to run this target after switching versions of Python.

Generate a UF2 Binary: `uf2`

```
idf.py uf2
```

This command generates a UF2 (USB Flashing Format) binary `uf2.bin` in the build directory. This file includes all the necessary binaries (bootloader, app, and partition table) for flashing the target.

This UF2 file can be copied to a USB mass storage device exposed by another ESP running the ESP USB Bridge project. The bridge MCU will use it to flash the target MCU. This is as simple as copying (or "drag-and-dropping") the file to the exposed disk accessed by a file explorer in your machine.

To generate a UF2 binary for the application only (not including the bootloader and partition table), use the `uf2-app` command.

The `idf.py uf2` command is functionally equivalent to `idf.py merge-bin -f uf2` described *above*. However, the `idf.py merge-bin` command provides more flexibility and options for merging binaries into various formats, not only uf2.

```
idf.py uf2-app
```

Read Otadata Partition: `read-otadata`

```
idf.py read-otadata
```

This command prints the contents of the `otadata` partition which stores the information about the currently selected OTA app slot. Refer to *Over The Air Updates (OTA)* for more about the `otadata` partition.

Global Options

To list all available root level options, run `idf.py --help`. To list options that are specific for a subcommand, run `idf.py <command> --help`, e.g., `idf.py monitor --help`. Here is a list of some useful options:

- `-C <dir>` allows overriding the project directory from the default current working directory.
- `-B <dir>` allows overriding the build directory from the default `build` subdirectory of the project directory.
- `--ccache` enables CCache when compiling source files if the CCache tool is installed. This can dramatically reduce the build time.

Important: Note that some older versions of CCache may exhibit bugs on some platforms, so if files are not rebuilt as expected, try disabling CCache and rebuilding the project. To enable CCache by default, set the `IDF_CCACHE_ENABLE` environment variable to a non-zero value.

- `-v` flag causes both `idf.py` and the build system to produce verbose build output. This can be useful for debugging build problems.

- `--cmake-warn-uninitialized` (or `-w`) causes CMake to print uninitialized variable warnings found in the project directory only. This only controls CMake variable warnings inside CMake itself, not other types of build warnings. This option can also be set permanently by setting the `IDF_CMAKE_WARN_UNINITIALIZED` environment variable to a non-zero value.
- `--no-hints` flag disables hints on resolving errors and disable capturing output.

Passing arguments via a `@file` It is possible to pass multiple arguments to `idf.py` via a file. The file or path to the file must be annotated with `@` at the beginning. Arguments in the file can be separated by newlines or spaces and are expanded exactly as if they had appeared in that order on the idf.py command line.

For example, let's have a file *custom_flash.txt*:

```
flash --baud 115200
```

Then the command can be executed as: `idf.py @custom_flash.txt monitor`

Arguments from a file can be combined with additional command line arguments, and multiple files annotated with `@` can be used simultaneously. For instance, if there is a second file `another_config.txt`, both can be utilized by specifying `idf.py @custom_flash.txt @another_config.txt monitor`.

A further example of how this argument file can be used, e.g., creating configuration profile files via @filename, is in the Multiple Build Configurations Example .

4.31.2 IDF Monitor

IDF Monitor uses the esp-idf-monitor package as a serial terminal program which relays serial data to and from the target device's serial port. It also provides some ESP-IDF-specific features.

IDF Monitor can be launched from an ESP-IDF project by running `idf.py monitor`.

Keyboard Shortcuts

For easy interaction with IDF Monitor, use the keyboard shortcuts given in the table. These keyboard shortcuts can be customized, for more details see *Configuration File* section.

Keyboard Shortcut	Action	Description
Ctrl +]	Exit the program	
Ctrl + T	Menu escape key	Press and follow it by one of the keys given below.
• Ctrl + T	Send the menu character itself to remote	
• Ctrl +]	Send the exit character itself to remote	
• Ctrl + P	Reset target into bootloader to pause app via RTS and DTR lines	Resets the target into the bootloader using the RTS and DTR lines (if connected). This stops the board from executing the application, making it useful when waiting for another device to start. For additional details, refer to *Target Reset into Bootloader*.
• Ctrl + R	Reset target board via RTS	Resets the target board and re-starts the application via the RTS line (if connected).
• Ctrl + F	Build and flash the project	Pauses idf_monitor to run the project `flash` target, then resumes idf_monitor. Any changed source files are recompiled and then re-flashed. Target `encrypted-flash` is run if idf_monitor was started with argument `-E`.
• Ctrl + A (or A)	Build and flash the app only	Pauses idf_monitor to run the `app-flash` target, then resumes idf_monitor. Similar to the `flash` target, but only the main app is built and re-flashed. Target `encrypted-app-flash` is run if idf_monitor was started with argument `-E`.
• Ctrl + Y	Stop/resume log output printing on screen	Discards all incoming serial data while activated. Allows to quickly pause and examine log output without quitting the monitor.
• Ctrl + L	Stop/resume log output saved to file	Creates a file in the project directory and the output is written to that file until this is disabled with the same keyboard shortcut (or IDF Monitor exits).
• Ctrl + I (or I)	Stop/resume printing timestamps	IDF Monitor can print a timestamp in the beginning of each line. The timestamp format can be changed by the `--timestamp-format` command line argument.
• Ctrl + H (or H)	Display all keyboard shortcuts	
• Ctrl + X (or X)	Exit the program	
Ctrl + C	Interrupt running application	Pauses IDF Monitor and runs GDB project debugger to debug the application at runtime. This requires *CONFIG_ESP_SYSTEM_GDBSTUB_RUNTIME* option to be enabled.

Any keys pressed, other than `Ctrl-]` and `Ctrl-T`, will be sent through the serial port.

ESP-IDF-specific Features

Automatic Address Decoding Whenever the chip outputs a hexadecimal address that points to executable code, IDF monitor looks up the location in the source code (file name and line number) and prints the location on the next line in yellow.

If an ESP-IDF app crashes and panics, a register dump and backtrace are produced, such as the following:

```
abort() was called at PC 0x42067cd5 on core 0
```

(continues on next page)

(continued from previous page)

```

```

To decode each address, IDF Monitor runs the following command in the background:

```
riscv32-esp-elf-addr2line -pfiaC -e build/PROJECT.elf ADDRESS
```

If an address is not matched in the app source code, IDF monitor also checks the ROM code. Instead of printing the source file name and line number, only the function name followed by `in ROM` is displayed:

```
abort() was called at PC 0x400481c1 on core 0
0x400481c1: ets_rsa_pss_verify in ROM

```

The ROM ELF file is automatically loaded from a location based on the `IDF_PATH` and `ESP_ROM_ELF_DIR` environment variables. This can be overridden by calling `esp_idf_monitor` and providing a path to a specific ROM ELF file: `python -m esp_idf_monitor --rom-elf-file [path to ROM ELF file]`.

Note: Set environment variable `ESP_MONITOR_DECODE` to `0` or call esp_idf_monitor with specific command line option: `python -m esp_idf_monitor --disable-address-decoding` to disable address decoding.

Target Reset on Connection By default, IDF Monitor will reset the target when connecting to it. The reset of the target chip is performed using the DTR and RTS serial lines. To prevent IDF Monitor from automatically resetting the target on connection, call IDF Monitor with the `--no-reset` option (e.g., `idf.py monitor --no-reset`). You can also set the environment variable `ESP_IDF_MONITOR_NO_RESET` to `1` to achieve the same behavior.

Note: The `--no-reset` option applies the same behavior even when connecting IDF Monitor to a particular port (e.g., `idf.py monitor --no-reset -p [PORT]`).

Target Reset into Bootloader IDF Monitor provides the capability to reset a chip into the bootloader using a pre-defined reset sequence that has been tuned to work in most environments. Additionally, users have the flexibility to set a custom reset sequence, allowing for fine-tuning and adaptability to diverse scenarios.

Using Pre-defined Reset Sequence IDF Monitor's default reset sequence is designed to work seamlessly across a wide range of environments. To trigger a reset into the bootloader using the default sequence, no additional configuration is required.

Custom Reset Sequence For more advanced users or specific use cases, IDF Monitor supports the configuration of a custom reset sequence using *Configuration File*. This is particularly useful in extreme edge cases where the default sequence may not suffice.

The sequence is defined with a string in the following format:

- Consists of individual commands divided by `|` (e.g. `R0|D1|W0.5`).
- Commands (e.g. `R0`) are defined by a code (`R`) and an argument (`0`).

Code	Action	Argument
D	Set DTR control line	`1/0`
R	Set RTS control line	`1/0`
U	Set DTR and RTS control lines at the same time (Unix-like systems only)	`0,0/0,1/1,0/1,1`
W	Wait for `N` seconds (where `N` is a float)	N

Example:

```
[esp-idf-monitor]
custom_reset_sequence = U0,1|W0.1|D1|R0|W0.5|D0
```

Refer to custom reset sequence from Esptool documentation for further details. Please note that `custom_reset_sequence` is the only used value from the Esptool configuration, and others will be ignored in IDF Monitor.

Share Configuration Across Tools The configuration for the custom reset sequence can be specified in a shared configuration file between IDF Monitor and Esptool. In this case, your configuration file name should be either `setup.cfg` or `tox.ini` so it would be recognized by both tools.

Example of a shared configuration file:

```
[esp-idf-monitor]
menu_key = T
skip_menu_key = True

[esptool]
custom_reset_sequence = U0,1|W0.1|D1|R0|W0.5|D0
```

Note: When using the `custom_reset_sequence` parameter in both the `[esp-idf-monitor]` section and the `[esptool]` section, the configuration from the `[esp-idf-monitor]` section will take precedence in IDF Monitor. Any conflicting configuration in the `[esptool]` section will be ignored.

This precedence rule also applies when the configuration is spread across multiple files. The global esp-idf-monitor configuration will take precedence over the local esptool configuration.

Launching GDB with GDBStub GDBStub is a useful runtime debugging feature that runs on the target and connects to the host over the serial port to receive debugging commands. GDBStub supports commands such as reading memory and variables, examining call stack frames etc. Although GDBStub is less versatile than JTAG debugging, it does not require any special hardware (such as a JTAG to USB bridge) as communication is done entirely over the serial port.

A target can be configured to run GDBStub in the background by setting the *CONFIG_ESP_SYSTEM_GDBSTUB_RUNTIME*. GDBStub will run in the background until a `Ctrl+C` message is sent over the serial port and causes the GDBStub to break (i.e., stop the execution of) the program, thus allowing GDBStub to handle debugging commands.

Furthermore, the panic handler can be configured to run GDBStub on a crash by setting the *CONFIG_ESP_SYSTEM_PANIC* to `GDBStub on panic`. When a crash occurs, GDBStub will output a special string pattern over the serial port to indicate that it is running.

In both cases (i.e., sending the `Ctrl+C` message, or receiving the special string pattern), IDF Monitor will automatically launch GDB in order to allow the user to send debugging commands. After GDB exits, the target is reset via the RTS serial line. If this line is not connected, users can reset their target (by pressing the board's Reset button).

Note: In the background, IDF Monitor runs the following command to launch GDB:

```
riscv32-esp-elf-gdb -ex "set serial baud BAUD" -ex "target remote PORT" -ex␣
↪interrupt build/PROJECT.elf :idf_target:`Hello NAME chip`
```

Output Filtering IDF monitor can be invoked as `idf.py monitor --print-filter="xyz"`, where `--print-filter` is the parameter for output filtering. The default value is an empty string, which means that everything is printed. Filtering can also be configured using the `ESP_IDF_MONITOR_PRINT_FILTER` environment variable.

Note: When using both the environment variable `ESP_IDF_MONITOR_PRINT_FILTER` and the argument `--print-filter`, the setting from the CLI argument will take precedence.

Restrictions on what to print can be specified as a series of `<tag>:<log_level>` items where `<tag>` is the tag string and `<log_level>` is a character from the set `{N, E, W, I, D, V, *}` referring to a level for *logging*.

For example, `--print_filter="tag1:W"` matches and prints only the outputs written with `ESP_LOGW("tag1", ...)` or at lower verbosity level, i.e., `ESP_LOGE("tag1", ...)`. Not specifying a `<log_level>` or using `*` defaults to a Verbose level.

Note: Use primary logging to disable at compilation the outputs you do not need through the *logging library*. Output filtering with the IDF monitor is a secondary solution that can be useful for adjusting the filtering options without recompiling the application.

Your app tags must not contain spaces, asterisks `*`, or colons `:` to be compatible with the output filtering feature.

If the last line of the output in your app is not followed by a carriage return, the output filtering might get confused, i.e., the monitor starts to print the line and later finds out that the line should not have been written. This is a known issue and can be avoided by always adding a carriage return (especially when no output follows immediately afterwards).

Examples of Filtering Rules:

- `*` can be used to match any tags. However, the string `--print_filter="*:I tag1:E"` with regards to `tag1` prints errors only, because the rule for `tag1` has a higher priority over the rule for `*`.
- The default (empty) rule is equivalent to `*:V` because matching every tag at the Verbose level or lower means matching everything.
- `"*:N"` suppresses not only the outputs from logging functions, but also the prints made by `printf`, etc. To avoid this, use `*:E` or a higher verbosity level.
- Rules `"tag1:V"`, `"tag1:v"`, `"tag1:"`, `"tag1:*"`, and `"tag1"` are equivalent.
- Rule `"tag1:W tag1:E"` is equivalent to `"tag1:E"` because any consequent occurrence of the same tag name overwrites the previous one.
- Rule `"tag1:I tag2:W"` only prints `tag1` at the Info verbosity level or lower and `tag2` at the Warning verbosity level or lower.
- Rule `"tag1:I tag2:W tag3:N"` is essentially equivalent to the previous one because `tag3:N` specifies that `tag3` should not be printed.
- `tag3:N` in the rule `"tag1:I tag2:W tag3:N *:V"` is more meaningful because without `tag3:N` the `tag3` messages could have been printed; the errors for `tag1` and `tag2` will be printed at the specified (or lower) verbosity level and everything else will be printed by default.

A More Complex Filtering Example The following log snippet was acquired without any filtering options:

```
load:0x40078000,len:13564
entry 0x40078d4c
E (31) esp_image: image at 0x30000 has invalid magic byte
W (31) esp_image: image at 0x30000 has invalid SPI mode 255
E (39) boot: Factory app partition is not bootable
I (568) cpu_start: Pro cpu up.
I (569) heap_init: Initializing. RAM available for dynamic allocation:
I (603) cpu_start: Pro cpu start user code
D (309) light_driver: [light_init, 74]:status: 1, mode: 2
D (318) vfs: esp_vfs_register_fd_range is successful for range <54; 64) and VFS ID␣
↪1
I (328) wifi: wifi driver task: 3ffdbf84, prio:23, stack:4096, core=0
```

The captured output for the filtering options `--print_filter="wifi esp_image:E light_driver:I"` is given below:

```
E (31) esp_image: image at 0x30000 has invalid magic byte
I (328) wifi: wifi driver task: 3ffdbf84, prio:23, stack:4096, core=0
```

The options `--print_filter="light_driver:D esp_image:N boot:N cpu_start:N vfs:N wifi:N *:V"` show the following output:

```
load:0x40078000,len:13564
entry 0x40078d4c
I (569) heap_init: Initializing. RAM available for dynamic allocation:
D (309) light_driver: [light_init, 74]:status: 1, mode: 2
```

Configuration File

`esp-idf-monitor` is using C0 control codes to interact with the console. Characters from the config file are converted to their C0 control codes. Available characters include the English alphabet (A-Z) and special symbols: `[`, `]`, `\`, `^`, `_`.

Warning: Please note that some characters may not work on all platforms or can be already reserved as a shortcut for something else. Use this feature with caution!

File Location The default name for a configuration file is `esp-idf-monitor.cfg`. First, the same directory `esp-idf-monitor` is being run if is inspected.

If a configuration file is not found here, the current user's OS configuration directory is inspected next:

- Linux: `/home/<user>/.config/esp-idf-monitor/`
- MacOS `/Users/<user>/.config/esp-idf-monitor/`
- Windows: `c:\Users\<user>\AppData\Local\esp-idf-monitor\`

If a configuration file is still not found, the last inspected location is the home directory:

- Linux: `/home/<user>/`
- MacOS `/Users/<user>/`
- Windows: `c:\Users\<user>\`

On Windows, the home directory can be set with the `HOME` or `USERPROFILE` environment variables. Therefore, the Windows configuration directory location also depends on these.

A different location for the configuration file can be specified with the `ESP_IDF_MONITOR_CFGFILE` environment variable, e.g., `ESP_IDF_MONITOR_CFGFILE = ~/custom_config.cfg`. This overrides the search priorities described above.

`esp-idf-monitor` will read settings from other usual configuration files if no other configuration file is used. It automatically reads from `setup.cfg` or `tox.ini` if they exist.

Configuration Options Below is a table listing the available configuration options:

Option Name	Description	Default Value
menu_key	Key to access the main menu.	`T`
exit_key	Key to exit the monitor.	`]`
chip_reset_key	Key to initiate a chip reset.	`R`
recompile_upload_key	Key to recompile and upload.	`F`
recompile_upload_app_key	Key to recompile and upload just the application.	`A`
toggle_output_key	Key to toggle the output display.	`Y`
toggle_log_key	Key to toggle the logging feature.	`L`
toggle_timestamp_key	Key to toggle timestamp display.	`I`
chip_reset_bootloader_key	Key to reset the chip to bootloader mode.	`P`
exit_menu_key	Key to exit the monitor from the menu.	`X`
skip_menu_key	Pressing the menu key can be skipped for menu commands.	`False`
custom_reset_sequence	Custom reset sequence for resetting into the bootloader.	N/A

Syntax The configuration file is in .ini file format: it must be introduced by an `[esp-idf-monitor]` header to be recognized as valid. This section then contains name = value entries. Lines beginning with `#` or `;` are ignored as comments.

```
# esp-idf-monitor.cfg file to configure internal settings of esp-idf-monitor
[esp-idf-monitor]
menu_key = T
exit_key = ]
chip_reset_key = R
recompile_upload_key = F
recompile_upload_app_key = A
toggle_output_key = Y
toggle_log_key = L
toggle_timestamp_key = I
chip_reset_bootloader_key = P
exit_menu_key = X
skip_menu_key = False
```

Known Issues with IDF Monitor

If you encounter any issues while using IDF Monitor, check our GitHub repository for a list of known issues and their current status. If you come across a problem that hasn't been documented yet, we encourage you to create a new issue report.

4.31.3 IDF Docker Image

IDF Docker image (`espressif/idf`) is intended for building applications and libraries with specific versions of ESP-IDF when doing automated builds.

The image contains:

- Common utilities such as `git`, `wget`, `curl`, and `zip`.
- Python 3.8 or newer.
- A copy of a specific version of ESP-IDF. See below for information about versions. `IDF_PATH` environment variable is set and points to the ESP-IDF location in the container.
- All the build tools required for the specific version of ESP-IDF: CMake, Ninja, cross-compiler toolchains, etc.
- All Python packages required by ESP-IDF are installed in a virtual environment.

The image `ENTRYPOINT` sets up the `PATH` environment variable to point to the correct version of tools, and activates the Python virtual environment. As a result, the environment is ready to use the ESP-IDF build system.

The image can also be used as a base for custom images, if additional utilities are required.

Tags

Multiple tags of this image are maintained:

- `latest`: tracks `master` branch of ESP-IDF
- `vX.Y`: corresponds to ESP-IDF release `vX.Y`
- `release-vX.Y`: tracks `release/vX.Y` branch of ESP-IDF

Note: Versions of ESP-IDF released before this feature was introduced do not have corresponding Docker image versions. You can check the up-to-date list of available tags at https://hub.docker.com/r/espressif/idf/tags.

Usage

Setting up Docker Before using the `espressif/idf` Docker image locally, make sure you have Docker installed. Follow the instructions at https://docs.docker.com/install/, if it is not installed yet.

If using the image in a CI environment, consult the documentation of your CI service on how to specify the image used for the build process.

Building a Project with CMake In the project directory, run:

```
docker run --rm -v $PWD:/project -w /project -u $UID -e HOME=/tmp espressif/idf␣
↪idf.py build
```

The above command explained:

- `docker run`: runs a Docker image. It is a shorter form of the command `docker container run`.
- `--rm`: removes the container when the build is finished.
- `-v $PWD:/project`: mounts the current directory on the host (`$PWD`) as `/project` directory in the container.
- `-w /project`: makes `/project` the working directory for the command.
- `-u $UID`: makes the command run with your user ID so that files are created as you (instead of root).
- `-e HOME=/tmp`: gives the user a home directory for storing temporary files created by `idf.py` in `~/.cache`.
- `espressif/idf`: uses Docker image `espressif/idf` with tag `latest`. The `latest` tag is implicitly added by Docker when no tag is specified.
- `idf.py build`: runs this command inside the container.

Note: When the mounted directory, `/project`, contains a git repository owned by a different user (`UID`) than the one running the Docker container, git commands executed within `/project` might fail, displaying an error message `fatal: detected dubious ownership in repository at '/project'`. To resolve this issue, you can designate the `/project` directory as safe by setting the IDF_GIT_SAFE_DIR environment variable during the Docker container startup. For instance, you can achieve this by including `-e IDF_GIT_SAFE_DIR='/project'` as a parameter. Additionally, multiple directories can be specified by using a `:` separator. To entirely disable this git security check, `*` can be used.

To build with a specific Docker image tag, specify it as `espressif/idf:TAG`, for example:

```
docker run --rm -v $PWD:/project -w /project -u $UID -e HOME=/tmp espressif/
↪idf:release-v4.4 idf.py build
```

You can check the up-to-date list of available tags at https://hub.docker.com/r/espressif/idf/tags.

Using the Image Interactively It is also possible to do builds interactively, to debug build issues or test the automated build scripts. Start the container with `-i -t` flags:

```
docker run --rm -v $PWD:/project -w /project -u $UID -e HOME=/tmp -it espressif/idf
```

Then inside the container, use `idf.py` as usual:

```
idf.py menuconfig
idf.py build
```

Note: Commands which communicate with the development board, such as `idf.py flash` and `idf.py monitor` does not work in the container, unless the serial port is passed through into the container. This can be done with Docker for Linux with the device option. However, currently, this is not possible with Docker for Windows (https://github.com/docker/for-win/issues/1018) and Docker for Mac (https://github.com/docker/for-mac/issues/900).

This limitation may be overcome by using remote serial ports. An example of how to do this can be found in the following *using remote serial port* section.

Note: On Linux, when adding the host serial port device into the container using options like `--device` or `--privileged`, and starting the container with a specific user using `-u $UID`, ensure that this user has read/write access to the device. This can be achieved by adding the container user into the group ID that is assigned to the device on the host, using the `--group-add` option. For instance, if the host device has the `dialout` group assigned, you can utilize `--group-add $(getent group dialout | cut -d':' -f3)` to add the container user to the host's `dialout` group.

Using Remote Serial Port The RFC2217 (Telnet) protocol can be used to remotely connect to a serial port. For more information please see the remote serial ports documentation in the ESP tool project. This method can also be used to access the serial port inside a Docker container if it cannot be accessed directly. Following is an example of how to use the Flash command from within a Docker container.

On host install and start `esp_rfc2217_server`:

- On Windows, the package is available as a one-file bundled executable created by `pyinstaller` and it can be downloaded from the esptool releases page in a ZIP archive along with other ESP tool utilities:

```
esp_rfc2217_server -v -p 4000 COM3
```

- On Linux or macOS, the package is available as part of `esptool`, which can be found in the ESP-IDF environment or by installing using `pip`:

```
pip install esptool
```

And then starting the server by executing

```
esp_rfc2217_server.py -v -p 4000 /dev/ttyUSB0
```

Now the device attached to the host can be flashed from inside a Docker container by using:

```
docker run --rm -v <host_path>:/<container_path> -w /<container_path> espressif/
↪idf idf.py --port 'rfc2217://host.docker.internal:4000?ign_set_control' flash
```

Please make sure that `<host_path>` is properly set to your project path on the host, and `<container_path>` is set as a working directory inside the container with the `-w` option. The `host.docker.internal` is a special Docker DNS name to access the host. This can be replaced with a host IP if necessary.

Building Custom Images

The Docker file in ESP-IDF repository provides several build arguments which can be used to customize the Docker image:

- `IDF_CLONE_URL`: URL of the repository to clone ESP-IDF from. Can be set to a custom URL when working with a fork of ESP-IDF. The default is `https://github.com/espressif/esp-idf.git`.
- `IDF_CLONE_BRANCH_OR_TAG`: Name of a git branch or tag used when cloning ESP-IDF. This value is passed to the `git clone` command using the `--branch` argument. The default is `master`.
- `IDF_CHECKOUT_REF`: If this argument is set to a non-empty value, `git checkout $IDF_CHECKOUT_REF` command performs after cloning. This argument can be set to the SHA of the specific commit to check out, for example, if some specific commit on a release branch is desired.
- `IDF_CLONE_SHALLOW`: If this argument is set to a non-empty value, `--depth=1 --shallow-submodules` arguments are used when performing `git clone`. Depth can be customized using `IDF_CLONE_SHALLOW_DEPTH`. Doing a shallow clone significantly reduces the amount of data downloaded and the size of the resulting Docker image. However, if switching to a different branch in

such a "shallow" repository is necessary, an additional `git fetch origin <branch>` command must be executed first.

- `IDF_CLONE_SHALLOW_DEPTH`: This argument specifies the depth value to use when doing a shallow clone. If not set, `--depth=1` will be used. This argument has effect only if `IDF_CLONE_SHALLOW` is used. Use this argument if you are building a Docker image for a branch, and the image has to contain the latest tag on that branch. To determine the required depth, run `git describe` for the given branch and note the offset number. Increment it by 1, then use it as the value of this argument. The resulting image will contain the latest tag on the branch, and consequently `git describe` command inside the Docker image will work as expected.
- `IDF_INSTALL_TARGETS`: Comma-separated list of ESP-IDF targets to install toolchains for, or `all` to install toolchains for all targets. Selecting specific targets reduces the amount of data downloaded and the size of the resulting Docker image. The default is `all`.

To use these arguments, pass them via the `--build-arg` command line option. For example, the following command builds a Docker image with a shallow clone of ESP-IDF v4.4.1 and tools for ESP32-C3 only:

```
docker build -t idf-custom:v4.4.1-esp32c3 \
    --build-arg IDF_CLONE_BRANCH_OR_TAG=v4.4.1 \
    --build-arg IDF_CLONE_SHALLOW=1 \
    --build-arg IDF_INSTALL_TARGETS=esp32c3 \
    tools/docker
```

4.31.4 IDF Windows Installer

Command-Line Parameters

Windows Installer `esp-idf-tools-setup` provides the following command-line parameters:

- `/CONFIG=[PATH]` - Path to `ini` configuration file to override default configuration of the installer. Default: `config.ini`.
- `/GITCLEAN=[yes|no]` - Perform `git clean` and remove untracked directories in offline-mode installation. Default: `yes`.
- `/GITRECURSIVE=[yes|no]` - Clone recursively all Git repository submodules. Default: yes.
- `/GITREPO=[URL|PATH]` - URL of repository to clone ESP-IDF. Default: `https://github.com/espressif/esp-idf.git`.
- `/GITRESET=[yes|no]` - Enable/Disable `git reset` of repository during installation. Default: `yes`.
- `/HELP` - Display command line options provided by Inno Setup installer.
- `/IDFDIR=[PATH]` - Path to directory where it is installed. Default: `{userdesktop}\esp-idf}`.
- `/IDFVERSION=[v4.3|v4.1|master]` - Use specific ESP-IDF version. E.g., v4.1, v4.2, master. Default: `empty`, pick the first version in the list.
- `/IDFVERSIONSURL=[URL]` - Use URL to download list of ESP-IDF versions. Default: `https://dl.espressif.com/dl/esp-idf/idf_versions.txt`.
- `/LOG=[PATH]` - Store installation log file in specific directory. Default: `empty`.
- `/OFFLINE=[yes|no]` - Execute installation of Python packages by `pip` in offline mode. The same result can be achieved by setting the environment variable `PIP_NO_INDEX`. Default: `no`.
- `/USEEMBEDDEDPYTHON=[yes|no]` - Use Embedded Python version for the installation. Set to `no` to allow the Python selection screen in the installer. Default: `yes`.
- `/PYTHONNOUSERSITE=[yes|no]` - Set `PYTHONNOUSERSITE` variable before launching any Python command to avoid loading Python packages from AppDataRoaming. Default: `yes`.
- `/PYTHONWHEELSURL=[URL]` - Specify URLs to PyPi repositories for resolving binary Python Wheel dependencies. The same result can be achieved by setting the environment variable `PIP_EXTRA_INDEX_URL`. Default: `https://dl.espressif.com/pypi`.
- `/SKIPSYSTEMCHECK=[yes|no]` - Skip System Check page. Default: `no`.
- `/VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL` - Perform silent installation.

Unattended Installation

The unattended installation of ESP-IDF can be achieved by following command-line parameters:

```
esp-idf-tools-setup-x.x.exe /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL
```

When running the installer from the command line, it detaches its process from the command line and starts a separate process in the background to perform the installation without blocking the use of the command line. The following PowerShell script allows you to wait for the installer to complete:

```
esp-idf-tools-setup-x.x.exe /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL
$InstallerProcess = Get-Process esp-idf-tools-setup
Wait-Process -Id $InstallerProcess.id
```

Custom Python and Custom Location of Python Wheels

The IDF installer is using by default embedded Python with reference to the Python Wheel mirror.

The following parameters allow to select custom Python and custom location of Python wheels:

```
esp-idf-tools-setup-x.x.exe /USEEMBEDDEDPYTHON=no /PYTHONWHEELSURL=https://pypi.
↪org/simple/
```

4.31.5 IDF Component Manager

The IDF Component Manager is a tool that downloads dependencies for any ESP-IDF CMake project. The download happens automatically during a run of CMake. It can source components either from the component registry or from a Git repository.

A list of components can be found on https://components.espressif.com/.

For detailed information about the IDF Component Manager, see the IDF Component Manager and ESP Component Registry Documentation.

Using with a Project

Dependencies for each component in the project are defined in a separate manifest file named `idf_component.yml` placed in the root of the component. The manifest file template can be created by running `idf.py create-manifest`. By default, a manifest file is created for the main component. You can explicitly either specify the directory where the manifest should be created using the `--path` option or specify the component in your `components` folder using `--component=my_component`. The `create-manifest` command can be run in the following ways:

- `idf.py create-manifest` creates a manifest file for the main component
- `idf.py create-manifest --component=my_component` creates a manifest file for the component **my_component** in the `components` directory
- `idf.py create-manifest --path="../../my_component"` creates a manifest file for the component **my_component** in the `my_component` directory

When a new manifest is added to one of the components in the project, it is necessary to reconfigure the project manually by running `idf.py reconfigure`. The build will then track changes in `idf_component.yml` manifests and automatically trigger CMake when necessary.

To add a dependency to a component (e.g., `my_component`) in your ESP-IDF project, you can run the command `idf.py add-dependency DEPENDENCY`. The `DEPENDENCY` argument represents an additional component managed by the IDF Component Manager that `my_component` depends on. It is defined in the format `namespace/name=1.0.0`, where *namespace/name* is the name of the component and *=1.0.0* is a version range of the

component, see the Versioning Documentation. By default, dependencies are added to the main component. You can either explicitly specify a directory where the manifest is located using the `--path` option, or specify the component in your `components` folder using `--component=my_component`. The `add-dependency` command can be run in the following ways:

- `idf.py add-dependency example/cmp` adds a dependency on the most recent version of `example/cmp` to the main component
- `idf.py add-dependency --component=my_component example/cmp<=3.3.3` adds a dependency on the version `<=3.3.3` of `example/cmp` to the component `my_component` in the `components` directory
- `idf.py add-dependency --path="../../my_component" example/cmp^3.3.3` adds a dependency on the version `^3.3.3` of `example/cmp` to the component `my_component` in the `my_component` directory

Note: The command `add-dependency` adds dependencies to your project explicitly from the Espressif Component Registry.

To update dependencies of the ESP-IDF project, you can run the command `idf.py update-dependencies`. You can also specify the path to the project directory using `--project-dir PATH`.

There is an example application build_system/cmake/component_manager that uses components installed by the component manager.

It is not necessary to have a manifest for components that do not need any managed dependencies.

When CMake configures the project (e.g., `idf.py reconfigure`) component manager does a few things:

- Processes `idf_component.yml` manifests for every component in the project and recursively solves dependencies.
- Creates a `dependencies.lock` file in the root of the project with a full list of dependencies.
- Downloads all dependencies to the `managed_components` directory.

The lock file `dependencies.lock` and the content of the `managed_components` directory are not supposed to be modified by a user. When the component manager runs, it always makes sure they are up to date. If these files were accidentally modified, it is possible to re-run the component manager by triggering CMake with `idf.py reconfigure`.

You may set the build property `DEPENDENCIES_LOCK` to specify the lock-file path in the top-level CMakeLists.txt. For example, adding `idf_build_set_property(DEPENDENCIES_LOCK dependencies.lock.${IDF_TARGET})` before `project(PROJECT_NAME)` could help generate different lock files for different targets.

Creating a Project From an Example

Some components on the registry contain example projects. To create a new project from an example you can run the command `idf.py create-project-from-example EXAMPLE`. The `EXAMPLE` argument should be in the format `namespace/name=1.0.0:example` where *namespace/name* is the name of the component, *=1.0.0* is a version range of the component (see the Versioning Documentation) and *example* is the example's name. You can find the list of examples for every component and the command to start a project for it in the Espressif Component Registry.

Defining Dependencies in the Manifest

You can easily define dependencies in the manifest file `idf_component.yml` by editing it directly in the text editor. Below are some basic examples that demonstrate how to define dependencies.

You can define a dependency from the registry by specifying the component name and the version range:

```
dependencies:
  # Define a dependency from the registry (https://components.espressif.com/
↪component/example/cmp)
  example/cmp: ">=1.0.0"
```

To define a dependency from a Git repository, provide the path to the component within the repository and the repository's URL:

```
dependencies:
  # Define a dependency from a Git repository
  test_component:
    path: test_component
    git: ssh://git@gitlab.com/user/components.git
```

During the development of components, you can use components from a local directory by specifying either a relative or an absolute path:

```
dependencies:
  # Define local dependency with relative path
  some_local_component:
    path: ../../projects/component
```

For detailed information about the manifest file format, see Manifest File Format Documentation.

Disabling the Component Manager

The component manager can be explicitly disabled by setting the `IDF_COMPONENT_MANAGER` environment variable to `0`.

4.31.6 IDF Clang-Tidy

The IDF Clang Tidy is a tool that uses clang-tidy to run static analysis on your current app.

> **Warning:** This functionality and the toolchain it relies on are still under development. There may be breaking changes before a final release.
>
> Only clang based toolchain is currently supported. It has to be activated by setting `IDF_TOOLCHAIN=clang` in the environment or in CMake cache before configuring the project.

> **Warning:** This tool does not support RISC-V based chips yet. For now, we do not provide clang based toolchain for RISC-V.

Prerequisites

If you have never run this tool before, take the following steps to get this tool prepared.

1. Run `idf_tools.py install esp-clang` to install the clang-tidy required binaries

   > **Note:** This toolchain is still under development. After the final release, you do not have to install them manually.

2. Run the export scripts (`export.sh` / `export.bat` / ...) again to refresh the environment variables.

Extra Commands

clang-check Run `idf.py clang-check` to re-generate the compilation database and run `clang-tidy` under your current project folder. The output would be written to `<project_dir>/warnings.txt`.

Run `idf.py clang-check --help` to see the full documentation.

clang-html-report

1. Run `pip install codereport` to install the additional dependency.
2. Run `idf.py clang-html-report` to generate an HTML report in folder `<project_dir>/html_report` according to the `warnings.txt`. Please open the `<project_dir>/html_report/index.html` in your browser to check the report.

Bug Report

This tool is hosted in espressif/clang-tidy-runner. If you were to face any bugs or have any feature request, please report them via Github issues

4.31.7 Downloadable IDF Tools

The ESP-IDF build process relies on a number of tools: cross-compiler toolchains, CMake build system, and others.

Installing the tools using an OS-specific package manager (e.g., apt, yum, brew, etc.) is the preferred method, when the required version of the tool is available. This recommendation is reflected in the *Get Started*. For example, on Linux and macOS, it is recommended to install CMake using an OS package manager.

However, some of the tools are specific to ESP-IDF and are not available in OS package repositories. Furthermore, different ESP-IDF versions require different tool versions for proper operation. To solve these two problems, ESP-IDF provides a set of scripts that can download and install the correct tool versions and set up the environment accordingly.

The rest of the document refers to these downloadable tools simply as "tools". Other kinds of tools used in ESP-IDF are:

- Python scripts bundled with ESP-IDF such as `idf.py`
- Python packages installed from PyPI

The following sections explain the installation method and provide the list of tools installed on each platform.

Note: This document is provided for advanced users who need to customize their installation, users who wish to understand the installation process, and ESP-IDF developers.

If you are looking for instructions on how to install the tools, see *Get Started*.

Tools Metadata File

The list of tools and tool versions required for each platform is located in tools/tools.json. The schema of this file is defined by tools/tools_schema.json.

This file is used by the tools/idf_tools.py script when installing the tools or setting up the environment variables.

Tools Installation Directory

The `IDF_TOOLS_PATH` environment variable specifies the location where the tools are to be downloaded and installed. If not set, the default location will be `HOME/.espressif` on Linux and macOS, and `%USER_PROFILE%\.espressif` on Windows.

Inside the `IDF_TOOLS_PATH` directory, the tools installation scripts create the following directories and files:

- `dist` —where the archives of the tools are downloaded.
- `tools` —where the tools are extracted. The tools are extracted into subdirectories: `tools/TOOL_NAME/VERSION/`. This arrangement allows different versions of tools to be installed side by side.
- `idf-env.json` —user install options, such as targets and features, are stored in this file. Targets are selected chip targets for which tools are installed and kept up-to-date. Features determine the Python package set which should be installed. These options will be discussed later.
- `python_env` —not related to the tools; virtual Python environments are installed in the sub-directories. Note that the Python environment directory can be placed elsewhere by setting the `IDF_PYTHON_ENV_PATH` environment variable.
- `espidf.constraints.*.txt` —one constraint file for each ESP-IDF release containing Python package version requirements.

GitHub Assets Mirror

Most of the tools downloaded by the tools installer are GitHub Release Assets, which are files attached to a software release on GitHub.

If GitHub downloads are inaccessible or slow to access, a GitHub assets mirror can be configured.

To use Espressif's download server, set the environment variable `IDF_GITHUB_ASSETS` to `dl.espressif.com/github_assets`, or `dl.espressif.cn/github_assets` for faster download in China. When the install process is downloading a tool from `github.com`, the URL will be rewritten to use this server instead.

Any mirror server can be used provided the URL matches the `github.com` download URL format. For any GitHub asset URL that the install process downloads, it will replace `https://github.com` with `https://${IDF_GITHUB_ASSETS}`.

Note: The Espressif download server currently does not mirror everything from GitHub, but only files attached as Assets to some releases, as well as source archives for some releases.

`idf_tools.py` Script

The tools/idf_tools.py script bundled with ESP-IDF performs several functions:

- `install`: Download the tool into the `${IDF_TOOLS_PATH}/dist` directory and extract it into `${IDF_TOOLS_PATH}/tools/TOOL_NAME/VERSION`.
  The `install` command accepts the list of tools to install in the `TOOL_NAME` or `TOOL_NAME@VERSION` format. If `all` is given, all the tools, including required and optional ones, are installed. If no argument or `required` is given, only the required tools are installed.
- `download`: Similar to `install` but doesn't extract the tools. An optional `--platform` argument may be used to download the tools for the specific platform.
- `export`: Lists the environment variables that need to be set to use the installed tools. For most of the tools, setting the `PATH` environment variable is sufficient, but some tools require extra environment variables.
  The environment variables can be listed in either `shell` or `key-value` formats, which can be set using the `--format` parameter:
  - `export` optional parameters:
    * `--unset`: Creates a statement that unsets specific global variables and restores the environment to its state before calling `export.{sh/fish}`.
    * `--add_paths_extras`: Adds extra ESP-IDF-related paths of `$PATH` to `${IDF_TOOLS_PATH}/esp-idf.json`, which is used to remove global variables when

the active ESP-IDF environment is deactivated. For example, while processing the `export.{sh/fish}` script, if new paths are added to the global variable `$PATH`, this option saves these new paths to the `${IDF_TOOLS_PATH}/esp-idf.json` file.

- `shell`: Produces output suitable for evaluation in the shell. For example, produce the following output on Linux and macOS:

```
export PATH="/home/user/.espressif/tools/tool/v1.0.0/bin:$PATH"
```

Produce the following output on Windows:

```
set "PATH=C:\Users\user\.espressif\tools\v1.0.0\bin;%PATH%"
```

Note: Exporting environment variables in Powershell format is not supported at the moment. `key-value` format may be used instead.

The output of this command may be used to update the environment variables if the shell supports it. For example

```
eval $($IDF_PATH/tools/idf_tools.py export)
```

- `key-value`: Produces output in the `VARIABLE=VALUE` format that is suitable for parsing by other scripts

```
PATH=/home/user/.espressif/tools/tool/v1.0.0:$PATH
```

Note that the script consuming this output has to perform expansion of `$VAR` or `%VAR%` patterns found in the output.

- `list`: Lists the known versions of the tools, and indicates which ones are installed.
  The following option is available to customize the output.
  - `--outdated`: Lists only outdated versions of tools installed in `IDF_TOOLS_PATH`.
- `check`: For each tool, checks whether the tool is available in the system path and in `IDF_TOOLS_PATH`.
- `install-python-env`: Creates a Python virtual environment in the `${IDF_TOOLS_PATH}/python_env` directory or directly in the directory set by the `IDF_PYTHON_ENV_PATH` environment variable, and install the required Python packages there.
  - An optional `--features` argument allows one to specify a comma-separated list of features to be added or removed.
    1. A feature that begins with − will be removed, and features with + or without any sign will be added. Example syntax for removing feature `XY` is `--features=-XY`, and for adding feature `XY` is `--features=+XY` or `--features=XY`. If both removing and adding options are provided with the same feature, no operation is performed.
    2. For each feature, a requirements file must exist. For example, feature `XY` is a valid feature if `${IDF_PATH}/tools/requirements/requirements.XY.txt` is an existing file with a list of Python packages to be installed.
    3. There is one mandatory `core` feature ensuring the core functionality of ESP-IDF, e.g., build, flash, monitor, debug in console. There can be an arbitrary number of optional features.
    4. The selected list of features is stored in `idf-env.json`.
    5. The requirement files contain a list of the desired Python packages to be installed and the `espidf.constraints.*.txt` file downloaded from https://dl.espressif.com and stored in `${IDF_TOOLS_PATH}`, which contains the package version requirements for a given ESP-IDF version.

Note: Although **it is not recommended**, the download and use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to `no`.

- `check-python-dependencies`: Checks if all required Python packages are installed. Packages from `${IDF_PATH}/tools/requirements/requirements.*.txt` files selected by the feature list of `idf-env.json` are checked with the package versions specified in the `espidf.constraints.*.txt` file.

Note: The constraint file is downloaded with the `install-python-env` command. Similar to the `install-python-env` command, the use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to `no`.

- `uninstall`: Prints and removes tools that are currently not used by the active ESP-IDF version.
  - `--dry-run`: Prints installed unused tools.
  - `--remove-archives`: Additionally removes all older versions of previously downloaded installation packages.

Install Scripts

Shell-specific user-facing installation scripts are provided in the root directory of ESP-IDF repository to facilitate tools installation. These are:

- `install.bat` for Windows Command Prompt
- `install.ps1` for Powershell
- `install.sh` for Bash
- `install.fish` for Fish

Apart from downloading and installing the tools in `IDF_TOOLS_PATH`, these scripts prepare a Python virtual environment, and install the required packages into that environment.

These scripts accept optionally a comma-separated list of chip targets and `--enable-*` arguments for enabling features. These arguments are passed to the `idf_tools.py` script which stores them in `idf-env.json`. Therefore, chip targets and features can be enabled incrementally.

To install tools for all chip targets, run the scripts without any optional arguments using `idf_tools.py install --targets=all`. Similarly, to install Python packages for core ESP-IDF functionality, run `idf_tools.py install-python-env --features=core`.

It is also possible to install tools for specific chip targets. For example, `install.sh esp32` installs tools only for ESP32. See *Step 3. Set up the Tools* for more examples.

`install.sh --enable-XY` enables feature `XY` (by running `idf_tools.py install-python-env --features=core,XY`).

Export Scripts

Since the installed tools are not permanently added to the user or system `PATH` environment variable, an extra step is required to use them in the command line. The following scripts modify the environment variables in the current shell to make the correct versions of the tools available:

- `export.bat` for Windows Command Prompt
- `export.ps1` for Powershell
- `export.sh` for Bash
- `export.fish` for Fish

Note: To modify the shell environment in Bash, `export.sh` must be "sourced" by using the `. ./export.sh` command. Please ensure to include the leading dot and space.

`export.sh` may be used with shells other than Bash (such as zsh). However, in this case, it is required to set the `IDF_PATH` environment variable before running the script. When used in Bash, the script guesses the `IDF_PATH` value from its own location.

In addition to calling `idf_tools.py`, these scripts list the directories that have been added to the `PATH`.

Other Installation Methods

Depending on the environment, more user-friendly wrappers for `idf_tools.py` are provided:

- *ESP-IDF Tools Installer* can download and install the tools. Internally the installer uses `idf_tools.py`.
- ESP-IDF Eclipse Plugin includes a menu item to set up the tools. Internally the plugin calls `idf_tools.py`.
- VSCode ESP-IDF Extension includes an onboarding flow. This flow helps set up the tools. Although the extension does not rely on `idf_tools.py`, the same installation method is used.

Custom Installation

Although the methods above are recommended for ESP-IDF users, they are not a must for building ESP-IDF applications. ESP-IDF build system expects that all the necessary tools are installed somewhere, and made available in the `PATH`.

Uninstall ESP-IDF

Uninstalling ESP-IDF requires removing both the tools and the environment variables that have been configured during the installation.

- Windows users using the *Windows ESP-IDF Tools Installer* can simply run the uninstall wizard to remove ESP-IDF.
- To remove an installation performed by running the supported *install scripts*, simply delete the *tools installation directory* including the downloaded and installed tools. Any environment variables set by the *export scripts* are not permanent and will not be present after opening a new environment.
- When dealing with a custom installation, in addition to deleting the tools as mentioned above, you may also need to manually revert any changes to environment variables or system paths that were made to accommodate the ESP-IDF tools (e.g., `IDF_PYTHON_ENV_PATH` or `IDF_TOOLS_PATH`). If you manually copied any tools, you would need to track and delete those files manually.
- If you installed any plugins like the ESP-IDF Eclipse Plugin or VSCode ESP-IDF Extension, you should follow the specific uninstallation instructions described in the documentation of those components.

Note: Uninstalling the ESP-IDF tools does not remove any project files or your code. Be mindful of what you are deleting to avoid losing any work. If you are unsure about a step, refer back to the installation instructions.

These instructions assume that the tools were installed following the procedures in this provided document. If you've used a custom installation method, you might need to adapt these instructions accordingly.

4.31.8 IDF Size

IDF Size is a tool for analyzing statically-allocated memory in ESP-IDF project. The main functionality is provided by the esp-idf-size Python package, while *idf.py* offers a more user-friendly and higher-level interface through the `size`, `size-components`, and `size-files` sub-commands. These sub-commands allow you to specify various options, such as the report's output format. For more details, please use the `--help` option. ESP-IDF also includes a handy `idf_size.py` wrapper to invoke the esp-idf-size Python module. For more information, use the command `idf_size.py --help`.

Size Summary `idf.py size`

This output provides a summary of the statically-allocated memory for different memory types in the firmware binary:

```
$ idf.py size
                                Memory Type Usage Summary
┌──────────────────────┬──────────────┬──────────┬────────────────┬────────────────┐

Total image size: 179712 bytes (.bin may be padded larger)
```

Espressif chips include various *Memory Types*, which are detailed in the Technical Reference Manual (TRM). These memory types are listed in the `Memory Type` column, along with the ELF `Sections` that are loaded into each type. The `Used` columns display the memory usage for each specific memory type or section. The `Remain` column indicates the remaining available memory for the specified memory type. The `Total` column shows the total available memory for that memory type, based on the memory region sizes defined in the linker script that map into the memory type.

Note: The `Total` memory available for each memory type, like `IRAM`, is determined by the memory region sizes specified in the link map file, which is generated by the linker script, with the MEMORY command, during the build process. The esp-idf-size tool includes YAML files for each target, detailing memory type ranges based on the TRM. The memory ranges from the link map file are mapped to these memory type ranges. This process calculates the total memory available for different memory types. Note that the total available size may differ from what is stated in the TRM, as some memory portions may be reserved for purposes such as the bootloader or cache, depending on the configuration. The remaining memory is calculated by subtracting the sizes of output `Sections` loaded to the specific memory type from the `Total` size.

Note: Certain memory types might map to the same hardware memory. On some targets, `IRAM` and `DRAM` could be mapped to the same hardware memory but at different virtual addresses, accessible through data and instruction buses. These memory types are referred to as `DIRAM` in the `Memory Type` column.

Below is a description of the most interesting memory types and output sections. Please note that all output sections with a non-zero size are included in the summary. Their names are determined by the output section names specified in the linker script.

- `DRAM`: Total amount of DRAM allocated at compile time. `Remain` indicates the amount of DRAM left to be used as heap memory at runtime. Note that due to meta data overhead, implementation constraints, and startup heap allocations, the actual size of the DRAM heap is smaller.
  - `.data`: Amount of DRAM allocated at compile time for the `.data` (i.e., all statically allocated variables that are initialized to non-zero values). `.data` also consumes space in the binary image to store the non-zero initialization values.
  - `.bss`: Amount of DRAM allocated at compile time for `.bss` (i.e., all statically allocated variables that are initialized to zero). `.bss` does not consume extra space in flash.
- `IRAM`: Total amount of IRAM allocated at compile time. `Remain` indicates the amount of IRAM left to be used as heap memory at runtime. Note that due to meta data overhead, implementation constraints, and startup heap allocations, the actual size of the IRAM heap is smaller.
  - `.text`: Amount of IRAM used for `.text` (i.e., all code that is executed from *IRAM*). `.text` also consumes space in the binary image as the code is initially stored there and is then copied over to IRAM on startup.
- `Flash Code`: Code executed from flash.
  - `.text`: Amount of flash used for `.text` (i.e., all code that is executed via the flash cache, see *IROM*).
- `Flash Data`: Data stored in flash.
  - `.rodata`: Amount of flash used for `.rodata` (i.e., read-only data that is loaded via the flash cache, see *DROM*).
- `Total image size` is the estimated total size of the binary file.

Component Usage Summary `idf.py size-components`

The summary output from `idf.py size` lacks sufficient detail to identify the primary cause of excessive binary size. For a more detailed analysis, use `idf.py size-components`, which indicates the contribution of each static library archive to the final binary size.

```
$ idf.py size-components
                                                                    Per-archive␣

```

Generally, one static library archive is built per component, although some are binary libraries included by a particular component, for example, `libnet80211.a` is included by `esp_wifi` component. There are also toolchain libraries such as `libc.a` and `libgcc.a` listed here, these provide Standard C/C++ Library and toolchain built-in functionality.

If the project is simple and only has a `main` component, then all of the project's code will be shown under `libmain.a`. If the project includes its own components (see *Build System*), then they will each be shown on a separate line.

The table is sorted in descending order of the total contribution of the static archive to the binary size. The columns indicate memory types and output sections as detailed in the Size Summary.

Note: The `(exe)` archive is a special archive that contains object files directly linked into the final binary, meaning they are not part of any archive file.

Note: The size of the `.rodata` section in the `Flash Data` memory type may appear very large for a single archive. This occurs due to linker relaxations. The linker may attempt to combine object file sections with `MERGE` and `STRINGS` flags from all archives into one to perform tail string optimization. Consequently, one archive may end up with a very large `.rodata` section, containing string literals from other archives. This is evident in the `.rodata` section of the `libesp_app_format.a` archive. The specific compiler behavior here can be turned off by enabling *CONFIG_COMPILER_NO_MERGE_CONSTANTS* option (only for GCC toolchain), please read help for more details.

Source File Usage Summary `idf.py size-files`

For even more details, run `idf.py size-files` to get a summary of the contribution each object file has made to the final binary size. Each object file corresponds to a single source file.

```
$ idf.py size-files
                                                
```

[... additional lines removed ...]
```

The table is sorted in descending order of the total contribution of the object files to the binary size. The columns indicate memory types and output sections as detailed in the Size Summary.

For example, we can see that the file `x509_crt_bundle.S.o` contributed 67,810 bytes to the total firmware size, all as `.rodata` in flash. Therefore we can guess that this application is using the *ESP x509 Certificate Bundle* feature and not using this feature would save at last this many bytes from the firmware size.

Some of the object files are linked from binary libraries and therefore you will not find a corresponding source file. To locate which component a source file belongs to, it is generally possible to search in the ESP-IDF source tree or look in the *Linker Map File* for the full path.

Comparing Two Binaries

When making changes that impact binary size, you can use the IDF Size tool to analyze the precise differences in size. The `--diff` option can be used with all previously mentioned sub-commands, allowing you to specify a path to a project build for comparison with the current project.

For example to compare two `hello_world` project builds, follow these steps. First, create two copies of the `hello_world` project directory. Name the first project directory `hello_world_Og`. This project will use the default *CONFIG_COMPILER_OPTIMIZATION* compiler optimization setting `Debug (-Og)` and will serve as the `REFERENCE` project. Name the second project directory `hello_world_Os`. This project will use the `Optimize for size (-Os)` setting, which can be enabled using `idf.py menuconfig`. This will be the `CURRENT` project. Build both projects. Then, from within the `hello_world_Os` project directory, run the following command:

```
$ idf.py size --diff ../hello_world_Og

 CURRENT   project file: "hello_world_Os/build/hello_world.map"
 REFERENCE project file: "hello_world_Og/build/hello_world.map"
 Difference is counted as CURRENT - REFERENCE, i.e. a positive number means that␣
↪CURRENT is larger.

↪     |
␣
↪└                        └              └              └                └                ┘
 Total image size: 164432 -15280 bytes (.bin may be padded larger)
```

In addition to the previously mentioned Size Summary example, each column now also shows the size differences. Each difference is shown as `CURRENT - REFERENCE`, meaning the current project sizes minus the sizes in the project specified with the *--diff* option. In this example, the final binary image of the `hello_world_Os` project is 15,280 bytes smaller than that of the `hello_world_Og` project. Additionally, the `hello_world_Os` project uses 6,168 bytes less in *Flash Code* memory, leaving 6,168 bytes more available in `Flash Code`, with no difference in the total available memory.

You can also use the diff mode to generate a table showing the differences at the component level (static library archive):

```
$ idf.py size-components --diff ../hello_world_Og
```

Additionally, at the level of each individual source file:

```
$ idf.py size-files --diff ../hello_world_Og
```

Showing Size When Linker Fails

If too much static memory is allocated, the linker will fail with an error such as `DRAM segment data does not fit, region `iram0_0_seg' overflowed by 44 bytes`, or similar.

In these cases, `idf.py size` will also fail. However, you can run `idf_size.py`, which is a convenient wrapper that allows you to call `esp-idf-size` directly from within the ESP-IDF environment and see the partial static memory usage. The `idf_size.py` script requires a link map file as an argument, which is located in the project's build directory as `<projectname>.map`.

```
$ idf_size.py <projectname>.map
warning:  DRAM overflow detected!: output section or its part .dram0.bss(addr:␣
↪1073422848, size: 2240) does not fit into any memory region and will be assigned␣

|    .bss_overflow      |         2240 |        0 |                |               |
└──────────────────────┴──────────────┴──────────┴────────────────┴───────────────┘
Total image size: 178145 bytes (.bin may be padded larger)
```

Sections that do not fit into the memory region will have the suffix `_overflow`.

4.31.9 QEMU Emulator

Espressif maintains a fork of the QEMU emulator with support for ESP32-C3. This fork implements emulation of the CPU, memory, and several peripherals of ESP32-C3. For more information about QEMU for ESP32-C3, see the QEMU README documentation.

idf.py allows for running and debugging applications in QEMU. This is a convenient way to test applications without having to flash them to real hardware.

Prerequisites

To use QEMU with `idf.py`, you first need to install the above-mentioned fork of QEMU. ESP-IDF provides pre-built binaries for x86_64 and arm64 Linux and macOS, as well as x86_64 Windows. Before you use the pre-built binaries on Linux and macOS platroms please install system dependencies:

- Ubuntu and Debian:

```
sudo apt-get install -y libgcrypt20 libglib2.0-0 libpixman-1-0 libsdl2-2.0-0␣
↪libslirp0
```

- CentOS:

```
sudo yum install -y --enablerepo=powertools libgcrypt glib2 pixman SDL2 libslirp
```

- Arch:

```
sudo pacman -S --needed libgcrypt glib2 pixman sdl2 libslirp
```

- macOS:

```
brew install libgcrypt glib pixman sdl2 libslirp
```

Then install the pre-built binaries with the following command:

```
python $IDF_PATH/tools/idf_tools.py install qemu-xtensa qemu-riscv32
```

After installing QEMU, make sure it is added to PATH by running `. ./export.sh` in the IDF directory.

If you are using a different platform, you need to build QEMU from source. Refer to official QEMU documentation for instructions.

Usage

Running an Application To run an IDF application in QEMU, use the following command:

```
idf.py qemu monitor
```

This command builds the application, starts QEMU and opens *IDF monitor*, and connects IDF Monitor to the emulated UART port. You can see the console output of the application and interact with it. IDF Monitor also provides automatic decoding of panic backtraces and UART core dumps.

Debugging To debug an application in QEMU, use the following command:

```
idf.py qemu gdb
```

This command builds the application, starts QEMU with the GDB server enabled, and opens an interactive GDB session. You can use GDB to debug the application as if it was running on real hardware.

To see console output while debugging in QEMU, use two terminals.

- In the first terminal, run:

  ```
  idf.py qemu --gdb monitor
  ```

  This command starts QEMU and IDF Monitor, and tells QEMU to wait for a GDB connection.
- In the second terminal, run:

  ```
  idf.py gdb
  ```

  This command starts an interactive GDB sessions and connects it to QEMU. You can now debug the application, and the console output will be visible in the first terminal.

It is also possible to run QEMU without the IDF Monitor:

```
idf.py qemu
```

In this case, the IDF Monitor is not used, and you can interact with QEMU process directly. To switch between the emulated UART console and QEMU console ("QEMU monitor"), use Ctrl-A shortcut. For example, to exit QEMU, press Ctrl-A, then type `q` and press Enter. You can use the QEMU console to enter commands, such as for inspecting registers and memory.

Graphics Support QEMU supports a virtual framebuffer device. This device doesn't exist in the real ESP32-C3 hardware, but it can be used to test graphics applications in QEMU.

To launch QEMU with a virtual framebuffer device enabled, use the following command:

```
idf.py qemu --graphics monitor
```

When the `--graphics` option is used, QEMU opens an additional window where the framebuffer contents are displayed.

To use the virtual framebuffer device in your application, you can add the espressif/esp_lcd_qemu_rgb component to your project. This component provides an esp_lcd compatible driver for the virtual framebuffer device.

4.32 Unit Testing in ESP32-C3

ESP-IDF provides the following methods to test software.

- Target based tests using a central unit test application which runs on the esp32c3. These tests use the Unity unit test framework. They can be integrated into an ESP-IDF component by placing them in the component's `test` subdirectory. This document mainly introduces this target based tests.
- Linux-host based unit tests in which part of the hardware can be abstracted via mocks. Currently, Linux-host based tests are still under development and only a small fraction of IDF components support them. More information on running IDF applications on the host can be found here: *Running Applications on the Host Machine*.

4.32.1 Normal Test Cases

Unit tests are located in the `test` subdirectory of a component. Tests are written in C, and a single C source file can contain multiple test cases. Test files start with the word "test".

Each test file should include the `unity.h` header and the header for the C module to be tested.

Tests are added in a function in the C file as follows:

```
TEST_CASE("test name", "[module name]")
{
        // Add test here
}
```

- The first argument is a descriptive name for the test.
- The second argument is an identifier in square brackets. Identifiers are used to group related test, or tests with specific properties.

Note: There is no need to add a main function with `UNITY_BEGIN()` and `UNITY_END()` in each test case. `unity_platform.c` will run `UNITY_BEGIN()` autonomously, and run the test cases, then call `UNITY_END()`.

The `test` subdirectory should contain a *component CMakeLists.txt*, since they are themselves components (i.e., a test component). ESP-IDF uses the Unity test framework located in the `unity` component. Thus, each test component should specify the `unity` component as a component requirement using the `REQUIRES` argument. Normally, components *should list their sources manually*; for component tests however, this requirement is relaxed and the use of the `SRC_DIRS` argument in `idf_component_register` is advised.

Overall, the minimal `test` subdirectory `CMakeLists.txt` file should contain the following:

```
idf_component_register(SRC_DIRS "."
                       INCLUDE_DIRS "."
                       REQUIRES unity)
```

See http://www.throwtheswitch.org/unity for more information about writing tests in Unity.

4.32.2 Multi-device Test Cases

The normal test cases will be executed on one DUT (Device Under Test). However, components that require some form of communication (e.g., GPIO, SPI) require another device to communicate with, thus cannot be tested through normal test cases. Multi-device test cases involve writing multiple test functions, and running them on multiple DUTs.

The following is an example of a multi-device test case:

```
void gpio_master_test()
{
    gpio_config_t slave_config = {
            .pin_bit_mask = 1 << MASTER_GPIO_PIN,
            .mode = GPIO_MODE_INPUT,
    };
```

(continues on next page)

(continued from previous page)

```
    gpio_config(&slave_config);
    unity_wait_for_signal("output high level");
    TEST_ASSERT(gpio_get_level(MASTER_GPIO_PIN) == 1);
}

void gpio_slave_test()
{
    gpio_config_t master_config = {
            .pin_bit_mask = 1 << SLAVE_GPIO_PIN,
            .mode = GPIO_MODE_OUTPUT,
    };
    gpio_config(&master_config);
    gpio_set_level(SLAVE_GPIO_PIN, 1);
    unity_send_signal("output high level");
}

TEST_CASE_MULTIPLE_DEVICES("gpio multiple devices test example", "[driver]", gpio_
↪master_test, gpio_slave_test);
```

The macro `TEST_CASE_MULTIPLE_DEVICES` is used to declare a multi-device test case.

- The first argument is test case name.
- The second argument is test case description.
- From the third argument, up to 5 test functions can be defined, each function will be the entry point of tests running on each DUT.

Running test cases from different DUTs could require synchronizing between DUTs. We provide `unity_wait_for_signal` and `unity_send_signal` to support synchronizing with UART. As the scenario in the above example, the slave should get GPIO level after master set level. DUT UART console will prompt and user interaction is required:

DUT1 (master) console:

```
Waiting for signal: [output high level]!
Please press "Enter" key to once any board send this signal.
```

DUT2 (slave) console:

```
Send signal: [output high level]!
```

Once the signal is sent from DUT2, you need to press "Enter" on DUT1, then DUT1 unblocks from `unity_wait_for_signal` and starts to change GPIO level.

4.32.3 Multi-stage Test Cases

The normal test cases are expected to finish without reset (or only need to check if reset happens). Sometimes we expect to run some specific tests after certain kinds of reset. For example, we want to test if the reset reason is correct after a wake up from deep sleep. We need to create a deep-sleep reset first and then check the reset reason. To support this, we can define multi-stage test cases, to group a set of test functions:

```
static void trigger_deepsleep(void)
{
    esp_sleep_enable_timer_wakeup(2000);
    esp_deep_sleep_start();
}

void check_deepsleep_reset_reason()
{
    soc_reset_reason_t reason = esp_rom_get_reset_reason(0);
    TEST_ASSERT(reason == RESET_REASON_CORE_DEEP_SLEEP);
```

(continues on next page)

(continued from previous page)

```
}

TEST_CASE_MULTIPLE_STAGES("reset reason check for deepsleep", "[esp32c3]", trigger_
↪deepsleep, check_deepsleep_reset_reason);
```

Multi-stage test cases present a group of test functions to users. It needs user interactions (select cases and select different stages) to run the case.

4.32.4 Tests For Different Targets

Some tests (especially those related to hardware) cannot run on all targets. Below is a guide how to make your unit tests run on only specified targets.

1. Wrap your test code by `!(TEMPORARY_)DISABLED_FOR_TARGETS()` macros and place them either in the original test file, or separate the code into files grouped by functions, but make sure all these files will be processed by the compiler. E.g.:

```
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
TEST_CASE("a test that is not ready for esp32 and esp8266 yet", "[]")
{
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
```

Once you need one of the tests to be compiled on a specified target, just modify the targets in the disabled list. It's more encouraged to use some general conception that can be described in `soc_caps.h` to control the disabling of tests. If this is done but some of the tests are not ready yet, use both of them (and remove `!(TEMPORARY_)DISABLED_FOR_TARGETS()` later). E.g.:

```
#if SOC_SDIO_SLAVE_SUPPORTED
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
TEST_CASE("a sdio slave tests that is not ready for esp64 yet", "[sdio_slave]")
{
    //available for esp32 now, and will be available for esp64 in the future
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
#endif //SOC_SDIO_SLAVE_SUPPORTED
```

2. For test code that you are 100% for sure that will not be supported (e.g., no peripheral at all), use `DISABLED_FOR_TARGETS`; for test code that should be disabled temporarily, or due to lack of runners, etc., use `TEMPORARY_DISABLED_FOR_TARGETS`.

Some old ways of disabling unit tests for targets, that have obvious disadvantages, are deprecated:

- DON'T put the test code under `test/target` folder and use CMakeLists.txt to choose one of the target folder. This is prevented because test code is more likely to be reused than the implementations. If you put something into `test/esp32` just to avoid building it on esp32s2, it's hard to make the code tidy if you want to enable the test again on esp32s3.
- DON'T use `CONFIG_IDF_TARGET_xxx` macros to disable the test items any more. This makes it harder to track disabled tests and enable them again. Also, a black-list style `#if !disabled` is preferred to white-list style `#if CONFIG_IDF_TARGET_xxx`, since you will not silently disable cases when new targets are added in the future. But for test implementations, it's allowed to use `#if CONFIG_IDF_TARGET_xxx` to pick one of the implementation code.
  - Test item: some items that will be performed on some targets, but skipped on other targets. E.g.
    There are three test items SD 1-bit, SD 4-bit and SDSPI. For ESP32-S2, which doesn't have SD host, among the tests only SDSPI is enabled on ESP32-S2.
  - Test implementation: some code will always happen, but in different ways. E.g.
    There is no SDIO PKT_LEN register on ESP8266. If you want to get the length from the slave as a step in the test process, you can have different implementation code protected by `#if CONFIG_IDF_TARGET_` reading in different ways.

But please avoid using `#else` macro. When new target is added, the test case will fail at building stage, so that the maintainer will be aware of this, and choose one of the implementations explicitly.

4.32.5 Building Unit Test App

Follow the setup instructions in the top-level esp-idf README. Make sure that `IDF_PATH` environment variable is set to point to the path of esp-idf top-level directory.

Change into `tools/unit-test-app` directory to configure and build it:

- `idf.py menuconfig` - configure unit test app.
- `idf.py -T all build` - build unit test app with tests for each component having tests in the `test` subdirectory.
- `idf.py -T "xxx yyy" build` - build unit test app with tests for some space-separated specific components (For instance: `idf.py -T heap build` - build unit tests only for `heap` component directory).
- `idf.py -T all -E "xxx yyy" build` - build unit test app with all unit tests, except for unit tests of some components (For instance: `idf.py -T all -E "ulp mbedtls" build` - build all unit tests excludes `ulp` and `mbedtls` components).

Note: Due to inherent limitations of Windows command prompt, following syntax has to be used in order to build unit-test-app with multiple components: `idf.py -T xxx -T yyy build` or with escaped quotes: `idf.py -T \`"xxx yyy\`" build` in PowerShell or `idf.py -T \^"ssd1306 hts221\^" build` in Windows command prompt.

When the build finishes, it will print instructions for flashing the chip. You can simply run `idf.py flash` to flash all build output.

You can also run `idf.py -T all flash` or `idf.py -T xxx flash` to build and flash. Everything needed will be rebuilt automatically before flashing.

Use menuconfig to set the serial port for flashing. For more information, see tools/unit-test-app/README.md.

4.32.6 Running Unit Tests

Note: We also provide the pytest-based framework pytest-embedded to help make running unit-tests more convenient and efficient. If you need to run tests in CI or run multiple tests in a row we recommend checking out this project. For more information see Pytest-embedded Docs and *ESP-IDF Tests with Pytest Guide*.

After flashing reset the ESP32-C3 and it will boot the unit test app.

When unit test app is idle, press "Enter" will make it print test menu with all available tests:

```
Here's the test menu, pick your combo:
(1)     "esp_ota_begin() verifies arguments" [ota]
(2)     "esp_ota_get_next_update_partition logic" [ota]
(3)     "Verify bootloader image in flash" [bootloader_support]
(4)     "Verify unit test app image" [bootloader_support]
(5)     "can use new and delete" [cxx]
(6)     "can call virtual functions" [cxx]
(7)     "can use static initializers for non-POD types" [cxx]
(8)     "can use std::vector" [cxx]
(9)     "static initialization guards work as expected" [cxx]
(10)    "global initializers run in the correct order" [cxx]
(11)    "before scheduler has started, static initializers work correctly" [cxx]
(12)    "adc2 work with wifi" [adc]
(13)    "gpio master/slave test example" [ignore][misc][test_env=UT_T2_1][multi_
↪device]
```

(continues on next page)

(continued from previous page)

```
        (1)     "gpio_master_test"
        (2)     "gpio_slave_test"
(14)    "SPI Master clockdiv calculation routines" [spi]
(15)    "SPI Master test" [spi][ignore]
(16)    "SPI Master test, interaction of multiple devs" [spi][ignore]
(17)    "SPI Master no response when switch from host1 (SPI2) to host2 (SPI3)"␣
↪[spi]
(18)    "SPI Master DMA test, TX and RX in different regions" [spi]
(19)    "SPI Master DMA test: length, start, not aligned" [spi]
(20)    "reset reason check for deepsleep" [esp32c3][test_env=UT_T2_1][multi_stage]
        (1)     "trigger_deepsleep"
        (2)     "check_deepsleep_reset_reason"
```

The normal case will print the case name and description. Master-slave cases will also print the sub-menu (the registered test function names).

Test cases can be run by inputting one of the following:

- Test case name in quotation marks to run a single test case
- Test case index to run a single test case
- Module name in square brackets to run all test cases for a specific module
- An asterisk to run all test cases

`[multi_device]` and `[multi_stage]` tags tell the test runner whether a test case is a multiple devices or multiple stages of test case. These tags are automatically added by `` `TEST_CASE_MULTIPLE_STAGES `` and `TEST_CASE_MULTIPLE_DEVICES` macros.

After you select a multi-device test case, it will print sub-menu:

```
Running gpio master/slave test example...
gpio master/slave test example
        (1)     "gpio_master_test"
        (2)     "gpio_slave_test"
```

You need to input a number to select the test running on the DUT.

Similar to multi-device test cases, multi-stage test cases will also print sub-menu:

```
Running reset reason check for deepsleep...
reset reason check for deepsleep
        (1)     "trigger_deepsleep"
        (2)     "check_deepsleep_reset_reason"
```

First time you execute this case, input `1` to run first stage (trigger deepsleep). After DUT is rebooted and able to run test cases, select this case again and input `2` to run the second stage. The case only passes if the last stage passes and all previous stages trigger reset.

4.32.7 Timing Code with Cache Compensated Timer

Instructions and data stored in external memory (e.g., SPI Flash and SPI RAM) are accessed through the CPU's unified instruction and data cache. When code or data is in cache, access is very fast (i.e., a cache hit).

However, if the instruction or data is not in cache, it needs to be fetched from external memory (i.e., a cache miss). Access to external memory is significantly slower, as the CPU must execute stall cycles whilst waiting for the instruction or data to be retrieved from external memory. This can cause the overall code execution speed to vary depending on the number of cache hits or misses.

Code and data placements can vary between builds, and some arrangements may be more favorable with regards to cache access (i.e., minimizing cache misses). This can technically affect execution speed, however these factors are usually irrelevant as their effect 'average out' over the device's operation.

The effect of the cache on execution speed, however, can be relevant in benchmarking scenarios (especially micro benchmarks). There might be some variability in measured time between runs and between different builds. A technique for eliminating for some of the variability is to place code and data in instruction or data RAM (IRAM/DRAM), respectively. The CPU can access IRAM and DRAM directly, eliminating the cache out of the equation. However, this might not always be viable as the size of IRAM and DRAM is limited.

The cache compensated timer is an alternative to placing the code/data to be benchmarked in IRAM/DRAM. This timer uses the processor's internal event counters in order to determine the amount of time spent on waiting for code/data in case of a cache miss, then subtract that from the recorded wall time.

```
// Start the timer
ccomp_timer_start();

// Function to time
func_code_to_time();

// Stop the timer, and return the elapsed time in microseconds relative to
// ccomp_timer_start
int64_t t = ccomp_timer_stop();
```

One limitation of the cache compensated timer is that the task that benchmarked functions should be pinned to a core. This is due to each core having its own event counters that are independent of each other. For example, if `ccomp_timer_start` gets called on one core, put to sleep by the scheduler, wakes up, and gets rescheduled on the other core, then the corresponding `ccomp_timer_stop` will be invalid.

4.32.8 Mocks

Note: Currently, mocking is only possible with some selected components when running on the Linux host. In the future, we plan to make essential components in IDF mock-able. This will also include mocking when running on the ESP32-C3.

One of the biggest problems regarding unit testing on embedded systems are the strong hardware dependencies. Running unit tests directly on the ESP32-C3 can be especially difficult for higher layer components for the following reasons:

- Decreased test reliability due to lower layer components and/or hardware setup.
- Increased difficulty in testing edge cases due to limitations of lower layer components and/or hardware setup
- Increased difficulty in identifying the root cause due to the large number of dependencies influencing the behavior

When testing a particular component, (i.e., the component under test), mocking allows the dependencies of the component under test to be substituted (i.e., mocked) entirely in software. Through mocking, hardware details are emulated and specified at run time, but only if necessary. To allow mocking, ESP-IDF integrates the CMock mocking framework as a component. With the addition of some CMake functions in the ESP-IDF build system, it is possible to conveniently mock the entirety (or a part) of an IDF component.

Ideally, all components that the component under test is dependent on should be mocked, thus allowing the test environment complete control over all interactions with the component under test. However, if mocking all dependent components becomes too complex or too tedious (e.g., because you need to mock too many function calls) you have the following options:

- Include more "real" IDF code in the tests. This may work but increases the dependency on the "real" code's behavior. Furthermore, once a test fails, you may not know if the failure is in your actual code under test or the "real" IDF code.
- Re-evaluate the design of the code under test and attempt to reduce its dependencies by dividing the code under test into more manageable components. This may seem burdensome but it is quite common that unit tests expose software design weaknesses. Fixing design weaknesses will not only help with unit testing in the short term, but will help future code maintenance as well.

Refer to cmock/CMock/docs/CMock_Summary.md for more details on how CMock works and how to create and use mocks.

Requirements

Mocking with CMock requires `Ruby` on the host machine. Furthermore, since mocking currently only works on the Linux target, the requirements of the latter also need to be fulfilled:

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the CMakeLists.txt of the application's root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

Mock a Component

If a mocked component, called a *component mock*, is already available in ESP-IDF, then it can be used right away as long as it satisfies the required functionality. Refer to *Component Linux/Mock Support Overview* to see which components are mocked already. Then refer to *Adjustments in Unit Test* in order to use the component mock.

It is necessary to create component mocks if they are not yet provided in ESP-IDF. To create a component mock, the component needs to be overwritten in a particular way. Overriding a component entails creating a component with the exact same name as the original component, then letting the build system discover it later than the original component (see *Multiple components with the same name* for more details).

In the component mock, the following parts are specified:

- The headers providing the functions to generate mocks for
- Include paths of the aforementioned headers
- Dependencies of the mock component (this is necessary e.g. if the headers include files from other components)

All these parts have to be specified using the IDF build system function `idf_component_mock`. You can use the IDF build system function `idf_component_get_property` with the tag `COMPONENT_OVERRIDEN_DIR` to access the component directory of the original component and then register the mock component parts using `idf_component_mock`:

```
idf_component_get_property(original_component_dir <original-component-name>␣
↪COMPONENT_OVERRIDEN_DIR)
...
idf_component_mock(INCLUDE_DIRS "${original_component_dir}/include"
    REQUIRES freertos
    MOCK_HEADER_FILES ${original_component_dir}/include/header_containing_
↪functions_to_mock.h)
```

The component mock also requires a separate `mock` directory containing a `mock_config.yaml` file that configures CMock. A simple `mock_config.yaml` could look like this:

```
:cmock:
  :plugins:
    - expect
    - expect_any_args
```

For more details about the CMock configuration yaml file, have a look at cmock/CMock/docs/CMock_Summary.md.

Note that the component mock does not have to mock the original component in its entirety. As long as the test project's dependencies and dependencies of other code to the original components are satisfied by the component mock, partial mocking is adequate. In fact, most of the component mocks in IDF in `tools/mocks` are only partially mocking the original component.

Examples of component mocks can be found under tools/mocks in the IDF directory. General information on how to *override an IDF component* can be found in *Multiple components with the same name*. There are several examples for testing code while mocking dependencies with CMock (non-exhaustive list):

- unit test for the NVS Page class .
- unit test for esp_event .
- unit test for mqtt .

Adjustments in Unit Test

The unit test needs to inform the cmake build system to mock dependent components (i.e., it needs to override the original component with the mock component). This is done by either placing the component mock into the project's `components` directory or adding the mock component's directory using the following line in the project's root `CMakeLists.txt`:

```
list(APPEND EXTRA_COMPONENT_DIRS "<mock_component_dir>")
```

Both methods will override existing components in ESP-IDF with the component mock. The latter is particularly convenient if you use component mocks that are already supplied by IDF.

Users can refer to the `esp_event` host-based unit test and its esp_event/host_test/esp_event_unit_test/CMakeLists.txt as an example of a component mock.

4.33 Running ESP-IDF Applications on Host

Note: Running ESP-IDF applications on host is currently still an experimental feature, thus there is no guarantee for API stability. However, user feedback via the ESP-IDF GitHub repository or the ESP32 forum is highly welcome, and may help influence the future of design of the ESP-IDF host-based applications.

This document provides an overview of the methods to run ESP-IDF applications on Linux, and what type of ESP-IDF applications can typically be run on Linux.

4.33.1 Introduction

Typically, an ESP-IDF application is built (cross-compiled) on a host machine, uploaded (i.e., flashed) to an ESP chip for execution, and monitored by the host machine via a UART/USB port. However, execution of an ESP-IDF application on an ESP chip can be limiting in various development/usage/testing scenarios.

Therefore, it is possible for an ESP-IDF application to be built and executed entirely within the same Linux host machine (henceforth referred to as "running on host"). Running ESP-IDF applications on host has several advantages:

- No need to upload to a target.
- Faster execution on a host machine, compared to running on an ESP chip.
- No requirements for any specific hardware, except the host machine itself.
- Easier automation and setup for software testing.
- Large number of tools for code and runtime analysis, e.g., Valgrind.

A large number of ESP-IDF components depend on chip-specific hardware. These hardware dependencies must be mocked or simulated when running on host. ESP-IDF currently supports the following mocking and simulation approaches:

1. Using the FreeRTOS POSIX/Linux simulator that simulates FreeRTOS scheduling. On top of this simulation, other APIs are also simulated or implemented when running on host.
2. Using CMock to mock all dependencies and run the code in complete isolation.

Note that despite the name, the FreeRTOS POSIX/Linux simulator currently also works on macOS. Running ESP-IDF applications on host machines is often used for testing. However, simulating the environment and mocking dependencies does not fully represent the target device. Thus, testing on the target device is still necessary, though with a different focus that usually puts more weight on integration and system testing.

Note: Another possibility to run applications on the host is to use the QEMU simulator. However, QEMU development for ESP-IDF applications is still a work in progress and has not been documented yet.

CMock-Based Approach

This approach uses the CMock framework to solve the problem of missing hardware and software dependencies. CMock-based applications running on the host machine have the added advantage that they usually only compile the necessary code, i.e., the (mostly mocked) dependencies instead of the entire system. For a general introduction to Mocks and how to configure and use them in ESP-IDF, please refer to *Mocks*.

POSIX/Linux Simulator Approach

The FreeRTOS POSIX/Linux simulator is available on ESP-IDF as a preview target already. This simulator allows ESP-IDF components to be implemented on the host, making them accessible to ESP-IDF applications when running on host. Currently, only a limited number of components are ready to be built on Linux. Furthermore, the functionality of each component ported to Linux may also be limited or different compared to the functionality when building that component for a chip target. For more information about whether the desired components are supported on Linux, please refer to *Component Linux/Mock Support Overview*.

Note that this simulator relies heavily on POSIX signals and signal handlers to control and interrupt threads. Hence, it has the following *limitations*:

- Functions that are not *async-signal-safe*, e.g. `printf()`, should be avoided. In particular, calling them from different tasks with different priority can lead to crashes and deadlocks.
- Calling any FreeRTOS primitives from threads not created by FreeRTOS API functions is forbidden.
- FreeRTOS tasks using any native blocking/waiting mechanism (e.g., `select()`), may be perceived as *ready* by the simulated FreeRTOS scheduler and therefore may be scheduled, even though they are actually blocked. This is because the simulated FreeRTOS scheduler only recognizes tasks blocked on any FreeRTOS API as *waiting*.
- APIs that may be interrupted by signals will continually receive the signals simulating FreeRTOS tick interrupts when invoked from a running simulated FreeRTOS task. Consequently, code that calls these APIs should be designed to handle potential interrupting signals or the API needs to be wrapped by the linker.

Since these limitations are not very practical, in particular for testing and development, we are currently evaluating if we can find a better solution for running ESP-IDF applications on the host machine.

Note furthermore that if you use the ESP-IDF FreeRTOS mock component (`tools/mocks/freertos`), these limitations do not apply. But that mock component will not do any scheduling, either.

Note: The FreeRTOS POSIX/Linux simulator allows configuring the *Amazon SMP FreeRTOS* version. However, the simulation still runs in single-core mode. The main reason allowing Amazon SMP FreeRTOS is to provide API compatibility with ESP-IDF applications written for Amazon SMP FreeRTOS.

4.33.2 Requirements for Using Mocks

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the CMakeLists.txt of the application's root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

If any mocks are used, then `Ruby` is required, too.

4.33.3 Build and Run

To build the application on Linux, the target has to be set to `linux` and then it can be built and run:

```
idf.py --preview set-target linux
idf.py build
idf.py monitor
```

4.33.4 Troubleshooting

Since the applications are compiled for the host, they can be debugged with all the tools available on the host. E.g., this could be GDB and Valgrind on Linux. For cases where no debugger is attached, the segmentation fault and Abort signal handlers are customized to print additional information to the user and to increase compatibility with the ESP-IDF tools.

Note: The following features are by no means a replacement for running the application in a debugger. It is only meant to give some additional information, e.g., if a battery of tests runs on Linux in a CI/CD system where only the application logs are collected. To trace down the actual issue in most cases, you will need to reproduce it with a debugger attached. A debugger is much more convenient too, because, for example, you do not need to convert addresses to line numbers.

Segmentation Faults

On Linux, applications prints an error message and a rudimentary backtrace once it encounters a segmentation fault. This information can be used to find the line numbers in the source code where the issue occurred. The following is an example of a segmentation fault in the Hello-World application:

```
...
Hello world!
ERROR: Segmentation Fault, here's your backtrace:
path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf(+0x2d1b)[0x55d3f636ad1b]
/lib/x86_64-linux-gnu/libc.so.6(+0x3c050)[0x7f49f0e00050]
path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf(+0x6198)[0x55d3f636e198]
path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf(+0x5909)[0x55d3f636d909]
```

(continues on next page)

(continued from previous page)

```
path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf(+0x2c93)[0x55d3f636ac93]
path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf(+0x484e)[0x55d3f636c84e]
/lib/x86_64-linux-gnu/libc.so.6(+0x89134)[0x7f49f0e4d134]
/lib/x86_64-linux-gnu/libc.so.6(+0x1097dc)[0x7f49f0ecd7dc]
```

Note that the addresses (`+0x...`) are relative binary addresses, which still need to be converted to the source code line numbers (see below).

Note furthermore that the backtrace is created from the signal handler, which means that the two uppermost stack frames are not of interest. Instead, the third line is the uppermost stack frame where the issue occurred:

```
path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf(+0x6198)[0x55d3f636e198]
```

To retrieve the actual line in the source code, we need to call the tool `addr2line` with the file name and the relative address (in this case `+0x6198`):

```
$ addr2line -e path/to/esp-idf/examples/get-started/hello_world/build/hello_world.
↪elf +0x6198
path/to/esp-idf/components/esp_hw_support/port/linux/chip_info.c:13
```

From here on, you should use elaborate debugging tools available on the host to further trace the issue down. For more information on `addr2line` and how to call it, see the addr2line man page.

Aborts

Once `abort()` has been called, the following line is printed:

```
ERROR: Aborted
```

4.33.5 Component Linux/Mock Support Overview

Note that any "Yes" here does not necessarily mean a full implementation or mocking. It can also mean a partial implementation or mocking of functionality. Usually, the implementation or mocking is done to a point where enough functionality is provided to build and run a test application.

Component	Mock	Simulation
cmock	No	Yes
driver	Yes	No
esp_app_format	No	Yes
esp_common	No	Yes
esp_event	Yes	Yes
esp_http_client	No	Yes
esp_http_server	No	Yes
esp_https_server	No	Yes
esp_hw_support	Yes	Yes
esp_netif	Yes	Yes

4.34 USB Serial/JTAG Controller Console

Generally, ESP chips implement a serial port using UART and can be connected to a serial console emulator on a host/PC via an external USB-UART bridge chip. However, on ESP chips that contain a USB Serial/JTAG Controller, the CDC-ACM portion of the controller implements a serial port that is connected directly to a host/PC, thus does not require an external USB-UART bridge chip.

ESP32-C3 contains a USB Serial/JTAG Controller providing the following functions:

- Bidirectional serial console, which can be used with *IDF Monitor* or another serial monitor.
- Flashing using `esptool.py` and `idf.py flash`.
- JTAG debugging, performed simultaneously with serial operations using tools like OpenOCD.

Note: The USB Serial/JTAG Controller is a fixed-function USB device that is implemented entirely in hardware, meaning that it cannot be reconfigured to perform any function other than a serial port and JTAG debugging functionality. This is in contrast to the USB OTG controllers in some ESP chips that can be configured to perform the function of multiple types of USB devices.

4.34.1 Hardware Requirements

Connect ESP32-C3 to the USB port as follows:

GPIO	USB
19	D+ (green)
18	D- (white)
GND	GND (black)
5V (or externally supplied)	+5V (red)

Some development boards may offer a USB connector for the USB Serial/JTAG Controller. In that case, no extra connections are required.

4.34.2 Software Configuration

The USB Serial/JTAG Controller can be used as the serial port by selecting `CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG` in the *CONFIG_ESP_CONSOLE_UART* option. Once selected, building and flashing the project can occur as usual.

Alternatively, you can access the output through the `usb_serial_jtag` port but make sure `CONFIG_ESP_CONSOLE_SECONDARY_USB_SERIAL_JTAG` is selected in the *CONFIG_ESP_CONSOLE_SECONDARY*.

Warning: Besides output, if you also want to input or use REPL with the console, please select `CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG`.

4.34.3 Uploading the Application

The USB Serial/JTAG Controller is able to put the ESP32-C3 into download mode automatically. Simply flash as usual, but specify the USB Serial/JTAG Controller port on your system: `idf.py flash -p PORT`, where `PORT` is the name of the proper port.

Note: The USB Serial/JTAG Controller's serial port usually appears:

- as `/dev/ttyACM*` on Linux
- as `/dev/cu*` on Mac
- as a `COM*` port in the Windows Device Manager

4.34.4 Limitations

There are several limitations to the USB Serial/JTAG console feature. The significance of these limitations depends on the type of application being developed, and the development workflow.

USB Pin Reconfiguration

If the application accidentally reconfigures the USB peripheral pins or disables the USB Serial/JTAG Controller, the device disappears from the system. After fixing the issue in the application, you need to manually put the ESP32-C3 into download mode by pulling low GPIO9 and resetting the chip.

If the application enters Deep-sleep mode, the USB Serial/JTAG device disappears from the system.

Data Buffering

For data transmitted from ESP32-C3 to PC Terminal (e.g., stdout, logs), the ESP32-C3 first writes to a small internal buffer. After this buffer becomes full (for example, if no PC Terminal is connected), the ESP32-C3 does a one-time wait of 50 ms for the PC Terminal to request the data. This can appear as a very brief pause in your application.

For data transmitted from the PC Terminal to ESP32-C3 (e.g., console commands), many PC Terminals wait for the ESP32-C3 to ingest the bytes before allowing you to send more data. This is in contrast to using a USB-to-Serial (UART) bridge chip, which always ingests the bytes and sends them to a (possibly not listening) ESP32-C3.

Note: In rare cases, it is possible that data sent from ESP32-C3 to the host gets 'stuck' in host memory. Sending more data will get it 'unstuck', but if the application does not send more data, depending on the driver, this data

needs to be flushed to the host manually. The non-blocking (default) driver and the VFS implementation will flush automatically after a newline. The blocking (interrupt-based) driver will automatically flush when its transmit buffer becomes empty.

Sleep Mode Considerations

The USB Serial/JTAG controller and its associated USB PHY are driven by particular clocks (e.g., APB and USB PHY clock) and belong to a particular power domain (e.g., digital power domain). Thus, any change to the clock and power domains associated with the USB Serial/JTAG controller, such as entering different sleep modes, can affect the controller's operation.

Deep-sleep When entering Deep-sleep, both the USB Serial/JTAG controller and the USB PHY are powered off, leading to the USB PHY's D+ line no longer being pulled up. As a result:

- When entering Deep-sleep, the USB Serial/JTAG device appears disconnected from the host/PC (even if the USB cable is still physically connected).
- When exiting Deep-sleep, the USB Serial/JTAG device reconnects to the host/PC.

Light-sleep When entering Light-sleep, the APB and USB PHY clock are gated. Thus, the USB Serial/JTAG controller is no longer able to receive or respond to any USB transactions from the connected host (including periodic CDC Data IN transactions). As a result:

- when entering Light-sleep, the USB Serial/JTAG device is unresponsive to the host/PC's USB CDC driver. The host/PC may then report the USB Serial/JTAG device as disconnected or erroneous (even if the USB cable is still physically connected).
- when exiting Light-sleep, it is possible that the host/PC does not re-enumerate (i.e., reconnect) the USB Serial/JTAG device given that the USB PHY's D+ line remains pulled up state during Light-sleep. Users may need to physically disconnect and then reconnect the USB cable.

Automatic and Manual Sleep Entry If users enter sleep manually (via `esp_light_sleep_start()` or `esp_deep_sleep_start()`), users should be cognizant of the fact that USB Serial/JTAG controller does not work during sleep. ESP-IDF **does not add any safety check to reject entry to sleep** even if the USB Serial/JTAG controller is connected. In the case where sleep is entered while the USB Serial/JTAG controller is connected, the connection can be re-established by unplugging and re-plugging the USB cable.

If users enter sleep automatically (via `esp_pm_configure()`), enabling the *CONFIG_USJ_NO_AUTO_LS_ON_CONNECTION* option allows the ESP32-C3 to automatically detect whether the USB Serial/JTAG controller is currently connected to a host, and prevent automatic entry to sleep as long as the connection persists. However, note that this option increases power consumption.

4.35 Wi-Fi Driver

4.35.1 ESP32-C3 Wi-Fi Feature List

The following features are supported:

- 4 virtual Wi-Fi interfaces, which are STA, AP, Sniffer and reserved.
- Station-only mode, AP-only mode, station/AP-coexistence mode
- IEEE 802.11b, IEEE 802.11g, IEEE 802.11n, and APIs to configure the protocol mode
- WPA/WPA2/WPA3/WPA2-Enterprise/WPA3-Enterprise/WAPI/WPS and DPP
- AMSDU, AMPDU, HT40, QoS, and other key features
- Modem-sleep

- The Espressif-specific ESP-NOW protocol and Long Range mode, which supports up to **1 km** of data traffic
- Up to 20 MBit/s TCP throughput and 30 MBit/s UDP throughput over the air
- Sniffer
- Both fast scan and all-channel scan
- Multiple antennas
- Channel state information

4.35.2 How To Write a Wi-Fi Application

Preparation

Generally, the most effective way to begin your own Wi-Fi application is to select an example which is similar to your own application, and port the useful part into your project. It is not a MUST, but it is strongly recommended that you take some time to read this article first, especially if you want to program a robust Wi-Fi application.

This article is supplementary to the Wi-Fi APIs/Examples. It describes the principles of using the Wi-Fi APIs, the limitations of the current Wi-Fi API implementation, and the most common pitfalls in using Wi-Fi. This article also reveals some design details of the Wi-Fi driver. We recommend you to select an example .

Setting Wi-Fi Compile-time Options

Refer to *Wi-Fi Menuconfig*.

Init Wi-Fi

Refer to *ESP32-C3 Wi-Fi station General Scenario* and *ESP32-C3 Wi-Fi AP General Scenario*.

Start/Connect Wi-Fi

Refer to *ESP32-C3 Wi-Fi station General Scenario* and *ESP32-C3 Wi-Fi AP General Scenario*.

Event-Handling

Generally, it is easy to write code in "sunny-day" scenarios, such as *WIFI_EVENT_STA_START* and *WIFI_EVENT_STA_CONNECTED*. The hard part is to write routines in "rainy-day" scenarios, such as *WIFI_EVENT_STA_DISCONNECTED*. Good handling of "rainy-day" scenarios is fundamental to robust Wi-Fi applications. Refer to *ESP32-C3 Wi-Fi Event Description*, *ESP32-C3 Wi-Fi station General Scenario*, and *ESP32-C3 Wi-Fi AP General Scenario*. See also the *overview of the Event Loop Library in ESP-IDF*.

Write Error-Recovery Routines Correctly at All Times

Just like the handling of "rainy-day" scenarios, a good error-recovery routine is also fundamental to robust Wi-Fi applications. Refer to *ESP32-C3 Wi-Fi API Error Code*.

4.35.3 ESP32-C3 Wi-Fi API Error Code

All of the ESP32-C3 Wi-Fi APIs have well-defined return values, namely, the error code. The error code can be categorized into:

- No errors, e.g., `ESP_OK` means that the API returns successfully.
- Recoverable errors, such as `ESP_ERR_NO_MEM`.
- Non-recoverable, non-critical errors.
- Non-recoverable, critical errors.

Whether the error is critical or not depends on the API and the application scenario, and it is defined by the API user.

The primary principle to write a robust application with Wi-Fi API is to always check the error code and write the error-handling code. Generally, the error-handling code can be used:

- For recoverable errors, in which case you can write a recoverable-error code. For example, when `esp_wifi_start()` returns `ESP_ERR_NO_MEM`, the recoverable-error code vTaskDelay can be called in order to get a microseconds' delay for another try.
- For non-recoverable, yet non-critical errors, in which case printing the error code is a good method for error handling.
- For non-recoverable and also critical errors, in which case "assert" may be a good method for error handling. For example, if `esp_wifi_set_mode()` returns `ESP_ERR_WIFI_NOT_INIT`, it means that the Wi-Fi driver is not initialized by `esp_wifi_init()` successfully. You can detect this kind of error very quickly in the application development phase.

In esp_common/include/esp_err.h, `ESP_ERROR_CHECK` checks the return values. It is a rather commonplace error-handling code and can be used as the default error-handling code in the application development phase. However, it is strongly recommended that API users write their own error-handling code.

4.35.4 ESP32-C3 Wi-Fi API Parameter Initialization

When initializing struct parameters for the API, one of two approaches should be followed:

- Explicitly set all fields of the parameter.
- Use get API to get current configuration first, then set application specific fields.

Initializing or getting the entire structure is very important, because most of the time the value 0 indicates that the default value is used. More fields may be added to the struct in the future and initializing these to zero ensures the application will still work correctly after ESP-IDF is updated to a new release.

4.35.5 ESP32-C3 Wi-Fi Programming Model

The ESP32-C3 Wi-Fi programming model is depicted as follows:

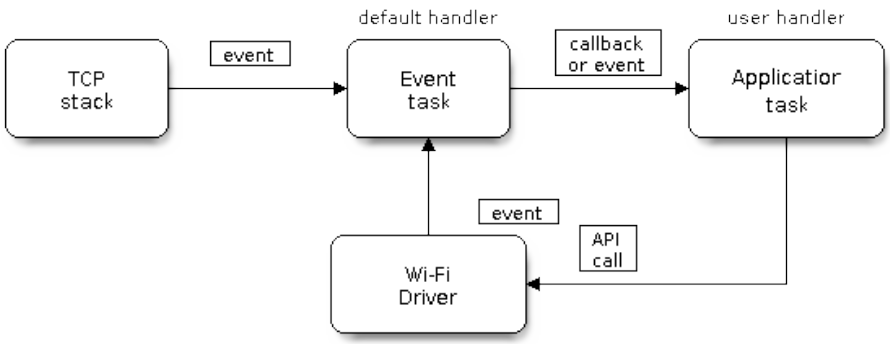

Fig. 60: Wi-Fi Programming Model

The Wi-Fi driver can be considered a black box that knows nothing about high-layer code, such as the TCP/IP stack, application task, and event task. The application task (code) generally calls *Wi-Fi driver APIs* to initialize Wi-Fi and handles Wi-Fi events when necessary. Wi-Fi driver receives API calls, handles them, and posts events to the application.

Wi-Fi event handling is based on the *esp_event library*. Events are sent by the Wi-Fi driver to the *default event loop*. Application may handle these events in callbacks registered using `esp_event_handler_register()`. Wi-Fi

events are also handled by *esp_netif component* to provide a set of default behaviors. For example, when Wi-Fi station connects to an AP, esp_netif will automatically start the DHCP client by default.

4.35.6 ESP32-C3 Wi-Fi Event Description

WIFI_EVENT_WIFI_READY

The Wi-Fi driver will never generate this event, which, as a result, can be ignored by the application event callback. This event may be removed in future releases.

WIFI_EVENT_SCAN_DONE

The scan-done event is triggered by `esp_wifi_scan_start()` and will arise in the following scenarios:

- The scan is completed, e.g., the target AP is found successfully, or all channels have been scanned.
- The scan is stopped by `esp_wifi_scan_stop()`.
- The `esp_wifi_scan_start()` is called before the scan is completed. A new scan will override the current scan and a scan-done event will be generated.

The scan-done event will not arise in the following scenarios:

- It is a blocked scan.
- The scan is caused by `esp_wifi_connect()`.

Upon receiving this event, the event task does nothing. The application event callback needs to call `esp_wifi_scan_get_ap_num()` and `esp_wifi_scan_get_ap_records()` to fetch the scanned AP list and trigger the Wi-Fi driver to free the internal memory which is allocated during the scan **(do not forget to do this!)**. Refer to *ESP32-C3 Wi-Fi Scan* for a more detailed description.

WIFI_EVENT_STA_START

If `esp_wifi_start()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will initialize the LwIP network interface (netif). Generally, the application event callback needs to call `esp_wifi_connect()` to connect to the configured AP.

WIFI_EVENT_STA_STOP

If `esp_wifi_stop()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will release the station's IP address, stop the DHCP client, remove TCP/UDP-related connections, and clear the LwIP station netif, etc. The application event callback generally does not need to do anything.

WIFI_EVENT_STA_CONNECTED

If `esp_wifi_connect()` returns `ESP_OK` and the station successfully connects to the target AP, the connection event will arise. Upon receiving this event, the event task starts the DHCP client and begins the DHCP process of getting the IP address. Then, the Wi-Fi driver is ready for sending and receiving data. This moment is good for beginning the application work, provided that the application does not depend on LwIP, namely the IP address. However, if the application is LwIP-based, then you need to wait until the *got ip* event comes in.

WIFI_EVENT_STA_DISCONNECTED

This event can be generated in the following scenarios:

- When `esp_wifi_disconnect()` or `esp_wifi_stop()` is called and the station is already connected to the AP.

- When `esp_wifi_connect()` is called, but the Wi-Fi driver fails to set up a connection with the AP due to certain reasons, e.g., the scan fails to find the target AP or the authentication times out. If there are more than one AP with the same SSID, the disconnected event will be raised after the station fails to connect all of the found APs.
- When the Wi-Fi connection is disrupted because of specific reasons, e.g., the station continuously loses N beacons, the AP kicks off the station, or the AP's authentication mode is changed.

Upon receiving this event, the default behaviors of the event task are:

- Shutting down the station's LwIP netif.
- Notifying the LwIP task to clear the UDP/TCP connections which cause the wrong status to all sockets. For socket-based applications, the application callback can choose to close all sockets and re-create them, if necessary, upon receiving this event.

The most common event handle code for this event in application is to call `esp_wifi_connect()` to reconnect the Wi-Fi. However, if the event is raised because `esp_wifi_disconnect()` is called, the application should not call `esp_wifi_connect()` to reconnect. It is the application's responsibility to distinguish whether the event is caused by `esp_wifi_disconnect()` or other reasons. Sometimes a better reconnection strategy is required. Refer to *Wi-Fi Reconnect* and *Scan When Wi-Fi Is Connecting*.

Another thing that deserves attention is that the default behavior of LwIP is to abort all TCP socket connections on receiving the disconnect. In most cases, it is not a problem. However, for some special applications, this may not be what they want. Consider the following scenarios:

- The application creates a TCP connection to maintain the application-level keep-alive data that is sent out every 60 seconds.
- Due to certain reasons, the Wi-Fi connection is cut off, and the *WIFI_EVENT_STA_DISCONNECTED* is raised. According to the current implementation, all TCP connections will be removed and the keep-alive socket will be in a wrong status. However, since the application designer believes that the network layer should **ignore** this error at the Wi-Fi layer, the application does not close the socket.
- Five seconds later, the Wi-Fi connection is restored because `esp_wifi_connect()` is called in the application event callback function. **Moreover, the station connects to the same AP and gets the same IPV4 address as before**.
- Sixty seconds later, when the application sends out data with the keep-alive socket, the socket returns an error and the application closes the socket and re-creates it when necessary.

In above scenarios, ideally, the application sockets and the network layer should not be affected, since the Wi-Fi connection only fails temporarily and recovers very quickly. The application can enable "Keep TCP connections when IP changed" via LwIP menuconfig.

IP_EVENT_STA_GOT_IP

This event arises when the DHCP client successfully gets the IPV4 address from the DHCP server, or when the IPV4 address is changed. The event means that everything is ready and the application can begin its tasks (e.g., creating sockets).

The IPV4 may be changed because of the following reasons:

- The DHCP client fails to renew/rebind the IPV4 address, and the station's IPV4 is reset to 0.
- The DHCP client rebinds to a different address.
- The static-configured IPV4 address is changed.

Whether the IPV4 address is changed or not is indicated by the field `ip_change` of `ip_event_got_ip_t`.

The socket is based on the IPV4 address, which means that, if the IPV4 changes, all sockets relating to this IPV4 will become abnormal. Upon receiving this event, the application needs to close all sockets and recreate the application when the IPV4 changes to a valid one.

IP_EVENT_GOT_IP6

This event arises when the IPV6 SLAAC support auto-configures an address for the ESP32-C3, or when this address changes. The event means that everything is ready and the application can begin its tasks, e.g., creating sockets.

IP_EVENT_STA_LOST_IP

This event arises when the IPV4 address becomes invalid.

IP_EVENT_STA_LOST_IP does not arise immediately after the Wi-Fi disconnects. Instead, it starts an IPV4 address lost timer. If the IPV4 address is got before ip lost timer expires, IP_EVENT_STA_LOST_IP does not happen. Otherwise, the event arises when the IPV4 address lost timer expires.

Generally, the application can ignore this event, because it is just a debug event to inform that the IPV4 address is lost.

WIFI_EVENT_AP_START

Similar to *WIFI_EVENT_STA_START*.

WIFI_EVENT_AP_STOP

Similar to *WIFI_EVENT_STA_STOP*.

WIFI_EVENT_AP_STACONNECTED

Every time a station is connected to ESP32-C3 AP, the *WIFI_EVENT_AP_STACONNECTED* will arise. Upon receiving this event, the event task will do nothing, and the application callback can also ignore it. However, you may want to do something, for example, to get the info of the connected STA.

WIFI_EVENT_AP_STADISCONNECTED

This event can happen in the following scenarios:

- The application calls `esp_wifi_disconnect()`, or `esp_wifi_deauth_sta()`, to manually disconnect the station.
- The Wi-Fi driver kicks off the station, e.g., because the AP has not received any packets in the past five minutes. The time can be modified by `esp_wifi_set_inactive_time()`.
- The station kicks off the AP.

When this event happens, the event task will do nothing, but the application event callback needs to do something, e.g., close the socket which is related to this station.

WIFI_EVENT_AP_PROBEREQRECVED

This event is disabled by default. The application can enable it via API `esp_wifi_set_event_mask()`. When this event is enabled, it will be raised each time the AP receives a probe request.

WIFI_EVENT_STA_BEACON_TIMEOUT

If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens, the *WIFI_EVENT_STA_BEACON_TIMEOUT* will arise. The application can set inactive time via API `esp_wifi_set_inactive_time()`.

WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START

The *WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START* will arise at the start of connectionless module *Interval*. See *connectionless module power save*.

4.35.7 ESP32-C3 Wi-Fi Station General Scenario

Below is a "big scenario" which describes some small scenarios in station mode:

1. Wi-Fi/LwIP Init Phase

- s1.1: The main task calls `esp_netif_init()` to create an LwIP core task and initialize LwIP-related work.
- s1.2: The main task calls `esp_event_loop_create()` to create a system Event task and initialize an application event's callback function. In the scenario above, the application event's callback function does nothing but relaying the event to the application task.
- s1.3: The main task calls `esp_netif_create_default_wifi_ap()` or `esp_netif_create_default_wifi_sta()` to create default network interface instance binding station or AP with TCP/IP stack.
- s1.4: The main task calls `esp_wifi_init()` to create the Wi-Fi driver task and initialize the Wi-Fi driver.
- s1.5: The main task calls OS API to create the application task.

Step 1.1 ~ 1.5 is a recommended sequence that initializes a Wi-Fi-/LwIP-based application. However, it is **NOT** a must-follow sequence, which means that you can create the application task in step 1.1 and put all other initialization in the application task. Moreover, you may not want to create the application task in the initialization phase if the application task depends on the sockets. Rather, you can defer the task creation until the IP is obtained.

2. Wi-Fi Configuration Phase

Once the Wi-Fi driver is initialized, you can start configuring the Wi-Fi driver. In this scenario, the mode is station, so you may need to call `esp_wifi_set_mode()` (WIFI_MODE_STA) to configure the Wi-Fi mode as station. You can call other *esp_wifi_set_xxx* APIs to configure more settings, such as the protocol mode, the country code, and the bandwidth. Refer to *ESP32-C3 Wi-Fi Configuration*.

Generally, the Wi-Fi driver should be configured before the Wi-Fi connection is set up. But this is **NOT** mandatory, which means that you can configure the Wi-Fi connection anytime, provided that the Wi-Fi driver is initialized successfully. However, if the configuration does not need to change after the Wi-Fi connection is set up, you should configure the Wi-Fi driver at this stage, because the configuration APIs (such as `esp_wifi_set_protocol()`) will cause the Wi-Fi to reconnect, which may not be desirable.

If the Wi-Fi NVS flash is enabled by menuconfig, all Wi-Fi configuration in this phase, or later phases, will be stored into flash. When the board powers on/reboots, you do not need to configure the Wi-Fi driver from scratch. You only need to call `esp_wifi_get_xxx` APIs to fetch the configuration stored in flash previously. You can also configure the Wi-Fi driver if the previous configuration is not what you want.

3. Wi-Fi Start Phase

- s3.1: Call `esp_wifi_start()` to start the Wi-Fi driver.
- s3.2: The Wi-Fi driver posts *WIFI_EVENT_STA_START* to the event task; then, the event task will do some common things and will call the application event callback function.
- s3.3: The application event callback function relays the *WIFI_EVENT_STA_START* to the application task. We recommend that you call `esp_wifi_connect()`. However, you can also call `esp_wifi_connect()` in other phrases after the *WIFI_EVENT_STA_START* arises.

4. Wi-Fi Connect Phase

- s4.1: Once `esp_wifi_connect()` is called, the Wi-Fi driver will start the internal scan/connection process.
- s4.2: If the internal scan/connection process is successful, the *WIFI_EVENT_STA_CONNECTED* will be generated. In the event task, it starts the DHCP client, which will finally trigger the DHCP process.
- s4.3: In the above-mentioned scenario, the application event callback will relay the event to the application task. Generally, the application needs to do nothing, and you can do whatever you want, e.g., print a log.

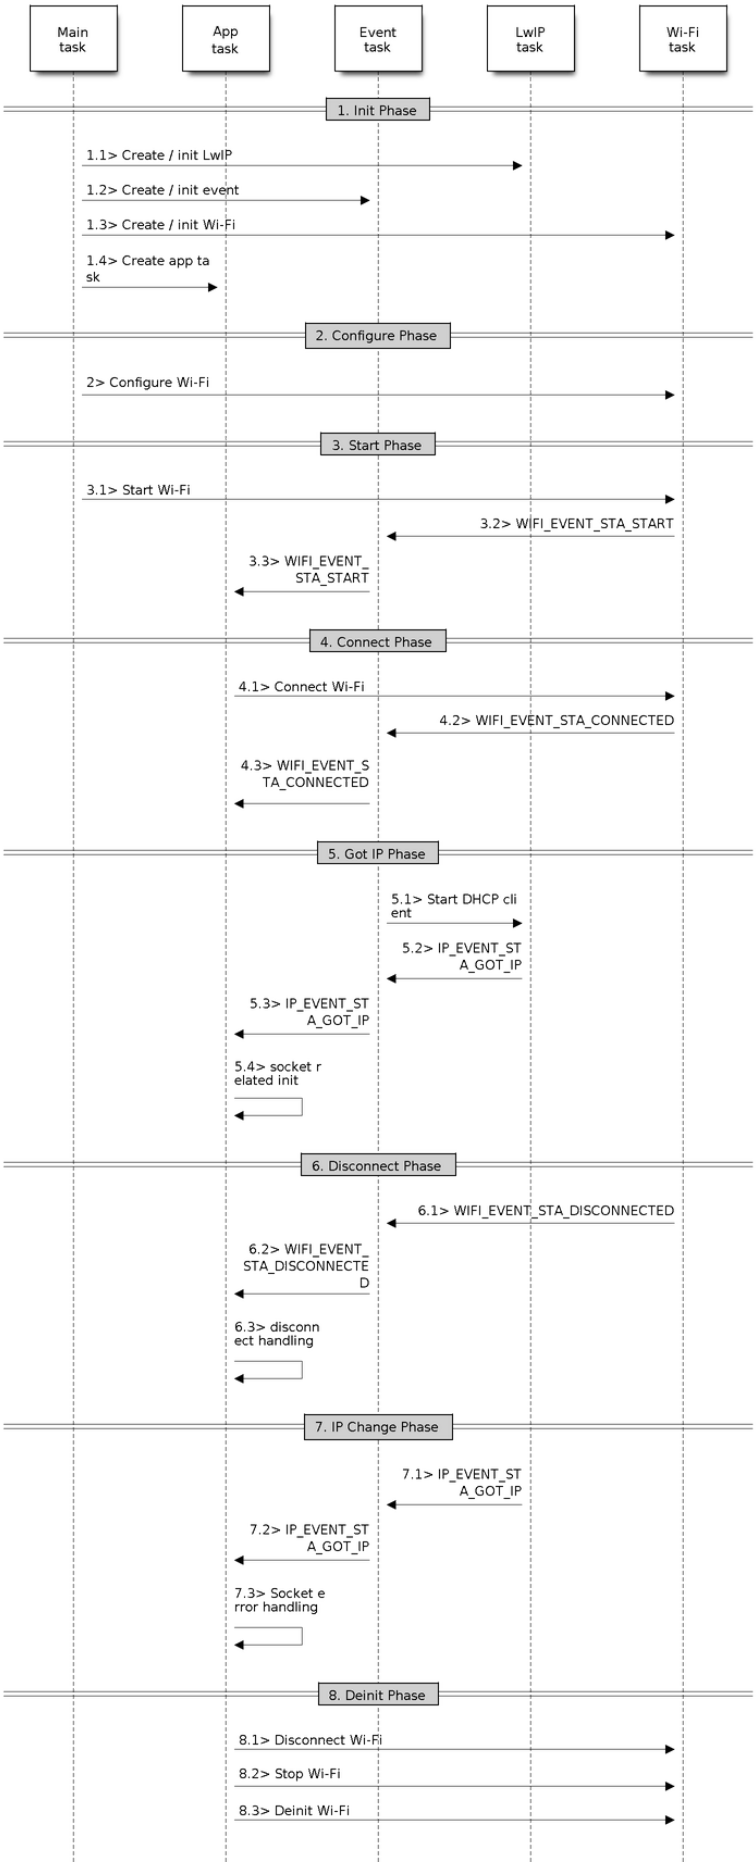

Fig. 61: Sample Wi-Fi Event Scenarios in Station Mode

In step 4.2, the Wi-Fi connection may fail because, for example, the password is wrong, or the AP is not found. In a case like this, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason for such a failure will be provided. For handling events that disrupt Wi-Fi connection, please refer to phase 6.

5. Wi-Fi 'Got IP' Phase

- s5.1: Once the DHCP client is initialized in step 4.2, the *got IP* phase will begin.
- s5.2: If the IP address is successfully received from the DHCP server, then *IP_EVENT_STA_GOT_IP* will arise and the event task will perform common handling.
- s5.3: In the application event callback, *IP_EVENT_STA_GOT_IP* is relayed to the application task. For LwIP-based applications, this event is very special and means that everything is ready for the application to begin its tasks, e.g., creating the TCP/UDP socket. A very common mistake is to initialize the socket before *IP_EVENT_STA_GOT_IP* is received. **DO NOT start the socket-related work before the IP is received.**

6. Wi-Fi Disconnect Phase

- s6.1: When the Wi-Fi connection is disrupted, e.g., the AP is powered off or the RSSI is poor, *WIFI_EVENT_STA_DISCONNECTED* will arise. This event may also arise in phase 3. Here, the event task will notify the LwIP task to clear/remove all UDP/TCP connections. Then, all application sockets will be in a wrong status. In other words, no socket can work properly when this event happens.
- s6.2: In the scenario described above, the application event callback function relays *WIFI_EVENT_STA_DISCONNECTED* to the application task. The recommended actions are: 1) call `esp_wifi_connect()` to reconnect the Wi-Fi, 2) close all sockets, and 3) re-create them if necessary. For details, please refer to *WIFI_EVENT_STA_DISCONNECTED*.

7. Wi-Fi IP Change Phase

- s7.1: If the IP address is changed, the *IP_EVENT_STA_GOT_IP* will arise with "ip_change" set to true.
- s7.2: **This event is important to the application. When it occurs, the timing is good for closing all created sockets and recreating them.**

8. Wi-Fi Deinit Phase

- s8.1: Call `esp_wifi_disconnect()` to disconnect the Wi-Fi connectivity.
- s8.2: Call `esp_wifi_stop()` to stop the Wi-Fi driver.
- s8.3: Call `esp_wifi_deinit()` to unload the Wi-Fi driver.

4.35.8 ESP32-C3 Wi-Fi AP General Scenario

Below is a "big scenario" which describes some small scenarios in AP mode:

4.35.9 ESP32-C3 Wi-Fi Scan

Currently, the `esp_wifi_scan_start()` API is supported only in station or station/AP mode.

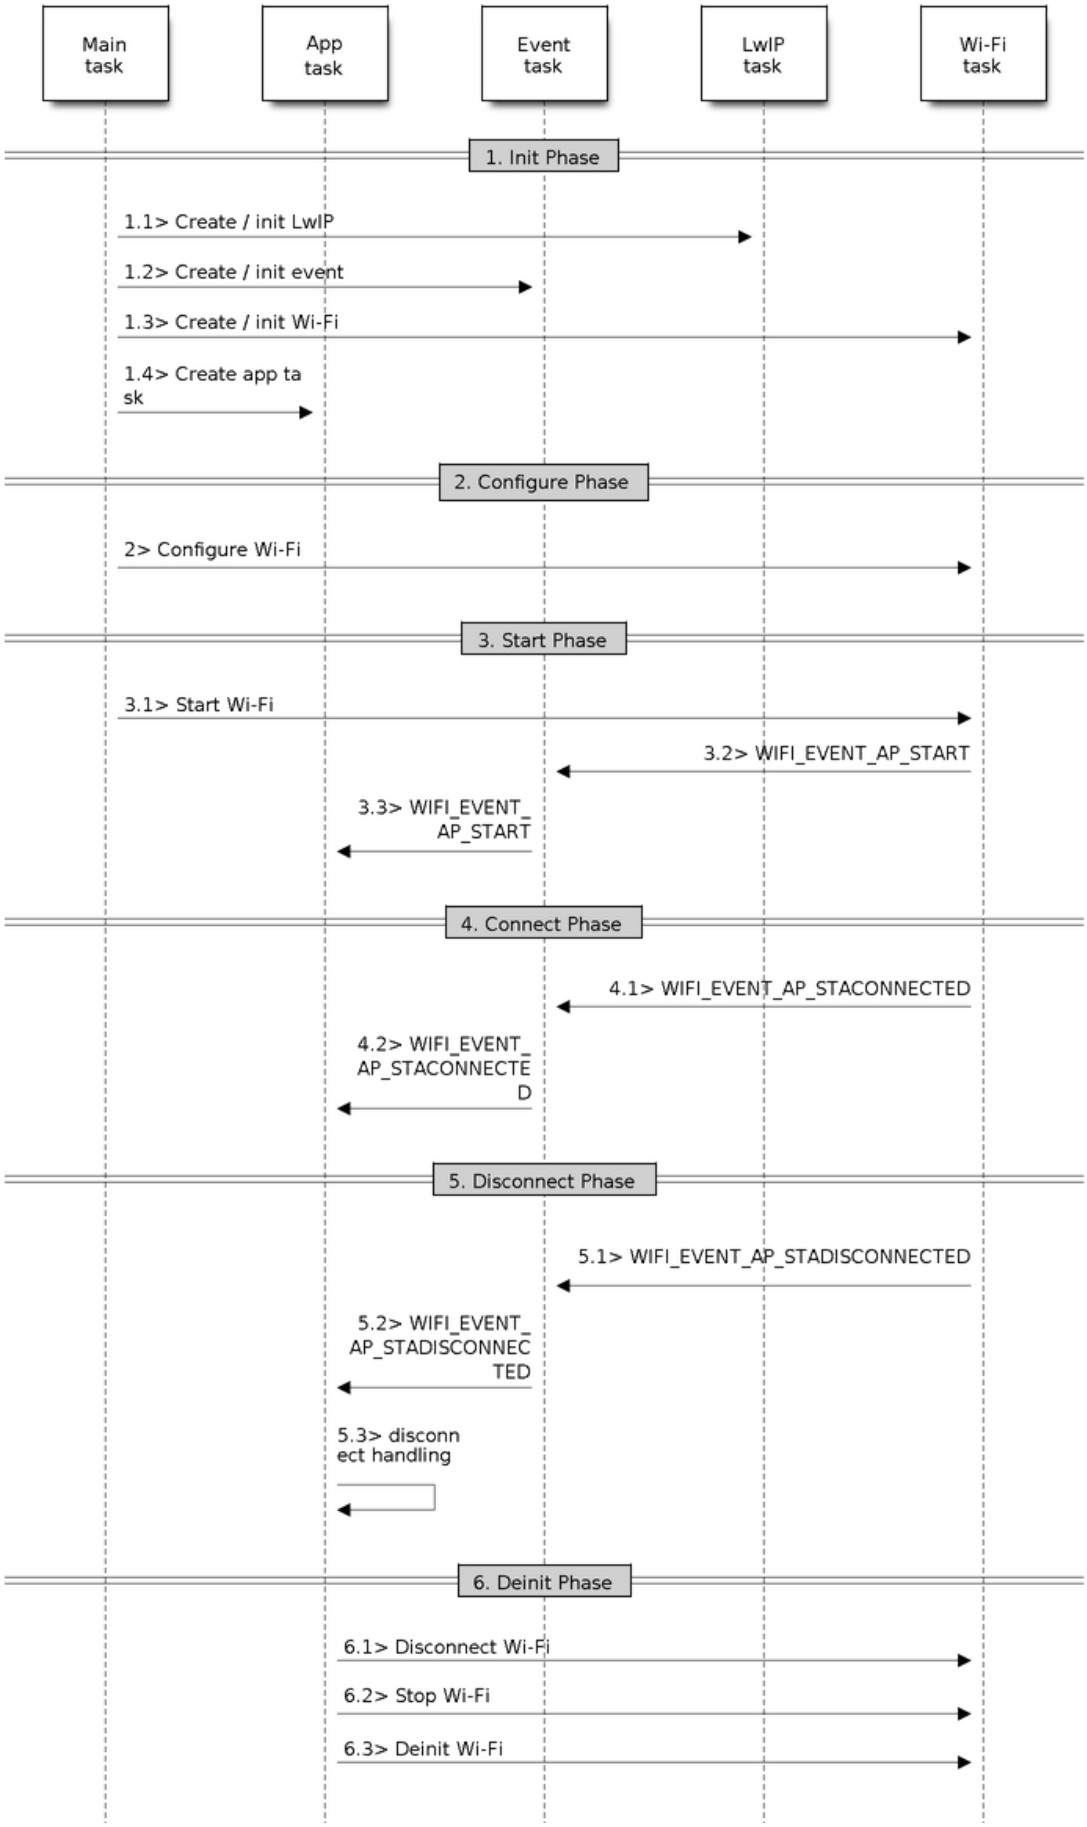

Fig. 62: Sample Wi-Fi Event Scenarios in AP Mode

Scan Type

Mode	Description
Active Scan	Scan by sending a probe request. The default scan is an active scan.
Passive Scan	No probe request is sent out. Just switch to the specific channel and wait for a beacon. Application can enable it via the scan_type field of `wifi_scan_config_t`.
Foreground Scan	This scan is applicable when there is no Wi-Fi connection in station mode. Foreground or background scanning is controlled by the Wi-Fi driver and cannot be configured by the application.
Background Scan	This scan is applicable when there is a Wi-Fi connection in station mode or in station/AP mode. Whether it is a foreground scan or background scan depends on the Wi-Fi driver and cannot be configured by the application.
All-Channel Scan	It scans all of the channels. If the channel field of `wifi_scan_config_t` is set to 0, it is an all-channel scan.
Specific Channel Scan	It scans specific channels only. If the channel field of `wifi_scan_config_t` set to 1-14, it is a specific-channel scan.

The scan modes in above table can be combined arbitrarily, so there are in total 8 different scans:

- All-Channel Background Active Scan
- All-Channel Background Passive Scan
- All-Channel Foreground Active Scan
- All-Channel Foreground Passive Scan
- Specific-Channel Background Active Scan
- Specific-Channel Background Passive Scan
- Specific-Channel Foreground Active Scan
- Specific-Channel Foreground Passive Scan

Scan Configuration

The scan type and other per-scan attributes are configured by *`esp_wifi_scan_start()`*. The table below provides a detailed description of `wifi_scan_config_t`.

Field	Description
ssid	If the SSID is not NULL, it is only the AP with the same SSID that can be scanned.
bssid	If the BSSID is not NULL, it is only the AP with the same BSSID that can be scanned.
channel	If "channel" is 0, there will be an all-channel scan; otherwise, there will be a specific-channel scan.
show_hidden	If "show_hidden" is 0, the scan ignores the AP with a hidden SSID; otherwise, the scan considers the hidden AP a normal one.
scan_type	If "scan_type" is WIFI_SCAN_TYPE_ACTIVE, the scan is "active"; otherwise, it is a "passive" one.
scan_time	This field is used to control how long the scan dwells on each channel. For passive scans, scan_time.passive designates the dwell time for each channel. For active scans, dwell times for each channel are listed in the table below. Here, min is short for scan time.active.min and max is short for scan_time.active.max. • min=0, max=0: scan dwells on each channel for 120 ms. • min>0, max=0: scan dwells on each channel for 120 ms. • min=0, max>0: scan dwells on each channel for `max` ms. • min>0, max>0: the minimum time the scan dwells on each channel is `min` ms. If no AP is found during this time frame, the scan switches to the next channel. Otherwise, the scan dwells on the channel for `max` ms. If you want to improve the performance of the scan, you can try to modify these two parameters.

There are also some global scan attributes which are configured by API *`esp_wifi_set_config()`*, refer to

Station Basic Configuration

Scan All APs on All Channels (Foreground)

Scenario:

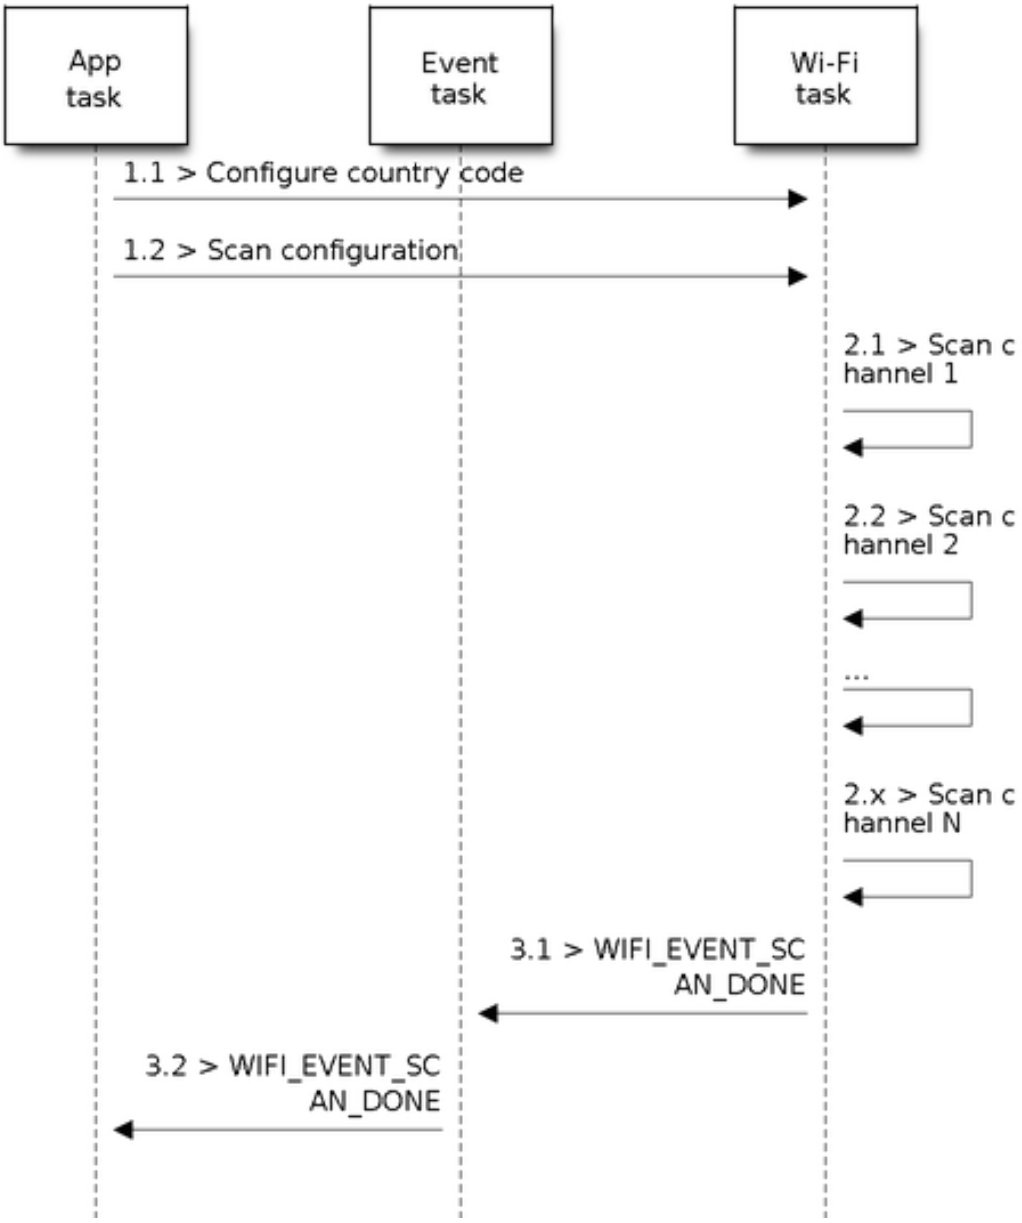

Fig. 63: Foreground Scan of all Wi-Fi Channels

The scenario above describes an all-channel, foreground scan. The foreground scan can only occur in station mode where the station does not connect to any AP. Whether it is a foreground or background scan is totally determined by the Wi-Fi driver, and cannot be configured by the application.

Detailed scenario description:

Scan Configuration Phase

- s1.1: Call `esp_wifi_set_country()` to set the country info if the default country info is not what you want. Refer to *Wi-Fi Country Code*.

- s1.2: Call `esp_wifi_scan_start()` to configure the scan. To do so, you can refer to *Scan Configuration*. Since this is an all-channel scan, just set the SSID/BSSID/channel to 0.

Wi-Fi Driver's Internal Scan Phase

- s2.1: The Wi-Fi driver switches to channel 1. In this case, the scan type is WIFI_SCAN_TYPE_ACTIVE, and a probe request is broadcasted. Otherwise, the Wi-Fi will wait for a beacon from the APs. The Wi-Fi driver will stay in channel 1 for some time. The dwell time is configured in min/max time, with the default value being 120 ms.
- s2.2: The Wi-Fi driver switches to channel 2 and performs the same operation as in step 2.1.
- s2.3: The Wi-Fi driver scans the last channel N, where N is determined by the country code which is configured in step 1.1.

Scan-Done Event Handling Phase

- s3.1: When all channels are scanned, *WIFI_EVENT_SCAN_DONE* will arise.
- s3.2: The application's event callback function notifies the application task that *WIFI_EVENT_SCAN_DONE* is received. `esp_wifi_scan_get_ap_num()` is called to get the number of APs that have been found in this scan. Then, it allocates enough entries and calls `esp_wifi_scan_get_ap_records()` to get the AP records. Please note that the AP records in the Wi-Fi driver will be freed once `esp_wifi_scan_get_ap_records()` is called. Do not call `esp_wifi_scan_get_ap_records()` twice for a single scan-done event. If `esp_wifi_scan_get_ap_records()` is not called when the scan-done event occurs, the AP records allocated by the Wi-Fi driver will not be freed. So, make sure you call `esp_wifi_scan_get_ap_records()`, yet only once.

Scan All APs on All Channels (Background)

Scenario:

The scenario above is an all-channel background scan. Compared to *Scan All APs on All Channels (Foreground)* , the difference in the all-channel background scan is that the Wi-Fi driver will scan the back-to-home channel for 30 ms before it switches to the next channel to give the Wi-Fi connection a chance to transmit/receive data.

Scan for Specific AP on All Channels

Scenario:

This scan is similar to *Scan All APs on All Channels (Foreground)*. The differences are:

- s1.1: In step 1.2, the target AP will be configured to SSID/BSSID.
- s2.1 ~ s2.N: Each time the Wi-Fi driver scans an AP, it will check whether it is a target AP or not. If the scan is `WIFI_FAST_SCAN` scan and the target AP is found, then the scan-done event will arise and scanning will end; otherwise, the scan will continue. Please note that the first scanned channel may not be channel 1, because the Wi-Fi driver optimizes the scanning sequence.

It is a possible situation that there are multiple APs that match the target AP info, e.g., two APs with the SSID of "ap" are scanned. In this case, if the scan is `WIFI_FAST_SCAN`, then only the first scanned "ap" will be found. If the scan is `WIFI_ALL_CHANNEL_SCAN`, both "ap" will be found and the station will connect the "ap" according to the configured strategy. Refer to *Station Basic Configuration*.

You can scan a specific AP, or all of them, in any given channel. These two scenarios are very similar.

Scan in Wi-Fi Connect

When `esp_wifi_connect()` is called, the Wi-Fi driver will try to scan the configured AP first. The scan in "Wi-Fi Connect" is the same as *Scan for Specific AP On All Channels*, except that no scan-done event will be generated

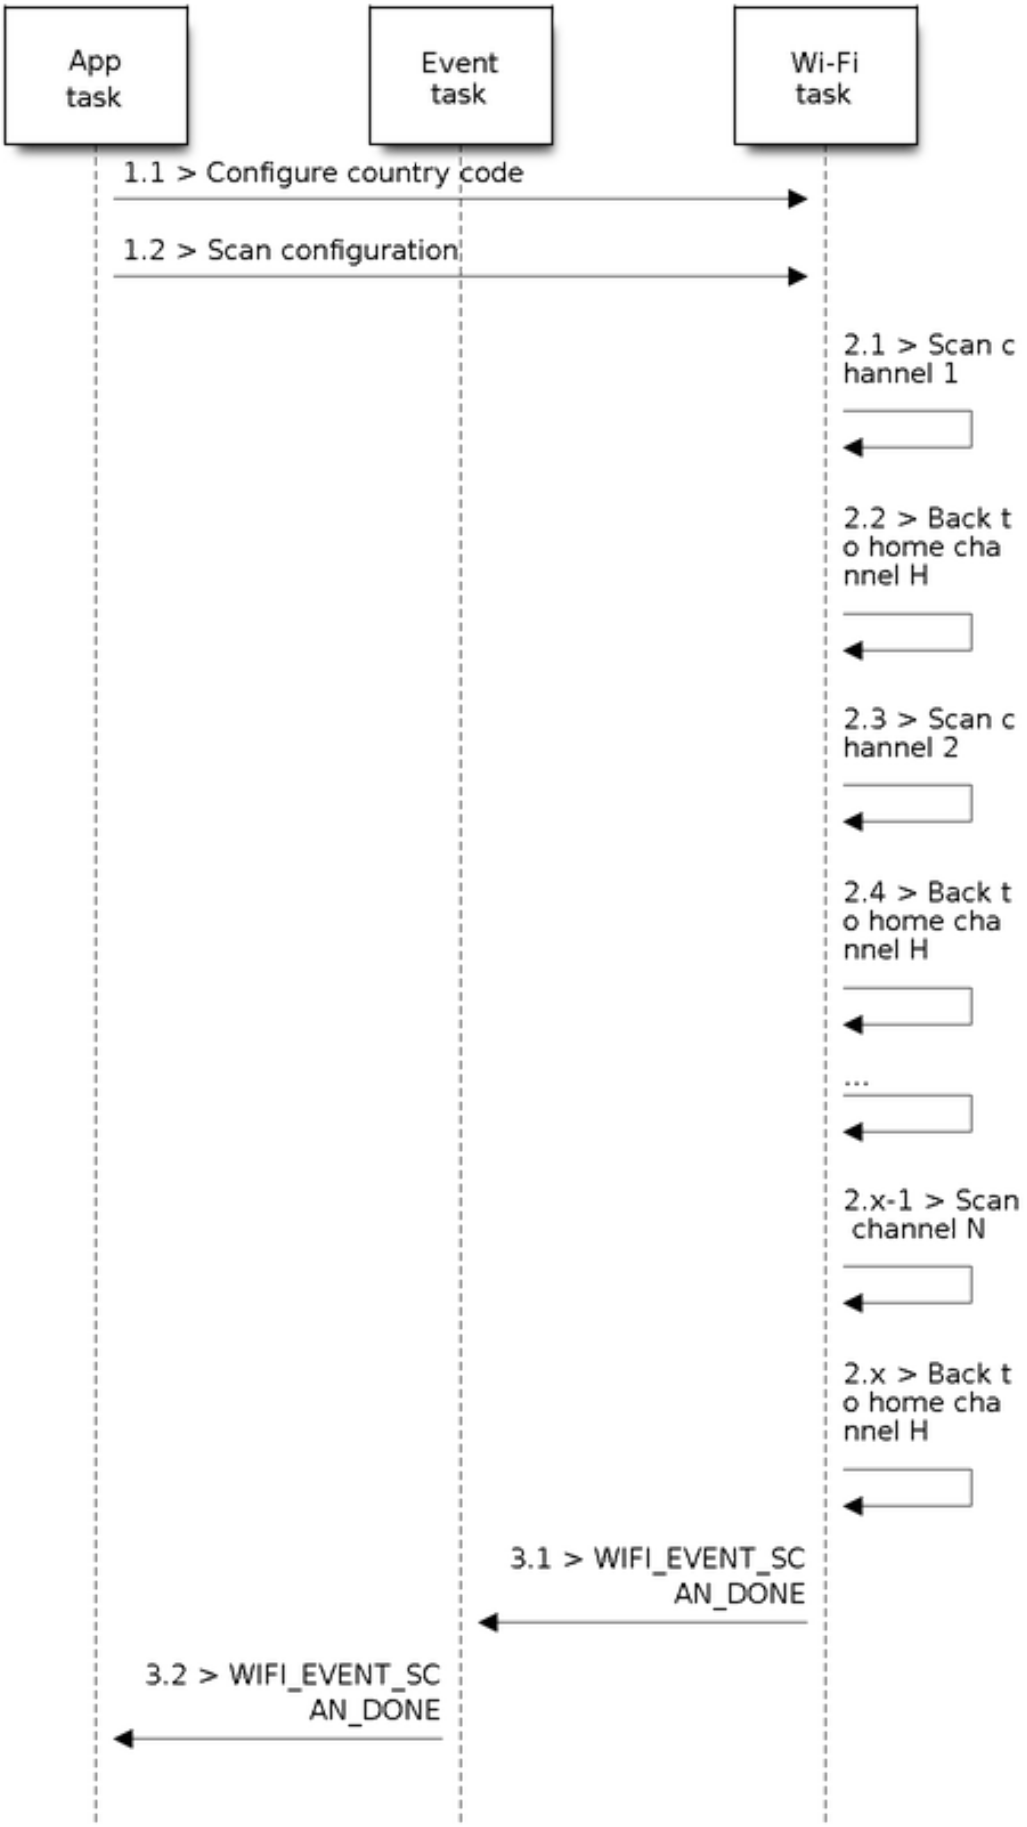

Fig. 64: Background Scan of all Wi-Fi Channels

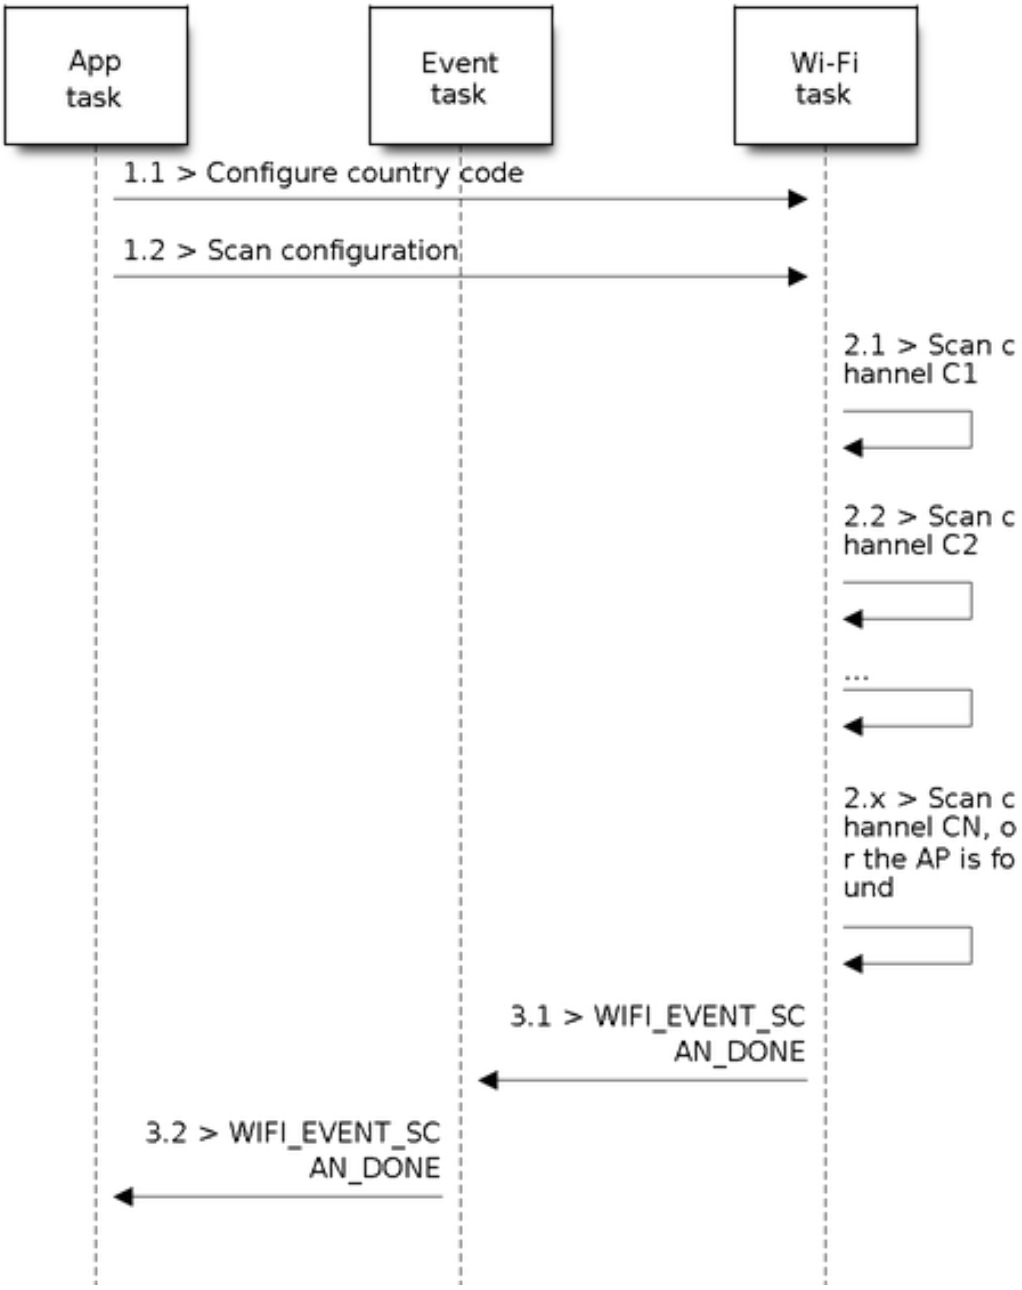

Fig. 65: Scan of specific Wi-Fi Channels

when the scan is completed. If the target AP is found, the Wi-Fi driver will start the Wi-Fi connection; otherwise, *WIFI_EVENT_STA_DISCONNECTED* will be generated. Refer to *Scan for Specific AP On All Channels*.

Scan in Blocked Mode

If the block parameter of `esp_wifi_scan_start()` is true, then the scan is a blocked one, and the application task will be blocked until the scan is done. The blocked scan is similar to an unblocked one, except that no scan-done event will arise when the blocked scan is completed.

Parallel Scan

Two application tasks may call `esp_wifi_scan_start()` at the same time, or the same application task calls `esp_wifi_scan_start()` before it gets a scan-done event. Both scenarios can happen. **However, the Wi-Fi driver does not support multiple concurrent scans adequately. As a result, concurrent scans should be avoided.** Support for concurrent scan will be enhanced in future releases, as the ESP32-C3's Wi-Fi functionality improves continuously.

Scan When Wi-Fi Is Connecting

The `esp_wifi_scan_start()` fails immediately if the Wi-Fi is connecting, because the connecting has higher priority than the scan. If scan fails because of connecting, the recommended strategy is to delay for some time and retry scan again. The scan will succeed once the connecting is completed.

However, the retry/delay strategy may not work all the time. Considering the following scenarios:

- The station is connecting a non-existing AP or it connects the existing AP with a wrong password, it always raises the event *WIFI_EVENT_STA_DISCONNECTED*.
- The application calls `esp_wifi_connect()` to reconnect on receiving the disconnect event.
- Another application task, e.g., the console task, calls `esp_wifi_scan_start()` to do scan, the scan always fails immediately because the station keeps connecting.
- When scan fails, the application simply delays for some time and retries the scan.

In the above scenarios, the scan will never succeed because the connecting is in process. So if the application supports similar scenario, it needs to implement a better reconnection strategy. For example:

- The application can choose to define a maximum continuous reconnection counter and stop reconnecting once the counter reaches the maximum.
- The application can choose to reconnect immediately in the first N continuous reconnection, then give a delay sometime and reconnect again.

The application can define its own reconnection strategy to avoid the scan starve to death. Refer to <*Wi-Fi Reconnect*>.

4.35.10 ESP32-C3 Wi-Fi Station Connecting Scenario

This scenario depicts the case if only one target AP is found in the scan phase. For scenarios where more than one AP with the same SSID is found, refer to *ESP32-C3 Wi-Fi Station Connecting When Multiple APs Are Found*.

Generally, the application can ignore the connecting process. Below is a brief introduction to the process for those who are really interested.

Scenario:

Scan Phase

- s1.1: The Wi-Fi driver begins scanning in "Wi-Fi Connect". Refer to *Scan in Wi-Fi Connect* for more details.

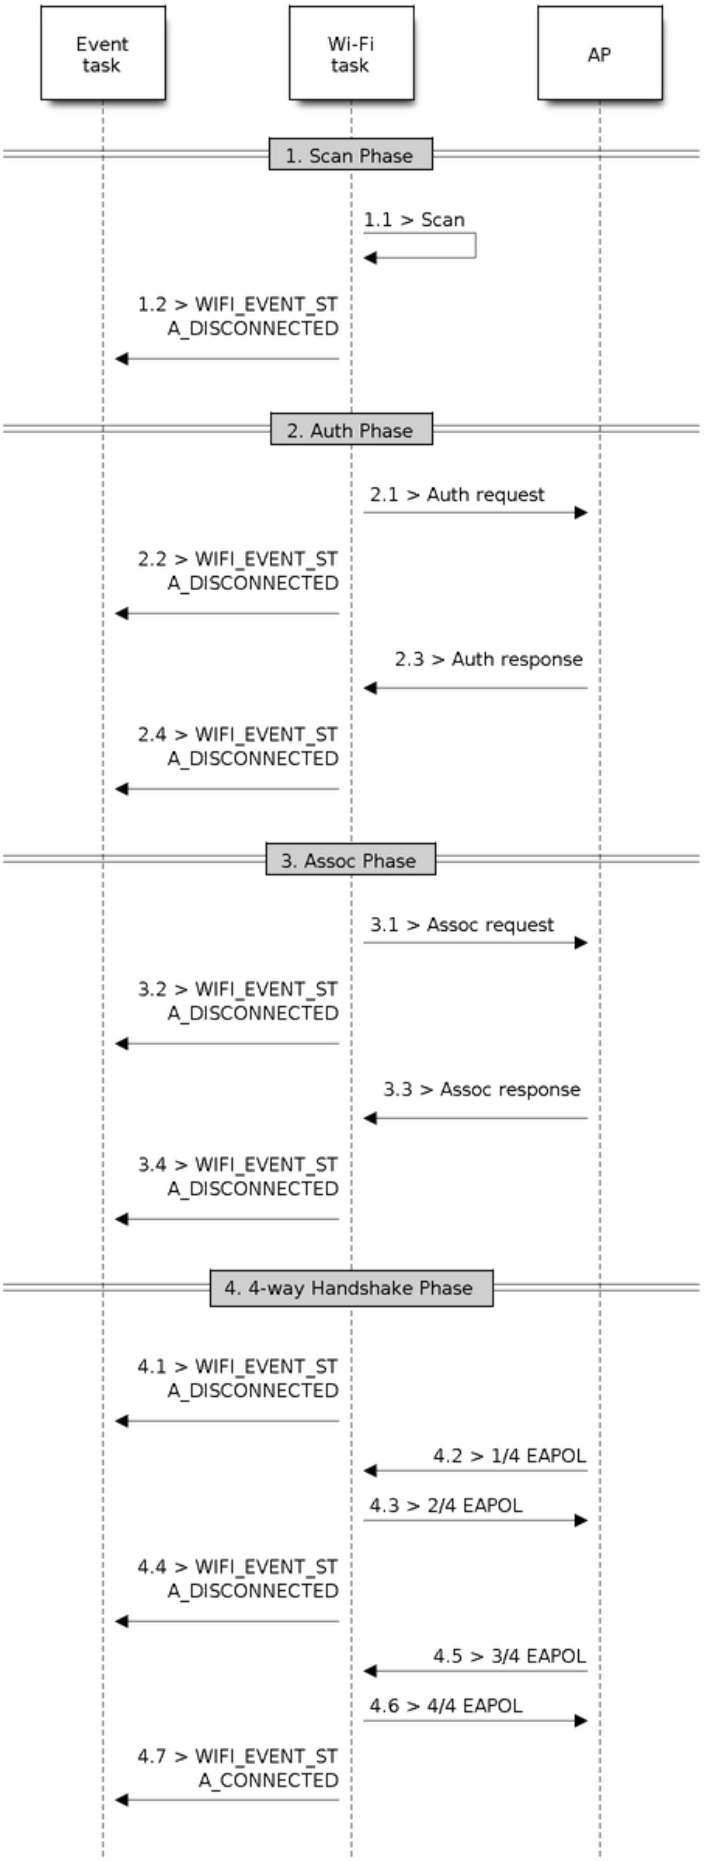

Fig. 66: Wi-Fi Station Connecting Process

- s1.2: If the scan fails to find the target AP, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code could either be `WIFI_REASON_NO_AP_FOUND` or `WIFI_REASON_NO_AP_FOUND_W_COMPATIBLE_SECURITY` or `WIFI_REASON_NO_AP_FOUND_IN_AUTHMODE_THRESHOLD` or `WIFI_REASON_NO_AP_FOUND_IN_RSSI_THRES` depending of the Station's configuration. Refer to *Wi-Fi Reason Code*.

Auth Phase

- s2.1: The authentication request packet is sent and the auth timer is enabled.
- s2.2: If the authentication response packet is not received before the authentication timer times out, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_AUTH_EXPIRE`. Refer to *Wi-Fi Reason Code*.
- s2.3: The auth-response packet is received and the auth-timer is stopped.
- s2.4: The AP rejects authentication in the response and *WIFI_EVENT_STA_DISCONNECTED* arises, while the reason code is `WIFI_REASON_AUTH_FAIL` or the reasons specified by the AP. Refer to *Wi-Fi Reason Code*.

Association Phase

- s3.1: The association request is sent and the association timer is enabled.
- s3.2: If the association response is not received before the association timer times out, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_ASSOC_EXPIRE`. Refer to *Wi-Fi Reason Code*.
- s3.3: The association response is received and the association timer is stopped.
- s3.4: The AP rejects the association in the response and *WIFI_EVENT_STA_DISCONNECTED* arises, while the reason code is the one specified in the association response. Refer to *Wi-Fi Reason Code*.

Four-way Handshake Phase

- s4.1: The handshake timer is enabled, and the 1/4 EAPOL is not received before the handshake timer expires. *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to *Wi-Fi Reason Code*.
- s4.2: The 1/4 EAPOL is received.
- s4.3: The station replies 2/4 EAPOL.
- s4.4: If the 3/4 EAPOL is not received before the handshake timer expires, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to *Wi-Fi Reason Code*.
- s4.5: The 3/4 EAPOL is received.
- s4.6: The station replies 4/4 EAPOL.
- s4.7: The station raises *WIFI_EVENT_STA_CONNECTED*.

Wi-Fi Reason Code

The table below shows the reason-code defined in ESP32-C3. The first column is the macro name defined in esp_wifi/include/esp_wifi_types.h. The common prefix `WIFI_REASON` is removed, which means that `UNSPECIFIED` actually stands for `WIFI_REASON_UNSPECIFIED` and so on. The second column is the value of the reason. This reason value is same as defined in section 9.4.1.7 of IEEE 802.11-2020. (For more information, refer to the standard mentioned above.) The last column describes the reason. Reason-codes starting from 200 are Espressif defined reason-codes and are not part of IEEE 802.11-2020.

Also note that REASON_NO_AP_FOUND_XXX codes are mentioned in increasing order of importance. So if a single AP has a combination of the above reasons for failure, the more important one will be reported. Additionally, if there are multiple APs that satisfy the identifying criteria and connecting to all of them fails for different reasons mentioned above, then the reason code reported is for the AP that failed connection due to the least important reason code, as it was the one closest to a successful connection.

Following reason codes are renamed to their shorter form to wrap the table in page width.

- TRANSMISSION_LINK_ESTABLISHMENT_FAILED : TX_LINK_EST_FAILED
- NO_AP_FOUND_W_COMPATIBLE_SECURITY : NO_AP_FOUND_SECURITY
- NO_AP_FOUND_IN_AUTHMODE_THRESHOLD : NO_AP_FOUND_AUTHMODE
- NO_AP_FOUND_IN_RSSI_THRESHOLD : NO_AP_FOUND_RSSI

Reason code	Value	Description
UNSPECIFIED	1	Generally, it means an internal failure, e.g., the memory runs out, the internal TX fails, or the reason is received from the remote side.
AUTH_EXPIRE	2	The previous authentication is no longer valid. For the ESP station, this reason is reported when: • auth is timed out. • the reason is received from the AP. For the ESP AP, this reason is reported when: • the AP has not received any packets from the station in the past five minutes. • the AP is stopped by calling `esp_wifi_stop()`. • the station is de-authed by calling `esp_wifi_deauth_sta()`.
AUTH_LEAVE	3	De-authenticated, because the sending station is leaving (or has left). For the ESP station, this reason is reported when: • it is received from the AP.
ASSOC_EXPIRE	4	Disassociated due to inactivity. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP has not received any packets from the station in the past five minutes. • the AP is stopped by calling `esp_wifi_stop()`. • the station is de-authed by calling `esp_wifi_deauth_sta()`.
ASSOC_TOOMANY	5	Disassociated, because the AP is unable to handle all currently associated STAs at the same time. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the stations associated with the AP reach the maximum number that the AP can support.
NOT_AUTHED	6	Class-2 frame received from a non-authenticated STA. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP receives a packet with data from a non-authenticated station.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Description
NOT_ASSOCED	7	Class-3 frame received from a non-associated STA. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP receives a packet with data from a non-associated station.
ASSOC_LEAVE	8	Disassociated, because the sending station is leaving (or has left) BSS. For the ESP station, this reason is reported when: • it is received from the AP. • the station is disconnected by `esp_wifi_disconnect()` and other APIs.
ASSOC_NOT_AUTHED	9	station requesting (re)association is not authenticated by the responding STA. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP receives packets with data from an associated, yet not authenticated, station.
DISASSOC_PWRCAP_BAD	10	Disassociated, because the information in the Power Capability element is unacceptable. For the ESP station, this reason is reported when: • it is received from the AP.
DISASSOC_SUPCHAN_BAD	11	Disassociated, because the information in the Supported Channels element is unacceptable. For the ESP station, this reason is reported when: • it is received from the AP.
BSS_TRANSITION_DISASSOC	12	AP wants us to move to another AP, sent as a part of BTM procedure. Please note that when station is sending BTM request and moving to another AP, ROAMING reason code will be reported instead of this. For the ESP station, this reason is reported when: • it is received from the AP.
IE_INVALID	13	Invalid element, i.e., an element whose content does not meet the specifications of the Standard in frame formats clause. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP parses a wrong WPA or RSN IE.
MIC_FAILURE	14	Message integrity code (MIC) failure. For the ESP station, this reason is reported when: • it is received from the AP.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Description
4WAY_HANDSHAKE_TIMEOUT	15	Four-way handshake times out. For legacy reasons, in ESP this reason code is replaced with `WIFI_REASON_HANDSHAKE_TIMEOUT`. For the ESP station, this reason is reported when: • the handshake times out. • it is received from the AP.
GROUP_KEY_UPDATE_TIMEOUT	16	Group-Key Handshake times out. For the ESP station, this reason is reported when: • it is received from the AP.
IE_IN_4WAY_DIFFERS	17	The element in the four-way handshake is different from the (Re-)Association Request/Probe and Response/Beacon frame. For the ESP station, this reason is reported when: • it is received from the AP. • the station finds that the four-way handshake IE differs from the IE in the (Re-)Association Request/Probe and Response/Beacon frame.
GROUP_CIPHER_INVALID	18	Invalid group cipher. For the ESP station, this reason is reported when: • it is received from the AP.
PAIRWISE_CIPHER_INVALID	19	Invalid pairwise cipher. For the ESP station, this reason is reported when: • it is received from the AP.
AKMP_INVALID	20	Invalid AKMP. For the ESP station, this reason is reported when: - it is received from the AP.
UNSUPP_RSN_IE_VERSION	21	Unsupported RSNE version. For the ESP station, this reason is reported when: • it is received from the AP.
INVALID_RSN_IE_CAP	22	Invalid RSNE capabilities. For the ESP station, this reason is reported when: • it is received from the AP.
802_1X_AUTH_FAILED	23	IEEE 802.1X. authentication failed. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • IEEE 802.1X. authentication fails.
CIPHER_SUITE_REJECTED	24	Cipher suite rejected due to security policies. For the ESP station, this reason is reported when: • it is received from the AP.
TDLS_PEER_UNREACHABLE	25	TDLS direct-link teardown due to TDLS peer STA unreachable via the TDLS direct link.
TDLS_UNSPECIFIED	26	TDLS direct-link teardown for unspecified reason.
SSP_REQUESTED_DISASSOC	27	Disassociated because session terminated by SSP request.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Description
NO_SSP_ROAMING_AGREEMENT	28	Disassociated because of lack of SSP roaming agreement.
BAD_CIPHER_OR_AKM	29	Requested service rejected because of SSP cipher suite or AKM requirement.
NOT_AUTHORIZED_THIS_LOCATION	30	Requested service not authorized in this location.
SERVICE_CHANGE_PRECLUDES_TS	31	TS deleted because QoS AP lacks sufficient bandwidth for this QoS STA due to a change in BSS service characteristics or operational mode (e.g., an HT BSS change from 40 MHz channel to 20 MHz channel).
UNSPECIFIED_QOS	32	Disassociated for unspecified, QoS-related reason.
NOT_ENOUGH_BANDWIDTH	33	Disassociated because QoS AP lacks sufficient bandwidth for this QoS STA.
MISSING_ACKS	34	Disassociated because excessive number of frames need to be acknowledged, but are not acknowledged due to AP transmissions and/or poor channel conditions.
EXCEEDED_TXOP	35	Disassociated because STA is transmitting outside the limits of its TXOPs.
STA_LEAVING	36	Requesting STA is leaving the BSS (or resetting).
END_BA	37	Requesting STA is no longer using the stream or session.
UNKNOWN_BA	38	Requesting STA received frames using a mechanism for which a setup has not been completed.
TIMEOUT	39	Requested from peer STA due to timeout
Reserved	40 ~ 45	Reserved as per IEEE80211-2020 specifications.
PEER_INITIATED	46	In a Disassociation frame: Disassociated because authorized access limit reached.
AP_INITIATED	47	In a Disassociation frame: Disassociated due to external service requirements.
INVALID_FT_ACTION_FRAME_COUNT	48	Invalid FT Action frame count.
INVALID_PMKID	49	Invalid pairwise master key identifier (PMKID).
INVALID_MDE	50	Invalid MDE.
INVALID_FTE	51	Invalid FTE
TX_LINK_EST_FAILED	67	TRANSMISSION_LINK_ESTABLISHMENT_FAILED will be reported when Transmission link establishment in alternative channel failed.
ALTERATIVE_CHANNEL_OCCUPIED	68	The alternative channel is occupied.
BEACON_TIMEOUT	200	Espressif-specific Wi-Fi reason code: when the station loses N beacons continuously, it will disrupt the connection and report this reason.
NO_AP_FOUND	201	Espressif-specific Wi-Fi reason code: when the station fails to scan the target AP, this reason code will be reported. In case of security mismatch or station's configuration mismatch, new reason codes NO_AP_FOUND_XXX will be reported.
AUTH_FAIL	202	Espressif-specific Wi-Fi reason code: the authentication fails, but not because of a timeout.
ASSOC_FAIL	203	Espressif-specific Wi-Fi reason code: the association fails, but not because of ASSOC_EXPIRE or ASSOC_TOOMANY.
HANDSHAKE_TIMEOUT	204	Espressif-specific Wi-Fi reason code: the handshake fails for the same reason as that in WIFI_REASON_4WAY_HANDSHAKE_TIMEOUT.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Description
CONNECTION_FAIL	205	Espressif-specific Wi-Fi reason code: the connection to the AP has failed.
AP_TSF_RESET	206	Espressif-specific Wi-Fi reason code: the disconnection happened due to AP's TSF reset.
ROAMING	207	Espressif-specific Wi-Fi reason code: the station is roaming to another AP, this reason code is just for info, station will automatically move to another AP.
ASSOC_COMEBACK_TIME_TOO_LONG	208	Espressif-specific Wi-Fi reason code: This reason code will be reported when Assoc comeback time in association response is too high.
SA_QUERY_TIMEOUT	209	Espressif-specific Wi-Fi reason code: This reason code will be reported when AP did not reply of SA query sent by ESP station.
NO_AP_FOUND_SECURITY	210	Espressif-specific Wi-Fi reason code: NO_AP_FOUND_W_COMPATIBLE_SECURITY will be reported if an AP that fits identifying criteria (e.g. ssid) is found but the connection is rejected due to incompatible security configuration. These situations could be: • The Access Point is offering WEP security, but our station's password is not WEP-compliant. • The station is configured in Open mode; however, the Access Point is broadcasting in secure mode. • The Access Point uses Enterprise security, but we haven't set up the corresponding enterprise configuration, and vice versa. • SAE-PK is configured in the station configuration, but the Access Point does not support SAE-PK. • SAE-H2E is configured in the station configuration; however, the AP only supports WPA3-PSK or WPA3-WPA2-PSK. • The station is configured in secure mode (Password or Enterprise mode); however, an Open AP is found during the scan. • SAE HnP is configured in the station configuration; however, the AP supports H2E only. • H2E is disabled in the station configuration; however, the AP is WPA3-EXT-PSK, which requires H2E support. • The Access Point requires PMF, but the station is not configured for PMF capable/required. • The station configuration requires PMF, but the AP is not configured for PMF capable/required. • The Access Point is using unsupported group management/pairwise ciphers. • OWE is not enabled in the station configuration, but the discovered AP is using OWE only mode. • The Access Point is broadcasting an invalid RSNXE in its beacons. • The Access Point is in Independent BSS mode.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Description
NO_AP_FOUND_AUTHMODE	211	Espressif-specific Wi-Fi reason code: NO_AP_FOUND_IN_AUTHMODE_THRESHOLD will be reported if an AP that fit identifying criteria (e.g. ssid) is found but the authmode threhsold set in the wifi_config_t is not met.
NO_AP_FOUND_RSSI	212	Espressif-specific Wi-Fi reason code: NO_AP_FOUND_IN_RSSI_THRESHOLD will be reported if an AP that fits identifying criteria (e.g. ssid) is found but the RSSI threhsold set in the wifi_config_t is not met.

Wi-Fi Reason code related to wrong password

The table below shows the Wi-Fi reason-code may related to wrong password.

Reason code	Value	Description
4WAY_HANDSHAKE_TIMEOUT	15	Four-way handshake times out. Setting wrong password when STA connecting to an encrypted AP.
NO_AP_FOUND	201	This may related to wrong password in the two scenarios: • Setting password when STA connecting to an unencrypted AP. • Does not set password when STA connecting to an encrypted AP.
HANDSHAKE_TIMEOUT	204	Four-way handshake fails.

Wi-Fi Reason code related to low RSSI

The table below shows the Wi-Fi reason-code may related to low RSSI.

Reason code	Value	Description
NO_AP_FOUND_IN_RSSI_THRESHOLD	202	The station fails to scan the target AP due to low RSSI
HANDSHAKE_TIMEOUT	204	Four-way handshake fails.

4.35.11 ESP32-C3 Wi-Fi Station Connecting When Multiple APs Are Found

This scenario is similar as *ESP32-C3 Wi-Fi Station Connecting Scenario*. The difference is that the station will not raise the event *WIFI_EVENT_STA_DISCONNECTED* unless it fails to connect all of the found APs.

4.35.12 Wi-Fi Reconnect

The station may disconnect due to many reasons, e.g., the connected AP is restarted. It is the application's responsibility to reconnect. The recommended reconnection strategy is to call `esp_wifi_connect()` on receiving event *WIFI_EVENT_STA_DISCONNECTED*.

Sometimes the application needs more complex reconnection strategy:

- If the disconnect event is raised because the `esp_wifi_disconnect()` is called, the application may not want to do the reconnection.
- If the `esp_wifi_scan_start()` may be called at anytime, a better reconnection strategy is necessary. Refer to *Scan When Wi-Fi Is Connecting*.

Another thing that need to be considered is that the reconnection may not connect the same AP if there are more than one APs with the same SSID. The reconnection always select current best APs to connect.

4.35.13 Wi-Fi Beacon Timeout

The beacon timeout mechanism is used by ESP32-C3 station to detect whether the AP is alive or not. If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens. The application can set inactive time via API `esp_wifi_set_inactive_time()`.

After the beacon times out, the station sends 5 probe requests to the AP. If still no probe response or beacon is received from AP, the station disconnects from the AP and raises the event *WIFI_EVENT_STA_DISCONNECTED*.

It should be considered that the timer used for beacon timeout will be reset during the scanning process. It means that the scan process will affect the triggering of the event *WIFI_EVENT_STA_BEACON_TIMEOUT*.

4.35.14 ESP32-C3 Wi-Fi Configuration

All configurations will be stored into flash when the Wi-Fi NVS is enabled; otherwise, refer to *Wi-Fi NVS Flash*.

Wi-Fi Mode

Call `esp_wifi_set_mode()` to set the Wi-Fi mode.

Mode	Description
`WIFI_MODE_NULL`	NULL mode: in this mode, the internal data struct is not allocated to the station and the AP, while both the station and AP interfaces are not initialized for RX/TX Wi-Fi data. Generally, this mode is used for Sniffer, or when you only want to stop both the station and the AP without calling `esp_wifi_deinit()` to unload the whole Wi-Fi driver.
`WIFI_MODE_STA`	Station mode: in this mode, `esp_wifi_start()` will init the internal station data, while the station' s interface is ready for the RX and TX Wi-Fi data. After `esp_wifi_connect()`, the station will connect to the target AP.
`WIFI_MODE_AP`	AP mode: in this mode, `esp_wifi_start()` will init the internal AP data, while the AP' s interface is ready for RX/TX Wi-Fi data. Then, the Wi-Fi driver starts broad-casting beacons, and the AP is ready to get connected to other stations.
`WIFI_MODE_APSTA`	Station/AP coexistence mode: in this mode, `esp_wifi_start()` will simultaneously initialize both the station and the AP. This is done in station mode and AP mode. Please note that the channel of the external AP, which the ESP station is connected to, has higher priority over the ESP AP channel.

Station Basic Configuration

API `esp_wifi_set_config()` can be used to configure the station. And the configuration will be stored in NVS. The table below describes the fields in detail.

Field	Description
ssid	This is the SSID of the target AP, to which the station wants to connect.
password	Password of the target AP.
scan_method	For `WIFI_FAST_SCAN` scan, the scan ends when the first matched AP is found. For `WIFI_ALL_CHANNEL_SCAN`, the scan finds all matched APs on all channels. The default scan is `WIFI_FAST_SCAN`.
bssid_set	If bssid_set is 0, the station connects to the AP whose SSID is the same as the field "ssid" , while the field "bssid" is ignored. In all other cases, the station connects to the AP whose SSID is the same as the "ssid" field, while its BSSID is the same the "bssid" field .
bssid	This is valid only when bssid_set is 1; see field "bssid_set" .
channel	If the channel is 0, the station scans the channel 1 ~ N to search for the target AP; otherwise, the station starts by scanning the channel whose value is the same as that of the "channel" field, and then scans the channel 1 ~ N but skip the specific channel to find the target AP. For example, if the channel is 3, the scan order will be 3, 1, 2, 4,..., N. If you do not know which channel the target AP is running on, set it to 0.
sort_method	This field is only for `WIFI_ALL_CHANNEL_SCAN`. If the sort_method is `WIFI_CONNECT_AP_BY_SIGNAL`, all matched APs are sorted by signal, and the AP with the best signal will be connected firstly. For example, the station wants to connect an AP whose SSID is "apxx" . If the scan finds two APs whose SSID equals to "apxx" , and the first AP' s signal is -90 dBm while the second AP' s signal is -30 dBm, the station connects the second AP firstly, and it would not connect the first one unless it fails to connect the second one. If the sort_method is `WIFI_CONNECT_AP_BY_SECURITY`, all matched APs are sorted by security. For example, the station wants to connect an AP whose SSID is "apxx" . If the scan finds two APs whose SSID is "apxx" , and the security of the first found AP is open while the second one is WPA2, the station connects to the second AP firstly, and it would not connect the first one unless it fails to connect the second one.
threshold	The threshold is used to filter the found AP. If the RSSI or security mode is less than the configured threshold, the AP will be discarded. If the RSSI is set to 0, it means the default threshold and the default RSSI threshold are -127 dBm. If the authmode threshold is set to 0, it means the default threshold and the default authmode threshold are open.

Attention: WEP/WPA security modes are deprecated in IEEE 802.11-2016 specifications and are recommended not to be used. These modes can be rejected using authmode threshold by setting threshold as WPA2 by threshold.authmode as `WIFI_AUTH_WPA2_PSK`.

AP Basic Configuration

API *`esp_wifi_set_config()`* can be used to configure the AP. And the configuration will be stored in NVS. The table below describes the fields in detail.

Field	Description
ssid	SSID of AP; if the ssid[0] is 0xFF and ssid[1] is 0xFF, the AP defaults the SSID to `ESP_aabbcc`, where "aabbcc" is the last three bytes of the AP MAC.
password	Password of AP; if the auth mode is `WIFI_AUTH_OPEN`, this field will be ignored.
ssid_len	Length of SSID; if ssid_len is 0, check the SSID until there is a termination character. If ssid_len > 32, change it to 32; otherwise, set the SSID length according to ssid_len.
channel	Channel of AP; if the channel is out of range, the Wi-Fi driver defaults to channel 1. So, please make sure the channel is within the required range. For more details, refer to *Wi-Fi Country Code*.
authmode	Auth mode of ESP AP; currently, ESP AP does not support AUTH_WEP. If the authmode is an invalid value, AP defaults the value to `WIFI_AUTH_OPEN`.
ssid_hidden	If ssid_hidden is 1, AP does not broadcast the SSID; otherwise, it does broadcast the SSID.
max_connection	The max number of stations allowed to connect in, the default value is 10. ESP Wi-Fi supports up to 10 (`ESP_WIFI_MAX_CONN_NUM`) Wi-Fi connections. Please note that ESP AP and ESP-NOW share the same encryption hardware keys, so the max_connection parameter will be affected by the *CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM*. The total number of encryption hardware keys is 17, if *CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM* <= 7, the max_connection can be set up to 10, otherwise the max_connection can be set up to (17 - *CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM*).
beacon_interval	Beacon interval; the value is 100 ~ 60000 ms, with default value being 100 ms. If the value is out of range, AP defaults it to 100 ms.

Wi-Fi Protocol Mode

Currently, the ESP-IDF supports the following protocol modes:

Protocol Mode	Description
802.11b	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B)` to set the station/AP to 802.11b-only mode.
802.11bg	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G)` to set the station/AP to 802.11bg mode.
802.11g	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G)` and esp_wifi_config_11b_rate(ifx, true) to set the station/AP to 802.11g mode.
802.11bgn	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N)` to set the station/ AP to BGN mode.
802.11gn	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_` and esp_wifi_config_11b_rate(ifx, true) to set the station/AP to 802.11gn mode.
802.11 BGNLR	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N|WIFI_PROTOCOL_LR)` to set the station/AP to BGN and the LR mode.
802.11 LR	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_LR)` to set the station/AP only to the LR mode. **This mode is an Espressif-patented mode which can achieve a one-kilometer line of sight range. Please make sure both the station and the AP are connected to an ESP device.**

Long Range (LR)

Long Range (LR) mode is an Espressif-patented Wi-Fi mode which can achieve a one-kilometer line of sight range. Compared to the traditional 802.11b mode, it has better reception sensitivity, stronger anti-interference ability, and longer transmission distance.

LR Compatibility Since LR is Espressif-unique Wi-Fi mode, only ESP32 chip series devices (except ESP32-C2) can transmit and receive the LR data. In other words, the ESP32 chip series devices (except ESP32-C2) should NOT transmit the data in LR data rate if the connected device does not support LR. The application can achieve this by configuring a suitable Wi-Fi mode. If the negotiated mode supports LR, the ESP32 chip series devices (except ESP32-C2) may transmit data in LR rate. Otherwise, ESP32 chip series devices (except ESP32-C2) will transmit all data in the traditional Wi-Fi data rate.

The following table depicts the Wi-Fi mode negotiation:

APSTA	BGN	BG	B	BGNLR	BGLR	BLR	LR
BGN	BGN	BG	B	BGN	BG	B	•
BG	BG	BG	B	BG	BG	B	•
B	B	B	B	B	B	B	•
BGNLR	•	•	•	BGNLR	BGLR	BLR	LR
BGLR	•	•	•	BGLR	BGLR	BLR	LR
BLR	•	•	•	BLR	BLR	BLR	LR
LR	•	•	•	LR	LR	LR	LR

In the above table, the row is the Wi-Fi mode of AP and the column is the Wi-Fi mode of station. The "-" indicates Wi-Fi mode of the AP and station are not compatible.

According to the table, the following conclusions can be drawn:

- For LR-enabled AP of ESP32-C3, it is incompatible with traditional 802.11 mode, because the beacon is sent in LR mode.
- For LR-enabled station of ESP32-C3 whose mode is NOT LR-only mode, it is compatible with traditional 802.11 mode.
- If both station and AP are ESP32 series chips devices (except ESP32-C2) and both of them have enabled LR mode, the negotiated mode supports LR.

If the negotiated Wi-Fi mode supports both traditional 802.11 mode and LR mode, it is the Wi-Fi driver's responsibility to automatically select the best data rate in different Wi-Fi modes and the application can ignore it.

LR Impacts to Traditional Wi-Fi Device The data transmission in LR rate has no impacts on the traditional Wi-Fi device because:

- The CCA and backoff process in LR mode are consistent with 802.11 specification.
- The traditional Wi-Fi device can detect the LR signal via CCA and do backoff.

In other words, the transmission impact in LR mode is similar to that in 802.11b mode.

LR Transmission Distance The reception sensitivity gain of LR is about 4 dB larger than that of the traditional 802.11b mode. Theoretically, the transmission distance is about 2 to 2.5 times the distance of 11B.

LR Throughput The LR rate has very limited throughput, because the raw PHY data rate LR is 1/2 Mbps and 1/4 Mbps.

When to Use LR The general conditions for using LR are:

- Both the AP and station are Espressif devices.
- Long distance Wi-Fi connection and data transmission is required.
- Data throughput requirements are very small, such as remote device control.

Wi-Fi Country Code

Call `esp_wifi_set_country()` to set the country info. The table below describes the fields in detail. Please consult local 2.4 GHz RF operating regulations before configuring these fields.

Field	Description
cc[3]	Country code string. This attribute identifies the country or noncountry entity in which the station/AP is operating. If it is a country, the first two octets of this string is the two-character country info as described in the document ISO/IEC3166-1. The third octet is one of the following: • an ASCII space character, which means the regulations under which the station/AP is operating encompass all environments for the current frequency band in the country. • an ASCII 'O' character, which means the regulations under which the station/AP is operating are for an outdoor environment only. • an ASCII 'I' character, which means the regulations under which the station/AP is operating are for an indoor environment only. • an ASCII 'X' character, which means the station/AP is operating under a non-country entity. The first two octets of the noncountry entity is two ASCII 'XX' characters. • the binary representation of the Operating Class table number currently in use. Refer to Annex E of IEEE Std 802.11-2020.
schan	Start channel. It is the minimum channel number of the regulations under which the station/AP can operate.
nchan	Total number of channels as per the regulations. For example, if the schan=1, nchan=13, then the station/AP can send data from channel 1 to 13.
policy	Country policy. This field controls which country info will be used if the configured country info is in conflict with the connected AP's. For more details on related policies, see the following section.

The default country info is:

```
wifi_country_t config = {
    .cc = "01",
    .schan = 1,
    .nchan = 11,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

If the Wi-Fi Mode is station/AP coexist mode, they share the same configured country info. Sometimes, the country info of AP, to which the station is connected, is different from the country info of configured. For example, the configured station has country info:

```
wifi_country_t config = {
    .cc = "JP",
    .schan = 1,
    .nchan = 14,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

but the connected AP has country info:

```
wifi_country_t config = {
    .cc = "CN",
    .schan = 1,
    .nchan = 13,
};
```

then country info of connected AP's is used.

The following table depicts which country info is used in different Wi-Fi modes and different country policies, and it also describes the impact on active scan.

Wi-Fi Mode	Policy	Description
Station	WIFI_COUNTRY_POLICY_AUTO	The connected AP has country IE in its beacon, the country info equals to the country info in beacon. Otherwise, use the default country info. For scan: Use active scan from 1 to 11 and use passive scan from 12 to 14. Always keep in mind that if an AP with hidden SSID and station is set to a passive scan channel, the passive scan will not find it. In other words, if the application hopes to find the AP with hidden SSID in every channel, the policy of country info should be configured to WIFI_COUNTRY_POLICY_MANUAL.
Station	WIFI_COUNTRY_POLICY_MANUAL	Always use the configured country info. For scan: Use active scan from schan to schan+nchan-1.
AP	WIFI_COUNTRY_POLICY_AUTO	Always use the configured country info.
AP	WIFI_COUNTRY_POLICY_MANUAL	Always use the configured country info.
Station/AP-coexistence	WIFI_COUNTRY_POLICY_AUTO	Station: Same as station mode with policy WIFI_COUNTRY_POLICY_AUTO. AP: If the station does not connect to any external AP, the AP uses the configured country info. If the station connects to an external AP, the AP has the same country info as the station.
Station/AP-coexistence	WIFI_COUNTRY_POLICY_MANUAL	Station: Same as station mode with policy WIFI_COUNTRY_POLICY_MANUAL. AP: Same as AP mode with policy WIFI_COUNTRY_POLICY_MANUAL.

Home Channel In AP mode, the home channel is defined as the AP channel. In station mode, home channel is defined as the channel of AP which the station is connected to. In station/AP-coexistence mode, the home channel of AP and station must be the same, and if they are different, the station's home channel is always in priority. For example, assume that the AP is on channel 6, and the station connects to an AP whose channel is 9. Since the station's home channel has higher priority, the AP needs to switch its channel from 6 to 9 to make sure that it has the same home channel as the station. While switching channel, the ESP32-C3 in AP mode will notify the connected stations about the channel migration using a Channel Switch Announcement (CSA). Station that supports channel switching will transit without disconnecting and reconnecting to the AP.

Wi-Fi Vendor IE Configuration

By default, all Wi-Fi management frames are processed by the Wi-Fi driver, and the application can ignore them. However, some applications may have to handle the beacon, probe request, probe response, and other management frames. For example, if you insert some vendor-specific IE into the management frames, it is only the management frames which contain this vendor-specific IE that will be processed. In ESP32-C3,

`esp_wifi_set_vendor_ie()` and `esp_wifi_set_vendor_ie_cb()` are responsible for this kind of tasks.

4.35.15 Wi-Fi Easy Connect™ (DPP)

Wi-Fi Easy Connect™ (or Device Provisioning Protocol) is a secure and standardized provisioning protocol for configuring Wi-Fi devices. More information can be found in *esp_dpp*.

WPA2-Enterprise

WPA2-Enterprise is the secure authentication mechanism for enterprise wireless networks. It uses RADIUS server for authentication of network users before connecting to the Access Point. The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, and PEAP. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both. When ESP32-C3 in station mode tries to connect an AP in enterprise mode, it sends authentication request to AP which is sent to RADIUS server by AP for authenticating the station. Based on different EAP methods, the parameters can be set in configuration which can be opened using `idf.py menuconfig`. WPA2_Enterprise is supported by ESP32-C3 only in station mode.

For establishing a secure connection, AP and station negotiate and agree on the best possible cipher suite to be used. ESP32-C3 supports 802.1X/EAP (WPA) method of AKM and Advanced encryption standard with Counter Mode Cipher Block Chaining Message Authentication protocol (AES-CCM) cipher suite. It also supports the cipher suites supported by mbedtls if *USE_MBEDTLS_CRYPTO* flag is set.

ESP32-C3 currently supports the following EAP methods:

- EAP-TLS: This is a certificate-based method and only requires SSID and EAP-IDF.
- PEAP: This is a Protected EAP method. Username and Password are mandatory.
- **EAP-TTLS: This is a credential-based method. Only server authentication is mandatory while user authenticatio**
  - PAP: Password Authentication Protocol.
  - CHAP: Challenge Handshake Authentication Protocol.
  - MSCHAP and MSCHAP-V2.
- EAP-FAST: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, USE_MBEDTLS_CRYPTO flag should be disabled to use this feature.

Detailed information on creating certificates and how to run wpa2_enterprise example on ESP32-C3 can be found in wifi/wifi_enterprise.

4.35.16 Wireless Network Management

Wireless Network Management allows client devices to exchange information about the network topology, including information related to RF environment. This makes each client network-aware, facilitating overall improvement in the performance of the wireless network. It is part of 802.11v specification. It also enables the client to support Network assisted Roaming. - Network assisted Roaming: Enables WLAN to send messages to associated clients, resulting clients to associate with APs with better link metrics. This is useful for both load balancing and in directing poorly connected clients.

Current implementation of 802.11v includes support for BSS transition management frames.

4.35.17 Radio Resource Measurement

Radio Resource Measurement (802.11k) is intended to improve the way traffic is distributed within a network. In a WLAN, each device normally connects to the access point (AP) that provides the strongest signal. Depending on the number and geographic locations of the subscribers, this arrangement can sometimes lead to excessive demand on one AP and underutilization of others, resulting in degradation of overall network performance. In a network

conforming to 802.11k, if the AP having the strongest signal is loaded to its full capacity, a wireless device can be moved to one of the underutilized APs. Even though the signal may be weaker, the overall throughput is greater because more efficient use is made of the network resources.

Current implementation of 802.11k includes support for beacon measurement report, link measurement report, and neighbor request.

Refer ESP-IDF example examples/wifi/roaming/README.md to set up and use these APIs. Example code only demonstrates how these APIs can be used, and the application should define its own algorithm and cases as required.

4.35.18 Fast BSS Transition

Fast BSS transition (802.11R FT), is a standard to permit continuous connectivity aboard wireless devices in motion, with fast and secure client transitions from one Basic Service Set (abbreviated BSS, and also known as a base station or more colloquially, an access point) to another performed in a nearly seamless manner **avoiding 802.1i 4 way handshake** . 802.11R specifies transitions between access points by redefining the security key negotiation protocol, allowing both the negotiation and requests for wireless resources to occur in parallel. The key derived from the server to be cached in the wireless network, so that a reasonable number of future connections can be based on the cached key, avoiding the 802.1X process

ESP32-C3 station supports FT for WPA2-PSK networks. Do note that ESP32-C3 station only support FT over the air protocol only.

A config option *CONFIG_ESP_WIFI_11R_SUPPORT* and configuration parameter `ft_enabled` in `wifi_sta_config_t` is provided to enable 802.11R support for station. Refer ESP-IDF example examples/wifi/roaming/README.md for further details.

> **Attention:** Distance measurement using RTT is not accurate, and factors such as RF interference, multi-path travel, antenna orientation, and lack of calibration increase these inaccuracies. For better results, it is suggested to perform FTM between two ESP32 chip series devices as station and AP.
>
> Refer to ESP-IDF example examples/wifi/ftm/README.md for steps on how to set up and perform FTM.

4.35.19 Wi-Fi Location

Wi-Fi Location will improve the accuracy of a device's location data beyond the Access Point, which will enable creation of new and feature-rich applications and services such as geo-fencing, network management, and navigation. One of the protocols used to determine the device location with respect to the Access Point is Fine Timing Measurement which calculates Time-of-Flight of a Wi-Fi frame.

Fine Timing Measurement (FTM)

FTM is used to measure Wi-Fi Round Trip Time (Wi-Fi RTT) which is the time a Wi-Fi signal takes to travel from a device to another device and back again. Using Wi-Fi RTT, the distance between the devices can be calculated with a simple formula of $RTT * c / 2$, where c is the speed of light.

FTM uses timestamps given by Wi-Fi interface hardware at the time of arrival or departure of frames exchanged between a pair of devices. One entity called FTM Initiator (mostly a station device) discovers the FTM Responder (can be a station or an Access Point) and negotiates to start an FTM procedure. The procedure uses multiple Action frames sent in bursts and its ACK's to gather the timestamps data. FTM Initiator gathers the data in the end to calculate an average Round-Trip-Time.

ESP32-C3 supports FTM in below configuration:

- ESP32-C3 as FTM Initiator in station mode.
- ESP32-C3 as FTM Responder in AP mode.

4.35.20 ESP32-C3 Wi-Fi Power-saving Mode

This subsection will briefly introduce the concepts and usage related to Wi-Fi Power Saving Mode, for a more detailed introduction please refer to the *Low Power Mode User Guide*

Station Sleep

Currently, ESP32-C3 Wi-Fi supports the Modem-sleep mode which refers to the legacy power-saving mode in the IEEE 802.11 protocol. Modem-sleep mode works in station-only mode and the station must connect to the AP first. If the Modem-sleep mode is enabled, station will switch between active and sleep state periodically. In sleep state, RF, PHY and BB are turned off in order to reduce power consumption. Station can keep connection with AP in modem-sleep mode.

Modem-sleep mode includes minimum and maximum power-saving modes. In minimum power-saving mode, station wakes up every DTIM to receive beacon. Broadcast data will not be lost because it is transmitted after DTIM. However, it cannot save much more power if DTIM is short for DTIM is determined by AP.

In maximum power-saving mode, station wakes up in every listen interval to receive beacon. This listen interval can be set to be longer than the AP DTIM period. Broadcast data may be lost because station may be in sleep state at DTIM time. If listen interval is longer, more power is saved, but broadcast data is more easy to lose. Listen interval can be configured by calling API `esp_wifi_set_config()` before connecting to AP.

Call `esp_wifi_set_ps(WIFI_PS_MIN_MODEM)` to enable Modem-sleep minimum power-saving mode or `esp_wifi_set_ps(WIFI_PS_MAX_MODEM)` to enable Modem-sleep maximum power-saving mode after calling `esp_wifi_init()`. When station connects to AP, Modem-sleep will start. When station disconnects from AP, Modem-sleep will stop.

Call `esp_wifi_set_ps(WIFI_PS_NONE)` to disable Modem-sleep mode entirely. Disabling it increases power consumption, but minimizes the delay in receiving Wi-Fi data in real time. When Modem-sleep mode is enabled, the delay in receiving Wi-Fi data may be the same as the DTIM cycle (minimum power-saving mode) or the listening interval (maximum power-saving mode).

Note that in coexist mode, Wi-Fi will remain active only during Wi-Fi time slice, and sleep during non Wi-Fi time slice even if `esp_wifi_set_ps(WIFI_PS_NONE)` is called. Please refer to *coexist policy*.

The default Modem-sleep mode is WIFI_PS_MIN_MODEM.

AP Sleep

Currently, ESP32-C3 AP does not support all of the power-saving feature defined in Wi-Fi specification. To be specific, the AP only caches unicast data for the stations connect to this AP, but does not cache the multicast data for the stations. If stations connected to the ESP32-C3 AP are power-saving enabled, they may experience multicast packet loss.

In the future, all power-saving features will be supported on ESP32-C3 AP.

Disconnected State Sleep

Disconnected state is the duration without Wi-Fi connection between `esp_wifi_start()` to `esp_wifi_stop()`.

Currently, ESP32-C3 Wi-Fi supports sleep mode in disconnected state if running at station mode. This feature could be configured by Menuconfig choice *CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE*.

If *CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE* is enabled, RF, PHY and BB would be turned off in disconnected state when IDLE. The current would be same with current at modem-sleep.

The choice *CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE* would be selected by default, while it would be selected forcefully in Menuconfig at coexistence mode.

Connectionless Modules Power-saving

Connectionless modules are those Wi-Fi modules not relying on Wi-Fi connection, e.g ESP-NOW, DPP, FTM. These modules start from `esp_wifi_start()`, working until `esp_wifi_stop()`.

Currently, if ESP-NOW works at station mode, its supported to sleep at both connected state and disconnected state.

Connectionless Modules TX For each connectionless module, its supported to TX at any sleeping time without any extra configuration.

Meanwhile, `esp_wifi_80211_tx()` is supported at sleep as well.

Connectionless Modules RX For each connectionless module, two parameters shall be configured to RX at sleep, which are *Window* and *Interval*.

At the start of *Interval* time, RF, PHY, BB would be turned on and kept for *Window* time. Connectionless Module could RX in the duration.

Interval

- There is only one *Interval*. Its configured by `esp_wifi_set_connectionless_interval()`. The unit is milliseconds.
- The default value of *Interval* is *ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE*.
- Event *WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START* would be posted at the start of *Interval*. Since *Window* also starts at that moment, its recommended to TX in that event.
- At connected state, the start of *Interval* would be aligned with TBTT.

Window

- Each connectionless module has its own *Window* after start. Connectionless Modules Power-saving would work with the max one among them.
- *Window* is configured by `module_name_set_wake_window()`. The unit is milliseconds.
- The default value of *Window* is the maximum.

Table 30: RF, PHY and BB usage under different circumstances

		Interval	
		`ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE`	1 - maximum
Window	0	not used	
	1 - maximum	default mode	used periodically (Window < Interval) / used all time (Window ≥ Interval)

Default Mode If *Interval* is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE` with non-zero *Window*, Connectionless Modules Power-saving would work in default mode.

In default mode, RF, PHY, BB would be kept on if no coexistence with non-Wi-Fi protocol.

With coexistence, RF, PHY, BB resources are allocated by coexistence module to Wi-Fi connectionless module and non-Wi-Fi module, using time-division method. In default mode, Wi-Fi connectionless module is allowed to use RF, BB, PHY periodically under a stable performance.

Its recommended to configure Connectionless Modules Power-saving to default mode if there is Wi-Fi connectionless module coexists with non-Wi-Fi module.

4.35.21 ESP32-C3 Wi-Fi Throughput

The table below shows the best throughput results gained in Espressif's lab and in a shielded box.

Type/Throughput	Air In Lab	Shield-box	Test Tool	IDF Version (commit ID)
Raw 802.11 Packet RX	N/A	**130 MBit/s**	Internal tool	NA
Raw 802.11 Packet TX	N/A	**130 MBit/s**	Internal tool	NA
UDP RX	30 MBit/s	50 MBit/s	iperf example	15575346
UDP TX	30 MBit/s	40 MBit/s	iperf example	15575346
TCP RX	20 MBit/s	35 MBit/s	iperf example	15575346
TCP TX	20 MBit/s	37 MBit/s	iperf example	15575346

When the throughput is tested by iperf example, the sdkconfig is examples/wifi/iperf/sdkconfig.defaults.esp32c3.

4.35.22 Wi-Fi 80211 Packet Send

The `esp_wifi_80211_tx()` API can be used to:

- Send the beacon, probe request, probe response, and action frame.
- Send the non-QoS data frame.

It cannot be used for sending encrypted or QoS frames.

Preconditions of Using `esp_wifi_80211_tx()`

- The Wi-Fi mode is station, or AP, or station/AP.
- Either `esp_wifi_set_promiscuous(true)`, or `esp_wifi_start()`, or both of these APIs return `ESP_OK`. This is because Wi-Fi hardware must be initialized before `esp_wifi_80211_tx()` is called. In ESP32-C3, both `esp_wifi_set_promiscuous(true)` and `esp_wifi_start()` can trigger the initialization of Wi-Fi hardware.
- The parameters of `esp_wifi_80211_tx()` are hereby correctly provided.

Data Rate

- The default data rate is 1 Mbps.
- Can set any rate through `esp_wifi_config_80211_tx_rate()` API.
- Can set any bandwidth through `esp_wifi_set_bandwidth()` API.

Side-Effects to Avoid in Different Scenarios

Theoretically, if the side-effects the API imposes on the Wi-Fi driver or other stations/APs are not considered, a raw 802.11 packet can be sent over the air with any destination MAC, any source MAC, any BSSID, or any other types of packet. However, robust or useful applications should avoid such side-effects. The table below provides some tips and recommendations on how to avoid the side-effects of `esp_wifi_80211_tx()` in different scenarios.

Scenario	Description
No Wi-Fi connection	In this scenario, no Wi-Fi connection is set up, so there are no side-effects on the Wi-Fi driver. If `en_sys_seq==true`, the Wi-Fi driver is responsible for the sequence control. If `en_sys_seq==false`, the application needs to ensure that the buffer has the correct sequence. Theoretically, the MAC address can be any address. However, this may impact other stations/APs with the same MAC/BSSID. Side-effect example#1 The application calls *esp_wifi_80211_tx()* to send a beacon with BSSID == mac_x in AP mode, but the mac_x is not the MAC of the AP interface. Moreover, there is another AP, e.g., "other-AP" , whose BSSID is mac_x. If this happens, an "unexpected behavior"may occur, because the stations which connect to the "other-AP"cannot figure out whether the beacon is from the "other-AP" or the *esp_wifi_80211_tx()*. To avoid the above-mentioned side-effects, it is recommended that: • If *esp_wifi_80211_tx()* is called in station mode, the first MAC should be a multicast MAC or the exact target-device' s MAC, while the second MAC should be that of the station interface. • If *esp_wifi_80211_tx()* is called in AP mode, the first MAC should be a multicast MAC or the exact target-device' s MAC, while the second MAC should be that of the AP interface. The recommendations above are only for avoiding side-effects and can be ignored when there are good reasons.
Have Wi-Fi connection	When the Wi-Fi connection is already set up, and the sequence is controlled by the application, the latter may impact the sequence control of the Wi-Fi connection as a whole. So, the `en_sys_seq` need to be true, otherwise `ESP_ERR_INVALID_ARG` is returned. The MAC-address recommendations in the "No Wi-Fi connection" scenario also apply to this scenario. If the Wi-Fi mode is station mode, the MAC address1 is the MAC of AP to which the station is connected, and the MAC address2 is the MAC of station interface, it is said that the packet is sent from the station to AP. Otherwise, if the Wi-Fi is in AP mode, the MAC address1 is the MAC of the station that connects to this AP, and the MAC address2 is the MAC of AP interface, it is said that the packet is sent from the AP to station. To avoid conflicting with Wi-Fi connections, the following checks are applied: • If the packet type is data and is sent from the station to AP, the ToDS bit in IEEE 80211 frame control should be 1 and the FromDS bit should be 0. Otherwise, the packet will be discarded by Wi-Fi driver. • If the packet type is data and is sent from the AP to station, the ToDS bit in IEEE 80211 frame control should be 0 and the FromDS bit should be 1. Otherwise, the packet will be discarded by Wi-Fi driver. • If the packet is sent from station to AP or from AP to station, the Power Management, More Data, and Re-Transmission bits should be 0. Otherwise, the packet will be discarded by Wi-Fi driver. `ESP_ERR_INVALID_ARG` is returned if any check fails.

4.35.23 Wi-Fi Sniffer Mode

The Wi-Fi sniffer mode can be enabled by *esp_wifi_set_promiscuous()*. If the sniffer mode is enabled, the following packets **can** be dumped to the application:

- 802.11 Management frame.
- 802.11 Data frame, including MPDU, AMPDU, and AMSDU.
- 802.11 MIMO frame, for MIMO frame, the sniffer only dumps the length of the frame.
- 802.11 Control frame.
- 802.11 CRC error frame.

The following packets will **NOT** be dumped to the application:

- Other 802.11 error frames.

For frames that the sniffer **can** dump, the application can additionally decide which specific type of packets can be filtered to the application by using `esp_wifi_set_promiscuous_filter()` and `esp_wifi_set_promiscuous_ctrl_filter()`. By default, it will filter all 802.11 data and management frames to the application. If you want to filter the 802.11 control frames, the filter parameter in `esp_wifi_set_promiscuous_filter()` should include *WIFI_PROMIS_FILTER_MASK_CTRL* type, and if you want to differentiate control frames further, then call `esp_wifi_set_promiscuous_ctrl_filter()`.

The Wi-Fi sniffer mode can be enabled in the Wi-Fi mode of `WIFI_MODE_NULL`, `WIFI_MODE_STA`, `WIFI_MODE_AP`, or `WIFI_MODE_APSTA`. In other words, the sniffer mode is active when the station is connected to the AP, or when the AP has a Wi-Fi connection. Please note that the sniffer has a **great impact** on the throughput of the station or AP Wi-Fi connection. Generally, the sniffer should be enabled **only if** the station/AP Wi-Fi connection does not experience heavy traffic.

Another noteworthy issue about the sniffer is the callback `wifi_promiscuous_cb_t`. The callback will be called directly in the Wi-Fi driver task, so if the application has a lot of work to do for each filtered packet, the recommendation is to post an event to the application task in the callback and defer the real work to the application task.

4.35.24 Wi-Fi Multiple Antennas

Please refer to the *PHY*

4.35.25 Wi-Fi Channel State Information

Channel state information (CSI) refers to the channel information of a Wi-Fi connection. In ESP32-C3, this information consists of channel frequency responses of sub-carriers and is estimated when packets are received from the transmitter. Each channel frequency response of sub-carrier is recorded by two bytes of signed characters. The first one is imaginary part and the second one is real part. There are up to three fields of channel frequency responses according to the type of received packet. They are legacy long training field (LLTF), high throughput LTF (HT-LTF), and space time block code HT-LTF (STBC-HT-LTF). For different types of packets which are received on channels with different state, the sub-carrier index and total bytes of signed characters of CSI are shown in the following table.

channel	secondary channel	none			below					above				
packet information	signal mode	non HT	HT		non HT	HT				non HT	HT			
	channel bandwidth	20 MHz	20 MHz		20 MHz	20 MHz		40 MHz		20 MHz	20 MHz		40 MHz	
	STBC	non STBC	non STBC	STBC	non STBC	non STBC	STBC	non STBC	STBC	non STBC	non STBC	STBC	non STBC	STBC
sub-carrier index	LLTF	0~31, -32~-1	0~31, -32~-1	0~31, -32~-1	0~63	0~63	0~63	0~63	0~63	-64~-1	-64~-1	-64~-1	-64~-1	-64~-1
	HT-LTF	•	0~31, -32~-1	0~31, -32~-1	•	0~63	0~62	0~63, -64~-1	0~60, -60~-1	•	-64~-1	-62~-1	0~63, -64~-1	0~60, -60~-1
	STBC-HT-LTF	•	•	0~31, -32~-1	•	•	0~62	•	0~60, -60~-1	•	•	-62~-1	•	0~60, -60~-1
total bytes		128	256	384	128	256	380	384	612	128	256	376	384	612

All of the information in the table can be found in the structure wifi_csi_info_t.

- Secondary channel refers to secondary_channel field of rx_ctrl field.
- Signal mode of packet refers to sig_mode field of rx_ctrl field.
- Channel bandwidth refers to cwb field of rx_ctrl field.
- STBC refers to stbc field of rx_ctrl field.
- Total bytes refers to len field.
- The CSI data corresponding to each Long Training Field (LTF) type is stored in a buffer starting from the buf field. Each item is stored as two bytes: imaginary part followed by real part. The order of each item is the same as the sub-carrier in the table. The order of LTF is: LLTF, HT-LTF, STBC-HT-LTF. However, all 3 LTFs may not be present, depending on the channel and packet information (see above).
- If first_word_invalid field of `wifi_csi_info_t` is true, it means that the first four bytes of CSI data is invalid due to a hardware limitation in ESP32-C3.
- More information like RSSI, noise floor of RF, receiving time and antenna is in the rx_ctrl field.

When imaginary part and real part data of sub-carrier are used, please refer to the table below.

PHY standard	Sub-carrier range	Pilot sub-carrier	Sub-carrier (total/data)
802.11a/g	-26 to +26	-21, -7, +7, +21	52 total, 48 usable
802.11n, 20 MHz	-28 to +28	-21, -7, +7, +21	56 total, 52 usable
802.11n, 40 MHz	-57 to +57	-53, -25, -11, +11, +25, +53	114 total, 108 usable

Note:

- For STBC packet, CSI is provided for every space-time stream without CSD (cyclic shift delay). As each cyclic shift on the additional chains shall be -200 ns, only the CSD angle of first space-time stream is recorded in sub-carrier 0 of HT-LTF and STBC-HT-LTF for there is no channel frequency response in sub-carrier 0. CSD[10:0] is 11 bits, ranging from -pi to pi.
- If LLTF, HT-LTF, or STBC-HT-LTF is not enabled by calling API `esp_wifi_set_csi_config()`, the total bytes of CSI data will be fewer than that in the table. For example, if LLTF and HT-LTF is not enabled

and STBC-HT-LTF is enabled, when a packet is received with the condition above/HT/40MHz/STBC, the total bytes of CSI data is 244 ((61 + 60) * 2 + 2 = 244. The result is aligned to four bytes, and the last two bytes are invalid).

4.35.26 Wi-Fi Channel State Information Configure

To use Wi-Fi CSI, the following steps need to be done.

- Select Wi-Fi CSI in menuconfig. Go to `Menuconfig > Components config > Wi-Fi > Wi-Fi CSI (Channel State Information)`.
- Set CSI receiving callback function by calling API `esp_wifi_set_csi_rx_cb()`.
- Configure CSI by calling API `esp_wifi_set_csi_config()`.
- Enable CSI by calling API `esp_wifi_set_csi()`.

The CSI receiving callback function runs from Wi-Fi task. So, do not do lengthy operations in the callback function. Instead, post necessary data to a queue and handle it from a lower priority task. Because station does not receive any packet when it is disconnected and only receives packets from AP when it is connected, it is suggested to enable sniffer mode to receive more CSI data by calling `esp_wifi_set_promiscuous()`.

4.35.27 Wi-Fi HT20/40

ESP32-C3 supports Wi-Fi bandwidth HT20 or HT40 and does not support HT20/40 coexist. `esp_wifi_set_bandwidth()` can be used to change the default bandwidth of station or AP. The default bandwidth for ESP32-C3 station and AP is HT40.

In station mode, the actual bandwidth is firstly negotiated during the Wi-Fi connection. It is HT40 only if both the station and the connected AP support HT40, otherwise it is HT20. If the bandwidth of connected AP is changes, the actual bandwidth is negotiated again without Wi-Fi disconnecting.

Similarly, in AP mode, the actual bandwidth is negotiated between AP and the stations that connect to the AP. It is HT40 if the AP and one of the stations support HT40, otherwise it is HT20.

In station/AP coexist mode, the station/AP can configure HT20/40 separately. If both station and AP are negotiated to HT40, the HT40 channel should be the channel of station because the station always has higher priority than AP in ESP32-C3. For example, the configured bandwidth of AP is HT40, the configured primary channel is 6, and the configured secondary channel is 10. The station is connected to an router whose primary channel is 6 and secondary channel is 2, then the actual channel of AP is changed to primary 6 and secondary 2 automatically.

Theoretically, the HT40 can gain better throughput because the maximum raw physicial (PHY) data rate for HT40 is 150 Mbps while it is 72 Mbps for HT20. However, if the device is used in some special environment, e.g., there are too many other Wi-Fi devices around the ESP32-C3 device, the performance of HT40 may be degraded. So if the applications need to support same or similar scenarios, it is recommended that the bandwidth is always configured to HT20.

4.35.28 Wi-Fi QoS

ESP32-C3 supports all the mandatory features required in WFA Wi-Fi QoS Certification.

Four ACs (Access Category) are defined in Wi-Fi specification, and each AC has its own priority to access the Wi-Fi channel. Moreover, a map rule is defined to map the QoS priority of other protocol, e.g., 802.11D or TCP/IP precedence is mapped to Wi-Fi AC.

The table below describes how the IP Precedences are mapped to Wi-Fi ACs in ESP32-C3. It also indicates whether the AMPDU is supported for this AC. The table is sorted from high to low priority. That is to say, the AC_VO has the highest priority.

IP Precedence	Wi-Fi AC	Support AMPDU?
6, 7	AC_VO (Voice)	No
4, 5	AC_VI (Video)	Yes
3, 0	AC_BE (Best Effort)	Yes
1, 2	AC_BK (Background)	Yes

The application can make use of the QoS feature by configuring the IP precedence via socket option IP_TOS. Here is an example to make the socket to use VI queue:

```
const int ip_precedence_vi = 4;
const int ip_precedence_offset = 5;
int priority = (ip_precedence_vi << ip_precedence_offset);
setsockopt(socket_id, IPPROTO_IP, IP_TOS, &priority, sizeof(priority));
```

Theoretically, the higher priority AC has better performance than the lower priority AC. However, it is not always true. Here are some suggestions about how to use the Wi-Fi QoS:

- Some really important application traffic can be put into the AC_VO queue. But avoid using the AC_VO queue for heavy traffic, as it may impact the management frames which also use this queue. Eventually, it is worth noting that the AC_VO queue does not support AMPDU, and its performance with heavy traffic is no better than other queues.
- Avoid using more than two precedences supported by different AMPDUs, e.g., when socket A uses precedence 0, socket B uses precedence 1, and socket C uses precedence 2. This can be a bad design because it may need much more memory. To be specific, the Wi-Fi driver may generate a Block Ack session for each precedence and it needs more memory if the Block Ack session is set up.

4.35.29 Wi-Fi AMSDU

ESP32-C3 supports receiving AMSDU.

4.35.30 Wi-Fi Fragment

ESP32-C3 supports Wi-Fi receiving and transmitting fragment.

4.35.31 WPS Enrollee

ESP32-C3 supports WPS enrollee feature in Wi-Fi mode `WIFI_MODE_STA` or `WIFI_MODE_APSTA`. Currently, ESP32-C3 supports WPS enrollee type PBC and PIN.

4.35.32 Wi-Fi Buffer Usage

This section is only about the dynamic buffer configuration.

Why Buffer Configuration Is Important

In order to get a high-performance system, consider the memory usage/configuration carefully for the following reasons:

- the available memory in ESP32-C3 is limited.
- currently, the default type of buffer in LwIP and Wi-Fi drivers is "dynamic", **which means that both the LwIP and Wi-Fi share memory with the application**. Programmers should always keep this in mind; otherwise, they will face a memory issue, such as "running out of heap memory".
- it is very dangerous to run out of heap memory, as this will cause ESP32-C3 an "undefined behavior". Thus, enough heap memory should be reserved for the application, so that it never runs out of it.

- the Wi-Fi throughput heavily depends on memory-related configurations, such as the TCP window size and Wi-Fi RX/TX dynamic buffer number.
- the peak heap memory that the ESP32-C3 LwIP/Wi-Fi may consume depends on a number of factors, such as the maximum TCP/UDP connections that the application may have.
- the total memory that the application requires is also an important factor when considering memory configuration.

Due to these reasons, there is not a good-for-all application configuration. Rather, it is recommended to consider memory configurations separately for every different application.

Dynamic vs. Static Buffer

The default type of buffer in Wi-Fi drivers is "dynamic". Most of the time the dynamic buffer can significantly save memory. However, it makes the application programming a little more difficult, because in this case the application needs to consider memory usage in Wi-Fi.

lwIP also allocates buffers at the TCP/IP layer, and this buffer allocation is also dynamic. See *lwIP documentation section about memory use and performance*.

Peak Wi-Fi Dynamic Buffer

The Wi-Fi driver supports several types of buffer (refer to *Wi-Fi Buffer Configure*). However, this section is about the usage of the dynamic Wi-Fi buffer only. The peak heap memory that Wi-Fi consumes is the **theoretically-maximum memory** that the Wi-Fi driver consumes. Generally, the peak memory depends on:

- b_{rx} the number of dynamic RX buffers that are configured
- b_{tx} the number of dynamic TX buffers that are configured
- m_{rx} the maximum packet size that the Wi-Fi driver can receive
- m_{tx} the maximum packet size that the Wi-Fi driver can send

So, the peak memory that the Wi-Fi driver consumes (p) can be calculated with the following formula:

$$p = (b_{rx} * m_{rx}) + (b_{tx} * m_{tx})$$

Generally, the dynamic TX long buffers and dynamic TX long long buffers can be ignored, because they are management frames which only have a small impact on the system.

4.35.33 How to Improve Wi-Fi Performance

The performance of ESP32-C3 Wi-Fi is affected by many parameters, and there are mutual constraints between each parameter. A proper configuration cannot only improve performance, but also increase available memory for applications and improve stability.

This section briefly explains the operating mode of the Wi-Fi/LwIP protocol stack and the role of each parameter. It also gives several recommended configuration ranks to help choose the appropriate rank according to the usage scenario.

Protocol Stack Operation Mode

The ESP32-C3 protocol stack is divided into four layers: Application, LwIP, Wi-Fi, and Hardware.

- During receiving, hardware puts the received packet into DMA buffer, and then transfers it into the RX buffer of Wi-Fi and LwIP in turn for related protocol processing, and finally to the application layer. The Wi-Fi RX buffer and the LwIP RX buffer shares the same buffer by default. In other words, the Wi-Fi forwards the packet to LwIP by reference by default.
- During sending, the application copies the messages to be sent into the TX buffer of the LwIP layer for TCP/IP encapsulation. The messages will then be passed to the TX buffer of the Wi-Fi layer for MAC encapsulation and wait to be sent.

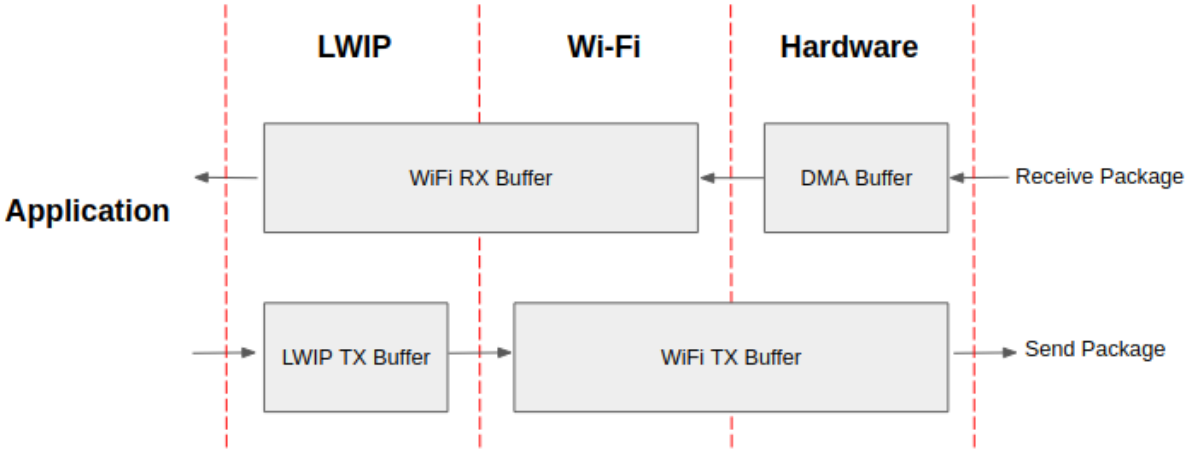

Fig. 67: ESP32-C3 datapath

Parameters

Increasing the size or number of the buffers mentioned above properly can improve Wi-Fi performance. Meanwhile, it will reduce available memory to the application. The following is an introduction to the parameters that users need to configure:

RX direction:

- *CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM* This parameter indicates the number of DMA buffer at the hardware layer. Increasing this parameter will increase the sender's one-time receiving throughput, thereby improving the Wi-Fi protocol stack ability to handle burst traffic.
- *CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM* This parameter indicates the number of RX buffer in the Wi-Fi layer. Increasing this parameter will improve the performance of packet reception. This parameter needs to match the RX buffer size of the LwIP layer.
- *CONFIG_ESP_WIFI_RX_BA_WIN* This parameter indicates the size of the AMPDU BA Window at the receiving end. This parameter should be configured to the smaller value between twice of *CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM* and *CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM*.
- *CONFIG_LWIP_TCP_WND_DEFAULT* This parameter represents the RX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_RX_BUFFER_NUM (KB) to reach a high and stable performance. Meanwhile, in case of multiple streams, this value needs to be reduced proportionally.

TX direction:

- *CONFIG_ESP_WIFI_TX_BUFFER* This parameter indicates the type of TX buffer, it is recommended to configure it as a dynamic buffer, which can make full use of memory.
- *CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM* This parameter indicates the number of TX buffer on the Wi-Fi layer. Increasing this parameter will improve the performance of packet sending. The parameter value needs to match the TX buffer size of the LwIP layer.
- *CONFIG_LWIP_TCP_SND_BUF_DEFAULT* This parameter represents the TX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_TX_BUFFER_NUM (KB) to reach a high and stable performance. In case of multiple streams, this value needs to be reduced proportionally.

Throughput optimization by placing code in IRAM:

Note: The buffer size mentioned above is fixed as 1.6 KB.

How to Configure Parameters

The memory of ESP32-C3 is shared by protocol stack and applications.

Here, several configuration ranks are given. In most cases, the user should select a suitable rank for parameter configuration according to the size of the memory occupied by the application.

The parameters not mentioned in the following table should be set to the default.

Rank	Iperf	Default	Minimum
Available memory (KB)	59	160	180
WIFI_STATIC_RX_BUFFER_NUM	20	8	3
WIFI_DYNAMIC_RX_BUFFER_NUM	40	16	6
WIFI_DYNAMIC_TX_BUFFER_NUM	40	16	6
WIFI_RX_BA_WIN	32	16	6
TCP_SND_BUF_DEFAULT (KB)	40	16	6
TCP_WND_DEFAULT (KB)	40	16	6
LWIP_IRAM_OPTIMIZATION	13	13	0
TCP TX throughput (Mbit/s)	38.1	27.2	20.4
TCP RX throughput (Mbit/s)	35.3	24.2	17.4
UDP TX throughput (Mbit/s)	40.6	38.9	34.1
UDP RX throughput (Mbit/s)	52.4	44.5	44.2

Note: The test was performed with a single stream in a shielded box using an ASUS RT-N66U router. ESP32-C3's CPU is single core with 160 MHz. ESP32-C3's flash is in QIO mode with 80 MHz.

Ranks:

- **Iperf rank** ESP32-C3 extreme performance rank used to test extreme performance.
- **Default rank** ESP32-C3's default configuration rank, the available memory, and performance are in balance.
- **Minimum rank** This is the minimum configuration rank of ESP32-C3. The protocol stack only uses the necessary memory for running. It is suitable for scenarios where there is no requirement for performance and the application requires lots of space.

4.35.34 Wi-Fi Menuconfig

Wi-Fi Buffer Configure

If you are going to modify the default number or type of buffer, it would be helpful to also have an overview of how the buffer is allocated/freed in the data path. The following diagram shows this process in the TX direction:

Description:

- The application allocates the data which needs to be sent out.
- The application calls TCPIP-/Socket-related APIs to send the user data. These APIs will allocate a PBUF used in LwIP, and make a copy of the user data.
- When LwIP calls a Wi-Fi API to send the PBUF, the Wi-Fi API will allocate a "Dynamic Tx Buffer" or "Static Tx Buffer", make a copy of the LwIP PBUF, and finally send the data.

The following diagram shows how buffer is allocated/freed in the RX direction:

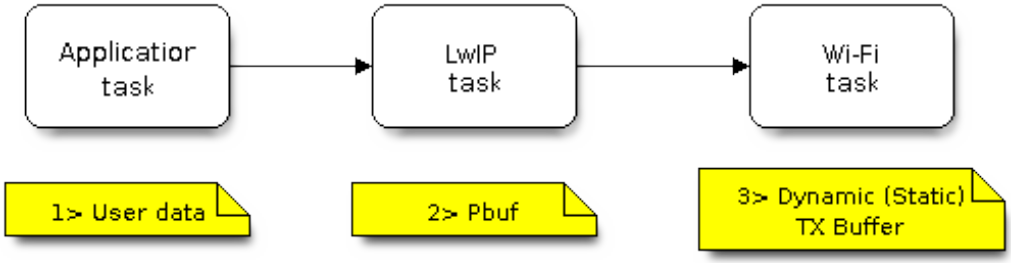

Fig. 68: TX Buffer Allocation

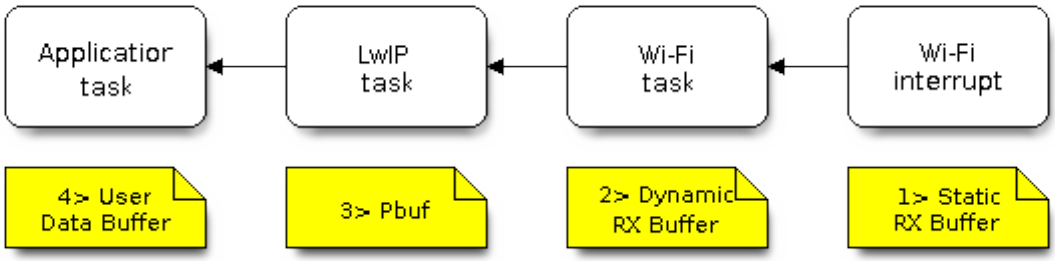

Fig. 69: RX Buffer Allocation

Description:

- The Wi-Fi hardware receives a packet over the air and puts the packet content to the "Static Rx Buffer", which is also called "RX DMA Buffer".
- The Wi-Fi driver allocates a "Dynamic Rx Buffer", makes a copy of the "Static Rx Buffer", and returns the "Static Rx Buffer" to hardware.
- The Wi-Fi driver delivers the packet to the upper-layer (LwIP), and allocates a PBUF for holding the "Dynamic Rx Buffer".
- The application receives data from LwIP.

The diagram shows the configuration of the Wi-Fi internal buffer.

Buffer Type	Alloc Type	Default	Configurable	Description
Static RX Buffer (Hardware RX Buffer)	Static	10 * 1600 Bytes	Yes	This is a kind of DMA memory. It is initialized in `esp_wifi_init()` and freed in `esp_wifi_deinit()`. The 'Static Rx Buffer' forms the hardware receiving list. Upon receiving a frame over the air, hardware writes the frame into the buffer and raises an interrupt to the CPU. Then, the Wi-Fi driver reads the content from the buffer and returns the buffer back to the list. If needs be, the application can reduce the memory statically allocated by Wi-Fi. It can reduce this value from 10 to 6 to save 6400 Bytes of memory. It is not recommended to reduce the configuration to a value less than 6 unless the AMPDU feature is disabled.
Dynamic RX Buffer	Dynamic	32	Yes	The buffer length is variable and it depends on the received frames' length. When the Wi-Fi driver receives a frame from the 'Hardware Rx Buffer', the 'Dynamic Rx Buffer' needs to be allocated from the heap. The number of the Dynamic Rx Buffer, configured in the menuconfig, is used to limit the total un-freed Dynamic Rx Buffer number.
Dynamic TX Buffer	Dynamic	32	Yes	This is a kind of DMA memory. It is allocated to the heap. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a 'Dynamic TX Buffer' and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffers are mutually exclusive.
Static TX Buffer	Static	16 * 1600Bytes	Yes	This is a kind of DMA memory. It is initialized in `esp_wifi_init()` and freed in `esp_wifi_deinit()`. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a 'Static TX Buffer' and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffer are mutually exclusive. The TX buffer must be a DMA buffer. For this reason, if PSRAM is enabled, the TX buffer must be static.
Management Short Buffer	Dynamic	8	NO	Wi-Fi driver's internal buffer.
Management Long Buffer	Dynamic	32	NO	Wi-Fi driver's internal buffer.
Management Long Long Buffer	Dynamic	32	NO	Wi-Fi driver's internal buffer.

Wi-Fi NVS Flash

If the Wi-Fi NVS flash is enabled, all Wi-Fi configurations set via the Wi-Fi APIs will be stored into flash, and the Wi-Fi driver will start up with these configurations the next time it powers on/reboots. However, the application can choose to disable the Wi-Fi NVS flash if it does not need to store the configurations into persistent memory, or has its own persistent storage, or simply due to debugging reasons, etc.

Wi-Fi Aggregate MAC Protocol Data Unit (AMPDU)

ESP32-C3 supports both receiving and transmitting AMPDU, and the AMPDU can greatly improve the Wi-Fi throughput.

Generally, the AMPDU should be enabled. Disabling AMPDU is usually for debugging purposes.

4.35.35 Troubleshooting

Please refer to a separate document with *Espressif Wireshark User Guide*.

Espressif Wireshark User Guide

1. Overview

1.1 What Is Wireshark? Wireshark (originally named "Ethereal") is a network packet analyzer that captures network packets and displays the packet data as detailed as possible. It uses WinPcap as its interface to directly capture network traffic going through a network interface controller (NIC).

You could think of a network packet analyzer as a measuring device used to examine what is going on inside a network cable, just like a voltmeter is used by an electrician to examine what is going on inside an electric cable.

In the past, such tools were either very expensive, proprietary, or both. However, with the advent of Wireshark, all that has changed.

Wireshark is released under the terms of the GNU General Public License, which means you can use the software and the source code free of charge. It also allows you to modify and customize the source code.

Wireshark is, perhaps, one of the best open source packet analyzers available today.

1.2 Some Intended Purposes Here are some examples of how Wireshark is typically used:

- Network administrators use it to troubleshoot network problems.
- Network security engineers use it to examine security problems.
- Developers use it to debug protocol implementations.
- People use it to learn more about network protocol internals.

Beside these examples, Wireshark can be used for many other purposes.

1.3 Features The main features of Wireshark are as follows:

- Available for UNIX and Windows
- Captures live packet data from a network interface
- Displays packets along with detailed protocol information
- Opens/saves the captured packet data
- Imports/exports packets into a number of file formats, supported by other capture programs
- Advanced packet filtering
- Searches for packets based on multiple criteria

- Colorizes packets according to display filters
- Calculates statistics
- ... and a lot more!

1.4 Wireshark Can or Cannot Do

- **Live capture from different network media**.
  Wireshark can capture traffic from different network media, including wireless LAN.
- **Import files from many other capture programs**.
  Wireshark can import data from a large number of file formats, supported by other capture programs.
- **Export files for many other capture programs**.
  Wireshark can export data into a large number of file formats, supported by other capture programs.
- **Numerous protocol dissectors**.
  Wireshark can dissect, or decode, a large number of protocols.
- **Wireshark is not an intrusion detection system**.
  It will not warn you if there are any suspicious activities on your network. However, if strange things happen, Wireshark might help you figure out what is really going on.
- **Wireshark does not manipulate processes on the network, it can only perform "measurements" within it**.
  Wireshark does not send packets on the network or influence it in any other way, except for resolving names (converting numerical address values into a human readable format), but even that can be disabled.

1. Where to Get Wireshark You can get Wireshark from the official website: https://www.wireshark.org/download.html

Wireshark can run on various operating systems. Please download the correct version according to the operating system you are using.

3. Step-by-step Guide **This demonstration uses Wireshark 2.2.6 on Linux.**

a) Start Wireshark

On Linux, you can run the shell script provided below. It starts Wireshark, then configures NIC and the channel for packet capture.

```
ifconfig $1 down
iwconfig $1 mode monitor
iwconfig $1 channel $2
ifconfig $1 up
Wireshark&
```

In the above script, the parameter `$1` represents NIC and `$2` represents channel. For example, `wlan0` in `./xxx.sh wlan0 6`, specifies the NIC for packet capture, and `6` identifies the channel of an AP or Soft-AP.

b) Run the Shell Script to Open Wireshark and Display Capture Interface

c) Select the Interface to Start Packet Capture

As the red markup shows in the picture above, many interfaces are available. The first one is a local NIC and the second one is a wireless NIC.

Please select the NIC according to your requirements. This document will use the wireless NIC to demonstrate packet capture.

Double click *wlan0* to start packet capture.

d) Set up Filters

Since all packets in the channel will be captured, and many of them are not needed, you have to set up filters to get the packets that you need.

Please find the picture below with the red markup, indicating where the filters should be set up.

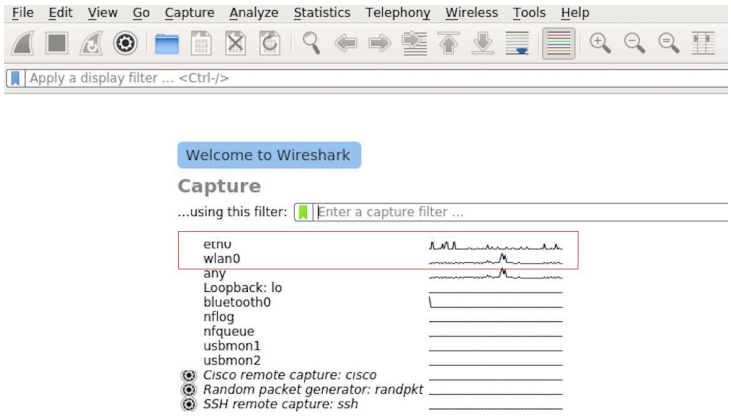

Fig. 70: Wireshark Capture Interface

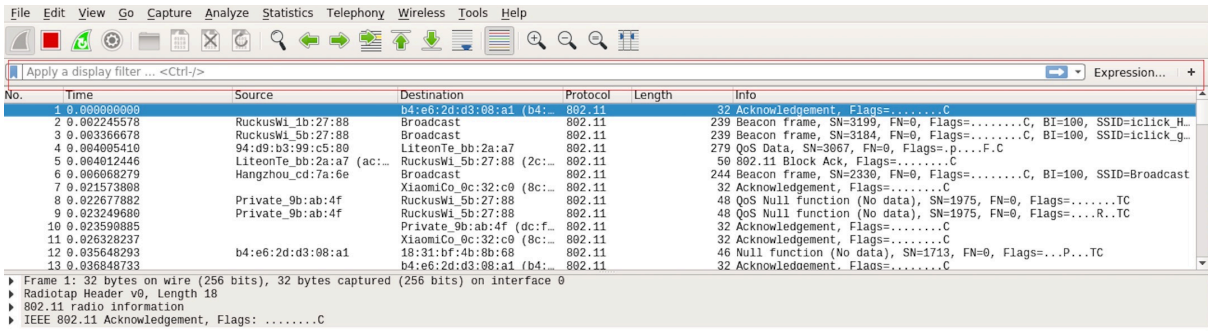

Fig. 71: Setting up Filters in Wireshark

Click *Filter*, the top left blue button in the picture below. The *display filter* dialogue box will appear.

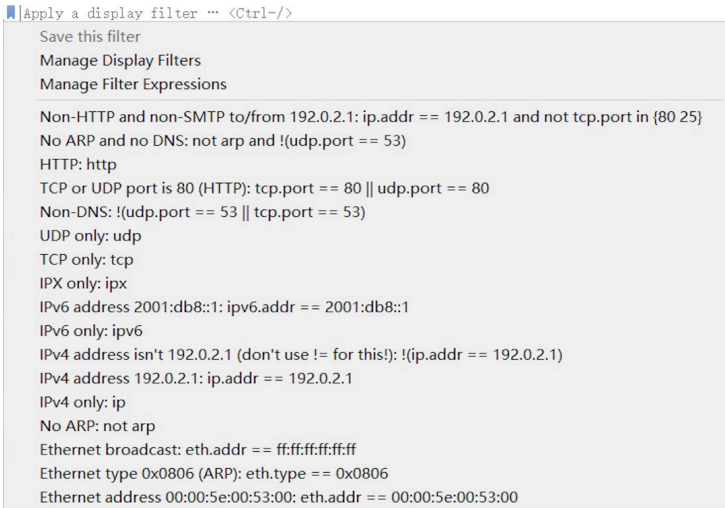

Fig. 72: *Display Filter* Dialogue Box

Click the *Expression* button to bring up the *Filter Expression* dialogue box and set the filter according to your requirements.

The quickest way: enter the filters directly in the toolbar.

Click on this area to enter or modify the filters. If you enter a wrong or unfinished filter, the built-in syntax check turns the background red. As soon as the correct expression is entered, the background becomes green.

The previously entered filters are automatically saved. You can access them anytime by opening the drop down list.

For example, as shown in the picture below, enter two MAC addresses as the filters and click *Apply* (the blue arrow). In this case, only the packet data transmitted between these two MAC addresses will be captured.

e) Packet List

You can click any packet in the packet list and check the detailed information about it in the box below the list. For example, if you click the first packet, its details will appear in that box.

f) Stop/Start Packet Capture

As shown in the picture below, click the red button to stop capturing the current packet.

Click the top left blue button to start or resume packet capture.

g) Save the Current Packet

On Linux, go to *File -> Export Packet Dissections -> As Plain Text File* to save the packet.

Please note that *All packets*, *Displayed* and *All expanded* must be selected.

By default, Wireshark saves the captured packet in a libpcap file. You can also save the file in other formats, e.g., txt, to analyze it in other tools.

4.36 Wi-Fi Security

4.36.1 ESP32-C3 Wi-Fi Security Features

- Support for Protected Management Frames (PMF)
- Support for WPA3-Personal

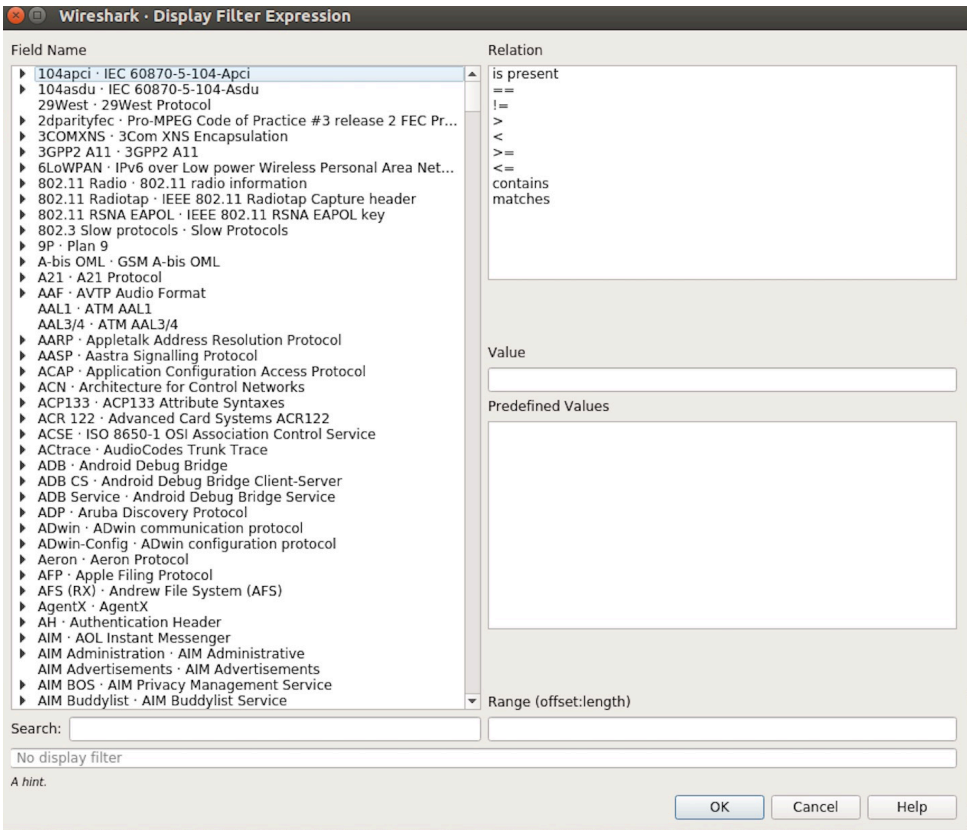

Fig. 73: *Filter Expression* Dialogue Box

Fig. 74: Filter Toolbar

Fig. 75: Example of MAC Addresses applied in the Filter Toolbar

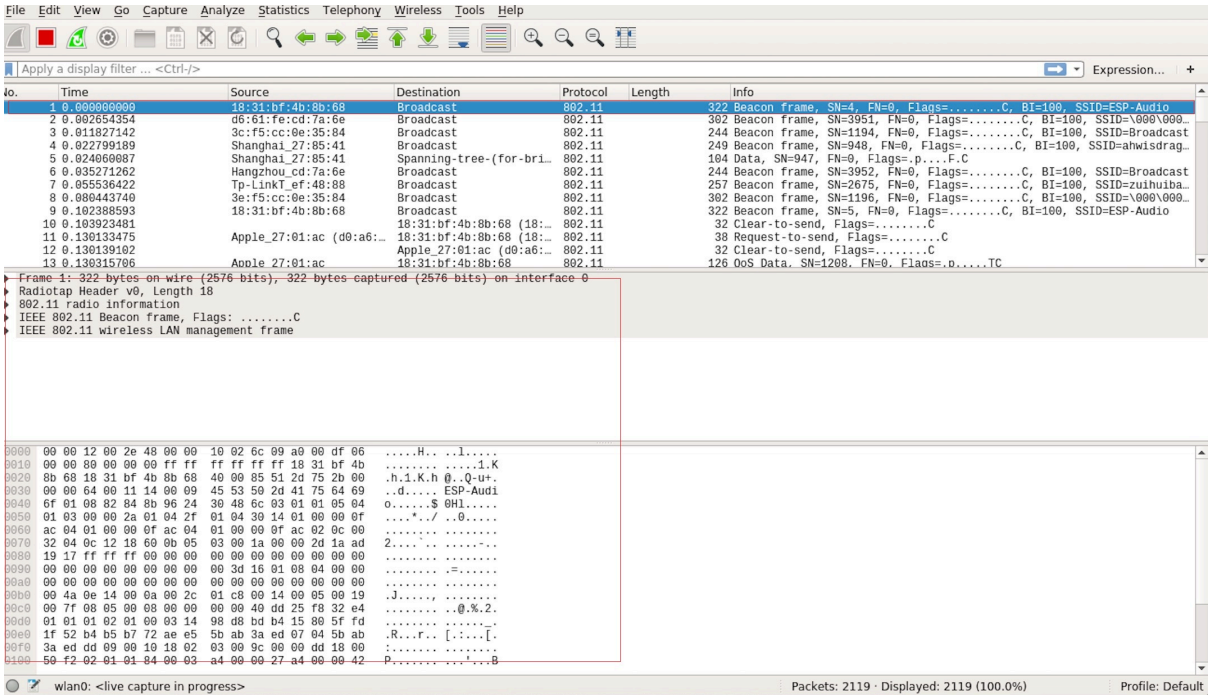

Fig. 76: Example of Packet List Details

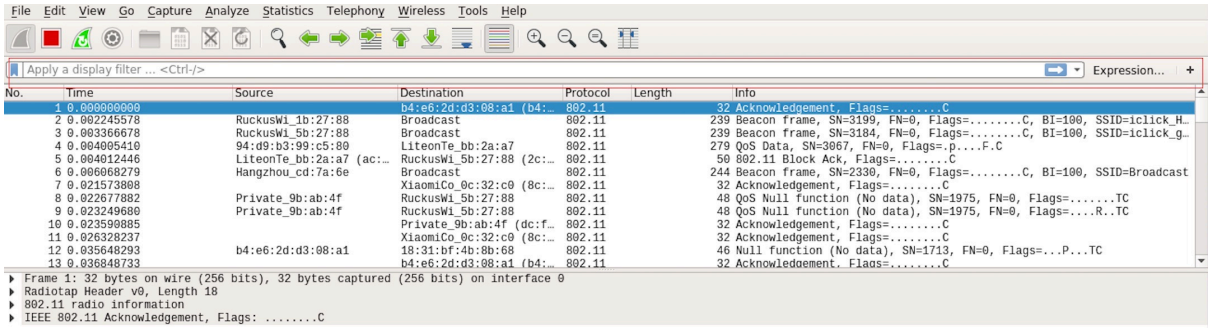

Fig. 77: Stopping Packet Capture

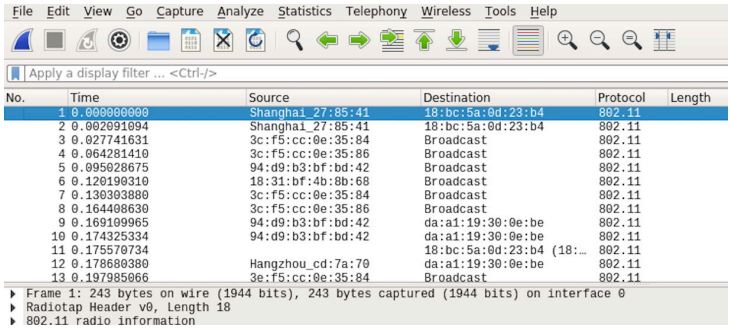

Fig. 78: Starting or Resuming the Packets Capture

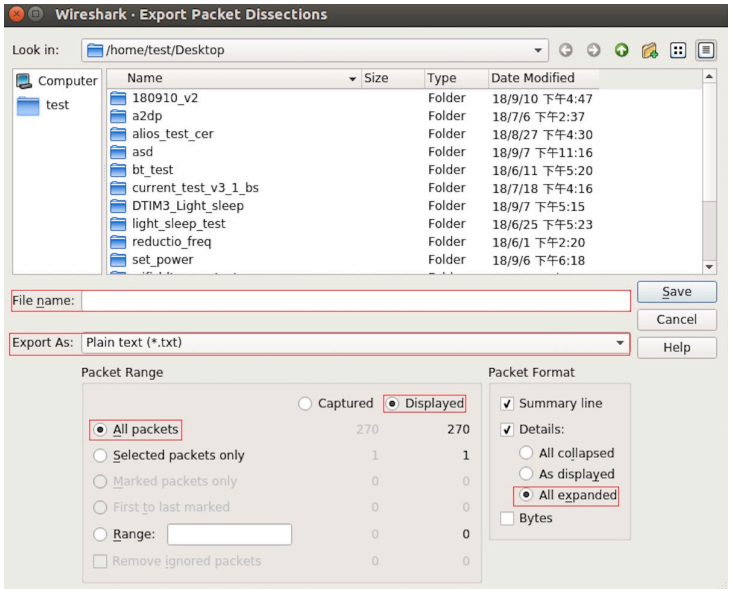

Fig. 79: Saving Captured Packets

- Support for Opportunistic Wireless Encryption (OWE)

In addition to traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), ESP32-C3 Wi-Fi supports state-of-the-art security protocols, namely Protected Management Frames (PMF), Wi-Fi Protected Access 3 and Enhanced Open™ based on Opportunistic Wireless Encryption. WPA3 provides better privacy and robustness against known attacks on traditional modes. Enhanced Open™ enhances the security and privacy of users connecting to open (public) Wireless Networks without authentication.

4.36.2 Protected Management Frames (PMF)

Introduction

In Wi-Fi, management frames such as beacons, probes, authentication/deauthentication, and association/disassociation are used by non-AP stations to scan and connect to an AP. Unlike data frames, these frames are sent unencrypted.

An attacker can use eavesdropping and packet injection to send spoofed authentication/deauthentication or association/disassociation frames at the right time, leading to attacks such as Denial-of-Service (DOS) and man-in-the-middle.

PMF provides protection against these attacks by encrypting unicast management frames and providing integrity checks for broadcast management frames. These include deauthentication, disassociation, and robust management frames. It also provides a Secure Association (SA) teardown mechanism to prevent spoofed association/authentication frames from disconnecting already connected clients.

There are three types of PMF configuration modes on both the station and AP sides:

- PMF Optional
- PMF Required
- PMF Disabled

API & Usage

ESP32-C3 supports PMF in both the station and SoftAP mode. For both, the default mode is PMF Optional. For even higher security, PMF Required mode can be enabled by setting the `required` flag in `pmf_cfg` while using the `esp_wifi_set_config()` API. This results in the device only connecting to a PMF-enabled device and

rejecting others. PMF Optional can be disabled using `esp_wifi_disable_pmf_config()` API. If SoftAP is started in WPA3 or WPA2/WPA3 mixed mode, trying to disable PMF results in an error.

Attention: `capable` flag in `pmf_cfg` is deprecated and set to `true` internally. This is to take the additional security benefit of PMF whenever possible.

4.36.3 Wi-Fi Enterprise

Introduction

Enterprise security is the secure authentication mechanism for enterprise wireless networks. It uses the RADIUS server for authentication of network users before connecting to the Access Point (AP). The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, PEAP, and EAP-FAST. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both.

Note: ESP32-C3 supports Wi-Fi Enterprise only in station mode.

ESP32-C3 supports **WPA2-Enterprise** and **WPA3-Enterprise**. WPA3-Enterprise builds upon the foundation of WPA2-Enterprise with the additional requirement of using Protected Management Frames (PMF) and server certificate validation on all WPA3 connections. **WPA3-Enterprise also offers an additional secure mode using 192-bit minimum-strength security protocols and cryptographic tools to better protect sensitive data.** The 192-bit security mode offered by WPA3-Enterprise ensures the right combination of cryptographic tools is used and sets a consistent baseline of security within a WPA3 network. WPA3-Enterprise 192-bit mode is only supported by modules having `SOC_WIFI_GCMP_SUPPORT` support. Enable *CONFIG_ESP_WIFI_SUITE_B_192* flag to support WPA3-Enterprise with 192-bit mode.

ESP32-C3 supports the following EAP methods:

- EAP-TLS: This is a certificate-based method and only requires SSID and EAP-IDF.
- PEAP: This is a Protected EAP method. Usernames and passwords are mandatory.
- **EAP-TTLS: This is a credential-based method. Only server authentication is mandatory while user authenticatio**
  - PAP: Password Authentication Protocol.
  - CHAP: Challenge Handshake Authentication Protocol.
  - MSCHAP and MSCHAP-V2.
- EAP-FAST: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, *CONFIG_ESP_WIFI_MBEDTLS_TLS_CLIENT* flag should be disabled to use this feature.

Example wifi/wifi_enterprise demonstrates all the supported Wi-Fi Enterprise methods except EAP-FAST. Please refer wifi/wifi_eap_fast for the EAP-FAST example. EAP method can be selected from the Example Configuration menu in `idf.py menuconfig`. Refer to examples/wifi/wifi_enterprise/README.md for information on how to generate certificates and run the example.

4.36.4 WPA3-Personal

Introduction

Wi-Fi Protected Access-3 (WPA3) is a set of enhancements to Wi-Fi access security intended to replace the current WPA2 standard. It includes new features and capabilities that offer significantly better protection against different types of attacks. It improves upon WPA2-Personal in the following ways:

- WPA3 uses Simultaneous Authentication of Equals (SAE), which is a password-authenticated key agreement method based on Diffie-Hellman key exchange. Unlike WPA2, the technology is resistant to offline-dictionary

attacks, where the attacker attempts to determine a shared password based on a captured 4-way handshake without any further network interaction.
- Disallows outdated protocols such as TKIP, which is susceptible to simple attacks like MIC key recovery attacks.
- Mandates Protected Management Frames (PMF), which provides protection for unicast and multicast robust management frames which include Disassoc and Deauth frames. This means that the attacker cannot disrupt an established WPA3 session by sending forged Assoc frames to the AP or Deauth/Disassoc frames to the station.
- Provides forward secrecy, which means the captured data cannot be decrypted even if the password is compromised after data transmission.

ESP32-C3 station also supports following additional Wi-Fi CERTIFIED WPA3™ features:

- **Transition Disable** : WPA3 defines transition modes for client devices so that they can connect to a network even when some of the APs in that network do not support the strongest security mode. Client device implementations typically configure network profiles in a transition mode by default. However, such a client device could be subject to an active downgrade attack in which the attacker causes the client device to use a lower security mode in order to exploit a vulnerability with that mode. WPA3 has introduced the Transition Disable feature to mitigate such attacks, by enabling client devices to change from a transition mode to an "only" mode when connecting to a network, once that network indicates it fully supports the higher security mode. Enable `transition_disable` in `wifi_sta_config_t` to enable this feature for ESP32-C3 station.
- **SAE PUBLIC-KEY (PK)** : As the password at small public networks is shared with multiple users, it may be relatively easy for an attacker to find out the password, which is sufficient to launch an evil twin attack. Such attacks are prevented by an extension to WPA3-Personal called SAE-PK. The SAE-PK authentication exchange is very similar to the regular SAE exchange, with the addition of a digital signature sent by the AP to the client device. The client device validates the public key asserted by the AP based on the password fingerprint and verifies the signature using the public key. So even if the attacker knows the password, it does not know the private key to generate a valid signature, and therefore the client device is protected against an evil twin attack. Enable *CONFIG_ESP_WIFI_ENABLE_SAE_PK* and `sae_pk_mode` in `wifi_sta_config_t` to add support of SAE PK for ESP32-C3 station.
- **SAE PWE Methods**: ESP32-C3 station as well as SoftAP supports SAE Password Element derivation method *Hunting And Pecking* and *Hash to Element (H2E)*. H2E is computationally efficient as it uses fewer iterations than Hunt and Peck, and also it mitigates side-channel attacks. These can be configured using the parameter `sae_pwe_h2e` from `wifi_sta_config_t` and `wifi_ap_config_t` for station and SoftAP respectively. Hunt and peck, H2E both can be enabled by using `WPA3_SAE_PWE_BOTH` configuration.

Please refer to the Security section of Wi-Fi Alliance's official website for further details.

Setting up WPA3 Personal with ESP32-C3

A configuration option *CONFIG_ESP_WIFI_ENABLE_WPA3_SAE* is provided to enable/disable WPA3 for the station. By default, it is kept enabled. If disabled, ESP32-C3 will not be able to establish a WPA3 connection. Also under the Wi-Fi component, a configuration option *CONFIG_ESP_WIFI_SOFTAP_SAE_SUPPORT* is provided to enable/disable WPA3 for SoftAP. Additionally, since PMF is mandated by WPA3 protocol, PMF Optional is set by default for station and SoftAP. PMF Required can be configured using Wi-Fi configuration. For WPA3 SoftAP, PMF Required is mandatory and will be configured and stored in NVS implicitly if not specified by the user.

Refer to *Protected Management Frames (PMF)* on how to set this mode.

After configuring all required settings for the WPA3-Personal station, application developers need not worry about the underlying security mode of the AP. WPA3-Personal is now the highest supported protocol in terms of security, so it is automatically selected for the connection whenever available. For example, if an AP is configured to be in WPA3 Transition Mode, where it advertises as both WPA2 and WPA3 capable, the station chooses WPA3 for the connection with the above settings.

After configuring all required setting for WPA3-Personal SoftAP, application developers have to set `WIFI_AUTH_WPA3_PSK` for *authmode* in `wifi_ap_config_t` to start AP in WPA3 security. SoftAP can be also configured to use `WIFI_AUTH_WPA2_WPA3_PSK` mixed mode.

Note that binary size will be increased by about 6.5 kilobytes after enabling *CONFIG_ESP_WIFI_SOFTAP_SAE_SUPPORT*.

4.36.5 Wi-Fi Enhanced Open™

Introduction

Enhanced Open™ is used for providing security and privacy to users connecting to open (public) wireless networks, particularly in scenarios where user authentication is not desired or distribution of credentials impractical. Each user is provided with unique individual encryption keys that protect data exchange between a user device and the Wi-Fi network. Protected Management Frames further protect management traffic between the access point and the user device. Enhanced Open™ is based on the Opportunistic Wireless Encryption (OWE) standard. OWE Transition Mode enables a seamless transition from Open unencrypted WLANs to OWE WLANs without adversely impacting the end-user experience.

Note: ESP32-C3 supports Wi-Fi Enhanced Open™ only in station mode.

Setting up OWE with ESP32-C3

A configuration option *CONFIG_ESP_WIFI_ENABLE_WPA3_OWE_STA* and configuration parameter `owe_enabled` in `wifi_sta_config_t` is provided to enable OWE support for the station. To use OWE transition mode, along with the configuration provided above, *authmode* from `wifi_scan_threshold_t` should be set to `WIFI_AUTH_OPEN`.

4.37 PHY

4.37.1 Multiple Antennas

Principles and Components of Multiple Antennas

Multi-antenna functionality primarily involves routing signals from internal antenna modules to specific IO pins, controlling external antenna switches through IO pins to select designated antennas, supporting up to 16 antennas.

The components of multiple antennas can be depicted as following picture:

```
                    ____________________________________________________________________
↪_____________
                ____|____                          __________                          ␣
↪              |
                |PHY      |--antenna_select[0] --> |         |                         ␣
↪              |
            ___|Antenna 0|--antenna_select[1] --> |         |                         ␣
↪              |
           /    |Module   |--antenna_select[2] --> |         |                         ␣
↪          ____|____
          /     |_________|--antenna_select[3] --> | IO MUX  |--GPIO[x0] --> ant_
↪sel_in[0]--|         | --- antenna 0
RX/TX ___/          |                             | And     |--GPIO[x1] --> ant_
↪sel_in[1]--| Antenna | --- antenna 1
         \       ____|____                         | GPIO    |--GPIO[x2] --> ant_
↪sel_in[2]--| Switch  | ...  ...
          \     |PHY      |--antenna_select[0] --> | Matrix  |--GPIO[x3] --> ant_
↪sel_in[3]--|_________| --- antenna 15
           \___|Antenna 1|--antenna_select[1] --> |         |
               |Module   |--antenna_select[2] --> |         |
               |_________|--antenna_select[3] --> |_________|
```

ESP32-C3 Multiple antennas primarily consists of three parts: the PHY Antenna Module inside the chip, IO MUX and GPIO Matrix, and external antenna switches.

1. PHY Antenna Module:
   - Both antenna modules support operation in transmit (TX) or receive (RX) mode, and can be configured via software to select a particular module for transmission or reception.
   - Each antenna module supports outputting up to 4 antenna selection signals `antenna_select[3:0]`, which can be configured by software and mapped to any IO pin individually.
   - When an antenna module is in operation, the logic level of the IO pin corresponds to the configured signal value.
2. IO MUX and GPIO Matrix:
   - Routes the internal 4-way antenna signals to specific IO pins.
3. External Antenna Switches:
   - Typically multi-way selectors, they choose the working antenna based on the logic level of the `ant_sel_in[x]` pin. For example, `ant_sel_in[3:0]` as `0b1011` selects antenna 11.

Steps for Multi-Antenna Usage

1. Determine the IO pins used for controlling antenna switching based on hardware circuit design and external antenna switches.
2. Configure antenna selection signals to output to specified IO pins.
   - API `esp_phy_set_ant_gpio()` is used to configure `antenna_selects[3:0]` signals to connect with `GPIO[x3:x0]`. If `GPIO[x0]` is connected to `antenna_select[0]`, `gpio_config->gpio_cfg[x0].gpio_select` should be set to 1, and the value of `gpio_config->gpio_cfg[x0].gpio_num` should be `GPIO[x0]`.
3. Configure internal antenna operation mode and output signals.
   - API `esp_phy_set_ant()` is used to configure the use of internal antenna module 0 or 1 for transmission or reception, and to configure the output signal values when antenna module 0 or 1 is in operation.
   - `ESP_PHY_ANT_MODE_AUTO` mode is currently not recommended for use.

Multi-Antenna Configuration Reference Example

Typically, the following steps can be performed to configure multi-antenna:

- Configure `antenna_selects` to connect with which GPIOs. For example, if four antennas are supported and GPIO20/GPIO21 are connected to `antenna_select[0]/antenna_select[1]`, the configuration is as follows:

```
esp_phy_ant_gpio_config_t ant_gpio_config = {
    .gpio_cfg[0] = { .gpio_select = 1, .gpio_num = 20 },
    .gpio_cfg[1] = { .gpio_select = 1, .gpio_num = 21 }
};
```

- Configure which antennas are enabled and how enabled antennas are used for receiving/sending data. For example, if antennas 1 and 3 are enabled, data reception needs to automatically select the better antenna, with antenna 1 set as the default antenna, and data transmission always selecting antenna 3. The configuration is as follows:

```
esp_phy_ant_config_t config = {
    .rx_ant_mode = ESP_PHY_ANT_MODE_AUTO,
    .rx_ant_default = ESP_PHY_ANT_ANT0,
    .tx_ant_mode = ESP_PHY_ANT_MODE_ANT1,
    .enabled_ant0 = 1,
    .enabled_ant1 = 3
};
```

Notes

1. Different antenna switches may have invalid input values for `ant_sel_in[3:0]`, meaning the number of antennas supported by ESP32-C3 via external antenna switches may be less than 16. For example, ESP32-WROOM-DA uses RTC6603SP as the antenna switch, supporting only 2 antennas. The two antenna selection input pins are active high and are connected to two GPIOs. `0b01` indicates antenna 0 is selected, `0b10` indicates antenna 1 is selected. Input values `0b00` and `0b11` are invalid.
2. Despite supporting up to 16 antennas, only a maximum of two antennas can be enabled simultaneously for sending and receiving data.
3. The use of `ESP_PHY_ANT_MODE_AUTO` mode is currently not recommended, primarily due to the following limitations:
   - For the antenna selection algorithm based on `ESP_PHY_ANT_MODE_AUTO` type for sending data, the antenna for sending data can only be set to `ESP_PHY_ANT_MODE_AUTO` when the antenna mode for receiving data is `ESP_PHY_ANT_MODE_AUTO`.
   - When the receiving or sending antenna mode is configured as `ESP_PHY_ANT_MODE_AUTO`, frequent antenna switching may occur if RF signal degradation is detected. Unstable RF signals can lead to frequent antenna switching, resulting in the overall RF performance not meeting expectations.

Recommended Scenarios for Using Multiple Antennas

1. Applications can either select specified antennas or implement their own antenna selection algorithms based on collected information, such as selecting antenna modes according to application-specific criteria. Refer to the IDF example examples/phy/antenna/README.md for designing antenna selection algorithms.
2. Configure antenna modes for both receiving and sending data as `ESP_PHY_ANT_MODE_ANT0` or `ESP_PHY_ANT_MODE_ANT1`.

Chapter 5

Security Guides

5.1 Overview

5.1.1 Security

This guide provides an overview of the overall security features available in various Espressif solutions. It is highly recommended to consider this guide while designing the products with the Espressif platform and the ESP-IDF software stack from the **security** perspective.

Note: In this guide, most used commands are in the form of `idf.py secure-<command>`, which is a wrapper around corresponding `espsecure.py <command>`. The `idf.py` based commands provides more user-friendly experience, although may lack some of the advanced functionality of their `espsecure.py` based counterparts.

Goals

High level security goals are as follows:

1. Preventing untrustworthy code from being executed
2. Protecting the identity and integrity of the code stored in the off-chip flash memory
3. Securing device identity
4. Secure storage for confidential data
5. Authenticated and encrypted communication from the device

Platform Security

Secure Boot The Secure Boot feature ensures that only authenticated software can execute on the device. The Secure Boot process forms a chain of trust by verifying all **mutable** software entities involved in the *Application Startup Flow*. Signature verification happens during both boot-up as well as in OTA updates.

Please refer to *Secure Boot v2* for detailed documentation about this feature.

Important: It is highly recommended that Secure Boot be enabled on all production devices.

Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Always keep the signing key private. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using `idf.py secure-` or `espsecure.py` commands. Both processes are vulnerable to timing or other side-channel attacks.
- Ensure that all security eFuses have been correctly programmed, including disabling of the debug interfaces, non-required boot mediums (e.g., UART DL mode), etc.

Flash Encryption The Flash Encryption feature helps to encrypt the contents on the off-chip flash memory and thus provides the **confidentiality** aspect to the software or data stored in the flash memory.

Please refer to *Flash Encryption* for detailed information about this feature.

Flash Encryption Best Practices

- It is recommended to use flash Encryption release mode for the production use-cases.
- It is recommended to have a unique flash encryption key per device.
- Enable *Secure Boot* as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

Device Identity The Digital Signature peripheral in ESP32-C3 produces hardware-accelerated RSA digital signatures with the assistance of HMAC, without the RSA private key being accessible by software. This allows the private key to be kept secured on the device without anyone other than the device hardware being able to access it.

DS peripheral can help to establish the **Secure Device Identity** to the remote endpoint, e.g., in the case of TLS mutual authentication based on the RSA cipher scheme.

Please refer to the *Digital Signature (DS)* for detailed documentation.

Memory Protection ESP32-C3 supports the **Memory Protection** scheme, either through architecture or special peripheral like PMS, which provides an ability to enforce and monitor permission attributes to memory and, in some cases, peripherals. ESP-IDF application startup code configures the permissions attributes like Read/Write access on data memories and Read/Execute access on instruction memories using the relevant peripheral. If there is any attempt made that breaks these permission attributes, e.g., a write operation to instruction memory region, then a violation interrupt is raised, and it results in system panic.

This feature depends on the config option *CONFIG_ESP_SYSTEM_MEMPROT_FEATURE* and it is kept enabled by default. Please note that the API for this feature is **private** and used exclusively by ESP-IDF code only.

Note: This feature can help to prevent the possibility of remote code injection due to the existing vulnerabilities in the software.

Debug Interfaces

JTAG

- JTAG interface stays disabled if any of the security features are enabled. Please refer to *JTAG with Flash Encryption or Secure Boot* for more information.
- JTAG interface can also be disabled in the absence of any other security features using *eFuse API*.
- ESP32-C3 supports soft disabling the JTAG interface and it can be re-enabled by programming a secret key through HMAC. (*HMAC for Enabling JTAG*)

UART Download Mode In ESP32-C3, Secure UART Download mode gets activated if any of the security features are enabled.

- Secure UART Download mode can also be enabled by calling `esp_efuse_enable_rom_secure_download_mode()`.
- This mode does not allow any arbitrary code to execute if downloaded through the UART download mode.
- It also limits the available commands in Download mode to update SPI config, e.g., changing baud rate, basic flash write, and the command to return a summary of currently enabled security features (`get_security_info`).
- To disable Download Mode entirely, select the *CONFIG_SECURE_UART_ROM_DL_MODE* to the recommended option `Permanently disable ROM Download Mode` or call `esp_efuse_disable_rom_download_mode()` at runtime.

Important: In Secure UART Download mode, `esptool.py` can only work with the argument `--no-stub`.

Network Security

Wi-Fi In addition to the traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), Wi-Fi driver in ESP-IDF also supports additional state-of-the-art security protocols. Please refer to the *Wi-Fi Security* for detailed documentation.

TLS (Transport Layer Security) It is recommended to use TLS (Transport Layer Security) in all external communications (e.g., cloud communication, OTA updates) from the ESP device. ESP-IDF supports *Mbed TLS* as the official TLS stack.

TLS is default integrated in *ESP HTTP Client*, *HTTPS Server* and several other components that ship with ESP-IDF.

Note: It is recommended to use the ESP-IDF protocol components in their default configuration, which has been ensured to be secure. Disabling of HTTPS and similar security-critical configurations should be avoided.

ESP-TLS Abstraction ESP-IDF provides an abstraction layer for the most-used TLS functionalities. Hence, it is recommended that an application uses the API exposed by *ESP-TLS*.

TLS Server Verification section highlights diverse ways in which the identity of server could be established on the device side.

ESP Certificate Bundle The *ESP x509 Certificate Bundle* API provides an easy way to include a bundle of custom x509 root certificates for TLS server verification. The certificate bundle is the easiest way to verify the identity of almost all standard TLS servers.

Important: It is highly recommended to verify the identity of the server based on X.509 certificates to avoid establishing communication with the **fake** server.

Managing Root Certificates Root Certificates embedded inside the application must be managed carefully. Any update to the root certificate list or the *ESP x509 Certificate Bundle* can have an impact on the TLS connection with the remote endpoint. This includes a connection to the OTA update server. In some cases, the problem shall be visible on the next OTA update and it may leave device unable to perform OTA updates forever.

Root certificates list update could have following reasons:

- New firmware has different set of remote endpoint(s).
- The existing certificate has expired.
- The certificate has been added or retracted from the upstream certificate bundle.

- The certificate list changed due to market share statistics (`CONFIG_MBEDTLS_CERTIFICATE_BUNDLE_DEFAULT_CMN` case).

Some guidelines to consider on this topic:

- Please consider enabling *OTA rollback* and then keep the successful connection to the OTA update server as the checkpoint to cancel the rollback process. This ensures that the newly updated firmware can successfully reach till the OTA update server, otherwise rollback process will go back to the previous firmware on the device.
- If you plan to enable the *CONFIG_MBEDTLS_HAVE_TIME_DATE* option, then please consider to have the time sync mechanism (SNTP) and sufficient number of trusted certificates in place.

Product Security

Secure Provisioning Secure Provisioning refers to a process of secure on-boarding of the ESP device on to the Wi-Fi network. This mechanism also allows provision of additional custom configuration data during the initial provisioning phase from the provisioning entity, e.g., Smartphone.

ESP-IDF provides various security schemes to establish a secure session between ESP and the provisioning entity, they are highlighted at *Security Schemes*.

Please refer to the *Wi-Fi Provisioning* documentation for details and the example code for this feature.

Note: Espressif provides Android and iOS Phone Apps along with their sources, so that it could be easy to further customize them as per the product requirement.

Secure OTA (Over-the-air) Updates

- OTA Updates must happen over secure transport, e.g., HTTPS.
- ESP-IDF provides a simplified abstraction layer *ESP HTTPS OTA* for this.
- If *Secure Boot* is enabled, then the server should host the signed application image.
- If *Flash Encryption* is enabled, then no additional steps are required on the server side, encryption shall be taken care on the device itself during flash write.
- OTA update *Rollback Process* can help to switch the application as `active` only after its functionality has been verified.

Anti-Rollback Protection Anti-rollback protection feature ensures that device only executes the application that meets the security version criteria as stored in its eFuse. So even though the application is trusted and signed by legitimate key, it may contain some revoked security feature or credential. Hence, device must reject any such application.

ESP-IDF allows this feature for the application only and it is managed through 2nd stage bootloader. The security version is stored in the device eFuse and it is compared against the application image header during both boot-up and over-the-air updates.

Please see more information to enable this feature in the *Anti-rollback* guide.

Encrypted Firmware Distribution Encrypted firmware distribution during over-the-air updates ensures that the application stays encrypted **in transit** from the server to the the device. This can act as an additional layer of protection on top of the TLS communication during OTA updates and protect the identity of the application.

Please see working example for this documented in *OTA Upgrades with Pre-Encrypted Firmware* section.

Secure Storage Secure storage refers to the application-specific data that can be stored in a secure manner on the device, i.e., off-chip flash memory. This is typically a read-write flash partition and holds device specific configuration data, e.g., Wi-Fi credentials.

ESP-IDF provides the **NVS (Non-volatile Storage)** management component which allows encrypted data partitions. This feature is tied with the platform *Flash Encryption* feature described earlier.

Please refer to the *NVS Encryption* for detailed documentation on the working and instructions to enable this feature.

Important: By default, ESP-IDF components writes the device specific data into the default NVS partition, including Wi-Fi credentials too, and it is recommended to protect this data using **NVS Encryption** feature.

Secure Device Control ESP-IDF provides capability to control an ESP device over `Wi-Fi/Ethernet + HTTP` or `BLE` in a secure manner using ESP Local Control component.

Please refer to the *ESP Local Control* for detailed documentation about this feature.

Security Policy

The ESP-IDF GitHub repository has attached Security Policy Brief.

Advisories

- Espressif publishes critical Security Advisories, which includes security advisories regarding both hardware and software.
- The specific advisories of the ESP-IDF software components are published through the GitHub repository.

Software Updates Critical security issues in the ESP-IDF components, and third-party libraries are fixed as and when we find them or when they are reported to us. Gradually, we make the fixes available in all applicable release branches in ESP-IDF.

Applicable security issues and CVEs for the ESP-IDF components, third-party libraries are mentioned in the ESP-IDF release notes.

Important: We recommend periodically updating to the latest bugfix version of the ESP-IDF release to have all critical security fixes available.

5.2 Features

5.2.1 Flash Encryption

This is a quick start guide to ESP32-C3's flash encryption feature. Using application code as an example, it demonstrates how to test and verify flash encryption operations during development and production.

Note: In this guide, most used commands are in the form of `idf.py secure-<command>`, which is a wrapper around corresponding `espsecure.py <command>`. The `idf.py` based commands provides more user-friendly experience, although may lack some of the advanced functionality of their `espsecure.py` based counterparts.

Introduction

Flash encryption is intended for encrypting the contents of the ESP32-C3's off-chip flash memory. Once this feature is enabled, firmware is flashed as plaintext, and then the data is encrypted in place on the first boot. As a result, physical readout of flash will not be sufficient to recover most flash contents.

Important: For production use, flash encryption should be enabled in the "Release" mode only.

Important: Enabling flash encryption limits the options for further updates of ESP32-C3. Before using this feature, read the document and make sure to understand the implications.

Encrypted Partitions

With flash encryption enabled, the following types of data are encrypted by default:

- *Second Stage Bootloader* (Firmware Bootloader)
- Partition Table
- *NVS Key Partition*
- Otadata
- All `app` type partitions

Other types of data can be encrypted conditionally:

- Any partition marked with the `encrypted` flag in the partition table. For details, see *Encrypted Partition Flag*.
- Secure Boot bootloader digest if Secure Boot is enabled (see below).

Relevant eFuses

The flash encryption operation is controlled by various eFuses available on ESP32-C3. The list of eFuses and their descriptions is given in the table below. The names in eFuse column are also used by `espefuse.py` tool and `idf.py` based eFuse commands. For usage in the eFuse API, modify the name by adding `ESP_EFUSE_`, for example: esp_efuse_read_field_bit (ESP_EFUSE_DISABLE_DL_ENCRYPT).

Table 1: eFuses Used in Flash Encryption

eFuse	Description	Bit Depth
`BLOCK_KEYN`	AES key storage. N is between 0 and 5.	256 bit key block
`KEY_PURPOSE_N`	Control the purpose of eFuse block `BLOCK_KEYN`, where N is between 0 and 5. For flash encryption, the only valid value is `4` for `XTS_AES_128_KEY`.	4
`DIS_DOWNLOAD_MANUAL_ENCRYPT`	If set, disable flash encryption when in download boot-modes.	1
`SPI_BOOT_CRYPT_CNT`	Enable encryption and decryption, when an SPI boot mode is set. Feature is enabled if 1 or 3 bits are set in the eFuse, disabled otherwise.	3

Note:

- R/W access control is available for all the eFuse bits listed in the table above.
- The default value of these bits is 0 after manufacturing.

Read and write access to eFuse bits is controlled by appropriate fields in the registers `WR_DIS` and `RD_DIS`. For more information on ESP32-C3 eFuses, see *eFuse manager*. To change protection bits of eFuse field using `idf.py`, use these two commands: efuse-read-protect and efuse-write-protect (idf.py based aliases of espefuse.py commands write_protect_efuse and read_protect_efuse). Example `idf.py efuse-write-protect DISABLE_DL_ENCRYPT`.

Flash Encryption Process

Assuming that the eFuse values are in their default states and the firmware bootloader is compiled to support flash encryption, the flash encryption process executes as shown below:

1. On the first power-on reset, all data in flash is un-encrypted (plaintext). The ROM bootloader loads the firmware bootloader.
2. Firmware bootloader reads the `SPI_BOOT_CRYPT_CNT` eFuse value (`0b000`). Since the value is `0` (even number of bits set), it configures and enables the flash encryption block. For more information on the flash encryption block, see ESP32-C3 Technical Reference Manual.
3. Firmware bootloader uses RNG (random) module to generate an 256 bit key and then writes it into *BLOCK_KEYN* eFuse. The software also updates the `KEY_PURPOSE_N` for the block where the key is stored. The key cannot be accessed via software as the write and read protection bits for *BLOCK_KEYN* eFuse are set. `KEY_PURPOSE_N` field is write-protected as well. The flash encryption is completely conducted by hardware, and the key cannot be accessed via software. If a valid key is already present in the eFuse (e.g., burned using espefuse tool) then the process of key generation is skipped and the same key is used for flash encryption process.
4. Flash encryption block encrypts the flash contents - the firmware bootloader, applications and partitions marked as `encrypted`. Encrypting in-place can take time, up to a minute for large partitions.
5. Firmware bootloader sets the first available bit in `SPI_BOOT_CRYPT_CNT` (0b001) to mark the flash contents as encrypted. Odd number of bits is set.
6. For *Development Mode*, the firmware bootloader allows the UART bootloader to re-flash encrypted binaries. Also, the `SPI_BOOT_CRYPT_CNT` eFuse bits are NOT write-protected. In addition, the firmware bootloader by default sets the eFuse bits `DIS_DOWNLOAD_ICACHE`, `DIS_PAD_JTAG`, `DIS_USB_JTAG` and `DIS_LEGACY_SPI_BOOT`.
7. For *Release Mode*, the firmware bootloader sets all the eFuse bits set under development mode as well as `DIS_DOWNLOAD_MANUAL_ENCRYPT`. It also write-protects the `SPI_BOOT_CRYPT_CNT` eFuse bits. To modify this behavior, see *Enabling UART Bootloader Encryption/Decryption*.
8. The device is then rebooted to start executing the encrypted image. The firmware bootloader calls the flash decryption block to decrypt the flash contents and then loads the decrypted contents into IRAM.

During the development stage, there is a frequent need to program different plaintext flash images and test the flash encryption process. This requires that Firmware Download mode is able to load new plaintext images as many times as it might be needed. However, during manufacturing or production stages, Firmware Download mode should not be allowed to access flash contents for security reasons.

Hence, two different flash encryption configurations were created: for development and for production. For details on these configurations, see Section *Flash Encryption Configuration*.

Flash Encryption Configuration

The following flash encryption modes are available:

- *Development Mode* - recommended for use only during development. In this mode, it is still possible to flash new plaintext firmware to the device, and the bootloader will transparently encrypt this firmware using the key stored in hardware. This allows, indirectly, to read out the plaintext of the firmware in flash.
- *Release Mode* - recommended for manufacturing and production. In this mode, flashing plaintext firmware to the device without knowing the encryption key is no longer possible.

This section provides information on the mentioned flash encryption modes and step by step instructions on how to use them.

Development Mode During development, you can encrypt flash using either an ESP32-C3 generated key or external host-generated key.

Using ESP32-C3 Generated Key Development mode allows you to download multiple plaintext images using Firmware Download mode.

To test flash encryption process, take the following steps:

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-C3 Flash Encryption Status*.

2. In *Project Configuration Menu*, do the following:

   - *Enable flash encryption on boot*.
   - *Select encryption mode* (**Development mode** by default).
   - *Select UART ROM download mode* (**enabled** by default).
   - *Select the appropriate bootloader log verbosity*.
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-C3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

A sample output of the first ESP32-C3 boot after enabling flash encryption is given below:

Example to check Flash Encryption status
This is esp32c3 chip with 1 CPU core(s), WiFi/BLE, silicon revision 0, 2MB␣
↪external flash
FLASH_CRYPT_CNT eFuse value is 1
Flash encryption feature is enabled in DEVELOPMENT mode
```

At this stage, if you need to update and re-flash binaries, see *Re-flashing Updated Partitions*.

Using Host Generated Key It is possible to pre-generate a flash encryption key on the host computer and burn it into the eFuse. This allows you to pre-encrypt data on the host and flash already encrypted data without needing

a plaintext flash update. This feature can be used in both *Development Mode* and *Release Mode*. Without a pre-generated key, data is flashed in plaintext and then ESP32-C3 encrypts the data in-place.

Note: This option is not recommended for production, unless a separate key is generated for each individual device.

To use a host generated key, take the following steps:

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-C3 Flash Encryption Status*.

2. Generate a random key by running:

```
idf.py secure-generate-flash-encryption-key my_flash_encryption_key.bin
```

3. **Before the first encrypted boot**, burn the key into your device's eFuse using the command below. This action can be done **only once**.

```
idf.py --port PORT efuse-burn-key BLOCK my_flash_encryption_key.bin XTS_
↪AES_128_KEY
```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`.

   If the key is not burned and the device is started after enabling flash encryption, the ESP32-C3 will generate a random key that software cannot access or modify.

4. In *Project Configuration Menu*, do the following:
   - *Enable flash encryption on boot*
   - *Select encryption mode* (**Development mode** by default)
   - *Select the appropriate bootloader log verbosity*
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

5. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

   Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

   This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-C3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

If using Development Mode, then the easiest way to update and re-flash binaries is *Re-flashing Updated Partitions*.

If using Release Mode, then it is possible to pre-encrypt the binaries on the host and then flash them as ciphertext. See *Manually Encrypting Files*.

Re-flashing Updated Partitions If you update your application code (done in plaintext) and want to re-flash it, you will need to encrypt it before flashing. To encrypt the application and flash it in one step, run:

```
idf.py encrypted-app-flash monitor
```

If all partitions needs to be updated in encrypted format, run:

```
idf.py encrypted-flash monitor
```

Release Mode In Release mode, UART bootloader cannot perform flash encryption operations. New plaintext images can ONLY be downloaded using the over-the-air (OTA) scheme which will encrypt the plaintext image before writing to flash.

To use this mode, take the following steps:

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-C3 Flash Encryption Status*.

2. In *Project Configuration Menu*, do the following:

   - *Enable flash encryption on boot*
   - *Select Release mode* (Note that once Release mode is selected, the `EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT` eFuse bit will be burned to disable flash encryption hardware in ROM Download Mode.)
   - *Select UART ROM download mode (Permanently switch to Secure mode (recommended))*. This is the default option, and is recommended. It is also possible to change this configuration setting to permanently disable UART ROM download mode, if this mode is not needed.
   - *Select the appropriate bootloader log verbosity*
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

3. Run the command given below to build and flash the complete images.

   ```
   idf.py flash monitor
   ```

   Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

   This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-C3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

Once the flash encryption is enabled in Release mode, the bootloader will write-protect the `SPI_BOOT_CRYPT_CNT` eFuse.

For subsequent plaintext field updates, use *OTA scheme*.

Note: If you have pre-generated the flash encryption key and stored a copy, and the UART download mode is not permanently disabled via *CONFIG_SECURE_UART_ROM_DL_MODE* , then it is possible to update the flash locally by pre-encrypting the files and then flashing the ciphertext. See *Manually Encrypting Files*.

Best Practices When using Flash Encryption in production:

- Do not reuse the same flash encryption key between multiple devices. This means that an attacker who copies encrypted data from one device cannot transfer it to a second device.

- The UART ROM Download Mode should be disabled entirely if it is not needed, or permanently set to "Secure Download Mode" otherwise. Secure Download Mode permanently limits the available commands to updating SPI config, changing baud rate, basic flash write, and returning a summary of the currently enabled security features with the *get_security_info* command. The default behaviour is to set Secure Download Mode on first boot in Release mode. To disable Download Mode entirely, select *CONFIG_SECURE_UART_ROM_DL_MODE* to "Permanently disable ROM Download Mode (recommended)" or call `esp_efuse_disable_rom_download_mode()` at runtime.
- Enable *Secure Boot* as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

Enable Flash Encryption Externally

In the process mentioned above, flash encryption related eFuses which ultimately enable flash encryption are programmed through the firmware bootloader. Alternatively, all the eFuses can be programmed with the help of `espefuse` tool. Please refer *Enable Flash Encryption Externally* for more details.

Possible Failures

Once flash encryption is enabled, the `SPI_BOOT_CRYPT_CNT` eFuse value will have an odd number of bits set. It means that all the partitions marked with the encryption flag are expected to contain encrypted ciphertext. Below are the three typical failure cases if the ESP32-C3 is erroneously loaded with plaintext data:

1. If the bootloader partition is re-flashed with a **plaintext firmware bootloader image**, the ROM bootloader will fail to load the firmware bootloader resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
```

Note: The value of invalid header will be different for every application.

Note: This error also appears if the flash contents are erased or corrupted.

2. If the firmware bootloader is encrypted, but the partition table is re-flashed with a **plaintext partition table image**, the bootloader will fail to read the partition table resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00

E (80) flash_parts: partition 0 invalid magic number 0x94f6
E (86) boot: Failed to verify partition table
E (91) boot: load partition table error!
```

3. If the bootloader and partition table are encrypted, but the application is re-flashed with a **plaintext application image**, the bootloader will fail to load the application resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00

```

ESP32-C3 Flash Encryption Status

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

To check if flash encryption on your ESP32-C3 device is enabled, do one of the following:

- flash the application example security/flash_encryption onto your device. This application prints the `SPI_BOOT_CRYPT_CNT` eFuse value and if flash encryption is enabled or disabled.
- *Find the serial port name* under which your ESP32-C3 device is connected, replace `PORT` with your port name in the following command, and run it:

```
idf.py efuse-summary
```

Reading and Writing Data in Encrypted Flash

ESP32-C3 application code can check if flash encryption is currently enabled by calling `esp_flash_encryption_enabled()`. Also, a device can identify the flash encryption mode by calling `esp_get_flash_encryption_mode()`.

Once flash encryption is enabled, be more careful with accessing flash contents from code.

Scope of Flash Encryption Whenever the `SPI_BOOT_CRYPT_CNT` eFuse is set to a value with an odd number of bits, all flash content accessed via the MMU's flash cache is transparently decrypted. It includes:

- Executable application code in flash (IROM).
- All read-only data stored in flash (DROM).
- Any data accessed via `spi_flash_mmap()`.
- The firmware bootloader image when it is read by the ROM bootloader.

Important: The MMU flash cache unconditionally decrypts all existing data. Data which is stored unencrypted in flash memory will also be "transparently decrypted" via the flash cache and will appear to software as random garbage.

Reading from Encrypted Flash To read data without using a flash cache MMU mapping, you can use the partition read function `esp_partition_read()`. This function will only decrypt data when it is read from an encrypted partition. Data read from unencrypted partitions will not be decrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also use the following SPI flash API functions:

- `esp_flash_read()` to read raw (encrypted) data which will not be decrypted
- `esp_flash_read_encrypted()` to read and decrypt data

Data stored using the Non-Volatile Storage (NVS) API is always stored and read decrypted from the perspective of flash encryption. It is up to the library to provide encryption feature if required. Refer to *NVS Encryption* for more details.

Writing to Encrypted Flash It is recommended to use the partition write function `esp_partition_write()`. This function will only encrypt data when it is written to an encrypted partition. Data written to unencrypted partitions will not be encrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also pre-encrypt and write data using the function `esp_flash_write_encrypted()`

Also, the following ROM function exist but not supported in esp-idf applications:

- `esp_rom_spiflash_write_encrypted` pre-encrypts and writes data to flash
- `SPIWrite` writes unencrypted data to flash

Since data is encrypted in blocks, the minimum write size for encrypted data is 16 bytes and the alignment is also 16 bytes.

Updating Encrypted Flash

OTA Updates OTA updates to encrypted partitions will automatically write encrypted data if the function `esp_partition_write()` is used.

Before building the application image for OTA updating of an already encrypted device, enable the option *Enable flash encryption on boot* in project configuration menu.

For general information about ESP-IDF OTA updates, please refer to *OTA*

Updating Encrypted Flash via Serial Flashing an encrypted device via serial bootloader requires that the serial bootloader download interface has not been permanently disabled via eFuse.

In Development Mode, the recommended method is *Re-flashing Updated Partitions*.

In Release Mode, if a copy of the same key stored in eFuse is available on the host then it is possible to pre-encrypt files on the host and then flash them. See *Manually Encrypting Files*.

Disabling Flash Encryption

If flash encryption was enabled accidentally, flashing of plaintext data will soft-brick the ESP32-C3. The device will reboot continuously, printing the error `flash read err, 1000` or `invalid header: 0xXXXXXX`.

For flash encryption in Development mode, encryption can be disabled by burning the `SPI_BOOT_CRYPT_CNT` eFuse. It can only be done one time per chip by taking the following steps:

1. In *Project Configuration Menu*, disable *Enable flash encryption on boot*, then save and exit.
2. Open project configuration menu again and **double-check** that you have disabled this option! If this option is left enabled, the bootloader will immediately re-enable encryption when it boots.
3. With flash encryption disabled, build and flash the new bootloader and application by running `idf.py flash`.
4. Use `idf.py` to disable the `SPI_BOOT_CRYPT_CNT` by running:

```
idf.py efuse-burn SPI_BOOT_CRYPT_CNT
```

Reset the ESP32-C3. Flash encryption will be disabled, and the bootloader will boot as usual.

Key Points About Flash Encryption

- Flash memory contents is encrypted using XTS-AES-128. The flash encryption key is 256 bits and stored in one `BLOCK_KEYN` eFuse internal to the chip and, by default, is protected from software access.
- Flash access is transparent via the flash cache mapping feature of ESP32-C3 - any flash regions which are mapped to the address space will be transparently decrypted when read.
  Some data partitions might need to remain unencrypted for ease of access or might require the use of flash-friendly update algorithms which are ineffective if the data is encrypted. NVS partitions for non-volatile storage cannot be encrypted since the NVS library is not directly compatible with flash encryption. For details, refer to *NVS Encryption*.
- If flash encryption might be used in future, the programmer must keep it in mind and take certain precautions when writing code that *uses encrypted flash*.
- If secure boot is enabled, re-flashing the bootloader of an encrypted device requires a "Re-flashable" secure boot digest (see *Flash Encryption and Secure Boot*).

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

> **Important:** Do not interrupt power to the ESP32-C3 while the first boot encryption pass is running. If power is interrupted, the flash contents will be corrupted and will require flashing with unencrypted data again. In this case, re-flashing will not count towards the flashing limit.

Limitations of Flash Encryption

Flash encryption protects firmware against unauthorised readout and modification. It is important to understand the limitations of the flash encryption feature:

- Flash encryption is only as strong as the key. For this reason, we recommend keys are generated on the device during first boot (default behaviour). If generating keys off-device, ensure proper procedure is followed and do not share the same key between all production devices.
- Not all data is stored encrypted. If storing data on flash, check if the method you are using (library, API, etc.) supports flash encryption.
- Flash encryption does not prevent an attacker from understanding the high-level layout of the flash. This is because the same AES key is used for every pair of adjacent 16 byte AES blocks. When these adjacent 16 byte blocks contain identical content (such as empty or padding areas), these blocks will encrypt to produce

matching pairs of encrypted blocks. This may allow an attacker to make high-level comparisons between encrypted devices (i.e., to tell if two devices are probably running the same firmware version).
- Flash encryption alone may not prevent an attacker from modifying the firmware of the device. To prevent unauthorised firmware from running on the device, use flash encryption in combination with *Secure Boot*.

Flash Encryption and Secure Boot

It is recommended to use flash encryption in combination with Secure Boot. However, if Secure Boot is enabled, additional restrictions apply to device re-flashing:

- *OTA Updates* are not restricted, provided that the new app is signed correctly with the Secure Boot signing key.

Advanced Features

The following section covers advanced features of flash encryption.

Encrypted Partition Flag Some partitions are encrypted by default. Other partitions can be marked in the partition table description as requiring encryption by adding the flag `encrypted` to the partitions' flag field. As a result, data in these marked partitions will be treated as encrypted in the same manner as an app partition.

```
# Name,   Type, SubType, Offset,  Size, Flags
nvs,      data, nvs,     0x9000,  0x6000
phy_init, data, phy,     0xf000,  0x1000
factory,  app,  factory, 0x10000, 1M
secret_data, 0x40, 0x01, 0x20000, 256K, encrypted
```

For details on partition table description, see *partition table*.

Further information about encryption of partitions:

- Default partition tables do not include any encrypted data partitions.
- With flash encryption enabled, the `app` partition is always treated as encrypted and does not require marking.
- If flash encryption is not enabled, the flag "encrypted" has no effect.
- You can also consider protecting `phy_init` data from physical access, readout, or modification, by marking the optional `phy` partition with the flag `encrypted`.
- The `nvs` partition cannot be encrypted, because the NVS library is not directly compatible with flash encryption.

Enabling UART Bootloader Encryption/Decryption On the first boot, the flash encryption process burns by default the following eFuses:

- `DIS_DOWNLOAD_MANUAL_ENCRYPT` which disables flash encryption operation when running in UART bootloader boot mode.
- `DIS_DOWNLOAD_ICACHE` which disables the entire MMU flash cache when running in UART bootloader mode.
- `DIS_PAD_JTAG` and `DIS_USB_JTAG` which disables JTAG.
- `DIS_DIRECT_BOOT` (old name `DIS_LEGACY_SPI_BOOT`) which disables direct boot mode

However, before the first boot you can choose to keep any of these features enabled by burning only selected eFuses and write-protect the rest of eFuses with unset value 0. For example:

```
idf.py --port PORT efuse-burn DIS_DOWNLOAD_MANUAL_ENCRYPT
idf.py --port PORT efuse-write-protect DIS_DOWNLOAD_MANUAL_ENCRYPT
```

Note: Set all appropriate bits before write-protecting!

Write protection of all the three eFuses is controlled by one bit. It means that write-protecting one eFuse bit will inevitably write-protect all unset eFuse bits.

Write protecting these eFuses to keep them unset is not currently very useful, as `esptool.py` does not support reading encrypted flash.

JTAG Debugging By default, when Flash Encryption is enabled (in either Development or Release mode) then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables flash encryption.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with Flash Encryption.

Manually Encrypting Files Manually encrypting or decrypting files requires the flash encryption key to be pre-burned in eFuse (see *Using Host Generated Key*) and a copy to be kept on the host. If the flash encryption is configured in Development Mode then it is not necessary to keep a copy of the key or follow these steps, the simpler *Re-flashing Updated Partitions* steps can be used.

The key file should be a single raw binary file (example: `key.bin`).

For example, these are the steps to encrypt the file `my-app.bin` to flash at offset 0x10000. Run `idf.py` as follows:

```
idf.py secure-encrypt-flash-data --aes-xts --keyfile /path/to/key.bin --address␣
↪0x10000 --output my-app-ciphertext.bin my-app.bin
```

The file `my-app-ciphertext.bin` can then be flashed to offset 0x10000 using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds.

Note: If the flashed ciphertext file is not recognized by the ESP32-C3 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset.

The command `idf.py decrypt-flash-data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

Technical Details

The following sections provide some reference information about the operation of flash encryption.

Flash Encryption Algorithm

- ESP32-C3 use the XTS-AES block cipher mode with 256 bit size for flash encryption.
- XTS-AES is a block cipher mode specifically designed for disc encryption and addresses the weaknesses other potential modes (e.g., AES-CTR) have for this use case. A detailed description of the XTS-AES algorithm can be found in IEEE Std 1619-2007.
- The flash encryption key is stored in one `BLOCK_KEYN` eFuse and, by default, is protected from further writes or software readout.
- To see the full flash encryption algorithm implemented in Python, refer to the *_flash_encryption_operation()* function in the `espsecure.py` source code.

5.2.2 Secure Boot v2

Important: This document is about Secure Boot v2, supported on ESP32-C3 (v3.0 onwards).

Secure Boot v2 uses RSA-PSS based app and bootloader *Second Stage Bootloader* verification. This document can also be used as a reference for signing apps using the RSA-PSS scheme without signing the bootloader.

`Secure Boot v2` is available for ESP32-C3 from chip revision v3.0 onwards. To use these options in menuconfig, set *CONFIG_ESP32C3_REV_MIN* greater than or equal to *v3.0*.

Note: In this guide, most used commands are in the form of `idf.py secure-<command>`, which is a wrapper around corresponding `espsecure.py <command>`. The `idf.py` based commands provides more user-friendly experience, although may lack some of the advanced functionality of their `espsecure.py` based counterparts.

Background

Secure Boot protects a device from running any unauthorized (i.e., unsigned) code by checking that each piece of software that is being booted is signed. On an ESP32-C3, these pieces of software include the second stage bootloader and each application binary. Note that the first stage bootloader does not require signing as it is ROM code and thus cannot be changed.

An RSA-based Secure Boot verification scheme, i.e., Secure Boot v2, is implemented on ESP32-C3 (v3.0 onwards).

The Secure Boot process on ESP32-C3 involves the following steps:

1. The first stage bootloader (i.e. ROM boot), which is residing in ROM, loads the second stage bootloader, and the second stage bootloader's RSA-PSS signature is verified. Only if the verification is successful, the second stage bootloader is executed.
2. When the second stage bootloader loads a particular application image, the application's RSA-PSS signature is verified. If the verification is successful, the application image is executed.

Advantages

- The RSA-PSS's public key is stored on the device. The corresponding RSA-PSS private key is kept at a secret place and is never accessed by the device.
- Up to three public keys can be generated and stored in the chip during manufacturing.
- ESP32-C3 provides the facility to permanently revoke individual public keys. This can be configured conservatively or aggressively.
  - Conservatively: The old key is revoked after the bootloader and application have successfully migrated to a new key.
  - Aggressively: The key is revoked as soon as verification with this key fails.
- The same image format and signature verification method is applied for applications and the software bootloader.
- No secrets are stored on the device. Therefore, it is immune to passive side-channel attacks, e.g., timing or power analysis.

Secure Boot v2 Process

This is an overview of the Secure Boot v2 Process. Instructions on how to enable Secure Boot are supplied in section *How To Enable Secure Boot v2*.

Secure Boot v2 verifies the bootloader image and application binary images using a dedicated *signature block*. Each image has a separately generated signature block which is appended to the end of the image.

Up to three signature blocks can be appended to the bootloader or application image in ESP32-C3.

Each signature block contains a signature of the preceding image as well as the corresponding RSA-3072 public key. For more details about the format, refer to *Signature Block Format*. A digest of the RSA-3072 public key is stored in the eFuse.

The application image is not only verified on every boot but also on each over the air (OTA) update. If the currently selected OTA app image cannot be verified, the bootloader will fall back and look for another correctly signed application image.

The Secure Boot v2 process follows these steps:

1. On startup, the ROM code checks the Secure Boot v2 bit in the eFuse. If Secure Boot is disabled, a normal boot will be executed; if Secure Boot is enabled, the boot will proceed according to the following steps.
2. The ROM code verifies the bootloader's signature block, see *Verifying a Signature Block*. If this fails, the boot process will be aborted.
3. The ROM code verifies the bootloader image using the raw image data, its corresponding signature block(s), and the eFuse, see *Verifying an Image*. If this fails, the boot process will be aborted.
4. The ROM code executes the bootloader.
5. The bootloader verifies the application image's signature block, see *Verifying a Signature Block*. If this fails, the boot process will be aborted.
6. The bootloader verifies the application image using the raw image data, its corresponding signature blocks, and the eFuse, see *Verifying an Image*. If this fails, the boot process will be aborted. If the verification fails but another application image is found, the bootloader will then try to verify that other image using steps 5 to 7. This repeats until a valid image is found or no other images are found.
7. The bootloader executes the verified application image.

Signature Block Format

The signature block starts on a 4 KB aligned boundary and has a flash sector of its own. The signature is calculated over all bytes in the image including the padding bytes, see *Secure Padding*.

The content of each signature block is shown in the following table:

Table 2: Content of a RSA Signature Block

Offset	Size (bytes)	Description
0	1	Magic byte.
1	1	Version number byte, currently 0x02, and 0x01 is for Secure Boot V1.
2	2	Padding bytes. Reserved, should be zero.
4	32	SHA-256 hash of only the image content, not including the signature block.
36	384	RSA Public Modulus used for signature verification, value 'n' in RFC8017.
420	4	RSA Public Exponent used for signature verification, value 'e' in RFC8017.
424	384	Pre-calculated R, derived from 'n'.
808	4	Pre-calculated M', derived from 'n'.
812	384	RSA-PSS Signature result (section 8.1.1 of RFC8017) of image content, computed using the following PSS parameters: SHA256 hash, MGF1 function, salt length 32 bytes, default trailer field 0xBC.
1196	4	CRC32 of the preceding 1196 bytes.
1200	16	Zero padding to length 1216 bytes.

Note: R and M' are used for hardware-assisted Montgomery Multiplication.

The remainder of the signature sector is erased flash (0xFF) which allows writing other signature blocks after the previous signature block.

Secure Padding

In the Secure Boot v2 scheme, the application image is padded to the flash MMU page size boundary to ensure that only verified contents are mapped in the internal address space, which is known as secure padding. The signature of the image is calculated after padding and then the signature block (4 KB) gets appended to the image.

- Default flash MMU page size is 64 KB
- Secure padding is applied through the option `--secure-pad-v2` in the `elf2image` conversion using `esptool.py`

The following table explains the Secure Boot v2 signed image with secure padding and signature block appended:

Table 3: Contents of a signed application

Offset	Size (KB)	Description
0	580	Unsigned application size, as an example
580	60	Secure padding, aligned to the next 64 KB boundary
640	4	Signature block

Note: Please note that the application image always starts on the next flash MMU page size boundary, default 64 KB, and hence the space left over after the signature block shown above can be utilized to store any other data partitions, e.g., `nvs`.

Verifying a Signature Block

A signature block is valid if the first byte is `0xe7` and a valid CRC32 is stored at offset 1196. Otherwise, it is invalid.

Verifying an Image

An image is verified if the public key stored in any signature block is valid for this device, and if the signature stored in that signature block matches with the signature calculated for the image data read from flash.

1. Compare the SHA-256 hash digest of the public key embedded in the bootloader's signature block with the digest(s) saved in the eFuses. If the public key's hash does not match any of the hashes from the eFuses, the verification fails.
2. Generate the application image digest and match it with the image digest in the signature block. If the digests do not match, the verification fails.
3. Use the public key to verify the signature of the bootloader image, using RSA-PSS (section 8.1.2 of RFC8017) with the image digest calculated in step (2) for comparison.

Bootloader Size

Enabling Secure Boot and/or flash encryption will increase the size of the bootloader, which might require updating the partition table offset. See *Bootloader Size*.

When *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* is disabled, the bootloader will use the `--pad-to-size` option in `elf2image` command of `esptool` for sector padding, with a size of 4 KB per sector.

eFuse Usage

- SECURE_BOOT_EN - Enables Secure Boot protection on boot.
- KEY_PURPOSE_X - Set the purpose of the key block on ESP32-C3 by programming SECURE_BOOT_DIGESTX (X = 0, 1, 2) into KEY_PURPOSE_X (X = 0, 1, 2, 3, 4, 5). Example: If KEY_PURPOSE_2 is set to SECURE_BOOT_DIGEST1, then BLOCK_KEY2 will have the Secure Boot v2 public key digest. The write-protection bit must be set, and this field does not have a read-protection bit.

- BLOCK_KEYX - The block contains the data corresponding to its purpose programmed in KEY_PURPOSE_X. Stores the SHA-256 digest of the public key is written to an eFuse key block. This digest is represented as 776 bytes, with offsets of 36 to 812, as per the *Signature Block Format*. The write-protection bit must be set, but the read-protection bit must not.
- KEY_REVOKEX - The revocation bits corresponding to each of the 3 key blocks. E.g., setting KEY_REVOKE2 revokes the key block whose key purpose is SECURE_BOOT_DIGEST2.
- SECURE_BOOT_AGGRESSIVE_REVOKE - Enables aggressive revocation of keys. The key is revoked as soon as verification with this key fails.

To ensure no trusted keys can be added later by an attacker, each unused key digest slot should be revoked with KEY_REVOKEX. It will be checked during app startup in `esp_secure_boot_init_checks()` and fixed unless *CONFIG_SECURE_BOOT_ALLOW_UNUSED_DIGEST_SLOTS* is enabled.

The key(s) must be readable in order to give software access to it. If the key(s) is read-protected then the software reads the key(s) as all zeros and the signature verification process will fail, and the boot process will be aborted.

How To Enable Secure Boot v2

1. Open the *Project Configuration Menu*, in `Security features` set `Enable hardware Secure Boot in bootloader` to enable Secure Boot.
2. The `Secure Boot v2` option will be selected and the `App Signing Scheme` will be set to RSA by default.
3. Specify the path to the Secure Boot signing key, relative to the project directory.
4. Select the desired UART ROM download mode in `UART ROM download mode`. By default, it is set to `Permanently switch to Secure mode` which is generally recommended. For production devices, the most secure option is to set it to `Permanently disabled`.
5. Set other menuconfig options as desired. Then exit menuconfig and save your configuration.
6. The first time you run `idf.py build`, if the signing key is not found then an error message will be printed with a command to generate a signing key via `idf.py secure-generate-signing-key`.

Important: A signing key generated this way will use the best random number source available to the OS and its Python installation, which is */dev/urandom* on OSX/Linux and *CryptGenRandom()* on Windows. If this random number source is weak, then the private key will be weak.

Important: For production environments, we recommend generating the key pair using OpenSSL or another industry-standard encryption program. See *Generating Secure Boot Signing Key* for more details.

7. Run `idf.py bootloader` to build a Secure Boot-enabled bootloader. The build output will include a prompt for a flashing command, using `esptool.py write_flash`.
8. When you are ready to flash the bootloader, run the specified command and then wait for flashing to complete. You have to enter it yourself, this step is not performed by the build system.
9. Run `idf.py flash` to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 6.

Note: `idf.py flash` does not flash the bootloader if Secure Boot is enabled.

10. Reset the ESP32-C3 and it will boot the software bootloader you flashed. The software bootloader will enable Secure Boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32-C3 to verify that Secure Boot is enabled and no errors have occurred due to the build configuration.

Note: Secure Boot will not be enabled until after a valid partition table and app image have been flashed. This is to

prevent accidents before the system is fully configured.

Note: If the ESP32-C3 is reset or powered down during the first boot, it will start the process again on the next boot.

11. On subsequent boots, the Secure Boot hardware will verify the software bootloader has not changed and the software bootloader will verify the signed app image using the validated public key portion of its appended signature block.

Restrictions After Secure Boot Is Enabled

- Any updated bootloader or app will need to be signed with a key matching the digest already stored in eFuse.
- After Secure Boot is enabled, no further eFuses can be read-protected. If *Flash Encryption* is enabled then the bootloader will ensure that any flash encryption key generated on the first boot will already be read-protected. If *CONFIG_SECURE_BOOT_INSECURE* is enabled, then this behavior can be disabled, but this is not recommended.
- Please note that enabling Secure Boot or flash encryption disables the USB-OTG USB stack in the ROM, disallowing updates via the serial emulation or Device Firmware Update (DFU) on that port.

Generating Secure Boot Signing Key

The build system will prompt you with a command to generate a new signing key via `idf.py secure-generate-signing-key`.

The `--version 2` parameter will generate the RSA 3072 private key for Secure Boot v2. Additionally `--scheme rsa3072` can be passed as well to generate RSA 3072 private key.

The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source and using the best available RSA-PSS key generation utilities.

For example, to generate a signing key using the OpenSSL command line:

For RSA 3072

```
openssl genrsa -out my_secure_boot_signing_key.pem 3072
```

Remember that the strength of the Secure Boot system depends on keeping the signing key private.

Remote Signing of Images

Signing Using `idf.py` For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default ESP-IDF Secure Boot configuration). The `espsecure.py` command line program can be used to sign app images and partition table data for Secure Boot, on a remote system.

To use remote signing, disable the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* and build the firmware. The private signing key does not need to be present on the build system.

After the app image and partition table are built, the build system will print signing steps using `idf.py`:

```
idf.py secure-sign-data BINARY_FILE --keyfile PRIVATE_SIGNING_KEY
```

The above command appends the image signature to the existing binary. You can use the *--output* argument to write the signed binary to a separate file:

```
idf.py secure-sign-data --keyfile PRIVATE_SIGNING_KEY --output SIGNED_BINARY_FILE␣
↪BINARY_FILE
```

Signing Using Pre-calculated Signatures If you have valid pre-calculated signatures generated for an image and their corresponding public keys, you can use these signatures to generate a signature sector and append it to the image. Note that the pre-calculated signature should be calculated over all bytes in the image including the secure-padding bytes.

In such cases, the firmware image should be built by disabling the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES*. This image will be secure-padded and to generate a signed binary use the following command:

```
idf.py secure-sign-data --pub-key PUBLIC_SIGNING_KEY --signature SIGNATURE_FILE --
↪output SIGNED_BINARY_FILE BINARY_FILE
```

The above command verifies the signature, generates a signature block (refer to *Signature Block Format*), and appends it to the binary file.

Signing Using an External Hardware Security Module (HSM) For security reasons, you might also use an external Hardware Security Module (HSM) to store your private signing key, which cannot be accessed directly but has an interface to generate the signature of a binary file and its corresponding public key.

In such cases, disable the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* and build the firmware. This secure-padded image then can be used to supply the external HSM for generating a signature. Refer to Signing using an External HSM to generate a signed image.

Note: For all the above three remote signing workflows, the signed binary is written to the filename provided to the `--output` argument, and the option `--append_signatures` allows us to append multiple signatures (up to 3) to the image.

Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using `idf.py secure-` commands. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all Secure Boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.
- Use Secure Boot in combination with *Flash Encryption* to prevent local readout of the flash contents.

Key Management

- Between 1 and 3 RSA-3072 public key pairs (Keys #0, #1, #2) should be computed independently and stored separately.
- The KEY_DIGEST eFuses should be write-protected after being programmed.
- The unused KEY_DIGEST slots must have their corresponding KEY_REVOKE eFuse burned to permanently disable them. This must happen before the device leaves the factory.
- The eFuses can either be written by the software bootloader during first boot after enabling `Secure Boot v2` from menuconfig or can be done using `espefuse.py` which communicates with the serial bootloader program in ROM.
- The KEY_DIGESTs should be numbered sequentially beginning at key digest #0. If key digest #1 is used, key digest #0 should be used. If key digest #2 is used, key digest #0 & #1 must be used.
- The software bootloader is non-OTA upgradeable, and is signed using at least one, possibly all three, private keys and flashed in the factory.

- Apps should only be signed with a single private key, with the others being stored securely elsewhere. However, they may be signed with multiple private keys if some are being revoked, see *Key Revocation* below.

Multiple Keys

- The bootloader should be signed with all the private key(s) that are needed for the life of the device, before it is flashed.
- The build system can sign with at most one private key, user has to run manual commands to append more signatures if necessary.
- You can use the append functionality of `idf.py secure-sign-data`, this command would also printed at the end of the Secure Boot V2 enabled bootloader compilation.

```
idf.py secure-sign-data -k secure_boot_signing_key2.pem --append_signatures -o␣
↪signed_bootloader.bin build/bootloader/bootloader.bin
```

- While signing with multiple private keys, it is recommended that the private keys be signed independently, if possible on different servers and stored separately.
- You can check the signatures attached to a binary using:

```
espsecure.py signature_info_v2 datafile.bin
```

Key Revocation

- Keys are processed in a linear order, i.e., key #0, key #1, key #2.
- Applications should be signed with only one key at a time, to minimize the exposure of unused private keys.
- The bootloader can be signed with multiple keys from the factory.

Note: Note that enabling the config *CONFIG_SECURE_BOOT_ALLOW_UNUSED_DIGEST_SLOTS* only makes sure that the **app** does not revoke the unused digest slots. But if you plan to enable secure boot during the fist boot up, the bootloader will intentionally revoke the unused digest slots while enabling secure boot, even if the above config is enabled. Because keeping the unused key slots unrevoked would be a security hazard. In case for any development workflow if you need to avoid this revocation, you should *Enable Secure Boot V2 Externally*, rather than enabling it during the boot up, so that the bootloader would not need to enable secure boot, and thus you could avoid its revocation strategy.

Conservative Approach Assuming a trusted private key (N-1) has been compromised, to update to new key pair (N).

1. The server sends an OTA update with an application signed with the new private key (#N).
2. The new OTA update is written to an unused OTA app partition.
3. The new application's signature block is validated. The public keys are checked against the digests programmed in the eFuse and the application is verified using the verified public key.
4. The active partition is set to the new OTA application's partition.
5. The device resets and loads the bootloader that is verified with key #N-1, which then boots the new app verified with key #N.
6. The new app verifies the bootloader with key #N as a final check, and then runs code to revoke key #N-1, i.e., sets KEY_REVOKE eFuse bit.
7. The API *esp_ota_revoke_secure_boot_public_key()* can be used to revoke the key #N-1.

- A similar approach can also be used to physically re-flash with a new key. For physical re-flashing, the bootloader content can also be changed at the same time.

Aggressive Approach ROM code has an additional feature of revoking a public key digest if the signature verification fails.

To enable this feature, you need to burn `SECURE_BOOT_AGGRESSIVE_REVOKE` eFuse or enable *CONFIG_SECURE_BOOT_ENABLE_AGGRESSIVE_KEY_REVOKE*.

Key revocation is not applicable unless Secure Boot is successfully enabled. Also, a key is not revoked in case of an invalid signature block or invalid image digest, it is only revoked in case the signature verification fails, i.e., revoke key only if failure in step 3 of *Verifying an Image*.

Once a key is revoked, it can never be used for verifying the signature of an image. This feature provides strong resistance against physical attacks on the device. However, this could also brick the device permanently if all the keys are revoked because of signature verification failure.

Technical Details

The following sections contain low-level reference descriptions of various Secure Boot elements:

Manual Commands Secure Boot is integrated into the ESP-IDF build system, so `idf.py build` will sign an app image, and `idf.py bootloader` will produce a signed bootloader if *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* is enabled.

However, it is possible to use the `idf.py` tool to make standalone signatures and digests.

To sign a binary image:

```
idf.py secure-sign-data --keyfile ./my_signing_key.pem --output ./image_signed.bin␣
↪image-unsigned.bin
```

Keyfile is the PEM file containing an RSA-3072 private signing key.

Secure Boot & Flash Encryption

If Secure Boot is used without *Flash Encryption*, it is possible to launch a `time-of-check to time-of-use` attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both features together.

Signed App Verification Without Hardware Secure Boot

The Secure Boot v2 signature of apps can be verified during an OTA update without the need to enable the hardware Secure Boot option. This approach utilizes the same app signature scheme as Secure Boot v2. However, unlike hardware Secure Boot, Software secure boot does not provide protection against an attacker with write access to flash memory, who could potentially bypass the signature verification.

This may be desirable in cases where the delay of Secure Boot verification on startup is unacceptable, and/or where the threat model does not include physical access or attackers writing to the bootloader or app partitions in flash.

In this mode, the public key that is present in the signature block of the currently running app will be used to verify the signature of a newly updated app. The signature on the running app is not verified during the update process, it is assumed to be valid. In this way, the system creates a chain of trust from the running app to the newly updated app.

For this reason, it is essential that the initial app flashed to the device is also signed. Upon startup, the application checks for signatures. If no valid signatures are found, the app will abort and no updates can be applied. This is done in order to prevent a situation where no further updates are possible and the device shall be bricked. The app should have only one valid signature block in the first position. Note again that, unlike hardware Secure Boot v2, the signature of the running app is not verified on boot. The system only verifies a signature block in the first position and ignores any other appended signatures.

Although multiple trusted keys are supported when using hardware Secure Boot, only the first public key in the signature block is used to verify updates if signature checking without Secure Boot is configured. If multiple trusted public keys are required, it is necessary to enable the full Secure Boot feature instead.

Note: In general, it is recommended to use full hardware Secure Boot unless certain that this option is sufficient for application security needs.

How To Enable Signed App Verification

1. Open *Project Configuration Menu* > `Security features`.
2. Ensure `App Signing Scheme` is `RSA`.
3. Enable *CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT*.
4. By default, `Sign binaries during build` will be enabled by selecting the `Require signed app images` option, which will sign binary files as a part of the build process. The file named in `Secure Boot private signing key` will be used to sign the image.
5. If you disable the `Sign binaries during build` option then all app binaries must be manually signed by following instructions in *Remote Signing of Images*.

Warning: It is very important that all apps flashed have been signed, either during the build or after the build.

Advanced Features

JTAG Debugging By default, when Secure Boot is enabled, JTAG debugging is disabled via eFuse. The bootloader does this on the first boot, at the same time it enables Secure Boot.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

5.3 Workflows

5.3.1 Host-Based Security Workflows

Introduction

It is recommended to have an uninterrupted power supply while enabling security features on ESP32 SoCs. Power failures during the secure manufacturing process could cause issues that are hard to debug and, in some cases, may cause permanent boot-up failures.

This guide highlights an approach where security features are enabled with the assistance of an external host machine. Security workflows are broken down into various stages and key material is generated on the host machine; thus, allowing greater recovery chances in case of power or other failures. It also offers better timings for secure manufacturing, e.g., in the case of encryption of firmware on the host machine vs. on the device.

Goals

1. Simplify the traditional workflow with stepwise instructions.
2. Design a more flexible workflow as compared to the traditional firmware-based workflow.
3. Improve reliability by dividing the workflow into small operations.
4. Eliminate dependency on *Second Stage Bootloader* (firmware bootloader).

Pre-requisite

- `esptool`: Please make sure the `esptool` has been installed. It can be installed by running:

```
pip install esptool
```

Scope

- *Enable Flash Encryption and Secure Boot V2 Externally*
- *Enable Flash Encryption Externally*
- *Enable Secure Boot V2 Externally*
- *Enable NVS Encryption Externally*

Security Workflows

Enable Flash Encryption and Secure Boot V2 Externally

Important: It is recommended to enable both Flash Encryption and Secure Boot V2 for a production use case.

When enabling the Flash Encryption and Secure Boot V2 together we need to enable them in the following order:

1. Enable the Flash Encryption feature by following the steps listed in *Enable Flash Encryption Externally*.
2. Enable the Secure Boot V2 feature by following the steps listed in *Enable Secure Boot V2 Externally*.

The reason for this order is as follows:

Note: To enable the Secure Boot (SB) V2, it is necessary to keep the SB V2 key readable. To protect the key's readability, the write protection for `RD_DIS` (`ESP_EFUSE_WR_DIS_RD_DIS`) is applied. However, this action poses a challenge when attempting to enable Flash Encryption, as the Flash Encryption (FE) key needs to remain unreadable. This conflict arises because the `RD_DIS` is already write-protected, making it impossible to read protect the FE key.

Enable Flash Encryption Externally

In this case, all the eFuses related to Flash Encryption are written with help of the espefuse tool. More details about flash encryption can be found in the *Flash Encryption Guide*

1. Check device status

   Ensure that you have an ESP32-C3 device with default Flash Encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-C3 Flash Encryption Status*.

   At this point, the Flash Encryption must not be already enabled on the chip. Additionally, the flash on the chip needs to be erased, which can be done by running:

   ```
   esptool.py --port PORT erase_flash
   ```

2. Generate a Flash Encryption key

   A random Flash Encryption key can be generated by running:

   ```
   espsecure.py generate_flash_encryption_key my_flash_encryption_key.bin
   ```

3. Burn the Flash Encryption key into eFuse

   This action **cannot be reverted**. It can be done by running:

   ```
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin XTS_
   ↪AES_128_KEY
   ```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`.

Warning: For the ESP32-C3 BLOCK9 (BLOCK_KEY5) can not be used by XTS_AES keys.

4. Burn the `SPI_BOOT_CRYPT_CNT` eFuse

   If you only want to enable Flash Encryption in **Development** mode and want to keep the ability to disable it in the future, Update the SPI_BOOT_CRYPT_CNT value in the below command from 7 to 0x1 (not recommended for production).

```
espefuse.py --port PORT --chip esp32c3 burn_efuse SPI_BOOT_CRYPT_CNT 7
```

5. Burn Flash Encryption-related security eFuses as listed below

   A) Burn security eFuses

   Important: For production use cases, it is highly recommended to burn all the eFuses listed below.

   - `DIS_DOWNLOAD_ICACHE`: Disable UART cache
   - `DIS_DIRECT_BOOT`: Disable direct boot (legacy SPI boot mode)
   - `DIS_USB_JTAG`: Disable USB switch to JTAG
   - `DIS_PAD_JTAG`: Disable JTAG permanently
   - `DIS_DOWNLOAD_MANUAL_ENCRYPT`: Disable UART bootloader encryption access

   The respective eFuses can be burned by running:

```
espefuse.py burn_efuse --port PORT EFUSE_NAME 0x1
```

   Note: Please update the EFUSE_NAME with the eFuse that you need to burn. Multiple eFuses can be burned at the same time by appending them to the above command (e.g., EFUSE_NAME VAL EFUSE_NAME2 VAL2). More documentation about *espefuse.py* can be found here.

   B) Write protect security eFuses

   After burning the respective eFuses we need to write_protect the security configurations. It can be done by burning following eFuse

```
espefuse.py --port PORT write_protect_efuse DIS_ICACHE
```

   Note: The write protection of above eFuse also write protects multiple other eFuses, Please refer to the ESP32-C3 eFuse table for more details.

6. Configure the project

   The bootloader and the application binaries for the project must be built with Flash Encryption Release mode with default configurations.

   Flash encryption Release mode can be set in the menuconfig as follows:

   - *Enable Flash Encryption on boot*
   - *Select Release mode* (Note that once Release mode is selected, the `EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT` eFuse bit will be burned to disable Flash Encryption hardware in ROM Download Mode)

- *Select UART ROM download mode (Permanently switch to Secure mode (recommended))*. This is the default option and is recommended. It is also possible to change this configuration setting to permanently disable UART ROM download mode, if this mode is not needed
- *Select the appropriate bootloader log verbosity*
- Save the configuration and exit

7. Build, Encrypt and Flash the binaries

   The binaries can be encrypted on the host machine by running:

```
espsecure.py encrypt_flash_data --aes_xts --keyfile my_flash_encryption_
↪key.bin --address 0x0 --output bootloader-enc.bin build/bootloader/
↪bootloader.bin

espsecure.py encrypt_flash_data --aes_xts --keyfile my_flash_encryption_
↪key.bin --address 0x8000 --output partition-table-enc.bin build/
↪partition_table/partition-table.bin

espsecure.py encrypt_flash_data --aes_xts --keyfile my_flash_encryption_
↪key.bin --address 0x10000 --output my-app-enc.bin build/my-app.bin
```

   In the above command the offsets are used for a sample firmware, the actual offset for your firmware can be obtained by checking the partition table entry or by running *idf.py partition-table*. Please note that not all the binaries need to be encrypted, the encryption applies only to those generated from the partitions which are marked as `encrypted` in the partition table definition file. Other binaries are flashed unencrypted, i.e., as a plain output of the build process.

   The above files can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds.

   When the application contains the following partition: `otadata`, `nvs_encryption_keys` they need to be encrypted as well. Please refer to *Encrypted Partitions* for more details about encrypted partitions.

   Note: If the flashed ciphertext file is not recognized by the ESP32-C3 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset. It is important to provide the correct offset as the ciphertext changes when the offset changes.

   The command `espsecure.py decrypt_flash_data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

8. Secure the ROM Download mode

Warning: Please perform the following step at the very end. After this eFuse is burned, the espefuse tool can no longer be used to burn additional eFuses.

Disable UART ROM DL mode:

- `UART_DOWNLOAD_DIS` : Disable the UART ROM Download mode

The eFuse can be burned by running:

```
espefuse.py --port PORT burn_efuse UART_DOWNLOAD_DIS
```

Enable Security Download mode:

- `ENABLE_SECURITY_DOWNLOAD`: Enable Secure ROM download mode

The eFuse can be burned by running:

```
espefuse.py --port PORT burn_efuse ENABLE_SECURITY_DOWNLOAD
```

Important:

9. Delete Flash Encryption key on host
   Once the Flash Encryption has been enabled for the device, the key **must be deleted immediately**. This ensures that the host cannot produce encrypted binaries for the same device going forward. This step is important to reduce the vulnerability of the flash encryption key.

Flash Encryption Guidelines

- It is recommended to generate a unique Flash Encryption key for each device for production use-cases.
- It is recommended to ensure that the RNG used by host machine to generate the Flash Encryption key has good entropy.
- See *Limitations of Flash Encryption* for more details.

Enable Secure Boot V2 Externally In this workflow, we shall use `espsecure` tool to generate signing keys and use the `espefuse` tool to burn the relevant eFuses. The details about the Secure Boot V2 process can be found at *Secure Boot V2 Guide*

1. Generate Secure Boot V2 Signing Private Key

   The Secure Boot V2 signing key for the RSA3072 scheme can be generated by running:

   ```
   espsecure.py generate_signing_key --version 2 --scheme rsa3072 secure_
   ↪boot_signing_key.pem
   ```

   A total of 3 keys can be used for Secure Boot V2 at once. These should be computed independently and stored separately. The same command with different key file names can be used to generate multiple Secure Boot V2 signing keys. It is recommended to use multiple keys in order to reduce dependency on a single key.

2. Generate Public Key Digest

   The public key digest for the private key generated in the previous step can be generated by running:

   ```
   espsecure.py digest_sbv2_public_key --keyfile secure_boot_signing_key.pem␣
   ↪--output digest.bin
   ```

   In case of multiple digests, each digest should be kept in a separate file.

3. Burn the key digest in eFuse

   The public key digest can be burned in the eFuse by running:

   ```
   espefuse.py --port PORT --chip esp32c3 burn_key BLOCK digest.bin SECURE_
   ↪BOOT_DIGEST0
   ```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`.

   In case of multiple digests, the other digests can be burned sequentially by changing the key purpose to `SECURE_BOOT_DIGEST1` and `SECURE_BOOT_DIGEST2` respectively.

4. Enable Secure Boot V2

   Secure Boot V2 eFuse can be enabled by running:

   ```
   espefuse.py --port PORT --chip esp32c3 burn_efuse SECURE_BOOT_EN
   ```

5. Burn relevant eFuses

A) Burn security eFuses

Important: For production use cases, it is highly recommended to burn all the eFuses listed below.

- `SOFT_DIS_JTAG`: Disable software access to JTAG peripheral
- `DIS_DIRECT_BOOT`: Disable direct boot (legacy SPI boot mode)
- `DIS_USB_JTAG`: Disable USB switch to JTAG
- `DIS_PAD_JTAG`: Disable JTAG permanently
- `SECURE_BOOT_AGGRESSIVE_REVOKE`: Aggressive revocation of key digests, see *Aggressive Approach* for more details.

The respective eFuses can be burned by running:

```
espefuse.py burn_efuse --port PORT EFUSE_NAME 0x1
```

Note: Please update the EFUSE_NAME with the eFuse that you need to burn. Multiple eFuses can be burned at the same time by appending them to the above command (e.g., EFUSE_NAME VAL EFUSE_NAME2 VAL2). More documentation about *espefuse.py* can be found here

B) Secure Boot V2-related eFuses

i) Disable the read-protection option:

The Secure Boot digest burned in the eFuse must be kept readable otherwise the Secure Boot operation would result in a failure. To prevent the accidental enabling of read protection for this key block, the following eFuse needs to be burned:

Important: After burning above-mentioned eFuse, the read protection cannot be enabled for any key. E.g., if Flash Encryption which requires read protection for its key is not enabled at this point, then it cannot be enabled afterwards. Please ensure that no eFuse keys are going to need read protection after completing this step.

```
espefuse.py -p $ESPPORT write_protect_efuse RD_DIS
```

ii) Revoke key digests:

The unused digest slots need to be revoked when we are burning the Secure Boot key. The respective slots can be revoked by running

```
espefuse.py --port PORT --chip esp32c3 burn_efuse EFUSE_REVOKE_BIT
```

The `EFUSE_REVOKE_BIT` in the above command can be `SECURE_BOOT_KEY_REVOKE0` or `SECURE_BOOT_KEY_REVOKE1` or `SECURE_BOOT_KEY_REVOKE2`. Please note that only the unused key digests must be revoked. Once revoked, the respective digest cannot be used again.

6. Configure the project

By default, the ROM bootloader would only verify the *Second Stage Bootloader* (firmware bootloader). The firmware bootloader would verify the app partition only when the *CONFIG_SECURE_BOOT* option is enabled (and *CONFIG_SECURE_BOOT_VERSION* is set to `SECURE_BOOT_V2_ENABLED`) while building the bootloader.

a) Open the *Project Configuration Menu*, in "Security features" set "Enable hardware Secure Boot in bootloader" to enable Secure Boot.

The "Secure Boot V2" option will be selected and the "App Signing Scheme" will be set to RSA by default.

b) Disable the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* for the project in the *Project Configuration Menu*. This shall make sure that all the generated binaries are secure padded and unsigned. This step is done to avoid generating signed binaries as we are going to manually sign the binaries using `espsecure` tool.

7. Build, Sign and Flash the binaries

After the above configurations, the bootloader and application binaries can be built with `idf.py build` command.

The Secure Boot V2 workflow only verifies the `bootloader` and `application` binaries, hence only those binaries need to be signed. The other binaries (e.g., `partition-table.bin`) can be flashed as they are generated in the build stage.

The `bootloader.bin` and `app.bin` binaries can be signed by running:

```
espsecure.py sign_data --version 2 --keyfile secure_boot_signing_key.pem -
↪-output bootloader-signed.bin build/bootloader/bootloader.bin

espsecure.py sign_data --version 2 --keyfile secure_boot_signing_key.pem -
↪-output my-app-signed.bin build/my-app.bin
```

If multiple keys Secure Boot keys are to be used then the same signed binary can be appended with a signature block signed with the new key as follows:

```
espsecure.py sign_data --keyfile secure_boot_signing_key2.pem --version 2␣
↪--append_signatures -o bootloader-signed2.bin bootloader-signed.bin

espsecure.py sign_data --keyfile secure_boot_signing_key2.pem --version 2␣
↪--append_signatures -o my-app-signed2.bin my-app-signed.bin
```

The same process can be repeated for the third key. Note that the names of the input and output files must not be the same.

The signatures attached to a binary can be checked by running:

```
espsecure.py signature_info_v2 bootloader-signed.bin
```

The above files along with other binaries (e.g., partition table) can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds. The flash offset for your firmware can be obtained by checking the partition table entry or by running `idf.py partition-table`.

8. Secure the ROM Download mode:

Warning: Please perform the following step at the very end. After this eFuse is burned, the espefuse tool can no longer be used to burn additional eFuses.

Disable UART ROM DL mode:

- `UART_DOWNLOAD_DIS` : Disable the UART ROM Download mode

The eFuse can be burned by running:

```
espefuse.py --port PORT burn_efuse UART_DOWNLOAD_DIS
```

Enable Security Download mode:

- `ENABLE_SECURITY_DOWNLOAD`: Enable Secure ROM download mode

The eFuse can be burned by running:

```
espefuse.py --port PORT burn_efuse ENABLE_SECURITY_DOWNLOAD
```

Secure Boot V2 Guidelines

- It is recommended to store the Secure Boot key in a highly secure place. A physical or a cloud HSM may be used for secure storage of the Secure Boot private key. Please take a look at *Remote Signing of Images* for more details.
- It is recommended to use all the available digest slots to reduce dependency on a single private key.

Enable NVS Encryption Externally

The details about NVS Encryption and related schemes can be found at *NVS Encryption*.

Enable NVS Encryption based on HMAC

1. Generate the HMAC key and NVS Encryption key

   In the HMAC based NVS scheme, there are two keys:

   - HMAC key - this is a 256 bit HMAC key that shall be stored in the eFuse
   - NVS Encryption key - This is the NVS Encryption key that is used to encrypt the NVS partition. This key is derived at run-time using the HMAC key.

   The above keys can be generated with the nvs_flash/nvs_partition_generator/nvs_partition_gen.py script with help of the following command:

   ```
   python3 nvs_partition_gen.py generate-key --key_protect_hmac --kp_hmac_
   ↪keygen --kp_hmac_keyfile hmac_key.bin --keyfile nvs_encr_key.bin
   ```

   This shall generate the respective keys in the `keys` folder.

2. Burn the HMAC key in the eFuse

   The NVS key can be burned in the eFuse of ESP32-C3 with help of following command:

   ```
   espefuse.py --port PORT burn_key BLOCK hmac_key.bin HMAC_UP
   ```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`.

3. Generate the encrypted NVS partition

   We shall generate the actual encrypted NVS partition on host. More details about generating the encryption NVS partition can be found at *Generate Encrypted NVS Partition*. For this purpose, the contents of the NVS file shall be available in a CSV file. Please check out *CSV File Format* for more details.

   The encrypted NVS partition can be generated with following command:

   ```
   python3 nvs_partition_gen.py encrypt sample_singlepage_blob.csv nvs_encr_
   ↪partition.bin 0x3000 --inputkey keys/nvs_encr_key.bin
   ```

   Some command arguments are explained below:

   - CSV file name - In this case *sample_singlepage_blob.csv* is the CSV file which contains the NVS data, Replace this with the file you wish to choose.
   - NVS partition offset - This is the offset at which that NVS partition shall be stored in the flash of ESP32-C3. The offset of your nvs-partition can be found be executing *idf.py partition-table* in the projtect directory. Please update the sample value of *0x3000* in the above-provided command to the correct offset.

4. Configure the project

- Enable *NVS Encryption* by enabling *CONFIG_NVS_ENCRYPTION*.
- Enable the HMAC based NVS Encryption by setting *CONFIG_NVS_SEC_KEY_PROTECTION_SCHEME* to `CONFIG_NVS_SEC_KEY_PROTECT_USING_HMAC`
- Set the HMAC efuse key id at *CONFIG_NVS_SEC_HMAC_EFUSE_KEY_ID* to the one in which the eFuse key was burned in Step 2.

5. Flash NVS partition

   The NVS partition (`nvs_encr_partition.bin`) generated in Step 3 can then be flashed to its respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, check the output printed when `idf.py build` succeeds. If Flash encryption is enabled for the chip then please encrypt the partition first before flashing. You may refer the flashing related steps of *Flash Encryption workflow*.

Enable NVS Encryption based on Flash Encryption In this case we generate NVS Encryption keys on a host. This key is then flashed on the chip and protected with help of the *Flash Encryption* feature.

1. Generate the NVS Encryption key

   For generation of respective keys, we shall use *NVS partition generator utility*. We shall generate the encryption key on host and this key key shall be stored on the flash of ESP32-C3 in encrypted state.

   The key can be generated with the nvs_flash/nvs_partition_generator/nvs_partition_gen.py script with help of the following command:

```
python3 nvs_partition_gen.py generate-key --keyfile nvs_encr_key.bin
```

   This shall generate the respective key in the `keys` folder.

2. Generate the encrypted NVS partition

   We shall generate the actual encrypted NVS partition on host. More details about generating the encryption NVS partition can be found at *Generate Encrypted NVS Partition*. For this, the contents of the NVS file shall be available in a CSV file. Please refer *CSV File Format* for more details.

   The encrypted NVS partition can be generated with following command:

```
python3 nvs_partition_gen.py encrypt sample_singlepage_blob.csv nvs_encr_
↪partition.bin 0x3000 --inputkey keys/nvs_encr_key.bin
```

   Some command arguments are explained below:

   - CSV file name - In this case *sample_singlepage_blob.csv* is the CSV file which contains the NVS data, Replace this with the file you wish to choose.
   - NVS partition offset - This is the offset at which that NVS partition shall be stored in the flash of ESP32-C3. The offset of your nvs-partition can be found be executing *idf.py partition-table* in the projtect directory. Please update the sample value of *0x3000* in the above-provided command to the correct offset.

3. Configure the project

- Enable *NVS Encryption* by enabling *CONFIG_NVS_ENCRYPTION*.
- Set NVS to use Flash Encryption based scheme by setting *CONFIG_NVS_SEC_KEY_PROTECTION_SCHEME* to `CONFIG_NVS_SEC_KEY_PROTECT_USING_FLASH_ENC`.

4. Flash NVS partition and NVS Encryption keys

   The NVS partition (`nvs_encr_partition.bin`) and NVS Encryption key (`nvs_encr_key.bin`) can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, check the output printed when `idf.py build` succeeds. If Flash encryption is enabled for the chip then please encrypt the partition first before flashing. You may refer the flashing related steps of *Flash Encryption workflow*.

5.4 Vulnerabilities

5.4.1 Vulnerabilities

This page briefly lists all of the vulnerabilities that are discovered and fixed in each release. Please note that for the on-going issues or the issues under embargo period, the information on this page may reflect once the desired resolution has been achieved.

Note: Please refer to `latest` version of this documentation guide for up-to-date information.

CVE-2024

CVE-2024-28183 Bootloader TOCTOU Vulnerability in Anti-rollback Scheme

- Espressif Advisory: NA (Published on GitHub)
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details
- Advisory pointer: GHSA-22x6-3756-pfp8

CVE-2023

CVE-2023-35818 Security Advisory Concerning Bypassing Secure Boot and Flash Encryption Using EMFI

- Espressif Advisory: AR2023-005
- Impact: Applicable for ESP32 Chip Revision v3.0/v3.1
- Resolution: Please see advisory for details

CVE-2023-24023 Security Advisory Concerning the Bluetooth BLUFFS Vulnerability

- Espressif Advisory: AR2023-010
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

CVE-2023-52160 Security Advisory for PEAP Phase-2 Authentication

- Espressif Advisory: AR2024-003
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

CVE-2022

CVE-2022-24893 Espressif Bluetooth Mesh Stack Vulnerability

- Espressif Advisory: NA (Published on GitHub)
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details
- Advisory pointer: GHSA-7f7f-jj2q-28wm

CVE-2021

CVE-2021-32020 Insufficient bounds checking during management of heap memory in FreeRTOS

- Impact: ESP-IDF uses its own heap allocator and hence not applicable
- Resolution: NA

CVE-2021-43997 Privilege escalation issue in FreeRTOS ARMv7-M and ARMv8-M MPU ports

- Impact: Not applicable for Espressif chips
- Resolution: NA

CVE-2021-3420 Security Advisory on "BadAlloc" Vulnerabilities

- Espressif Advisory: AR2021-005
- Impact: Not applicable for ESP-IDF
- Resolution: NA

CVE-2021-31571 Security Advisory on "BadAlloc" Vulnerabilities

- Espressif Advisory: AR2021-005
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

CVE-2021-31572 Security Advisory on "BadAlloc" Vulnerabilities

- Espressif Advisory: AR2021-005
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

CVE-2021-28139 Security Advisory for Bluetooth Vulnerability

- Covers additional CVEs: CVE-2020-10135, CVE-2020-13595, CVE-2020-26555, CVE-2020-26556, CVE-2020-26557, CVE-2020-26558, CVE-2020-26559, CVE-2020-26560, CVE-2021-28135, CVE-2021-28136
- Espressif Advisory: AR2021-004
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

CVE-2020

CVE-2020-22283 Buffer overflow vulnerability in lwIP stack

- Espressif Advisory: NA
- Impact: Applicable for ESP-IDF
- Resolution: Fix cherry-picked and available in ESP-IDF >= v4.4.1

CVE-2020-22284 Buffer overflow vulnerability in lwIP stack

- Espressif Advisory: NA
- Impact: Applicable for ESP-IDF
- Resolution: Fix cherry-picked and available in ESP-IDF >= v4.4.1

CVE-2020-26142 Security Advisory for WLAN FragAttacks

- Espressif Advisory: AR2023-008
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

CVE-2020-12638 Security Advisory Concerning Wi-Fi Authentication Bypass

- Espressif Advisory: AR2020-002
- Impact: Applicable for ESP-IDF
- Resolution: Please see advisory for details

Chapter 6

Migration Guides

6.1 ESP-IDF 5.x Migration Guide

6.1.1 Migration from 4.4 to 5.0

Bluetooth Low Energy

Bluedroid

The following Bluedroid macros, types, and functions have been renamed:

- bt/host/bluedroid/api/include/api/esp_gap_ble_api.h
  - In *esp_gap_ble_cb_event_t*:
    - `ESP_GAP_BLE_SET_PREFERED_DEFAULT_PHY_COMPLETE_EVT` renamed to `ESP_GAP_BLE_SET_PREFERRED_DEFAULT_PHY_COMPLETE_EVT`
    - `ESP_GAP_BLE_SET_PREFERED_PHY_COMPLETE_EVT` renamed to `ESP_GAP_BLE_SET_PREFERRED_PHY_COMPLETE_EVT`
    - `ESP_GAP_BLE_CHANNEL_SELETE_ALGORITHM_EVT` renamed to `ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT`
  - `esp_ble_wl_opration_t` renamed to *esp_ble_wl_operation_t*
  - `esp_ble_gap_cb_param_t.pkt_data_lenth_cmpl` renamed to `pkt_data_length_cmpl`
  - `esp_ble_gap_cb_param_t.update_whitelist_cmpl.wl_opration` renamed to `wl_operation`
  - `esp_ble_gap_set_prefered_default_phy` renamed to *esp_ble_gap_set_preferred_default_phy()*
  - `esp_ble_gap_set_prefered_phy` renamed to *esp_ble_gap_set_preferred_phy()*
- bt/host/bluedroid/api/include/api/esp_gatt_defs.h
  - In *esp_gatt_status_t*:
    - `ESP_GATT_ENCRYPED_MITM` renamed to `ESP_GATT_ENCRYPTED_MITM`
    - `ESP_GATT_ENCRYPED_NO_MITM` renamed to `ESP_GATT_ENCRYPTED_NO_MITM`

Nimble

The following Nimble APIs have been removed:

- bt/host/nimble/esp-hci/include/esp_nimble_hci.h
  - Remove `esp_err_t esp_nimble_hci_and_controller_init(void)`
    - Controller initialization, enable and HCI initialization calls have been moved to *nimble_port_init*. This function can be deleted directly.
  - Remove `esp_err_t esp_nimble_hci_and_controller_deinit(void)`
    - Controller deinitialization, disable and HCI deinitialization calls have been moved to *nimble_port_deinit*. This function can be deleted directly.

ESP-BLE-MESH

The following ESP-BLE-MESH macro has been renamed:

- bt/esp_ble_mesh/api/esp_ble_mesh_defs.h
  - In *`esp_ble_mesh_prov_cb_event_t`*:
    - `ESP_BLE_MESH_PROVISIONER_DRIECT_ERASE_SETTINGS_COMP_EVT` renamed to `ESP_BLE_MESH_PROVISIONER_DIRECT_ERASE_SETTINGS_COMP_EVT`

Build System

Migrating from GNU Make Build System ESP-IDF v5.0 no longer supports GNU make-based projects. Please follow the *build system* guide for migration.

Update Fragment File Grammar The former grammar, supported in ESP-IDF v3.x, was dropped in ESP-IDF v5.0. Here are a few notes on how to migrate properly:

1. Indentation is now enforced: improperly indented fragment files generate a runtime parse exception. Although the former version did not enforce this, the previous documentation and examples demonstrated properly indented grammar.
2. Migrate the old condition entry to the `if...elif...else` structure for conditionals. You can refer to the *Configuration-Dependent Placements* for detailed grammar.
3. Mapping fragments now requires a name like other fragment types.

Specify Component Requirements Explicitly In previous versions of ESP-IDF, some components were always added as public requirements (dependencies) to every component in the build, in addition to the *common component requirements*:

- `driver`
- `efuse`
- `esp_timer`
- `lwip`
- `vfs`
- `esp_wifi`
- `esp_event`
- `esp_netif`
- `esp_eth`
- `esp_phy`

This means that it was possible to include header files of those components without specifying them as requirements in `idf_component_register`. This behavior was caused by transitive dependencies of various common components.

In ESP-IDF v5.0, this behavior is fixed and these components are no longer added as public requirements by default.

Every component depending on one of the components which isn't part of common requirements has to declare this dependency explicitly. This can be done by adding `REQUIRES <component_name>` or `PRIV_REQUIRES`

<component_name> in idf_component_register call inside component's CMakeLists.txt. See *Component Requirements* for more information on specifying requirements.

Setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS Variables ESP-IDF v5.0 includes a number of improvements to support building projects with space characters in their paths. To make that possible, there are some changes related to setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS variables in project CMakeLists.txt files.

Adding non-existent directories to COMPONENT_DIRS or EXTRA_COMPONENT_DIRS is no longer supported and will result in an error.

Using string concatenation to define COMPONENT_DIRS or EXTRA_COMPONENT_DIRS variables is now deprecated. These variables should be defined as CMake lists, instead. For example, use:

```
set(EXTRA_COMPONENT_DIRS path1 path2)
list(APPEND EXTRA_COMPONENT_DIRS path3)
```

instead of:

```
set(EXTRA_COMPONENT_DIRS "path1 path2")
set(EXTRA_COMPONENT_DIRS "${EXTRA_COMPONENT_DIRS} path3")
```

Defining these variables as CMake lists is compatible with previous ESP-IDF versions.

Update Usage of target_link_libraries with project_elf ESP-IDF v5.0 fixes CMake variable propagation issues for components. This issue caused compiler flags and definitions that were supposed to apply to one component to be applied to every component in the project.

As a side effect of this, user projects from ESP-IDF v5.0 onwards must use target_link_libraries with project_elf explicitly and custom CMake projects must specify PRIVATE, PUBLIC, or INTERFACE arguments. This is a breaking change and is not backward compatible with previous ESP-IDF versions.

For example:

```
target_link_libraries(${project_elf} PRIVATE "-Wl,--wrap=esp_panic_handler")
```

instead of:

```
target_link_libraries(${project_elf} "-Wl,--wrap=esp_panic_handler")
```

Update CMake Version In ESP-IDF v5.0 minimal CMake version was increased to 3.16 and versions lower than 3.16 are not supported anymore. Run tools/idf_tools.py install cmake to install a suitable version if your OS version doesn't have one.

This affects ESP-IDF users who use system-provided CMake and custom CMake.

Reorder the Applying of the Target-Specific Config Files ESP-IDF v5.0 reorders the applying order of target-specific config files and other files listed in SDKCONFIG_DEFAULTS. Now, target-specific files will be applied right after the file brings it in, before all latter files in SDKCONFIG_DEFAULTS.

For example:

```
If ``SDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig_devkit1"``, and there is a␣
↪file ``sdkconfig.defaults.esp32`` in the same folder, then the files will be␣
↪applied in the following order: (1) sdkconfig.defaults (2) sdkconfig.defaults.
↪esp32 (3) sdkconfig_devkit1.
```

If you have a key with different values in the target-specific files of the former item (e.g., sdkconfig.defaults.esp32 above) and the latter item (e.g., sdkconfig_devkit1 above), please note the latter will override the target-specific file of the former.

If you do want to have some target-specific config values, please put it into the target-specific file of the latter item (e.g., `sdkconfig_devkit1.esp32`).

GCC

GCC Version The previous GCC version was GCC 8.4.0. This has now been upgraded to GCC 11.2.0 on all targets. Users that need to port their code from GCC 8.4.0 to 11.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 9
- Porting to GCC 10
- Porting to GCC 11

Warnings The upgrade to GCC 11.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user's code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter, and ways to suppress them.

> **Warning:** Users are advised to check that a warning is indeed a false positive before attempting to suppress them it.

`-Wstringop-overflow`, `-Wstringop-overread`, `-Wstringop-truncation`, and `-Warray-bounds` Users that use memory/string copy/compare functions will run into one of the `-Wstringop` warnings if the compiler cannot properly determine the size of the memory/string. The examples below demonstrate code that triggers these warnings and how to suppress them.

```
#pragma GCC diagnostic push
#pragma GCC diagnostic ignored "-Wstringop-overflow"
#pragma GCC diagnostic ignored "-Warray-bounds"
    memset(RTC_SLOW_MEM, 0, CONFIG_ULP_COPROC_RESERVE_MEM); // <<-- This line␣
↪leads to warnings
#pragma GCC diagnostic pop
```

```
#pragma GCC diagnostic push
#if     __GNUC__ >= 11
#pragma GCC diagnostic ignored "-Wstringop-overread" // <<-- This key had been␣
↪introduced since GCC 11
#endif
#pragma GCC diagnostic ignored "-Warray-bounds"
            memcpy(backup_write_data, (void *)EFUSE_PGM_DATA0_REG, sizeof(backup_
↪write_data)); // <<-- This line leads to warnings
#pragma GCC diagnostic pop
```

`-Waddress-of-packed-member` GCC will issue this warning when accessing an unaligned member of a packed `struct` due to the incurred penalty of unaligned memory access. However, all ESP chips (on both Xtensa and RISC-V architectures) allow for unaligned memory access and incur no extra penalty. Thus, this warning can be ignored in most cases.

```
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c: In function
↪'btc_to_bta_gatt_id':
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c:105:21: warning:␣
↪taking address of packed member of 'struct <anonymous>' may result in an␣
↪unaligned pointer value [-Waddress-of-packed-member]
  105 |     btc_to_bta_uuid(&p_dest->uuid, &p_src->uuid);
      |                     ^~~~~~~~~~~~~
```

If the warning occurs in multiple places across multiple source files, users can suppress the warning at the CMake level as demonstrated below.

```
set_source_files_properties(
    "host/bluedroid/bta/gatt/bta_gattc_act.c"
    "host/bluedroid/bta/gatt/bta_gattc_cache.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatts.c"
    PROPERTIES COMPILE_FLAGS -Wno-address-of-packed-member)
```

However, if there are only one or two instances, users can suppress the warning directly in the source code itself as demonstrated below.

```
#pragma GCC diagnostic push
#if     __GNUC__ >= 9
#pragma GCC diagnostic ignored "-Waddress-of-packed-member" <<-- This key had been␣
↪introduced since GCC 9
#endif
    uint32_t* reg_ptr = (uint32_t*)src;
#pragma GCC diagnostic pop
```

`llabs()` for 64-bit Integers The function `abs()` from stdlib.h takes `int` argument. Please use `llabs()` for types that are intended to be 64-bit. It is particularly important for `time_t`.

Espressif Toolchain Changes

`int32_t` and `uint32_t` for Xtensa Compiler The types `int32_t` and `uint32_t` have been changed from the previous `int` and `unsigned int` to `long` and `unsigned long` respectively for the Xtensa compiler. This change now matches upstream GCC which `long` integers for `int32_t` and `uint32_t` on Xtensa, RISC-V, and other architectures.

	2021r2 and older, GCC 8	2022r1, GCC 11
Xtensa	(unsigned) int	(unsigned) long
riscv32	(unsigned) long	(unsigned) long

The change mostly affects code that formats strings using types provided by `<inttypes.h>`. When using these fixed-width types (e.g., `uint32_t`), users will need to replace placeholders such as `%i` and `%x` with `PRIi32` and `PRIx32` respectively. Types *not* defined in `<inttypes.h>` (e.g., `int`) do *not* need this special formatting.

In other cases, it should be noted that enums have the `int` type.

In common, `int32_t` and `int`, as well as `uint32_t` and `unsigned int`, are different types.

If users do not make the aforementioned updates to format strings in their applications, the following error will be reported during compilation:

```
/Users/name/esp/esp-rainmaker/components/esp-insights/components/esp_diagnostics/
↪include/esp_diagnostics.h:238:29: error: format '%u' expects argument of type
↪'unsigned int', but argument 3 has type 'uint32_t' {aka 'long unsigned int'} [-
↪Werror=format=]
238 |     esp_diag_log_event(tag, "EV (%u) %s: " format, esp_log_timestamp(), tag,
↪##__VA_ARGS__); \
    |                              ^~~~~~~~~~~~~~         ~~~~~~~~~~~~~~~~~~~
    |                                                     |
    |                                                     uint32_t {aka long␣
↪unsigned int}
                                                 uint32_t {aka long unsigned int}
```

Removing `CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` Build Option `CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` option was introduced to allow building of legacy code dating from the rigid GCC 5 toolchain. However, enough time has passed to allow for the warnings to be fixed, thus this option has been removed.

For now in GCC 11, users are advised to review their code and fix the compiler warnings where possible.

Networking

Wi-Fi

Callback Function Type `esp_now_recv_cb_t` Previously, the first parameter of `esp_now_recv_cb_t` was of type `const uint8_t *mac_addr`, which only included the address of ESP-NOW peer device.

This now changes. The first parameter is of type `esp_now_recv_info_t`, which has members `src_addr`, `des_addr` and `rx_ctrl`. Therefore, the following updates are required:

- Redefine ESP-NOW receive callback function.
- `src_addr` can be used to replace original `mac_addr`.
- `des_addr` is the destination MAC address of ESP-NOW packet, which can be unitcast or broadcast address. With `des_addr`, the user can distinguish unitcast and broadcast ESP-NOW packets where broadcast ESP-NOW packets can be non-encrypted even when encryption policy is configured for the ESP-NOW.
- `rx_ctrl` is Rx control info of the ESP-NOW packet, which provides more information about the packet.

Please refer to the ESP-NOW example: wifi/espnow/main/espnow_example_main.c

Ethernet

`esp_eth_ioctl()` API Previously, the *`esp_eth_ioctl()`* API had the following issues:

- The third parameter (which is of type `void *`) would accept an `int`/`bool` type arguments (i.e., not pointers) as input in some cases. However, these cases were not documented properly.
- To pass `int`/`bool` type argument as the third parameter, the argument had to be "unnaturally" casted to a `void *` type, to prevent a compiler warning as demonstrated in the code snippet below. This casting could lead to misuse of the *`esp_eth_ioctl()`* function.

```
esp_eth_ioctl(eth_handle, ETH_CMD_S_FLOW_CTRL, (void *)true);
```

Therefore, the usage of *`esp_eth_ioctl()`* is now unified. Arguments to the third parameter must be passed as pointers to a specific data type to/from where data is stored/read by *`esp_eth_ioctl()`*. The code snippets below demonstrate the usage of *`esp_eth_ioctl()`*.

Usage example to set Ethernet configuration:

```
eth_duplex_t new_duplex_mode = ETH_DUPLEX_HALF;
esp_eth_ioctl(eth_handle, ETH_CMD_S_DUPLEX_MODE, &new_duplex_mode);
```

Usage example to get Ethernet configuration:

```
eth_duplex_t duplex_mode;
esp_eth_ioctl(eth_handle, ETH_CMD_G_DUPLEX_MODE, &duplex_mode);
```

KSZ8041/81 and LAN8720 Driver Update The KSZ8041/81 and LAN8720 drivers are updated to support more devices (i.e., generations) from their associated product families. The drivers can recognize particular chip numbers and their potential support by the driver.

As a result, the specific "chip number" functions calls are replaced by generic ones as follows:

- Removed `esp_eth_phy_new_ksz8041()` and `esp_eth_phy_new_ksz8081()`, and use *`esp_eth_phy_new_ksz80xx()`* instead
- Removed `esp_eth_phy_new_lan8720()`, and use *`esp_eth_phy_new_lan87xx()`* instead

ESP NETIF Glue Event Handlers `esp_eth_set_default_handlers()` and `esp_eth_clear_default_handlers()` functions are removed. Registration of the default IP layer handlers for Ethernet is now handled automatically. If you have already followed the suggestion to fully initialize the Ethernet driver and network interface before registering their Ethernet/IP event handlers, then no action is required (except for deleting the affected functions). Otherwise, you may start the Ethernet driver right after they register the user event handler.

PHY Address Auto-detect The Ethernet PHY address auto-detect function `esp_eth_detect_phy_addr()` is renamed to *`esp_eth_phy_802_3_detect_phy_addr()`* and its header declaration is moved to esp_eth/include/esp_eth_phy_802_3.h.

SPI-Ethernet Module Initialization The SPI-Ethernet Module initialization is now simplified. Previously, you had to manually allocate an SPI device using *`spi_bus_add_device()`* before instantiating the SPI-Ethernet MAC.

Now, you no longer need to call *`spi_bus_add_device()`* as SPI devices are allocated internally. As a result, the `eth_dm9051_config_t`, `eth_w5500_config_t`, and `eth_ksz8851snl_config_t` configuration structures are updated to include members for SPI device configuration (e.g., to allow fine tuning of SPI timing which may be dependent on PCB design). Likewise, the `ETH_DM9051_DEFAULT_CONFIG`, `ETH_W5500_DEFAULT_CONFIG`, and `ETH_KSZ8851SNL_DEFAULT_CONFIG` configuration initialization macros are updated to accept new input parameters. Refer to *Ethernet API Reference Guide* for an example of SPI-Ethernet Module initialization.

Ethernet Driver APIs for creating MAC instances (*esp_eth_mac_new_*()*) have been reworked to accept two parameters, instead of one common configuration. Now, the configuration includes

- Vendor specific MAC configuration
- Ethernet driver MAC configuration

This is applicable to internal Ethernet MAC `esp_eth_mac_new_esp32()` as well as to external MAC devices, such as `esp_eth_mac_new_ksz8851snl()`, `esp_eth_mac_new_dm9051()`, and `esp_eth_mac_new_w5500()`

TCP/IP Adapter The TCP/IP Adapter was a network interface abstraction component used in ESP-IDF prior to v4.1. This section outlines migration from `tcpip_adapter` API to its successor *ESP-NETIF*.

Updating Network Connection Code

Network Stack Initialization

- You may simply replace `tcpip_adapter_init()` with `esp_netif_init()`. However, please should note that the `esp_netif_init()` function now returns standard error codes. See *ESP-NETIF* for more details.
- The `esp_netif_deinit()` function is provided to de-initialize the network stack.
- You should also replace `#include "tcpip_adapter.h"` with `#include "esp_netif.h"`.

Network Interface Creation Previously, the TCP/IP Adapter defined the following network interfaces statically:

- WiFi Station
- WiFi Access Point
- Ethernet

This now changes. Network interface instance should be explicitly constructed, so that the *ESP-NETIF* can connect to the TCP/IP stack. For example, after the TCP/IP stack and the event loop are initialized, the initialization code for WiFi must explicitly call `esp_netif_create_default_wifi_sta();` or `esp_netif_create_default_wifi_ap();`.

Please refer to the example initialization code for these three interfaces:

- WiFi Station: wifi/getting_started/station/main/station_example_main.c
- WiFi Access Point: wifi/getting_started/softAP/main/softap_example_main.c
- Ethernet: ethernet/basic/main/ethernet_example_main.c

Other `tcpip_adapter` API Replacement All the `tcpip_adapter` functions have their `esp-netif` counter-part. Please refer to the `esp_netif.h` grouped into these sections:

- Setters/Getters
- DHCP
- DNS
- IP address

The TCP/IP Adapter API `tcpip_adapter_get_sta_list()` that was used to acquire a list of associated Wi-Fi stations to the Software Access Point (softAP) has been moved to the Wi-Fi component and renamed to `esp_wifi_ap_get_sta_list_with_ip()`, which is a special case of the ESP-NETIF API *`esp_netif_dhcps_get_clients_by_mac()`* that could be used more generally to provide a list of clients connected to a DHCP server no matter which network interface the server is running on.

Default Event Handlers Event handlers are moved from `tcpip_adapter` to appropriate driver code. There is no change from application code perspective, as all events should be handled in the same way. Please note that for IP-related event handlers, application code usually receives IP addresses in the form of an `esp-netif` specific struct instead of the LwIP structs. However, both structs are binary compatible.

This is the preferred way to print the address:

```
ESP_LOGI(TAG, "got ip:" IPSTR, IP2STR(&event->ip_info.ip));
```

Instead of

```
ESP_LOGI(TAG, "got ip:%s", ip4addr_ntoa(&event->ip_info.ip));
```

Since `ip4addr_ntoa()` is a LwIP API, the esp-netif provides `esp_ip4addr_ntoa()` as a replacement. However, the above method using `IP2STR()` is generally preferred.

IP Addresses You are advised to use `esp-netif` defined IP structures. Please note that with default compatibility enabled, the LwIP structs still work.

- esp-netif IP address definitions

Peripherals

Peripheral Clock Gating As usual, peripheral clock gating is still handled by driver itself, users do not need to take care of the peripheral module clock gating.

However, for advanced users who implement their own drivers based on `hal` and `soc` components, the previous clock gating include path has been changed from `driver/periph_ctrl.h` to `esp_private/periph_ctrl.h`.

RTC Subsystem Control RTC control APIs have been moved from `driver/rtc_cntl.h` to `esp_private/rtc_ctrl.h`.

ADC

ADC Oneshot & Continuous Mode Drivers The ADC oneshot mode driver has been redesigned.

- The new driver is in `esp_adc` component and the include path is `esp_adc/adc_oneshot.h`.
- The legacy driver is still available in the previous include path `driver/adc.h`.

The ADC continuous mode driver has been moved from `driver` component to `esp_adc` component.

- The include path has been changed from `driver/adc.h` to `esp_adc/adc_continuous.h`.

Attempting to use the legacy include path `driver/adc.h` of either driver triggers the build warning below by default. However, the warning can be suppressed by enabling the *CONFIG_ADC_SUPPRESS_DEPRECATE_WARN* Kconfig option.

```
legacy adc driver is deprecated, please migrate to use esp_adc/adc_oneshot.h and␣
↪esp_adc/adc_continuous.h for oneshot mode and continuous mode drivers␣
↪respectively
```

ADC Calibration Driver The ADC calibration driver has been redesigned.

- The new driver is in `esp_adc` component and the include path is `esp_adc/adc_cali.h` and `esp_adc/adc_cali_scheme.h`.

Legacy driver is still available by including `esp_adc_cal.h`. However, if users still would like to use the include path of the legacy driver, users should add `esp_adc` component to the list of component requirements in CMakeLists.txt.

Attempting to use the legacy include path `esp_adc_cal.h` triggers the build warning below by default. However, the warning can be suppressed by enabling the *CONFIG_ADC_CALI_SUPPRESS_DEPRECATE_WARN* Kconfig option.

```
legacy adc calibration driver is deprecated, please migrate to use esp_adc/adc_
↪cali.h and esp_adc/adc_cali_scheme.h
```

API Changes

- The ADC power management APIs `adc_power_acquire` and `adc_power_release` have made private and moved to `esp_private/adc_share_hw_ctrl.h`.
  - The two APIs were previously made public due to a HW errata workaround.
  - Now, ADC power management is completely handled internally by drivers.
  - Users who still require this API can include `esp_private/adc_share_hw_ctrl.h` to continue using these functions.
- `driver/adc2_wifi_private.h` has been moved to `esp_private/adc_share_hw_ctrl.h`.

- Enums `ADC_UNIT_BOTH`, `ADC_UNIT_ALTER`, and `ADC_UNIT_MAX` in `adc_unit_t` have been removed.
- The following enumerations have been removed as some of their enumeration values are not supported on all chips. This would lead to the driver triggering a runtime error if an unsupported value is used.
  - Enum `ADC_CHANNEL_MAX`
  - Enum `ADC_ATTEN_MAX`
  - Enum `ADC_CONV_UNIT_MAX`
- API `hall_sensor_read` on ESP32 has been removed. Hall sensor is no longer supported on ESP32.
- API `adc_set_i2s_data_source` and `adc_i2s_mode_init` have been deprecated. Related enum `adc_i2s_source_t` has been deprecated. Please migrate to use `esp_adc/adc_continuous.h`.
- API `adc_digi_filter_reset`, `adc_digi_filter_set_config`, `adc_digi_filter_get_config` and `adc_digi_filter_enable` have been removed. These APIs behaviours are not guaranteed. Enum `adc_digi_filter_idx_t`, `adc_digi_filter_mode_t` and structure `adc_digi_iir_filter_t` have been removed as well.
- API `esp_adc_cal_characterize` has been deprecated, please migrate to `adc_cali_create_scheme_curve_fitting` or `adc_cali_create_scheme_line_fitting` instead.
- API `esp_adc_cal_raw_to_voltage` has been deprecated, please migrate to `adc_cali_raw_to_voltage` instead.
- API `esp_adc_cal_get_voltage` has been deprecated, please migrate to `adc_oneshot_get_calibrated_result` instead.

GPIO

- The previous Kconfig option *RTCIO_SUPPORT_RTC_GPIO_DESC* has been removed, thus the `rtc_gpio_desc` array is unavailable. Please use `rtc_io_desc` array instead.
- The user callback of a GPIO interrupt should no longer read the GPIO interrupt status register to get the GPIO's pin number of triggering the interrupt. You should use the callback argument to determine the GPIO's pin number instead.
  - Previously, when a GPIO interrupt occurs, the GPIO's interrupt status register is cleared after calling the user callbacks. Thus, it was possible for users to read the GPIO's interrupt status register inside the callback to determine which GPIO was used to trigger the interrupt.
  - However, clearing the interrupt status register after calling the user callbacks can potentially cause edge-triggered interrupts to be lost. For example, if an edge-triggered interrupt is triggered/retriggered while the user callbacks are being called, that interrupt will be cleared without its registered user callback being handled.
  - Now, the GPIO's interrupt status register is cleared **before** invoking the user callbacks. Thus, users can no longer read the GPIO interrupt status register to determine which pin has triggered the interrupt. Instead, users should use the callback argument to pass the pin number.

Sigma-Delta Modulator The Sigma-Delta Modulator driver has been redesigned into *SDM*.

- The new driver implements a factory pattern, where the SDM channels are managed in a pool internally, thus users do not have to fix a SDM channel to a GPIO manually.
- All SDM channels can be allocated dynamically.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/sigmadelta.h`. However, by default, including `driver/sigmadelta.h` triggers the build warning below. The warning can be suppressed by Kconfig option *CONFIG_SDM_SUPPRESS_DEPRECATE_WARN*.

```
The legacy sigma-delta driver is deprecated, please use driver/sdm.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- SDM channel representation has changed from `sigmadelta_channel_t` to *sdm_channel_handle_t*, which is an opaque pointer.
- SDM channel configurations are stored in *sdm_config_t* now, instead the previous `sigmadelta_config_t`.
- In the legacy driver, users do not have to set the clock source for SDM channel. But in the new driver, users need to set a proper one in the *sdm_config_t::clk_src*. The available clock sources are listed in the *soc_periph_sdm_clk_src_t*.
- In the legacy driver, users need to set a `prescale` for the channel, which reflects the frequency in which the modulator outputs a pulse. In the new driver, users should use *sdm_config_t::sample_rate_hz* to set the over sample rate.
- In the legacy driver, users set `duty` to decide the output analog value, it is now renamed to a more appropriate name `density`.

Breaking Changes in Usage

- Channel configuration was done by channel allocation, in *sdm_new_channel()*. In the new driver, only the `density` can be changed at runtime, by *sdm_channel_set_pulse_density()*. Other parameters like `gpio number` and `prescale` are only allowed to set during channel allocation.
- Before further channel operations, users should **enable** the channel in advance, by calling *sdm_channel_enable()*. This function helps to manage some system level services, like **Power Management**.

Timer Group Driver Timer Group driver has been redesigned into *GPTimer*, which aims to unify and simplify the usage of general purpose timer.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/timer.h`. However, by default, including `driver/timer.h` triggers the build warning below. The warning can be suppressed by the Kconfig option *CONFIG_GPTIMER_SUPPRESS_DEPRECATE_WARN*.

```
legacy timer group driver is deprecated, please migrate to driver/gptimer.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- `timer_group_t` and `timer_idx_t` which used to identify the hardware timer are removed from user's code. In the new driver, a timer is represented by *gptimer_handle_t*.
- Definition of timer clock source is moved to *gptimer_clock_source_t*, the previous `timer_src_clk_t` is not used.
- Definition of timer count direction is moved to *gptimer_count_direction_t*, the previous `timer_count_dir_t` is not used.
- Only level interrupt is supported, `timer_intr_t` and `timer_intr_mode_t` are not used.
- Auto-reload is enabled by set the *gptimer_alarm_config_t::auto_reload_on_alarm* flag. `timer_autoreload_t` is not used.

Breaking Changes in Usage

- Timer initialization is done by creating a timer instance from *gptimer_new_timer()*. Basic configurations like clock source, resolution and direction should be set in *gptimer_config_t*. Note that, specific configurations of alarm events are not needed during the installation stage of the driver.
- Alarm event is configured by *gptimer_set_alarm_action()*, with parameters set in the *gptimer_alarm_config_t*.
- Setting and getting count value are done by *gptimer_get_raw_count()* and *gptimer_set_raw_count()*. The driver does not help convert the raw value into UTC time-stamp. Instead, the conversion should be done from user's side as the timer resolution is also known to the user.
- The driver will install the interrupt service as well if *gptimer_event_callbacks_t::on_alarm* is set to a valid callback function. In the callback, users do not have to deal with the low level registers (like "clear interrupt status", "re-enable alarm event" and so on). So functions like

timer_group_get_intr_status_in_isr and timer_group_get_auto_reload_in_isr are not used anymore.

- To update the alarm configurations when alarm event happens, one can call *gptimer_set_alarm_action()* in the interrupt callback, then the alarm will be re-enabled again.
- Alarm will always be re-enabled by the driver if *gptimer_alarm_config_t::auto_reload_on_alarm* is set to true.

UART

Removed/Deprecated items	Replacement	Remarks
uart_isr_register()	None	UART interrupt handling is implemented by driver itself.
uart_isr_free()	None	UART interrupt handling is implemented by driver itself.
use_ref_tick in *uart_config_t*	*uart_config_t::source_clk*	Select the clock source.
uart_enable_pattern_det_intr()	*uart_enable_pattern_det_baud_intr()*	Enable pattern detection interrupt.

I2C

Removed/Deprecated items	Replacement	Remarks
i2c_isr_register()	None	I2C interrupt handling is implemented by driver itself.
i2c_isr_register()	None	I2C interrupt handling is implemented by driver itself.
i2c_opmode_t	None	It is not used anywhere in ESP-IDF.

SPI

Removed/Deprecated items	Replacement	Remarks
spi_cal_clock()	*spi_get_actual_clock()*	Get SPI real working frequency.

- The internal header file spi_common_internal.h has been moved to esp_private/spi_common_internal.h.

LEDC

Removed/Deprecated items	Replacement	Remarks
bit_num in *ledc_timer_config_t*	*ledc_timer_config_t::duty_resolution*	Set resolution of the duty cycle.

Temperature Sensor Driver The temperature sensor driver has been redesigned and it is recommended to use the new driver. However, the old driver is still available but cannot be used with the new driver simultaneously.

The new driver can be included via driver/temperature_sensor.h. The old driver is still available in the previous include path driver/temp_sensor.h. However, including driver/temp_sensor.h triggers the build warning below by default. The warning can be suppressed by enabling the menuconfig option *CONFIG_TEMP_SENSOR_SUPPRESS_DEPRECATE_WARN*.

```
legacy temperature sensor driver is deprecated, please migrate to driver/
↪temperature_sensor.h
```

Configuration contents has been changed. In the old version, users need to configure clk_div and dac_offset. While in the new version, users only need to choose tsens_range.

The process of using temperature sensor has been changed. In the old version, users can use config->start->read_celsius to get value. In the new version, users should install the temperature sensor driver firstly, by temperature_sensor_install and uninstall it when finished. For more information, please refer to *Temperature Sensor* .

RMT Driver RMT driver has been redesigned (see *RMT transceiver*), which aims to unify and extend the usage of RMT peripheral.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/rmt.h`. However, including `driver/rmt.h` triggers the build warning below by default. The warning can be suppressed by the Kconfig option *CONFIG_RMT_SUPPRESS_DEPRECATE_WARN*.

```
The legacy RMT driver is deprecated, please use driver/rmt_tx.h and/or driver/rmt_
↪rx.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- `rmt_channel_t` which used to identify the hardware channel are removed from user space. In the new driver, RMT channel is represented by `rmt_channel_handle_t`. The channel is dynamically allocated by the driver, instead of designated by user.
- `rmt_item32_t` is replaced by `rmt_symbol_word_t`, which avoids a nested union inside a struct.
- `rmt_mem_t` is removed, as we do not allow users to access RMT memory block (a.k.an RMTMEM) directly. Direct access to RMTMEM does not make sense but make mistakes, especially when the RMT channel also connected with a DMA channel.
- `rmt_mem_owner_t` is removed, as the ownership is controlled by driver, not by user anymore.
- `rmt_source_clk_t` is replaced by `rmt_clock_source_t`, and note they are not binary compatible.
- `rmt_data_mode_t` is removed, the RMT memory access mode is configured to always use Non-FIFO and DMA mode.
- `rmt_mode_t` is removed, as the driver has stand alone install functions for TX and RX channels.
- `rmt_idle_level_t` is removed, setting IDLE level for TX channel is available in `rmt_transmit_config_t::eot_level`.
- `rmt_carrier_level_t` is removed, setting carrier polarity is available in `rmt_carrier_config_t::polarity_active_low`.
- `rmt_channel_status_t` and `rmt_channel_status_result_t` are removed, they are not used anywhere.
- Transmitting by RMT channel does not expect user to prepare the RMT symbols, instead, user needs to provide an RMT Encoder to tell the driver how to convert user data into RMT symbols.

Breaking Changes in Usage

- Channel installation has been separated for TX and RX channels into `rmt_new_tx_channel()` and `rmt_new_rx_channel()`.
- `rmt_set_clk_div` and `rmt_get_clk_div` are removed. Channel clock configuration can only be done during channel installation.
- `rmt_set_rx_idle_thresh` and `rmt_get_rx_idle_thresh` are removed. In the new driver, the RX channel IDLE threshold is redesigned into a new concept `rmt_receive_config_t::signal_range_max_ns`.
- `rmt_set_mem_block_num` and `rmt_get_mem_block_num` are removed. In the new driver, the memory block number is determined by `rmt_tx_channel_config_t::mem_block_symbols` and `rmt_rx_channel_config_t::mem_block_symbols`.
- `rmt_set_tx_carrier` is removed, the new driver uses `rmt_apply_carrier()` to set carrier behavior.
- `rmt_set_mem_pd` and `rmt_get_mem_pd` are removed. The memory power is managed by the driver automatically.
- `rmt_memory_rw_rst`, `rmt_tx_memory_reset` and `rmt_rx_memory_reset` are removed. Memory reset is managed by the driver automatically.
- `rmt_tx_start` and `rmt_rx_start` are merged into a single function `rmt_enable()`, for both TX and RX channels.
- `rmt_tx_stop` and `rmt_rx_stop` are merged into a single function `rmt_disable()`, for both TX and RX channels.
- `rmt_set_memory_owner` and `rmt_get_memory_owner` are removed. RMT memory owner guard is added automatically by the driver.

- rmt_set_tx_loop_mode and rmt_get_tx_loop_mode are removed. In the new driver, the loop mode is configured in *rmt_transmit_config_t::loop_count*.
- rmt_set_source_clk and rmt_get_source_clk are removed. Configuring clock source is only possible during channel installation by *rmt_tx_channel_config_t::clk_src* and *rmt_rx_channel_config_t::clk_src*.
- rmt_set_rx_filter is removed. In the new driver, the filter threshold is redesigned into a new concept *rmt_receive_config_t::signal_range_min_ns*.
- rmt_set_idle_level and rmt_get_idle_level are removed. Setting IDLE level for TX channel is available in *rmt_transmit_config_t::eot_level*.
- rmt_set_rx_intr_en, rmt_set_err_intr_en, rmt_set_tx_intr_en, rmt_set_tx_thr_intr_en and rmt_set_rx_thr_intr_en are removed. The new driver does not allow user to turn on/off interrupt from user space. Instead, it provides callback functions.
- rmt_set_gpio and rmt_set_pin are removed. The new driver does not support to switch GPIO dynamically at runtime.
- rmt_config is removed. In the new driver, basic configuration is done during the channel installation stage.
- rmt_isr_register and rmt_isr_deregister are removed, the interrupt is allocated by the driver itself.
- rmt_driver_install is replaced by *rmt_new_tx_channel()* and *rmt_new_rx_channel()*.
- rmt_driver_uninstall is replaced by *rmt_del_channel()*.
- rmt_fill_tx_items, rmt_write_items and rmt_write_sample are removed. In the new driver, user needs to provide an encoder to "translate" the user data into RMT symbols.
- rmt_get_counter_clock is removed, as the channel clock resolution is configured by user from *rmt_tx_channel_config_t::resolution_hz*.
- rmt_wait_tx_done is replaced by *rmt_tx_wait_all_done()*.
- rmt_translator_init, rmt_translator_set_context and rmt_translator_get_context are removed. In the new driver, the translator has been replaced by the RMT encoder.
- rmt_get_ringbuf_handle is removed. The new driver does not use Ringbuffer to save RMT symbols. Instead, the incoming data are saved to the user provided buffer directly. The user buffer can even be mounted to DMA link internally.
- rmt_register_tx_end_callback is replaced by *rmt_tx_register_event_callbacks()*, where user can register *rmt_tx_event_callbacks_t::on_trans_done* event callback.
- rmt_set_intr_enable_mask and rmt_clr_intr_enable_mask are removed, as the interrupt is handled by the driver, user does not need to take care of it.
- rmt_add_channel_to_group and rmt_remove_channel_from_group are replaced by RMT sync manager. Please refer to *rmt_new_sync_manager()*.
- rmt_set_tx_loop_count is removed. The loop count in the new driver is configured in *rmt_transmit_config_t::loop_count*.
- rmt_enable_tx_loop_autostop is removed. In the new driver, TX loop auto stop is always enabled if available, it is not configurable anymore.

LCD

- The LCD panel initialization flow is slightly changed. Now the *esp_lcd_panel_init()* will not turn on the display automatically. User needs to call *esp_lcd_panel_disp_on_off()* to manually turn on the display. Note, this is different from turning on backlight. With this breaking change, user can flash a predefined pattern to the screen before turning on the screen. This can help avoid random noise on the screen after a power on reset.
- *esp_lcd_panel_disp_off()* is deprecated, please use *esp_lcd_panel_disp_on_off()* instead.
- dc_as_cmd_phase is removed. The SPI LCD driver currently does not support a 9-bit SPI LCD. Please always use a dedicated GPIO to control the LCD D/C line.
- The way to register RGB panel event callbacks has been moved from the esp_lcd_rgb_panel_config_t into a separate API esp_lcd_rgb_panel_register_event_callbacks(). However, the event callback signature is not changed.
- Previous relax_on_idle flag in esp_lcd_rgb_panel_config_t has been renamed into esp_lcd_rgb_panel_config_t::refresh_on_demand, which expresses the same meaning but

with a clear name.

- If the RGB LCD is created with the `refresh_on_demand` flag enabled, the driver will not start a refresh in the *`esp_lcd_panel_draw_bitmap()`*. Now users have to call `esp_lcd_rgb_panel_refresh()` to refresh the screen by themselves.
- `esp_lcd_color_space_t` is deprecated, please use *`lcd_color_space_t`* to describe the color space, and use *`lcd_rgb_element_order_t`* to describe the data order of RGB color.

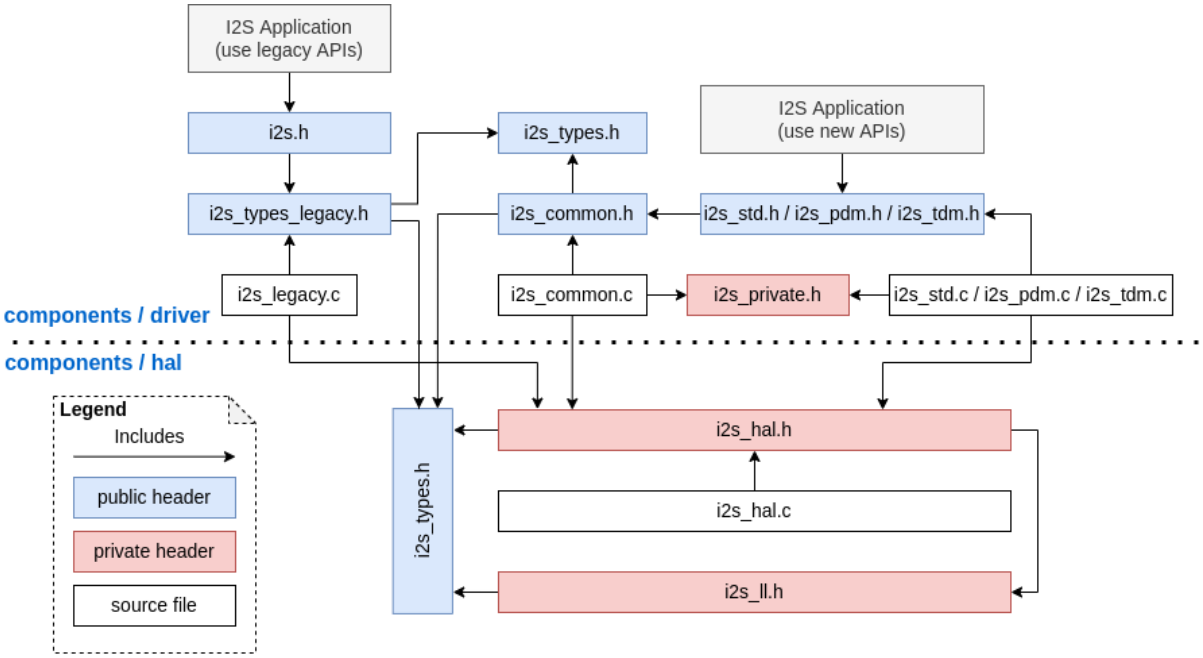
Dedicated GPIO Driver

- All of the dedicated GPIO related Low Level (LL) functions in `cpu_ll.h` have been moved to `dedic_gpio_cpu_ll.h` and renamed.

I2S Driver The I2S driver has been redesigned (see *I2S Driver*), which aims to rectify the shortcomings of the driver that were exposed when supporting all the new features of ESP32-C3 & ESP32-S3. The new driver's APIs are available by including corresponding I2S mode's header files esp_driver_i2s/include/driver/i2s_std.h, esp_driver_i2s/include/driver/i2s_pdm.h, or esp_driver_i2s/include/driver/i2s_tdm.h.

Meanwhile, the old driver's APIs in driver/deprecated/driver/i2s.h are still supported for backward compatibility. But there will be warnings if users keep using the old APIs in their projects, these warnings can be suppressed by the Kconfig option *CONFIG_I2S_SUPPRESS_DEPRECATE_WARN*.

Here is the general overview of the current I2S files:



Breaking changes in Concepts

Independent TX/RX channels The minimum control unit in new I2S driver are now individual TX/RX channels instead of an entire I2S controller (that consists of multiple channels).

- The TX and RX channels of the same I2S controller can be controlled separately, meaning that they are configured such that they can be started or stopped separately.
- The *`i2s_chan_handle_t`* handle type is used to uniquely identify I2S channels. All the APIs require the channel handle and users need to maintain the channel handles by themselves.
- On the ESP32-C3 and ESP32-S3, TX and RX channels in the same controller can be configured to different clocks or modes.
- However, on the ESP32 and ESP32-S2, the TX and RX channels of the same controller still share some hardware resources. Thus, configurations may cause one channel to affect another channel in the same controller.

- The channels can be registered to an available I2S controller automatically by setting *i2s_port_t::I2S_NUM_AUTO* as I2S port ID which causes the driver to search for the available TX/RX channels. However, the driver also supports registering channels to a specific port.
- In order to distinguish between TX/RX channels and sound channels, the term "channel" in the context of the I2S driver only refers to TX/RX channels. Meanwhile, sound channels are referred to as "slots".

I2S Mode Categorization I2S communication modes are categorized into the following three modes. Note that:

- **Standard mode**: Standard mode always has two slots, it can support Philips, MSB, and PCM (short frame sync) formats. Please refer to esp_driver_i2s/include/driver/i2s_std.h for more details.
- **PDM mode**: PDM mode only supports two slots with 16-bit data width, but the configurations of PDM TX and PDM RX are slightly different. For PDM TX, the sample rate can be set by `i2s_pdm_tx_clk_config_t::sample_rate`, and its clock frequency depends on the up-sampling configuration. For PDM RX, the sample rate can be set by `i2s_pdm_rx_clk_config_t::sample_rate`, and its clock frequency depends on the down-sampling configuration. Please refer to esp_driver_i2s/include/driver/i2s_pdm.h for details.
- **TDM mode**: TDM mode can support up to 16 slots. It can work in Philips, MSB, PCM (short frame sync), and PCM (long frame sync) formats. Please refer to esp_driver_i2s/include/driver/i2s_tdm.h for details.

When allocating a new channel in a specific mode, users should initialize that channel by its corresponding function. It is strongly recommended to use the helper macros to generate the default configurations in case the default values are changed in the future.

Independent Slot and Clock Configuration The slot configurations and clock configurations can be configured separately.

- Call *i2s_channel_init_std_mode()*, `i2s_channel_init_pdm_rx_mode()`, *i2s_channel_init_pdm_tx_mode()*, or *i2s_channel_init_tdm_mode()* to initialize the slot/clock/gpio_pin configurations.
- Calling *i2s_channel_reconfig_std_slot()*, `i2s_channel_reconfig_pdm_rx_slot()`, *i2s_channel_reconfig_pdm_tx_slot()*, or *i2s_channel_reconfig_tdm_slot()* can change the slot configurations after initialization.
- Calling *i2s_channel_reconfig_std_clock()*, `i2s_channel_reconfig_pdm_rx_clock()`, *i2s_channel_reconfig_pdm_tx_clock()*, or *i2s_channel_reconfig_tdm_clock()* can change the clock configurations after initialization.
- Calling *i2s_channel_reconfig_std_gpio()*, `i2s_channel_reconfig_pdm_rx_gpio()`, *i2s_channel_reconfig_pdm_tx_gpio()*, or *i2s_channel_reconfig_tdm_gpio()* can change the GPIO configurations after initialization.

Misc

- States and state-machine are adopted in the new I2S driver to avoid APIs called in wrong state.
- ADC and DAC modes are removed. They are only supported in their own drivers and the legacy I2S driver.

Breaking Changes in Usage To use the new I2S driver, please follow these steps:

1. Call *i2s_new_channel()* to acquire channel handles. We should specify the work role and I2S port in this step. Besides, the TX or RX channel handle will be generated by the driver. Inputting both two TX and RX channel handles is not necessary but at least one handle is needed. In the case of inputting both two handles, the driver will work at the duplex mode. Both TX and RX channels will be available on a same port, and they will share the MCLK, BCLK and WS signal. But if only one of the TX or RX channel handle is inputted, this channel will only work in the simplex mode.
2. Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()` or `i2s_channel_init_tdm_mode()` to initialize the channel to the specified mode. Corresponding slot, clock and GPIO configurations are needed in this step.
3. (Optional) Call *i2s_channel_register_event_callback()* to register the ISR event callback functions. I2S events now can be received by the callback function synchronously, instead of from the event queue asynchronously.

4. Call *i2s_channel_enable()* to start the hardware of I2S channel. In the new driver, I2S does not start automatically after installed, and users are supposed to know clearly whether the channel has started or not.
5. Read or write data by *i2s_channel_read()* or *i2s_channel_write()*. Certainly, only the RX channel handle is suppoesd to be inputted in *i2s_channel_read()* and the TX channel handle in *i2s_channel_write()*.
6. (Optional) The slot, clock and GPIO configurations can be changed by corresponding 'reconfig' functions, but *i2s_channel_disable()* must be called before updating the configurations.
7. Call *i2s_channel_disable()* to stop the hardware of I2S channel.
8. Call *i2s_del_channel()* to delete and release the resources of the channel if it is not needed any more, but the channel must be disabled before deleting it.

TWAI Driver The deprecated `CAN` peripheral driver is removed. Please use `TWAI` driver instead (i.e., include `driver/twai.h` in your application).

Register Access Macros Previously, all register access macros could be used as expressions, so the following was allowed:

```
uint32_t val = REG_SET_BITS(reg, bits, mask);
```

In ESP-IDF v5.0, register access macros which write or read-modify-write the register can no longer be used as expressions, and can only be used as statements. This applies to the following macros: `REG_WRITE`, `REG_SET_BIT`, `REG_CLR_BIT`, `REG_SET_BITS`, `REG_SET_FIELD`, `WRITE_PERI_REG`, `CLEAR_PERI_REG_MASK`, `SET_PERI_REG_MASK`, `SET_PERI_REG_BITS`.

To store the value which would have been written into the register, split the operation as follows:

```
uint32_t new_val = REG_READ(reg) | mask;
REG_WRITE(reg, new_val);
```

To get the value of the register after modification (which may be different from the value written), add an explicit read:

```
REG_SET_BITS(reg, bits, mask);
uint32_t new_val = REG_READ(reg);
```

Protocols

Mbed TLS For ESP-IDF v5.0, Mbed TLS has been updated from v2.x to v3.1.0.

For more details about Mbed TLS's migration from version 2.x to version 3.0 or greater, please refer to the official guide.

Breaking Changes (Summary)

Most Structure Fields Are Now Private

- Direct access to fields of structures (`struct` types) declared in public headers is no longer supported.
- Appropriate accessor functions (getter/setter) must be used for the same. A temporary workaround would be to use `MBEDTLS_PRIVATE` macro (**not recommended**).
- For more details, refer to the official guide.

SSL

- Removed support for TLS 1.0, 1.1, and DTLS 1.0
- Removed support for SSL 3.0

Deprecated Functions Were Removed from Cryptography Modules

- The functions `mbedtls_*_ret()` (related to MD, SHA, RIPEMD, RNG, HMAC modules) was renamed to replace the corresponding functions without `_ret` appended and updated return value.
- For more details, refer to the official guide.

Deprecated Config Options Following are some of the important config options deprecated by this update. The configs related to and/or dependent on these have also been deprecated.

- `MBEDTLS_SSL_PROTO_SSL3` : Support for SSL 3.0
- `MBEDTLS_SSL_PROTO_TLS1` : Support for TLS 1.0
- `MBEDTLS_SSL_PROTO_TLS1_1`: Support for TLS 1.1
- `MBEDTLS_SSL_PROTO_DTLS` : Support for DTLS 1.1 (Only DTLS 1.2 is supported now)
- `MBEDTLS_DES_C` : Support for 3DES ciphersuites
- `MBEDTLS_RC4_MODE` : Support for RC4-based ciphersuites

Note: This list includes only major options configurable through `idf.py menuconfig`. For more details on deprecated options, refer to the official guide.

Miscellaneous

Disabled Diffie-Hellman Key Exchange Modes The Diffie-Hellman Key Exchange modes have now been disabled by default due to security risks (see warning text here). Related configs are given below:

- `MBEDTLS_DHM_C` : Support for the Diffie-Hellman-Merkle module
- `MBEDTLS_KEY_EXCHANGE_DHE_PSK` : Support for Diffie-Hellman PSK (pre-shared-key) TLS authentication modes
- `MBEDTLS_KEY_EXCHANGE_DHE_RSA` : Support for cipher suites with the prefix `TLS-DHE-RSA-WITH-`

Note: During the initial step of the handshake (i.e., `client_hello`), the server selects a cipher from the list that the client publishes. As the DHE_PSK/DHE_RSA ciphers have now been disabled by the above change, the server would fall back to an alternative cipher; if in a rare case, it does not support any other cipher, the handshake would fail. To retrieve the list of ciphers supported by the server, one must attempt to connect with the server with a specific cipher from the client-side. Few utilities can help do this, e.g., `sslscan`.

Remove `certs` Module from X509 Library

- The `mbedtls/certs.h` header is no longer available in mbedtls 3.1. Most applications can safely remove it from the list of includes.

Breaking Change for `esp_crt_bundle_set` API

- The *`esp_crt_bundle_set()`* API now requires one additional argument named `bundle_size`. The return type of the API has also been changed to *`esp_err_t`* from `void`.

Breaking Change for `esp_ds_rsa_sign` API

- The `esp_ds_rsa_sign()` API now requires one less argument. The argument `mode` is no longer required.

HTTPS Server

Breaking Changes (Summary) Names of variables holding different certs in *`httpd_ssl_config_t`* structure have been updated.

- *`httpd_ssl_config::servercert`* variable inherits role of `cacert_pem` variable.
- *`httpd_ssl_config::servercert_len`* variable inherits role of `cacert_len` variable
- *`httpd_ssl_config::cacert_pem`* variable inherits role of `client_verify_cert_pem` variable
- *`httpd_ssl_config::cacert_len`* variable inherits role of `client_verify_cert_len` variable

The return type of the *`httpd_ssl_stop()`* API has been changed to *`esp_err_t`* from `void`.

ESP HTTPS OTA

Breaking Changes (Summary)

- The function *`esp_https_ota()`* now requires pointer to *`esp_https_ota_config_t`* as argument instead of pointer to *`esp_http_client_config_t`*.

ESP-TLS

Breaking Changes (Summary)

`esp_tls_t` Structure Is Now Private The *`esp_tls_t`* has now been made completely private. You cannot access its internal structures directly. Any necessary data that needs to be obtained from the ESP-TLS handle can be done through respective getter/setter functions. If there is a requirement of a specific getter/setter function, please raise an issue on ESP-IDF.

The list of newly added getter/setter function is as as follows:

- *`esp_tls_get_ssl_context()`* - Obtain the ssl context of the underlying ssl stack from the ESP-TLS handle.

Function Deprecations And Recommended Alternatives Following table summarizes the deprecated functions removed and their alternatives to be used from ESP-IDF v5.0 onwards.

Deprecated Function	Alternative
`esp_tls_conn_new()`	*`esp_tls_conn_new_sync()`*
`esp_tls_conn_delete()`	*`esp_tls_conn_destroy()`*

- The function *`esp_tls_conn_http_new()`* has now been termed as deprecated. Please use the alternative function *`esp_tls_conn_http_new_sync()`* (or its asynchronous *`esp_tls_conn_http_new_async()`*). Note that the alternatives need an additional parameter *`esp_tls_t`*, which has to be initialized using the *`esp_tls_init()`* function.

HTTP Server

Breaking Changes (Summary)

- `http_server.h` header is no longer available in `esp_http_server`. Please use `esp_http_server.h` instead.

ESP HTTP Client

Breaking Changes (Summary)

- The functions *esp_http_client_read()* and *esp_http_client_fetch_headers()* now return an additional return value `-ESP_ERR_HTTP_EAGAIN` for timeout errors - call timed-out before any data was ready.

TCP Transport

Breaking Changes (Summary)

- The function `esp_transport_read()` now returns `0` for a connection timeout and `< 0` for other errors. Please refer `esp_tcp_transport_err_t` for all possible return values.

MQTT Client

Breaking Changes (Summary)

- *esp_mqtt_client_config_t* have all fields grouped in sub structs.

Most common configurations are listed below:

- Broker address now is set in `esp_mqtt_client_config_t::broker::address::uri`
- Security related to broker verification in `esp_mqtt_client_config_t::broker::verification`
- Client username is set in `esp_mqtt_client_config_t::credentials::username`
- *esp_mqtt_client_config_t* no longer supports the `user_context` field. Please use *esp_mqtt_client_register_event()* instead for registering an event handler; the last argument `event_handler_arg` can be used to pass user context to the handler.

ESP-Modbus

Breaking Changes (Summary) The ESP-IDF component `freemodbus` has been removed from ESP-IDF and is supported as a separate component. Additional information for the `ESP-Modbus` component can be found in the separate repository:

- ESP-Modbus component on GitHub

The `main` component folder of the new application shall include the component manager manifest file `idf_component.yml` as in the example below:

```
dependencies:
  espressif/esp-modbus:
    version: "^1.0"
```

The `esp-modbus` component can be found in component manager registry. Refer to component manager documentation for more information on how to set up the component manager.

For applications targeting v4.x releases of ESP-IDF that need to use new `esp-modbus` component, adding the component manager manifest file `idf_component.yml` will be sufficient to pull in the new component. However, users should also exclude the legacy `freemodbus` component from the build. This can be achieved using the statement below in the project's `CMakeLists.txt`:

```
set(EXCLUDE_COMPONENTS freemodbus)
```

Provisioning

Protocomm The `pop` field in the *`protocomm_set_security()`* API is now deprecated. Please use the `sec_params` field instead of `pop`. This parameter should contain the structure (including the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` parameter should contain the pointer to the structure of type *`protocomm_security2_params_t`*.

Wi-Fi Provisioning

- The `pop` field in the *`wifi_prov_mgr_start_provisioning()`* API is now deprecated. For backward compatibility, `pop` can be still passed as a string for security version 1. However, for security version 2, the `wifi_prov_sec_params` argument needs to be passed instead of `pop`. This parameter should contain the structure (containing the security parameters) as required by the protocol version used. For example, when using security version 2, the `wifi_prov_sec_params` parameter should contain the pointer to the structure of type *`wifi_prov_security2_params_t`*. For security 1, the behaviour and the usage of the API remain the same.
- The API *`wifi_prov_mgr_is_provisioned()`* does not return *`ESP_ERR_INVALID_STATE`* error any more. This API now works without any dependency on provisioning manager initialization state.

ESP Local Control The `pop` field in the *`esp_local_ctrl_proto_sec_cfg_t`* API is now deprecated. Please use the `sec_params` field instead of `pop`. This field should contain the structure (containing the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` field should contain pointer to the structure of type *`esp_local_ctrl_security2_params_t`*.

Removed or Deprecated Components

Components Moved to ESP-IDF Component Registry Following components are removed from ESP-IDF and moved to ESP-IDF Component Registry:

- libsodium
- cbor
- jsmn
- esp_modem
- nghttp
- mdns
- esp_websocket_client
- asio
- freemodbus
- sh2lib
- expat
- coap
- esp-cryptoauthlib
- qrcode
- tjpgd
- esp_serial_slave_link
- tinyusb

Note: Please note that http parser functionality which was previously part of `nghttp` component is now part of http_parser component.

These components can be installed using `idf.py add-dependency` command.

For example, to install libsodium component with the exact version X.Y, run `idf.py add-dependency libsodium==X.Y`.

To install libsodium component with the latest version compatible to X.Y according to semver rules, run `idf.py add-dependency libsodium~X.Y`.

To find out which versions of each component are available, open https://components.espressif.com, search for the component by its name and check the versions listed on the component page.

Deprecated Components The following components are removed since they were deprecated in ESP-IDF v4.x:

- `tcpip_adapter`. Please use the *ESP-NETIF* component instead; you can follow the *TCP/IP Adapter*.

Note: OpenSSL-API component is no longer supported. It is not available in the IDF Component Registry, either. Please use *ESP-TLS* or mbedtls API directly.

Note: `esp_adc_cal` component is no longer supported. New adc calibration driver is in `esp_adc` component. Legacy adc calibration driver has been moved into `esp_adc` component. To use legacy `esp_adc_cal` driver APIs, you should add `esp_adc` component to the list of component requirements in CMakeLists.txt. Also check *Peripherals Migration Guide* for more details.

The targets components are no longer necessary after refactoring and have been removed:

- `esp32`
- `esp32s2`
- `esp32s3`
- `esp32c2`
- `esp32c3`
- `esp32h2`

Storage

New Component for the Partition APIs Breaking change: all the Partition API code has been moved to a new component esp_partition. For the complete list of affected functions and data-types, see header file esp_partition.h .

These API functions and data-types were previously a part of the spi_flash component, and thus possible dependencies on the `spi_flash` in existing applications may cause the build failure, in case of direct esp_partition_* APIs/data-types use (for instance, `fatal error: esp_partition.h: No such file or directory` at lines with `#include "esp_partition.h"`). If you encounter such an issue, please update your project's CMakeLists.txt file as follows:

Original dependency setup:

```
idf_component_register(...
                       REQUIRES spi_flash)
```

Updated dependency setup:

```
idf_component_register(...
                       REQUIRES spi_flash esp_partition)
```

Note: Please update relevant `REQUIRES` or `PRIV_REQUIRES` section according to your project. The above-presented code snippet is just an example.

If the issue persists, please let us know and we will assist you with your code migration.

SDMMC/SDSPI SD card frequency on SDMMC/SDSPI interface can be now configured through `sdmmc_host_t.max_freq_khz` to a specific value, not only `SDMMC_FREQ_PROBING` (400 kHz), `SDMMC_FREQ_DEFAULT` (20 MHz), or `SDMMC_FREQ_HIGHSPEED` (40 MHz). Previously, in case you have specified a custom frequency other than any of the above-mentioned values, the closest lower-or-equal one was selected anyway.

Now, the underlying drivers calculate the nearest fitting value, given by available frequency dividers instead of an enumeration item selection. This could cause troubles in communication with your SD card without a change of the existing application code.If you encounter such an issue, please, keep trying different frequencies around your desired value unless you find the one working well. To check the frequency value calculated and actually applied, use `void sdmmc_card_print_info(FILE* stream, const sdmmc_card_t* card)` function.

FatFs FatFs is now updated to v0.14. As a result, the function signature of `f_mkfs()` has changed. The new signature is `FRESULT f_mkfs (const TCHAR* path, const MKFS_PARM* opt, void* work, UINT len);` which uses `MKFS_PARM` struct as a second argument.

Partition Table The partition table generator no longer supports misaligned partitions. When generating a partition table, `ESP-IDF` only accepts partitions with offsets that align to 4 KB. This change only affects generating new partition tables. Reading and writing to already existing partitions remains unchanged.

VFS The `esp_vfs_semihost_register()` function signature is changed as follows:

- The new signature is `esp_err_t esp_vfs_semihost_register(const char* base_path);`
- The `host_path` parameter of the old signature no longer exists. Instead, the OpenOCD command `ESP_SEMIHOST_BASEDIR` should be used to set the full path on the host.

Function Signature Changes The following functions now return `esp_err_t` instead of `void` or `nvs_iterator_t`. Previously, when parameters were invalid or when something goes wrong internally, these functions would `assert()` or return a `nullptr`. With an `esp_err_t` returned, you can get better error reporting.

- *`nvs_entry_find()`*
- *`nvs_entry_next()`*
- *`nvs_entry_info()`*

Because the `esp_err_t` return type changes, the usage patterns of `nvs_entry_find()` and `nvs_entry_next()` become different. Both functions now modify iterators via parameters instead of returning an iterator.

The old programming pattern to iterate over an NVS partition was as follows:

```
nvs_iterator_t it = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_
↪ANY);
while (it != NULL) {
        nvs_entry_info_t info;
        nvs_entry_info(it, &info);
        it = nvs_entry_next(it);
        printf("key '%s', type '%d'", info.key, info.type);
};
```

The new programming pattern to iterate over an NVS partition is now:

```
nvs_iterator_t it = nullptr;
esp_err_t res = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY, &
↪it);
while(res == ESP_OK) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info); // Can omit error check if parameters are␣
↪guaranteed to be non-NULL
    printf("key '%s', type '%d'", info.key, info.type);
    res = nvs_entry_next(&it);
}
nvs_release_iterator(it);
```

Iterator Validity Note that because the function signature changes, if there is a parameter error, you may get an invalid iterator from `nvs_entry_find()`. Hence, it is important to initialize the iterator to `NULL` before using `nvs_entry_find()`, so that you can avoid complex error checking before calling `nvs_release_iterator()`. A good example is the programming pattern above.

Removed SDSPI Deprecated API Structure `sdspi_slot_config_t` and function `sdspi_host_init_slot()` are removed, and replaced by structure `sdspi_device_config_t` and function `sdspi_host_init_device()` respectively.

ROM SPI Flash In versions before v5.0, ROM SPI flash functions were included via `esp32**/rom/spi_flash.h`. Thus, code written to support different ESP chips might be filled with ROM headers of different targets. Furthermore, not all of the APIs could be used on all ESP chips.

Now, the common APIs are extracted to `esp_rom_spiflash.h`. Although it is not a breaking change, you are strongly recommended to only use the functions from this header (i.e., prefixed with `esp_rom_spiflash` and included by `esp_rom_spiflash.h`) for better cross-compatibility between ESP chips.

To make ROM SPI flash APIs clearer, the following functions are also renamed:

- `esp_rom_spiflash_lock()` to `esp_rom_spiflash_set_bp()`
- `esp_rom_spiflash_unlock()` to `esp_rom_spiflash_clear_bp()`

SPI Flash Driver The `esp_flash_speed_t enum` type is now deprecated. Instead, you may now directly pass the real clock frequency value to the flash configuration structure. The following example demonstrates how to configure a flash frequency of 80MHz:

```
esp_flash_spi_device_config_t dev_cfg = {
    // Other members
    .freq_mhz = 80,
    // Other members
};
```

Legacy SPI Flash Driver To make SPI flash drivers more stable, the legacy SPI flash driver is removed from v5.0. The legacy SPI flash driver refers to default spi_flash driver since v3.0, and the SPI flash driver with configuration option `CONFIG_SPI_FLASH_USE_LEGACY_IMPL` enabled since v4.0. The major breaking change here is that the legacy spi_flash driver is no longer supported from v5.0. Therefore, the legacy driver APIs and the `CONFIG_SPI_FLASH_USE_LEGACY_IMPL` configuration option are both removed. Please use the new spi_flash driver's APIs instead.

Removed items	Replacement
`spi_flash_erase_sector()`	`esp_flash_erase_region()`
`spi_flash_erase_range()`	`esp_flash_erase_region()`
`spi_flash_write()`	`esp_flash_write()`
`spi_flash_read()`	`esp_flash_read()`
`spi_flash_write_encrypted()`	`esp_flash_write_encrypted()`
`spi_flash_read_encrypted()`	`esp_flash_read_encrypted()`

Note: New functions with prefix `esp_flash` accept an additional `esp_flash_t*` parameter. You can simply set it to NULL. This will make the function to run the main flash (`esp_flash_default_chip`).

The `esp_spi_flash.h` header is deprecated as system functions are no longer public. To use flash memory mapping APIs, you may include `spi_flash_mmap.h` instead.

System

Inter-Processor Call IPC (Inter-Processor Call) feature is no longer a stand-alone component and has been integrated into the `esp_system` component.

Thus, any project presenting a `CMakeLists.txt` file with the parameters `PRIV_REQUIRES esp_ipc` or `REQUIRES esp_ipc` should be modified to simply remove these options as the `esp_system` component is included by default.

ESP Clock The ESP Clock API (functions/types/macros prefixed with `esp_clk`) has been made into a private API. Thus, the previous include paths `#include "ESP32-C3/clk.h"` and `#include "esp_clk.h"` have been removed. If users still require usage of the ESP Clock API (though this is not recommended), it can be included via `#include "esp_private/esp_clk.h"`.

Note: Private APIs are not stable and no are longer subject to the ESP-IDF versioning scheme's breaking change rules. Thus, it is not recommended for users to continue calling private APIs in their applications.

Cache Error Interrupt The Cache Error Interrupt API (functions/types/macros prefixed with `esp_cache_err`) has been made into a private API. Thus, the previous include path `#include "ESP32-C3/cache_err_int.h"` has been removed. If users still require usage of the Cache Error Interrupt API (though this is not recommended), it can be included via `#include "esp_private/cache_err_int.h"`.

`bootloader_support`

- The function `bootloader_common_get_reset_reason()` has been removed. Please use the function `esp_rom_get_reset_reason()` in the ROM component.
- The functions `esp_secure_boot_verify_sbv2_signature_block()` and `esp_secure_boot_verify_rsa_signature_block()` have been removed without replacement. We do not expect users to use these directly. If they are indeed still necessary, please open a feature request on GitHub explaining why these functions are necessary to you.

Brownout The Brownout API (functions/types/macros prefixed with `esp_brownout`) has been made into a private API. Thus, the previous include path `#include "brownout.h"` has been removed. If users still require usage of the Brownout API (though this is not recommended), it can be included via `#include "esp_private/brownout.h"`.

Trax The Trax API (functions/types/macros prefixed with `trax_`) has been made into a private API. Thus, the previous include path `#include "trax.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/trax.h"`.

ROM The previously deprecated ROM-related header files located in `components/esp32/rom/` (old include path: `rom/*.h`) have been moved. Please use the new target-specific path from `components/esp_rom/include/ESP32-C3/` (new include path: `ESP32-C3/rom/*.h`).

esp_hw_support

- The header files `soc/cpu.h` have been deleted and deprecated CPU util functions have been removed. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header files `hal/cpu_ll.h`, `hal/cpu_hal.h`, `hal/soc_ll.h`, `hal/soc_hal.h` and `interrupt_controller_hal.h` CPU API functions have been deprecated. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header file `compare_set.h` have been deleted. ESP-IDF developers should use `esp_cpu_compare_and_set()` function provided in `esp_cpu.h` instead.
- `esp_cpu_get_ccount()`, `esp_cpu_set_ccount()` and `esp_cpu_in_ocd_debug_mode()` were removed from `esp_cpu.h`. ESP-IDF developers should use respectively `esp_cpu_get_cycle_count()`, `esp_cpu_set_cycle_count()` and `esp_cpu_dbgr_is_attached()` instead.
- The header file `esp_intr.h` has been deleted. Please include `esp_intr_alloc.h` to allocate and manipulate interrupts.
- The Panic API (functions/types/macros prefixed with `esp_panic`) has been made into a private API. Thus, the previous include path `#include "esp_panic.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/panic_reason.h"`. Besides, developers should include `esp_debug_helpers.h` instead to use any debug-related helper functions, e.g., print backtrace.
- The header file `soc_log.h` is now renamed to `esp_hw_log.h` and has been made private. Users are encouraged to use logging APIs provided under `esp_log.h` instead.
- The header files `spinlock.h`, `clk_ctrl_os.h`, and `rtc_wdt.h` must now be included without the `soc` prefix. For example, `#include "spinlock.h"`.
- `esp_chip_info()` returns the chip version in the format = 100 * `major eFuse version` + `minor eFuse version`. Thus, the `revision` in the `esp_chip_info_t` structure is expanded to `uint16_t` to fit the new format.

PSRAM

- The target-specific header file `spiram.h` and the header file `esp_spiram.h` have been removed. A new component `esp_psram` is created instead. For PSRAM/SPIRAM-related functions, users now include `esp_psram.h` and set the `esp_psram` component as a component requirement in their `CMakeLists.txt` project files.
- `esp_spiram_get_chip_size` and `esp_spiram_get_size` have been deleted. You should use `esp_psram_get_size` instead.

eFuse

- The parameter type of function `esp_secure_boot_read_key_digests()` changed from `ets_secure_boot_key_digests_t*` to `esp_secure_boot_key_digests_t*`. The new type is the same as the old one, except that the `allow_key_revoke` flag has been removed. The latter was always set to `true` in current code, not providing additional information.
- Added eFuse wafer revisions: major and minor. The `esp_efuse_get_chip_ver()` API is not compatible with these changes, so it was removed. Instead, please use the following APIs: `efuse_hal_get_major_chip_version()`, `efuse_hal_get_minor_chip_version()` or `efuse_hal_chip_revision()`.

esp_common `EXT_RAM_ATTR` is deprecated. Use the new macro `EXT_RAM_BSS_ATTR` to put `.bss` on PSRAM.

esp_system

- The header files `esp_random.h`, `esp_mac.h`, and `esp_chip_info.h`, which were all previously indirectly included via the header file `esp_system.h`, must now be included directly. These indirect inclusions from `esp_system.h` have been removed.
- The Backtrace Parser API (functions/types/macros prefixed with `esp_eh_frame_`) has been made into a private API. Thus, the previous include path `#include "eh_frame_parser.h"` has been removed. If users still require usage of the Backtrace Parser API (though this is not recommended), it can be included via `#include "esp_private/eh_frame_parser.h"`.
- The Interrupt Watchdog API (functions/types/macros prefixed with `esp_int_wdt_`) has been made into a private API. Thus, the previous include path `#include "esp_int_wdt.h"` has been removed. If users still require usage of the Interrupt Watchdog API (though this is not recommended), it can be included via `#include "esp_private/esp_int_wdt.h"`.

SoC Dependency

- Public API headers listed in the Doxyfiles will not expose unstable and unnecessary SoC header files, such as `soc/soc.h` and `soc/rtc.h`. That means the user has to explicitly include them in their code if these "missing" header files are still wanted.
- Kconfig option `LEGACY_INCLUDE_COMMON_HEADERS` is also removed.
- The header file `soc/soc_memory_types.h` has been deprecated. Users should use the `esp_memory_utils.h` instead. Including `soc/soc_memory_types.h` will bring a build warning like `soc_memory_types.h is deprecated, please migrate to esp_memory_utils.h`

APP Trace One of the timestamp sources has changed from the legacy timer group driver to the new *GPTimer*. Kconfig choices like `APPTRACE_SV_TS_SOURCE_TIMER00` has been changed to `APPTRACE_SV_TS_SOURCE_GPTIMER`. User no longer need to choose the group and timer ID.

esp_timer The FRC2-based legacy implementation of `esp_timer` available on ESP32 has been removed. The simpler and more efficient implementation based on the LAC timer is now the only option.

ESP Image The image SPI speed enum definitions have been renamed.

- Enum `ESP_IMAGE_SPI_SPEED_80M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_1`.
- Enum `ESP_IMAGE_SPI_SPEED_40M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_2`.
- Enum `ESP_IMAGE_SPI_SPEED_26M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_3`.
- Enum `ESP_IMAGE_SPI_SPEED_20M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_4`.

Task Watchdog Timers

- The API for `esp_task_wdt_init()` has changed as follows:
  - Configuration is now passed as a configuration structure.
  - The function will now handle subscribing of the idle tasks if configured to do so.
- The former `CONFIG_ESP_TASK_WDT` configuration option has been renamed to *CONFIG_ESP_TASK_WDT_INIT* and a new *CONFIG_ESP_TASK_WDT_EN* option has been introduced.

FreeRTOS

Legacy API and Data Types Previously, the `configENABLE_BACKWARD_COMPATIBILITY` option was set by default, thus allowing pre FreeRTOS v8.0.0 function names and data types to be used. The `configENABLE_BACKWARD_COMPATIBILITY` is now disabled by default, thus legacy FreeRTOS names/types are no longer supported by default. Users should do one of the following:

- Update their code to remove usage of legacy FreeRTOS names/types.
- Enable the *CONFIG_FREERTOS_ENABLE_BACKWARD_COMPATIBILITY* to explicitly allow the usage of legacy names/types.

Tasks Snapshot The header `task_snapshot.h` has been removed from `freertos/task.h`. ESP-IDF developers should include `freertos/task_snapshot.h` if they need tasks snapshot API.

The function `vTaskGetSnapshot()` now returns `BaseType_t`. Return value shall be `pdTRUE` on success and `pdFALSE` otherwise.

FreeRTOS Asserts Previously, FreeRTOS asserts were configured separately from the rest of the system using the `FREERTOS_ASSERT` kconfig option. This option has now been removed and the configuration is now done through `COMPILER_OPTIMIZATION_ASSERTION_LEVEL`.

Port Macro API The file `portmacro_deprecated.h` which was added to maintain backward compatibility for deprecated APIs is removed. Users are advised to use the alternate functions for the deprecated APIs as listed below:

- `portENTER_CRITICAL_NESTED()` is removed. Users should use the `portSET_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `portEXIT_CRITICAL_NESTED()` is removed. Users should use the `portCLEAR_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `vPortCPUInitializeMutex()` is removed. Users should use the `spinlock_initialize()` function instead.
- `vPortCPUAcquireMutex()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUAcquireMutexTimeout()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUReleaseMutex()` is removed. Users should use the `spinlock_release()` function instead.

App Update

- The functions *`esp_ota_get_app_description()`* and *`esp_ota_get_app_elf_sha256()`* have been termed as deprecated. Please use the alternative functions *`esp_app_get_description()`* and *`esp_app_get_elf_sha256()`* respectively. These functions have now been moved to a new component esp_app_format. Please refer to the header file esp_app_desc.h .

Bootloader Support

- The *`esp_app_desc_t`* structure, which used to be declared in esp_app_format.h , is now declared in esp_app_desc.h .
- The function `bootloader_common_get_partition_description()` has now been made private. Please use the alternative function *`esp_ota_get_partition_description()`*. Note that this function takes *`esp_partition_t`* as its first argument instead of `esp_partition_pos_t`.

Chip Revision The bootloader checks the chip revision at the beginning of the application loading. The application can only be loaded if the version is >= *CONFIG_ESP32C3_REV_MIN* and < `CONFIG_ESP32C3_REV_MAX_FULL`.

During the OTA upgrade, the version requirements and chip revision in the application header are checked for compatibility. The application can only be updated if the version is >= *CONFIG_ESP32C3_REV_MIN* and < `CONFIG_ESP32C3_REV_MAX_FULL`.

Tools

ESP-IDF Monitor ESP-IDF Monitor makes the following changes regarding baud-rate:

- ESP-IDF monitor now uses the custom console baud-rate (*CONFIG_ESP_CONSOLE_UART_BAUDRATE*) by default instead of 115200.
- Setting a custom baud from menuconfig is no longer supported.
- A custom baud-rate can be specified from command line with the `idf.py monitor -b <baud>` command or through setting environment variables.
- Please note that the baud-rate argument has been renamed from `-B` to `-b` in order to be consistent with the global baud-rate `idf.py -b <baud>`. Run `idf.py monitor --help` for more information.

Deprecated Commands `idf.py` sub-commands and `cmake` target names have been unified to use hyphens (-) instead of underscores (_). Using a deprecated sub-command or target name will produce a warning. Users are advised to migrate to using the new sub-commands and target names. The following changes have been made:

Table 1: Deprecated Sub-command and Target Names

Old Name	New Name
efuse_common_table	efuse-common-table
efuse_custom_table	efuse-custom-table
erase_flash	erase-flash
partition_table	partition-table
partition_table-flash	partition-table-flash
post_debug	post-debug
show_efuse_table	show-efuse-table
erase_otadata	erase-otadata
read_otadata	read-otadata

Esptool The `CONFIG_ESPTOOLPY_FLASHSIZE_DETECT` option has been renamed to *CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE* and has been disabled by default. New and existing projects migrated to ESP-IDF v5.0 have to set *CONFIG_ESPTOOLPY_FLASHSIZE*. If this is not possible due to an unknown flash size at build time, then *CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE* can be enabled. However, once enabled, to keep the digest valid, an SHA256 digest is no longer appended to the image when updating the binary header with the flash size during flashing.

Windows Environment The Msys/Mingw-based Windows environment support got deprecated in ESP-IDF v4.0 and was entirely removed in v5.0. Please use *ESP-IDF Tools Installer* to set up a compatible environment. The options include Windows Command Line, Power Shell and the graphical user interface based on Eclipse IDE. In addition, a VS Code-based environment can be set up with the supported plugin: https://github.com/espressif/vscode-esp-idf-extension.

6.1.2 Migration from 5.0 to 5.1

GCC

GCC Version The previous GCC version was GCC 11.2.0. This has now been upgraded to GCC 12.2.0 on all targets. Users that need to port their code from GCC 11.2.0 to 12.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 12

Warnings The upgrade to GCC 12.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user's code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter and ways to fix them.

`-Wuse-after-free` Typically, this warning should not produce false-positives for release-level code. But this may appear in test cases. There is an example of how it was fixed in ESP-IDF's `test_realloc.c`.

```
void *x = malloc(64);
void *y = realloc(x, 48);
TEST_ASSERT_EQUAL_PTR(x, y);
```

Pointers may be converted to int to avoid warning `-Wuse-after-free`.

```
int x = (int) malloc(64);
int y = (int) realloc((void *) x, 48);
TEST_ASSERT_EQUAL_UINT32((uint32_t) x, (uint32_t) y);
```

`-Waddress` GCC 12.2.0 introduces an enhanced version of the `-Waddress` warning option, which is now more eager in detecting the checking of pointers to an array in if-statements.

The following code triggers the warning:

```
char array[8];
...
if (array)
    memset(array, 0xff, sizeof(array));
```

Eliminating unnecessary checks resolves the warning.

```
char array[8];
...
memset(array, 0xff, sizeof(array));
```

RISC-V Builds Outside of ESP-IDF The RISC-V extensions `zicsr` and `zifencei` have been separated from the `I` extension. GCC 12 reflects this change, and as a result, when building for RISC-V ESP32 chips outside of the ESP-IDF framework, you must include the `_zicsr_zifencei` postfix when specifying the -march option in your build system.

Example:

```
riscv32-esp-elf-gcc main.c -march=rv32imac
```

Now is replaced with:

```
riscv32-esp-elf-gcc main.c -march=rv32imac_zicsr_zifencei
```

Peripherals

GPSPI Following items are deprecated. Since ESP-IDF v5.1, GPSPI clock source is configurable.

- `spi_get_actual_clock` is deprecated, you should use *`spi_device_get_actual_freq()`* instead.

LEDC

- *`soc_periph_ledc_clk_src_legacy_t::LEDC_USE_RTC8M_CLK`* is deprecated. Please use `LEDC_USE_RC_FAST_CLK` instead.

Storage

FatFs `esp_vfs_fat_sdmmc_unmount()` is now deprecated, and you can use *`esp_vfs_fat_sdcard_unmount()`* instead. This API is deprecated in previous ESP-IDF versions, but without a deprecation warning or migration guide. Since ESP-IDF v5.1, calling this `esp_vfs_fat_sdmmc_unmount()` API will generate a deprecation warning.

SPI_FLASH

- *`spi_flash_get_counters()`* is deprecated, please use *`esp_flash_get_counters()`* instead.
- *`spi_flash_dump_counters()`* is deprecated, please use *`esp_flash_dump_counters()`* instead.
- *`spi_flash_reset_counters()`* is deprecated, please use *`esp_flash_reset_counters()`* instead.

Networking

SNTP SNTP module now provides thread safe APIs to access lwIP functionality. It is recommended to use *ESP_NETIF* API. Please refer to the chapter *SNTP API* for more details.

System

FreeRTOS

Power Management

- `esp_pm_config_esp32xx_t` is deprecated, use `esp_pm_config_t` instead.
- `esp32xx/pm.h` is deprecated, use `esp_pm.h` instead.

6.1.3 Migration from 5.1 to 5.2

GCC

GCC Version The previous GCC version was GCC 12.2.0. This has now been upgraded to GCC 13.2.0 on all targets. Users that need to port their code from GCC 12.2.0 to 13.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 13

Common Porting Problems and Fixes

`stdio.h` No Longer Includes `sys/types.h`

Issue Compilation errors may occur in code that previously worked with the old toolchain. For example:

```
#include <stdio.h>
clock_t var; // error: expected specifier-qualifier-list before 'clock_t'
```

Solution To resolve this issue, the correct header must be included. Refactor the code like this:

```
#include <time.h>
clock_t var;
```

Peripherals

UART

- *`UART_FIFO_LEN`* is deprecated. Please use *`UART_HW_FIFO_LEN`* instead.

I2C I2C driver has been redesigned (see *I2C API Reference*), which aims to unify the interface and extend the usage of I2C peripheral. Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/i2c.h`.

The major breaking changes in concept and usage are listed as follows:

Major Changes in Concepts

- `i2c_config_t` which was used to configure the I2C bus, but it doesn't really tell whether to configure master or slave. So in the new design, master and slave initialization are separate, user can call `i2c_master_bus_config_t` or `i2c_slave_config_t`.
- `i2c_mode_t` which was used to tell whether I2C controller works in slave mode or master mode. This enumerator has been deprecated. In the new driver, users don'tneed to manually set the mode anymore since master and slave APIs are different.
- `i2c_rw_t` which was used to tell whether I2C master controller is performing a *write* or a *read* operation. This is now deprecated.
- `i2c_addr_mode_t` was renamed to `i2c_addr_bit_len_t`.

- In the legacy driver, operations needed to be chained with a command list (dynamically or statically created). The new driver now handles this internally, making the operations more size and space efficient.
- Capability flags like `I2C_SCLK_SRC_FLAG_FOR_NOMAL` are used to select clock source in the legacy driver. In the new driver, users can select clock source directly.

Major Changes in Usage

- I2C bus initialization is done in two parts: first, initialization of the bus with *`i2c_new_master_bus()`*, then, initialization of the I2C device with *`i2c_master_bus_add_device()`*.
- `i2c_reset_tx_fifo` and `i2c_reset_rx_fifo` have been removed, since it is never required to reset the fifo by users. Whole bus can still be reset by calling `i2c_master_bus_reset`.
- `i2c_cmd_link_xxx` functions have been removed, user doesn't need to use link to link commands on its own.
- `i2c_master_write_to_device` has been renamed to `i2c_master_transmit`.
- `i2c_master_read_from_device` has been renamed to `i2c_master_receive`.
- `i2c_master_write_read_device` has been renamed to `i2c_master_transmit_receive`
- `i2c_slave_write_buffer` has been renamed to `i2c_slave_transmit`
- `i2c_slave_read_buffer` has been renamed to `i2c_slave_receive`

Protocols

CoAP CoAP examples have been moved to idf-extra-components repository.

HTTP2 http2_request example has been moved to idf-extra-components repository.

Storage

NVS Encryption

- For SoCs with the HMAC peripheral (`SOC_HMAC_SUPPORTED`), turning on *Flash Encryption* will no longer automatically turn on *NVS Encryption*.
- You will need to explicitly turn on NVS encryption and select the required scheme (flash encryption-based or HMAC peripheral-based). You can select the HMAC peripheral-based scheme (*CONFIG_NVS_SEC_KEY_PROTECTION_SCHEME*), even if flash encryption is not enabled.
- SoCs without the HMAC peripheral will still automatically turn on NVS encryption when flash encryption is enabled.

System

FreeRTOS

IDF FreeRTOS Upgrade The IDF FreeRTOS kernel (which is a dual-core SMP implementation of FreeRTOS) has been upgraded to be based on Vanilla FreeRTOS v10.5.1. With this upgrade, the design and implementation of IDF FreeRTOS has also been changed significantly. As a result, users should take note of the following changes to kernel behavior and API:

- When enabling single-core mode via the *CONFIG_FREERTOS_UNICORE* option, the kernel's behavior will now be identical to Vanilla FreeRTOS (see *Single-Core Mode* for more details).
- For SMP related APIs that were added by IDF FreeRTOS, checks on `xCoreID` arguments are now stricter. Providing out of range values for `xCoreID` arguments will now trigger an assert.
- The following SMP related APIs are now deprecated and replaced due to naming consistency reasons:
  - `xTaskGetAaffinity()` is deprecated, call `xTaskGetCoreID()` instead.
  - `xTaskGetIdleTaskHandleForCPU()` is deprecated, call `xTaskGetIdleTaskHandleForCore()` instead.
  - `xTaskGetCurrentTaskHandleForCPU()` is deprecated, call `xTaskGetCurrentTaskHandleForCore()` instead.

Task Snapshot The Task Snapshot API has been made private due to a lack of a practical way for the API to be used from user code (the scheduler must be halted before the API can be called).

Panic Handler Behavior The choice `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` in the configuration option *CONFIG_ESP_SYSTEM_PANIC* has been made dependent on whether the `esp_gdbstub` component is included in the build. When trimming the list of components in the build using `set(COMPONENTS main)`, `esp_gdbstub` component has to be added to this list of components to make the `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` option available.

Wi-Fi

Wi-Fi Enterprise Security APIs defined in *esp_wpa2.h* have been deprecated. Please use newer APIs from *esp_eap_client.h*.

Wi-Fi Disconnect Reason Codes For the event WIFI_EVENT_STA_DISCONNECTED, the original reason code WIFI_REASON_NO_AP_FOUND has been split as follows:

- REASON_NO_AP_FOUND(original and still used in some scenarios)
- REASON_NO_AP_FOUND_IN_RSSI_THRESHOLD
- REASON_NO_AP_FOUND_IN_AUTHMODE_THRESHOLD
- REASON_NO_AP_FOUND_W_COMPATIBLE_SECURITY

For details, please refer to *Wi-Fi Reason Code*.

WiFi Multiple Antennas WiFi multiple antennas api will be deprecated. Please use newer APIs from *esp_phy.h*.

6.1.4 Migration from 5.2 to 5.3

Bluetooth Classic

Bluedroid

The following Bluedroid API have been deprecated:

- /bt/host/bluedroid/api/include/api/esp_bt_device.h
  - Deprecate `esp_err_t esp_bt_dev_set_device_name(const char *name)`

    * Set device name API has been replaced by `esp_err_t esp_bt_gap_set_device_name(const char *name)` or `esp_err_t esp_ble_gap_set_device_name(const char *name)`. The original function has been deprecated.
  - Deprecate `esp_err_t esp_bt_dev_get_device_name(void)`
    * Get device name API has been replaced by `esp_err_t esp_bt_gap_get_device_name(void)` or `esp_err_t esp_ble_gap_get_device_name(void)`. The original function has been deprecated.

GCC

Common Porting Problems and Fixes

`sys/dirent.h` No Longer Includes Function Prototypes

Issue Compilation errors may occur in code that previously worked with the old toolchain. For example:

```
#include <sys/dirent.h>
/* .... */
DIR* dir = opendir("test_dir");
/* .... */
/**
 * Compile error:
 * test.c: In function 'test_opendir':
 * test.c:100:16: error: implicit declaration of function 'opendir' [-
↪Werror=implicit-function-declaration]
 *   100 |     DIR* dir = opendir(path);
 *       |                ^~~~~~~
 */
```

Solution To resolve this issue, the correct header must be included. Refactor the code like this:

```
#include <dirent.h>
/* .... */
DIR* dir = opendir("test_dir");
```

Peripherals

Drivers In order to control the dependence of other components on drivers at a smaller granularity, the original peripheral drivers under the `driver` component were split into separate components:

- *esp_driver_gptimer* - Driver for general purpose timers
- *esp_driver_pcnt* - Driver for pulse counter
- *esp_driver_gpio* - Driver for GPIO
- *esp_driver_spi* - Driver for GPSPI
- *esp_driver_mcpwm* - Driver for Motor Control PWM
- *esp_driver_sdmmc* - Driver for SDMMC
- *esp_driver_sdspi* - Driver for SDSPI
- *esp_driver_sdio* - Driver for SDIO

- *esp_driver_ana_cmpr* - Driver for Analog Comparator
- *esp_driver_i2s* - Driver for I2S
- *esp_driver_dac* - Driver for DAC
- *esp_driver_rmt* - Driver for RMT
- *esp_driver_tsens* - Driver for Temperature Sensor
- *esp_driver_sdm* - Driver for Sigma-Delta Modulator
- *esp_driver_i2c* - Driver for I2C
- *esp_driver_uart* - Driver for UART
- *esp_driver_ledc* - Driver for LEDC
- *esp_driver_parlio* - Driver for Parallel IO
- *esp_driver_usb_serial_jtag* - Driver for USB_SERIAL_JTAG

For compatibility, the original `driver` component is still treated as an all-in-one component by registering these *esp_driver_xyz* components as its public dependencies. In other words, you do not need to modify the CMake file of an existing project, but you now have a way to specify the specific peripheral driver that your project depends on.

Originally, you may have used **linker.lf** to specify the link location of some driver functions in memory space, but now, because the location of the driver files have been moved, you need to make changes your **linker.lf** file accordingly. For example, a linker.lf file with the following entries:

```
[mapping:my_mapping_scheme]
archive: libdriver.a
entries:
    gpio (noflash)
```

Should be changed to:

```
[mapping:my_mapping_scheme]
archive: libesp_driver_gpio.a
entries:
    gpio (noflash)
```

Secure Element The ATECC608A secure element interfacing example has been moved to ESP Cryptoauthlib Repository on GitHub.

This example is also part of the esp-cryptoauthlib in the component manager registry.

I2S Due to the cumbersome usage of the secondary pointer of DMA buffer, the `data` field in the callback event `i2s_event_data_t` is deprecated, please use the newly added first-level pointer `dma_buf` instead.

Protocols

ESP HTTPS OTA

Breaking Changes (Summary)

- If the image length is found in the HTTP header and `esp_https_ota_config_t::bulk_flash_erase` is set to true, then instead of erasing the entire flash, the erase operation will be performed to accommodate the size of the image length.

Security

Platform security features When flash encryption is enabled, only the app images present in the app partition are encrypted, instead of encrypting the whole partition. This can help to optimize the encryption time required during the first boot.

This could be configured using the config `CONFIG_SECURE_FLASH_ENCRYPT_ONLY_IMAGE_LEN_IN_APP_PART`, which is enabled by default from ESP-IDF v5.3, and is disabled for all earlier releases to avoid any breaking behaviour.

Storage

VFS The UART implementation of VFS operators has been moved from *vfs* component to *esp_driver_uart* component.

APIs with *esp_vfs_dev_uart_* prefix are all deprecated, replaced with new APIs in *uart_vfs.h* starting with *uart_vfs_dev_* prefix. Specifically, - `esp_vfs_dev_uart_register` has been renamed to `uart_vfs_dev_register` - `esp_vfs_dev_uart_port_set_rx_line_endings` has been renamed to `uart_vfs_dev_port_set_rx_line_endings` - `esp_vfs_dev_uart_port_set_tx_line_endings` has been renamed to `uart_vfs_dev_port_set_tx_line_endings` - `esp_vfs_dev_uart_use_nonblocking` has been renamed to `uart_vfs_dev_use_nonblocking` - `esp_vfs_dev_uart_use_driver` has been renamed to `uart_vfs_dev_use_driver`

For compatibility, *vfs* component still registers *esp_driver_uart* as its private dependency. In other words, you do not need to modify the CMake file of an existing project.

System

Power Management

- `esp_sleep_enable_ext1_wakeup_with_level_mask` is deprecated, use `esp_sleep_enable_ext1_wakeup_io()` and `esp_sleep_disable_ext1_wakeup_io()` instead.

Unit Testing In the past versions of Unity framework, it was possible to omit a semicolon at the end of a `TEST_ASSERT_*` macro statement. This is no longer the case in the newer version of Unity, used in ESP-IDF v5.3.

For example, the following code:

```
TEST_ASSERT(some_func() == ESP_OK)
```

will now result in a compilation error. To fix this, add a semicolon at the end of the statement:

TEST_ASSERT(some_func() == ESP_OK);

Partition Table Partition Table generation tool has been fixed to ensure that the size of partition of type `app` is having flash sector (minimum erase size) aligned size (please see *Offset & Size*). If the partition does not have aligned size, partition table generator tool will raise an error. This fix ensures that OTA updates for a case where the file size is close or equal to the size of partition works correctly (erase operation does not go beyond the partition size).

In case you have the `app` partition size which is not a multiple of the 4 KB then please note that while migrating to ESP-IDF v5.3, you must align this size to its lower 4 KB boundary for the build to succeed. This does not impact the partition table for existing devices as such but ensures that generated firmware size remains within the OTA update capability limit.

6.1.5 Migration from 5.3 to 5.4

System

Log

- *esp_log_buffer_hex* is deprecated, use *ESP_LOG_BUFFER_HEX* instead.
- *esp_log_buffer_char* is deprecated, use *ESP_LOG_BUFFER_CHAR* instead.

ESP ROM

- All target-specific header files has been moved from *components/esp_rom/include/{target}/* to */esp_rom/{target}/include/{target}/*, and *components/esp_rom/CMakeLists.txt* has been modified accordingly. If you encounter an error indicating a missing header file, such as `fatal error: esp32s3/rom/efuse.h: No such file or directory`, try removing the leading relative path from the header file include command. In your current and future development, when including any header files located in *components/esp_rom* path, directly use the header file name without the chip-specific relative folder path.
- All target-specific *rom/miniz.h* files are removed because they are deprecated.

Chapter 7

Libraries and Frameworks

7.1 Cloud Frameworks

ESP32-C3 supports multiple cloud frameworks using agents built on top of ESP-IDF. Here are the pointers to various supported cloud frameworks' agents and examples:

7.1.1 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. ESP RainMaker on GitHub.

7.1.2 AWS IoT

https://github.com/espressif/esp-aws-iot is an open source repository for ESP32-C3 based on Amazon Web Services' aws-iot-device-sdk-embedded-C.

7.1.3 Azure IoT

https://github.com/espressif/esp-azure is an open source repository for ESP32-C3 based on Microsoft Azure's azure-iot-sdk-c SDK.

7.1.4 Google IoT Core

https://github.com/espressif/esp-google-iot is an open source repository for ESP32-C3 based on Google's iot-device-sdk-embedded-c SDK.

7.1.5 Aliyun IoT

https://github.com/espressif/esp-aliyun is an open source repository for ESP32-C3 based on Aliyun's iotkit-embedded SDK.

7.1.6 Joylink IoT

https://github.com/espressif/esp-joylink is an open source repository for ESP32-C3 based on Joylink's joylink_dev_sdk SDK.

7.1.7 Tencent IoT

https://github.com/espressif/esp-welink is an open source repository for ESP32-C3 based on Tencent's welink SDK.

7.1.8 Tencentyun IoT

https://github.com/espressif/esp-qcloud is an open source repository for ESP32-C3 based on Tencentyun's qcloud-iot-sdk-embedded-c SDK.

7.1.9 Baidu IoT

https://github.com/espressif/esp-baidu-iot is an open source repository for ESP32-C3 based on Baidu's iot-sdk-c SDK.

7.2 Espressif's Frameworks

Here you will find a collection of the official Espressif libraries and frameworks.

7.2.1 Espressif Audio Development Framework

The ESP-ADF is a comprehensive framework for audio applications including:

- CODEC's HAL
- Music players and recorders
- Audio processing
- Bluetooth speakers
- Internet radios
- Hands-free devices
- Speech decognition

This framework is available on GitHub: ESP-ADF.

7.2.2 ESP-CSI

ESP-CSI is an experimental implementation that uses the Wi-Fi Channel State Information to detect the presence of a human body.

See the ESP-CSI project for more information.

7.2.3 Espressif DSP Library

The library provides algorithms optimized specifically for digital signal processing applications. This library supports:

- Matrix multiplication
- Dot product
- FFT (Fast Fourier Transform)

- IIR (Infinite Impulse Response)
- FIR (Finite Impulse Response)
- Vector math operations

This library is available on Github: ESP-DSP library.

7.2.4 ESP-WIFI-MESH Development Framework

This framework is based on the ESP-WIFI-MESH protocol with the following features:

- Fast network configuration
- Stable upgrade
- Efficient debugging
- LAN control
- Various application demos

This framework is available on Github: ESP-MDF.

7.2.5 ESP-WHO

The ESP-WHO is a face detection and recognition framework using the ESP32 and camera.

This framework is available on Github: ESP-WHO.

7.2.6 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. Using ESP RainMaker, you can create AIoT devices from the firmware to the integration with voice-assistant, phone apps and cloud backend.

This project is available on Github: ESP RainMaker on GitHub.

7.2.7 ESP-IoT-Solution

ESP-IoT-Solution contains commonly used device drivers and code frameworks when developing IoT systems. The device drivers and code frameworks within the ESP-IoT-Solution are organized as separate components, allowing them to be easily integrated into an ESP-IDF project.

ESP-IoT-Solution includes:

- Device drivers for sensors, display, audio, GUI, input, actuators, etc.
- Framework and documentation for low power, security, storage, etc.
- Guide for Espressif open source solutions from practical application point.

This solution is available on Github: ESP-IoT-Solution on GitHub.

7.2.8 ESP-Protocols

The ESP-Protocols repository contains a collection of protocol components for ESP-IDF. The code within ESP-Protocols is organized into separate components, allowing them to be easily integrated into an ESP-IDF project. Additionally, each component is available in IDF Component Registry.

ESP-Protocols components:

- esp_modem enables connectivity with GSM/LTE modems using AT commands or PPP protocol. See the esp_modem documentation.
- mdns (mDNS) is a multicast UDP service that is used to provide local network service and host discovery. See the mdns documentation.

- esp_websocket_client is a managed component for ESP-IDF that contains implementation of WebSocket protocol client for ESP32. See the esp_websocket_client documentation. For detailes of WebSocket protocol client, see WebSocket_protocol_client.
- asio is a cross-platform C++ library, see https://think-async.com/Asio/. It provides a consistent asynchronous model using a modern C++ approach. See the asio documentation.

7.2.9 ESP-BSP

The ESP-BSP repository contains Board Support Packages (BSPs) for various Espressif's and third-party development boards. BSPs help to quickly get started with a supported board. Usually they contain pinout definition and helper functions that will initialize peripherals for the specific board. Additionally, the BSPs contain drivers for external chips populated on the development board, such as sensors, displays, audio codecs, etc.

7.2.10 ESP-IDF-CXX

ESP-IDF-CXX contains C++ wrappers for part of ESP-IDF. The focuses are on ease of use, safety, automatic resource management. They also move error checking from runtime to compile time to prevent running failure. There are C++ classes for ESP-Timer, I2C, SPI, GPIO and other peripherals or features of ESP-IDF. ESP-IDF-CXX is available as a component from the component registry. Please check the project's README.md for more information.

Chapter 8

Contributions Guide

We welcome contributions to the ESP-IDF project!

8.1 How to Contribute

Contributions to ESP-IDF - fixing bugs, adding features, adding documentation - are welcome. We accept contributions via Github Pull Requests.

8.2 Before Contributing

Before sending us a Pull Request, please consider this list of points:

- Is the contribution entirely your own work, or already licensed under an Apache License 2.0 compatible Open Source License? If not then we unfortunately cannot accept it. Please check the *Copyright Header Guide* for additional information.
- Does any new code conform to the ESP-IDF *Style Guide*?
- Have you installed the *pre-commit hook* for ESP-IDF project?
- Does the code documentation follow requirements in *Documenting Code*?
- Is the code adequately commented for people to understand how it is structured?
- Is there documentation or examples that go with code contributions? There are additional suggestions for writing good examples in examples readme.
- Are comments and documentation written in clear English, with no spelling or grammar errors?
- Example contributions are also welcome. Please check the *Creating Examples* guide for these.
- If the contribution contains multiple commits, are they grouped together into logical changes (one major change per pull request)? Are any commits with names like "fixed typo" squashed into previous commits?
- If you are unsure about any of these points, please open the Pull Request anyhow and then ask us for feedback.

8.3 Pull Request Process

After you open the Pull Request, there will probably be some discussion in the comments field of the request itself.

Once the Pull Request is ready to merge, it will first be merged into our internal git system for in-house automated testing.

If this process passes, it will be merged into the public GitHub repository.

8.4 Legal Part

Before a contribution can be accepted, you will need to sign our *Contributor Agreement*. You will be prompted for this automatically as part of the Pull Request process.

8.5 Related Documents

8.5.1 Espressif IoT Development Framework Style Guide

About This Guide

Purpose of this style guide is to encourage use of common coding practices within the ESP-IDF.

Style guide is a set of rules which are aimed to help create readable, maintainable, and robust code. By writing code which looks the same way across the code base we help others read and comprehend the code. By using same conventions for spaces and newlines we reduce chances that future changes will produce huge unreadable diffs. By following common patterns for module structure and by using language features consistently we help others understand code behavior.

We try to keep rules simple enough, which means that they can not cover all potential cases. In some cases one has to bend these simple rules to achieve readability, maintainability, or robustness.

When doing modifications to third-party code used in ESP-IDF, follow the way that particular project is written. That will help propose useful changes for merging into upstream project.

C Code Formatting

Naming

- Any variable or function which is only used in a single source file should be declared `static`.
- Public names (non-static variables and functions) should be namespaced with a per-component or per-unit prefix, to avoid naming collisions. ie `esp_vfs_register()` or `esp_console_run()`. Starting the prefix with `esp_` for Espressif-specific names is optional, but should be consistent with any other names in the same component.
- Static variables should be prefixed with `s_` for easy identification. For example, `static bool s_invert`.
- Avoid unnecessary abbreviations (ie shortening `data` to `dat`), unless the resulting name would otherwise be very long.

Indentation Use 4 spaces for each indentation level. Do not use tabs for indentation. Configure the editor to emit 4 spaces each time you press tab key.

Vertical Space Place one empty line between functions. Do not begin or end a function with an empty line.

```
void function1()
{
    do_one_thing();
    do_another_thing();
                                // INCORRECT, do not place empty line here
}
                                // place empty line here
void function2()
{
                                // INCORRECT, do not use an empty line here
    int var = 0;
    while (var < SOME_CONSTANT) {
        do_stuff(&var);
```

(continues on next page)

(continued from previous page)

```
    }
}
```

The maximum line length is 120 characters as long as it does not seriously affect the readability.

Horizontal Space Always add single space after conditional and loop keywords:

```
if (condition) {     // correct
    // ...
}

switch (n) {         // correct
    case 0:
        // ...
}

for(int i = 0; i < CONST; ++i) {     // INCORRECT
    // ...
}
```

Add single space around binary operators. No space is necessary for unary operators. It is okay to drop space around multiply and divide operators:

```
const int y = y0 + (x - x0) * (y1 - y0) / (x1 - x0);     // correct

const int y = y0 + (x - x0)*(y1 - y0)/(x1 - x0);         // also okay

int y_cur = -y;                                          // correct
++y_cur;

const int y = y0+(x-x0)*(y1-y0)/(x1-x0);                 // INCORRECT
```

No space is necessary around `.` and `->` operators.

Sometimes adding horizontal space within a line can help make code more readable. For example, you can add space to align function arguments:

```
esp_rom_gpio_connect_in_signal(PIN_CAM_D6,   I2S0I_DATA_IN14_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_D7,   I2S0I_DATA_IN15_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_HREF, I2S0I_H_ENABLE_IDX,  false);
esp_rom_gpio_connect_in_signal(PIN_CAM_PCLK, I2S0I_DATA_IN15_IDX, false);
```

Note however that if someone goes to add new line with a longer identifier as first argument (e.g., `PIN_CAM_VSYNC`), it will not fit. So other lines would have to be realigned, adding meaningless changes to the commit.

Therefore, use horizontal alignment sparingly, especially if you expect new lines to be added to the list later.

Never use TAB characters for horizontal alignment.

Never add trailing whitespace at the end of the line.

Braces

- Function definition should have a brace on a separate line:

```
// This is correct:
void function(int arg)
{

}
```

(continues on next page)

(continued from previous page)

```
// NOT like this:
void function(int arg) {

}
```

- Within a function, place opening brace on the same line with conditional and loop statements:

```
if (condition) {
    do_one();
} else if (other_condition) {
    do_two();
}
```

Comments Use `//` for single line comments. For multi-line comments it is okay to use either `//` on each line or a `/* */` block.

Although not directly related to formatting, here are a few notes about using comments effectively.

- Do not use single comments to disable some functionality:

```
void init_something()
{
    setup_dma();
    // load_resources();                // WHY is this thing commented, asks␣
↪the reader?
    start_timer();
}
```

- If some code is no longer required, remove it completely. If you need it you can always look it up in git history of this file. If you disable some call because of temporary reasons, with an intention to restore it in the future, add explanation on the adjacent line:

```
void init_something()
{
    setup_dma();
    // TODO: we should load resources here, but loader is not fully integrated␣
↪yet.
    // load_resources();
    start_timer();
}
```

- Same goes for `#if 0 ... #endif` blocks. Remove code block completely if it is not used. Otherwise, add comment explaining why the block is disabled. Do not use `#if 0 ... #endif` or comments to store code snippets which you may need in the future.
- Do not add trivial comments about authorship and change date. You can always look up who modified any given line using git. E.g., this comment adds clutter to the code without adding any useful information:

```
void init_something()
{
    setup_dma();
    // XXX add 2016-09-01
    init_dma_list();
    fill_dma_item(0);
    // end XXX add
    start_timer();
}
```

Line Endings Commits should only contain files with LF (Unix style) endings.

Windows users can configure git to check out CRLF (Windows style) endings locally and commit LF endings by setting the `core.autocrlf` setting. *Github has a document about setting this option <github-line-endings>.*

If you accidentally have some commits in your branch that add LF endings, you can convert them to Unix by running this command in an MSYS2 or Unix terminal (change directory to the IDF working directory and check the correct branch is currently checked out, beforehand):

```
git rebase --exec 'git diff-tree --no-commit-id --name-only -r HEAD | xargs␣
↪dos2unix && git commit -a --amend --no-edit --allow-empty' master
```

(Note that this line rebases on master, change the branch name at the end to rebase on another branch.)

For updating a single commit, it is possible to run `dos2unix FILENAME` and then run `git commit --amend`

Formatting Your Code ESP-IDF uses Astyle to format source code. The configuration is stored in tools/ci/astyle-rules.yml file.

Initially, all components are excluded from formatting checks. You can enable formatting checks for the component by removing it from `components_not_formatted_temporary` list. Then run:

```
pre-commit run --files <path_to_files> astyle_py
```

Alternatively, you can run `astyle_py` manually. You can install it with `pip install astyle_py==VERSION`. Make sure you have the same version installed as the one specified in .pre-commit-config.yaml file. With `astyle_py` installed, run:

```
astyle_py --rules=$IDF_PATH/tools/ci/astyle-rules.yml <path-to-file>
```

Type Definitions Should be snake_case, ending with _t suffix:

```
typedef int signed_32_bit_t;
```

Enum Enums should be defined through the *typedef* and be namespaced:

```
typedef enum
{
    MODULE_FOO_ONE,
    MODULE_FOO_TWO,
    MODULE_FOO_THREE
} module_foo_t;
```

Assertions The standard C `assert()` function, defined in `assert.h` should be used to check conditions that should be true in source code. In the default configuration, an assert condition that returns `false` or 0 will call `abort()` and trigger a *Fatal Error*.

`assert()` should only be used to detect unrecoverable errors due to a serious internal logic bug or corruption, where it is not possible for the program to continue. For recoverable errors, including errors that are possible due to invalid external input, an *error value should be returned*.

Note: When asserting a value of type `esp_err_t` is equal to `ESP_OK`, use the *ESP_ERROR_CHECK Macro* instead of an `assert()`.

It is possible to configure ESP-IDF projects with assertions disabled (see *CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL*). Therefore, functions called in an `assert()` statement should not have side-effects.

It is also necessary to use particular techniques to avoid "variable set but not used" warnings when assertions are disabled, due to code patterns such as:

```
int res = do_something();
assert(res == 0);
```

Once the `assert` is optimized out, the `res` value is unused and the compiler will warn about this. However the function `do_something()` must still be called, even if assertions are disabled.

When the variable is declared and initialized in a single statement, a good strategy is to cast it to `void` on a new line. The compiler will not produce a warning, and the variable can still be optimized out of the final binary:

```
int res = do_something();
assert(res == 0);
(void)res;
```

If the variable is declared separately, for example if it is used for multiple assertions, then it can be declared with the GCC attribute `__attribute__((unused))`. The compiler will not produce any unused variable warnings, but the variable can still be optimized out:

```
int res __attribute__((unused));

res = do_something();
assert(res == 0);

res = do_something_else();
assert(res != 0);
```

Header File Guards

All public facing header files should have preprocessor guards. A pragma is preferred:

```
#pragma once
```

over the following pattern:

```
#ifndef FILE_NAME_H
#define FILE_NAME_H
...
#endif // FILE_NAME_H
```

In addition to guard macros, all C header files should have `extern "C"` guards to allow the header to be used from C++ code. Note that the following order should be used: `pragma once`, then any `#include` statements, then `extern "C"` guards:

```
#pragma once

#include <stdint.h>

#ifdef __cplusplus
extern "C" {
#endif

/* declarations go here */

#ifdef __cplusplus
}
#endif
```

Include Statements

When writing `#include` statements, try to maintain the following order:

- C standard library headers.
- Other POSIX standard headers and common extensions to them (such as `sys/queue.h`.)
- Common IDF headers (`esp_log.h`, `esp_system.h`, `esp_timer.h`, `esp_sleep.h`, etc.)
- Headers of other components, such as FreeRTOS.
- Public headers of the current component.
- Private headers.

Use angle brackets for C standard library headers and other POSIX headers (`#include <stdio.h>`).

Use double quotes for all other headers (`#include "esp_log.h"`).

C++ Code Formatting

The same rules as for C apply. Where they are not enough, apply the following rules.

File Naming C++ Header files have the extension `.hpp`. C++ source files have the extension `.cpp`. The latter is important for the compiler to distinguish them from normal C source files.

Naming

- **Class and struct** names shall be written in `CamelCase` with a capital letter as beginning. Member variables and methods shall be in `snake_case`. An exception from `CamelCase` is if the readability is severely decreased, e.g., in `GPIOOutput`, then an underscore _ is allowed to make it more readable: `GPIO_Output`.
- **Namespaces** shall be in lower `snake_case`.
- **Templates** are specified in the line above the function declaration.
- Interfaces in terms of Object-Oriented Programming shall be named without the suffix `...Interface`. Later, this makes it easier to extract interfaces from normal classes and vice versa without making a breaking change.

Member Order in Classes In order of precedence:

- First put the public members, then the protected, then private ones. Omit public, protected or private sections without any members.
- First put constructors/destructors, then member functions, then member variables.

For example:

```
class ForExample {
public:
    // first constructors, then default constructor, then destructor
    ForExample(double example_factor_arg);
    ForExample();
    ~ForExample();

    // then remaining pubic methods
    set_example_factor(double example_factor_arg);

    // then public member variables
    uint32_t public_data_member;

private:
    // first private methods
    void internal_method();

    // then private member variables
    double example_factor;
};
```

Spacing

- Do not indent inside namespaces.
- Put `public`, `protected` and `private` labels at the same indentation level as the corresponding `class` label.

Simple Example

```
// file spaceship.h
#ifndef SPACESHIP_H_
#define SPACESHIP_H_
#include <cstdlib>

namespace spaceships {

class SpaceShip {
public:
    SpaceShip(size_t crew);
    size_t get_crew_size() const;

private:
    const size_t crew;
};

class SpaceShuttle : public SpaceShip {
public:
    SpaceShuttle();
};

class Sojuz : public SpaceShip {
public:
    Sojuz();
};

template <typename T>
class CargoShip {
public:
    CargoShip(const T &cargo);

private:
    T cargo;
};

} // namespace spaceships

#endif // SPACESHIP_H_

// file spaceship.cpp
#include "spaceship.h"

namespace spaceships {

// Putting the curly braces in the same line for constructors is OK if it only␣
↪initializes
// values in the initializer list
SpaceShip::SpaceShip(size_t crew) : crew(crew) { }

size_t SpaceShip::get_crew_size() const
{
    return crew;
}
```

(continues on next page)

(continued from previous page)

```
SpaceShuttle::SpaceShuttle() : SpaceShip(7)
{
    // doing further initialization
}

Sojuz::Sojuz() : SpaceShip(3)
{
    // doing further initialization
}

template <typename T>
CargoShip<T>::CargoShip(const T &cargo) : cargo(cargo) { }

} // namespace spaceships
```

CMake Code Style

- Indent with four spaces.
- Maximum line length 120 characters. When splitting lines, try to focus on readability where possible (for example, by pairing up keyword/argument pairs on individual lines).
- Do not put anything in the optional parentheses after `endforeach()`, `endif()`, etc.
- Use lowercase (`with_underscores`) for command, function, and macro names.
- For locally scoped variables, use lowercase (`with_underscores`).
- For globally scoped variables, use uppercase (`WITH_UNDERSCORES`).
- Otherwise follow the defaults of the cmake-lint project.

Configuring the Code Style for a Project Using EditorConfig

EditorConfig helps developers define and maintain consistent coding styles between different editors and IDEs. The EditorConfig project consists of a file format for defining coding styles and a collection of text editor plugins that enable editors to read the file format and adhere to defined styles. EditorConfig files are easily readable and they work nicely with version control systems.

For more information, see EditorConfig Website.

Third Party Component Code Styles

ESP-IDF integrates a number of third party components where these components may have differing code styles.

FreeRTOS The code style adopted by FreeRTOS is described in the FreeRTOS style guide. Formatting of FreeRTOS source code is automated using Uncrustify, thus a copy of the FreeRTOS code style's Uncrustify configuration (`uncrustify.cfg`) is stored within ESP-IDF FreeRTOS component.

If a FreeRTOS source file is modified, the updated file can be formatted again by following the steps below:

1. Ensure that Uncrustify (v0.69.0) is installed on your system
2. Run the following command on the update FreeRTOS source file (where `source.c` is the path to the source file that requires formatting).

```
uncrustify -c $IDF_PATH/components/freertos/FreeRTOS-Kernel/uncrustify.cfg --
↪replace source.c --no-backup
```

Documenting Code

Please see the guide here: *Documenting Code*.

Structure

To be written.

Language Features

To be written.

8.5.2 Install Pre-commit Hook for ESP-IDF Project

Install `pre-commit`

Run `pip install pre-commit`.

Install `pre-commit` Hook

1. Go to the ESP-IDF project directory.
2. Run `pre-commit install --allow-missing-config -t pre-commit -t commit-msg`. Install hook by this approach will let you commit successfully even in branches without the `.pre-commit-config.yaml`
3. pre-commit hook will run automatically when you are running `git commit` command

Uninstall `pre-commit` Hook

Run `pre-commit uninstall`.

Related Documents

For detailed usage, please refer to the documentation of pre-commit.

Common Problems For Windows Users

`/usr/bin/env: python: Permission denied.`

If you are in Git Bash, please check the python executable location by run `which python`.

If the executable is under `~/AppData/Local/Microsoft/WindowsApps/`, then it is a link to Windows AppStore, not a real one.

Please install Python manually and update this in your `PATH` environment variable.

Your `USERPROFILE` contains non-ASCII characters

`pre-commit` may fail when initializing an environment for a particular hook when the path of `pre-commit`'s cache contains non-ASCII characters. The solution is to set `PRE_COMMIT_HOME` to a path containing only standard characters before running pre-commit.

- CMD: `set PRE_COMMIT_HOME=C:\somepath\pre-commit`
- PowerShell: `$Env:PRE_COMMIT_HOME = "C:\somepath\pre-commit"`
- git bash: `export PRE_COMMIT_HOME="/c/somepath/pre-commit"`

8.5.3 Documenting Code

The purpose of this description is to provide a quick summary of the documentation style used in espressif/esp-idf repository and how to add new documentation.

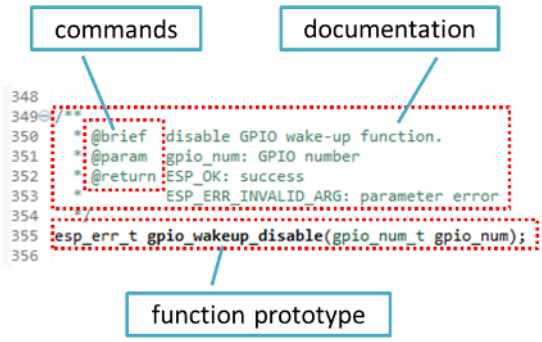
Introduction

When documenting code for this repository, please follow Doxygen style. You are doing it by inserting special commands, for instance `@param`, into standard comments blocks, for example:

```
/**
 * @param ratio this is oxygen to air ratio
 */
```

Doxygen can phrase the code, extract the commands together with subsequent text, and build documentation out of it.

Typical comment block, that contains documentation of a function, looks like below:

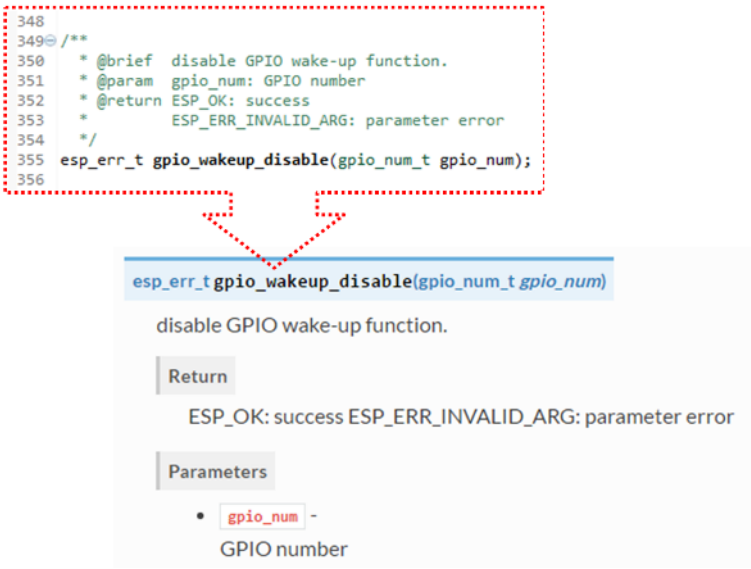


Doxygen supports a couple of formatting styles. It also gives you great flexibility on the level of details to include in documentation. To get familiar with available features, please check data-rich and very well-organized Doxygen Manual.

Why We Need Doxygen?

The ultimate goal is to ensure that all the code is consistently documented, so we can use tools like Sphinx and Breathe to aid preparation and automatic updates of API documentation when the code changes.

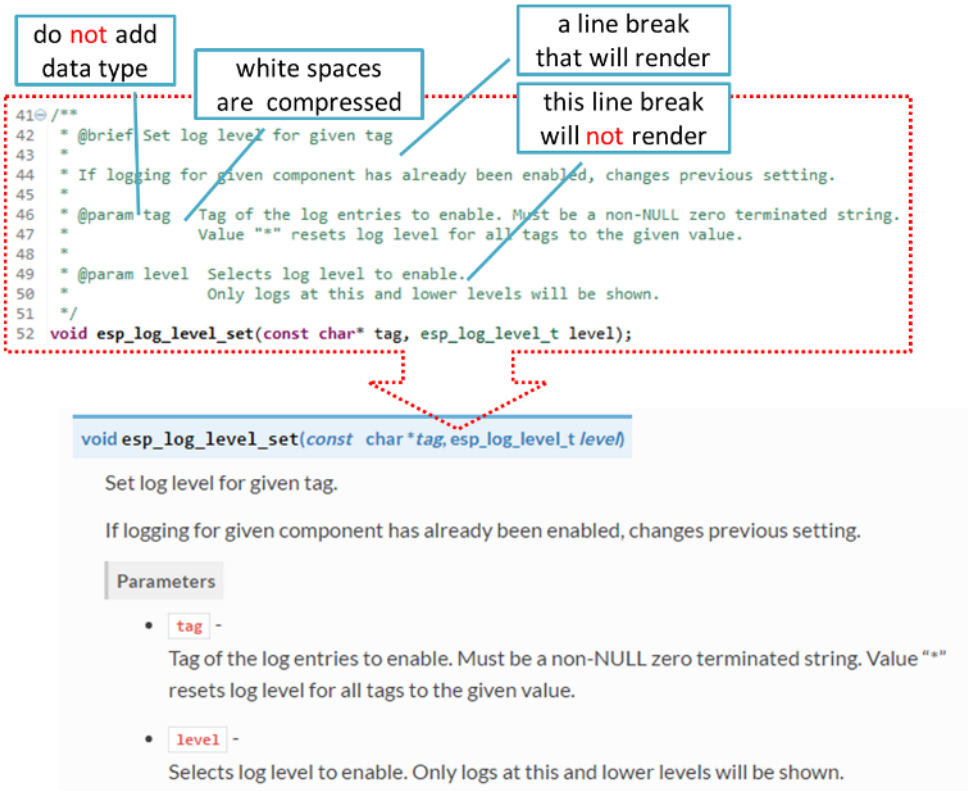
With these tools, the above piece of code renders like below:



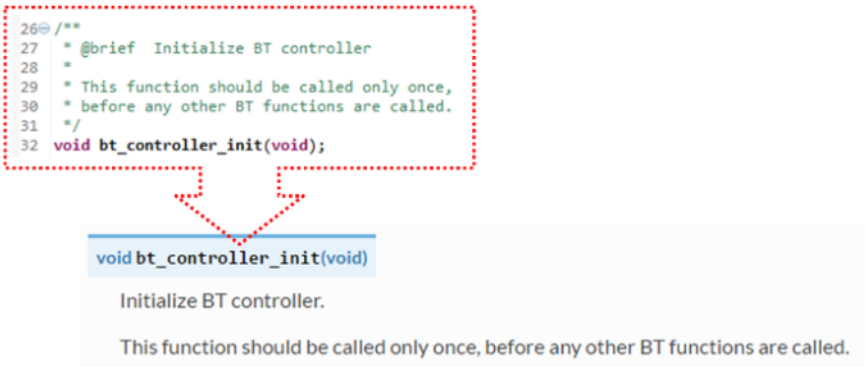
Go for It!

When writing code for this repository, please follow guidelines below:

1. Document all building blocks of code, including functions, structs, typedefs, enums, macros, etc. Provide enough information about purpose, functionality, and limitations of documented items, as you would like to see them documented when reading the code by others.
2. Documentation of function should describe what this function does. If it accepts input parameters and returns some value, all of them should be explained.
3. Do not add a data type before parameter or any other characters besides spaces. All spaces and line breaks are compressed into a single space. If you like to break a line, then break it twice.



4. If function has void input or does not return any value, then skip `@param` or `@return`.



5. When documenting a `define` as well as members of a `struct` or `enum`, place specific comment like below after each member.

6. To provide well-formatted lists, break the line after command (like `@return` in the example below).

```
*
* @return
*     - ESP_OK if erase operation was successful
*     - ESP_ERR_NVS_INVALID_HANDLE if handle has been closed or is NULL
*     - ESP_ERR_NVS_READ_ONLY if handle was opened as read only
*     - ESP_ERR_NVS_NOT_FOUND if the requested key does not exist
*     - other error codes from the underlying storage driver
*
```

7. Overview of functionality of documented header file, or group of files that make a library, should be placed in a separate `README.rst` file of the same directory. If this directory contains header files for different APIs, then the file name should be `apiname-readme.rst`.

Go One Extra Mile

Here are a couple of tips on how you can make your documentation even better and more useful to the reader and writer.

When writing code, please follow the guidelines below:

1. Add code snippets to illustrate implementation. To do so, enclose snippet using `@code{c}` and `@endcode` commands.

```
*
* @code{c}
* // Example of using nvs_get_i32:
* int32_t max_buffer_size = 4096; // default value
* esp_err_t err = nvs_get_i32(my_handle, "max_buffer_size", &max_buffer_size);
* assert(err == ESP_OK || err == ESP_ERR_NVS_NOT_FOUND);
* // if ESP_ERR_NVS_NOT_FOUND was returned, max_buffer_size will still
* // have its default value.
```

(continues on next page)

(continued from previous page)

```
* @endcode
*
```

The code snippet should be enclosed in a comment block of the function that it illustrates.

2. To highlight some important information use command `@attention` or `@note`.

```
*
* @attention
*     1. This API only impact WIFI_MODE_STA or WIFI_MODE_APSTA mode
*     2. If the ESP32 is connected to an AP, call esp_wifi_disconnect to␣
↪disconnect.
*
```

Above example also shows how to use a numbered list.

3. To provide common description to a group of similar functions, enclose them using `/**@{*/` and `/**@}*/` markup commands.

```
/**@{*/
/**
 * @brief common description of similar functions
 *
 */
void  first_similar_function (void);
void second_similar_function (void);
/**@}*/
```

For practical example see nvs_flash/include/nvs.h.

4. You may want to go even further and skip some code like repetitive defines or enumerations. In such case, enclose the code within `/** @cond */` and `/** @endcond */` commands. Example of such implementation is provided in esp_driver_gpio/include/driver/gpio.h.
5. Use markdown to make your documentation even more readable. You will add headers, links, tables and more.

```
*
* [ESP32-C3 Technical Reference Manual](https://www.espressif.com/sites/
↪default/files/documentation/esp32-c3_technical_reference_manual_en.pdf)
*
```

Note: Code snippets, notes, links, etc., will not make it to the documentation, if not enclosed in a comment block associated with one of the documented objects.

6. Prepare one or more complete code examples together with description. Place description to a separate file `README.md` in specific folder of examples directory.

Standardize Document Format

When it comes to text, please follow guidelines below to provide well-formatted Markdown (.md) or reST (.rst) documents.

1. Please ensure that one paragraph is written in one line. Do not break lines like below. Breaking lines to enhance readability is only suitable for writing code. To make the text easier to read, it is recommended to place an empty line to separate the paragraph.

2. Please make the line number of CN and EN documents consistent like below. The benefit of this approach is that it can save time for both writers and translators. When non-bilingual writers need to update text, they only need to update the same line in the corresponding CN or EN document. For translators, if documents are updated in English, then translators can quickly locate where to update in the corresponding CN document later. Besides, by comparing the total number of lines in EN and CN documents, you can quickly find out whether the CN version lags behind the EN version.

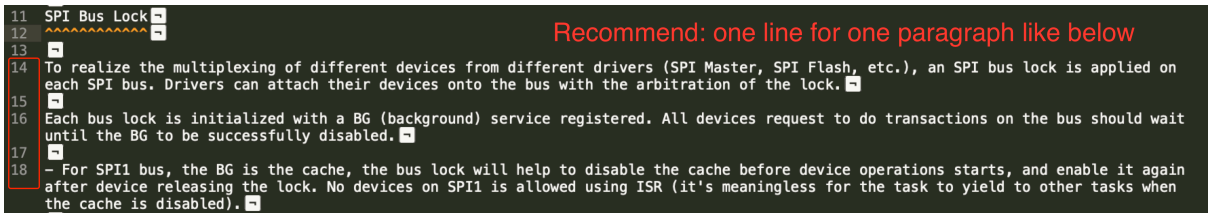


Fig. 1: One line for one paragraph (click to enlarge)

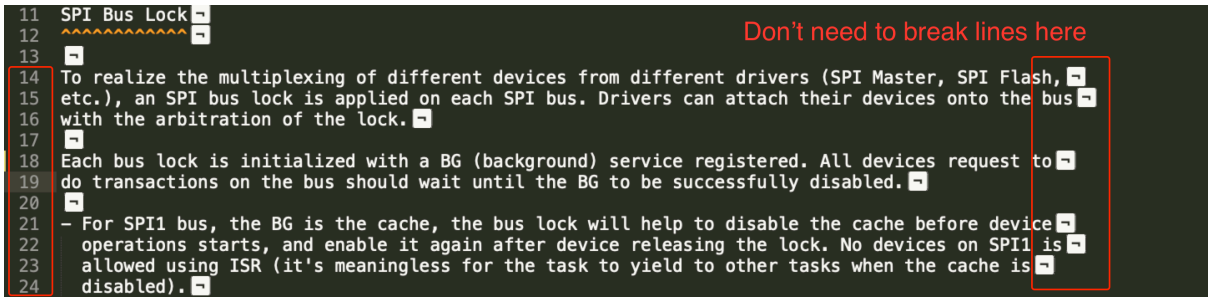

Fig. 2: No line breaks within the same paragraph (click to enlarge)

Fig. 3: Keep the line number for EN and CN documents consistent (click to enlarge)

Building Documentation

The documentation is built with the *esp-docs* Python package, which is a wrapper around Sphinx.

To install it simply do:

```
pip install esp-docs
```

After a successful install then the documentation can be built from the docs folder with:

```
build-docs build
```

or for specific target and language with:

```
build-docs -t esp32 -l en build
```

For more in-depth documentation about *esp-docs* features please see the documentation at esp-docs.

Wrap Up

We love good code that is doing cool things. We love it even better, if it is well-documented, so we can quickly make it run and also do the cool things.

Go ahead, contribute your code and documentation!

8.5.4 Creating Examples

Each ESP-IDF example is a complete project that someone else can copy and adapt the code to solve their own problem. Examples should demonstrate ESP-IDF functionality, while keeping this purpose in mind.

Structure

- The `main` directory should contain a source file named `(something)_example_main.c` with the main functionality.
- If the example has additional functionality, split it logically into separate C or C++ source files under `main` and place a corresponding header file in the same directory.
- If the example has a lot of additional functionality, consider adding a `components` directory to the example project and make some example-specific components with library functionality. Only do this if the components are specific to the example, if they are generic or common functionality then they should be added to ESP-IDF itself.
- The example should have a `README.md` file. Use the template example README and adapt it for your particular example.
- Examples should have a `pytest_<example name>.py` file for running an automated example test. If submitting a GitHub Pull Request which includes an example, it is OK not to include this file initially. The details can be discussed as part of the Pull Request. Please refer to *IDF Tests with Pytest Guide* for details.

General Guidelines

Example code should follow the *Espressif IoT Development Framework Style Guide*.

Checklist

Checklist before submitting a new example:

- Example does one distinct thing. If the example does more than one thing at a time, split it into two or more examples.
- Example has a `README.md` file which is similar to the template example README .
- Functions and variables in the example are named according to *naming section of the style guide*. For non-static names which are only specific to the example's source files, you can use `example` or something similar as a prefix.
- All code in the example is well structured and commented.
- Any unnecessary code (old debugging logs, commented-out code, etc.) is removed from the example.
- Options in the example (like network names, addresses, etc) are not hard-coded. Use configuration items if possible, or otherwise declare macros or constants.
- Configuration items are provided in a `KConfig.projbuild` file with a menu named "Example Configuration". See existing example projects to see how this is done.
- All original example code has a license header saying it is "in the public domain / CC0", and a warranty disclaimer clause. Alternatively, the example is licensed under Apache License 2.0. See existing examples for headers to adapt from.
- Any adapted or third party example code has the original license header on it. This code must be licensed compatible with Apache License 2.0.

8.5.5 API Documentation Template

Note: *INSTRUCTIONS*

1. Use this file (docs/en/api-reference/template.rst) as a template to document API.
2. Change the file name to the name of the header file that represents the documented API.
3. Include respective files with descriptions from the API folder using `..include::`
   - README.rst
   - example.rst
   - ...
4. Optionally provide description right in this file.
5. Once done, remove all instructions like this one and any superfluous headers.

Overview

Note: *INSTRUCTIONS*

1. Provide overview where and how this API may be used.
2. Include code snippets to illustrate functionality of particular functions when applicable.
3. To distinguish between sections, use the following heading levels:
   - # with overline, for parts
   - * with overline, for chapters
   - = for sections
   - – for subsections
   - ^ for subsubsections
   - " for paragraphs

Application Example

Note: *INSTRUCTIONS*

1. Prepare one or more practical examples to demonstrate functionality of this API.
2. Each example should follow pattern of projects located in `esp-idf/examples/` folder.
3. Place example in this folder, and add `README.md` file.
4. Provide overview of demonstrated functionality in `README.md`.
5. With good overview readers should be able to understand what example does without opening the source code.
6. Depending on complexity of example, break down description of code into parts and provide overview of functionality of each part.
7. Include flow diagram and screenshots of application output if applicable.
8. Finally add in this section synopsis of each example together with link to respective folder in `esp-idf/examples/`.

API Reference

Note: *INSTRUCTIONS*

1. ESP-IDF repository provides automatic update of API reference documentation using *code markup retrieved by Doxygen from header files*.
2. Update is done on each documentation build by invoking Sphinx extension `esp_extensions/run_doxygen.py` for all header files listed in the `INPUT` statement of docs/doxygen/Doxyfile.
3. Each line of the `INPUT` statement (other than a comment that begins with `##`) contains a path to header file `*.h` that is used to generate corresponding `*.inc` files:

```
##
## Wi-Fi - API Reference
##
../components/esp32/include/esp_wifi.h \
../components/esp32/include/esp_smartconfig.h \
```

4. When the headers are expanded, any macros defined by default in `sdkconfig.h` as well as any macros defined in SOC-specific `include/soc/*_caps.h` headers will be expanded. This allows the headers to include or exclude material based on the `IDF_TARGET` value.
5. The `*.inc` files contain formatted reference of API members generated automatically on each documentation build. All `*.inc` files are placed in Sphinx `_build` directory. To see directives generated, e.g., `esp_wifi.h`, run `python gen-dxd.py esp32/include/esp_wifi.h`.
6. To show contents of `*.inc` file in documentation, include it as follows:

```
.. include-build-file:: inc/esp_wifi.inc
```

   For example see docs/en/api-reference/network/esp_wifi.rst
7. Optionally, rather that using `*.inc` files, you may want to describe API in you own way. See docs/en/api-reference/storage/fatfs.rst for example.
   Below is the list of common `.. doxygen...::` directives:
   - Functions - `.. doxygenfunction:: name_of_function`
   - Unions - `.. doxygenunion:: name_of_union`
   - Structures - `.. doxygenstruct:: name_of_structure` together with `:members:`
   - Macros - `.. doxygendefine:: name_of_define`
   - Type Definitions - `.. doxygentypedef:: name_of_type`
   - Enumerations - `.. doxygenenum:: name_of_enumeration`

   See Breathe documentation for additional information.
   To provide a link to header file, use the *link custom role* directive as follows:

```
* :component_file:`path_to/header_file.h`
```

8. In any case, to generate API reference, the file docs/doxygen/Doxyfile should be updated with paths to `*.h` headers that are being documented.
9. When changes are committed and documentation is built, check how this section has been rendered. *Correct annotations* in respective header files, if required.

8.5.6 Contributor Agreement

Individual Contributor Non-Exclusive License Agreement Including the Traditional Patent License OPTION

Thank you for your interest in contributing to this Espressif project hosted on GitHub ("We" or "Us").

The purpose of this contributor agreement ("Agreement") is to clarify and document the rights granted by contributors to Us. To make this document effective, please follow the instructions in the *Contributions Guide*.

1. DEFINITIONS **You** means the Individual Copyright owner who submits a Contribution to Us. If You are an employee and submit the Contribution as part of your employment, You must have had Your employer approve this Agreement or sign the Entity version of this Agreement.

Contribution means any original work of authorship (software and/or documentation) including any modifications or additions to an existing work, Submitted by You to Us, in which You own the Copyright. If You do not own the Copyright in the entire work of authorship, please contact Us by submitting a comment on GitHub.

Copyright means all rights protecting works of authorship owned or controlled by You, including copyright, moral and neighboring rights, as appropriate, for the full term of their existence including any extensions by You.

Material means the software or documentation made available by Us to third parties. When this Agreement covers more than one software project, the Material means the software or documentation to which the Contribution was Submitted. After You Submit the Contribution, it may be included in the Material.

Submit means any form of physical, electronic, or written communication sent to Us, including but not limited to electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, Us, but excluding communication that is conspicuously marked or otherwise designated in writing by You as "Not a Contribution."

Submission Date means the date You Submit a Contribution to Us.

Documentation means any non-software portion of a Contribution.

2. COPYRIGHT LICENSE 2.1 Grant of Copyright License to Us

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, NON-exclusive, perpetual and irrevocable license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, under the Copyright covering the Contribution to use the Contribution by all means, including, but not limited to:

- to publish the Contribution
- to modify the Contribution, to prepare derivative works based upon or containing the Contribution and to combine the Contribution with other software code
- to reproduce the Contribution in original or modified form
- to distribute, to make the Contribution available to the public, display and publicly perform the Contribution in original or modified form

2.2 Moral Rights remain unaffected to the extent they are recognized and not waivable by applicable law. Notwithstanding, You may add your name in the header of the source code files of Your Contribution and We will respect this attribution when using Your Contribution.

3. PATENT LICENSE 3.1 Grant of Patent License to US

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, non-exclusive, perpetual and irrevocable (except as stated in Section 3.2) patent license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, to make, have made, use, sell, offer for sale, import and otherwise transfer the Contribution and the Contribution in combination with the Material (and portions of such combination). This license applies to all patents owned or controlled by You, whether already acquired or hereafter acquired, that would be infringed by making, having made, using, selling, offering for sale, importing or otherwise transferring of Your Contribution(s) alone or by combination of Your Contribution(s) with the Material.

3.2 Revocation of Patent License

You reserve the right to revoke the patent license stated in section 3.1 if We make any infringement claim that is targeted at your Contribution and not asserted for a Defensive Purpose. An assertion of claims of the Patents shall be considered for a "Defensive Purpose" if the claims are asserted against an entity that has filed, maintained, threatened, or voluntarily participated in a patent infringement lawsuit against Us or any of Our licensees.

4. DISCLAIMER THE CONTRIBUTION IS PROVIDED "AS IS". MORE PARTICULARLY, ALL EXPRESSED OR IMPLIED WARRANTIES INCLUDING, WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT ARE EXPRESSLY DISCLAIMED BY YOU TO US AND BY US TO YOU. TO THE EXTENT THAT ANY SUCH WARRANTIES CANNOT BE DISCLAIMED, SUCH WARRANTY IS LIMITED IN DURATION TO THE MINIMUM PERIOD PERMITTED BY LAW.

5. Consequential Damage Waiver TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT WILL YOU OR US BE LIABLE FOR ANY LOSS OF PROFITS, LOSS OF ANTICIPATED SAVINGS, LOSS OF DATA, INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL AND EXEMPLARY DAMAGES ARISING OUT OF THIS AGREEMENT REGARDLESS OF THE LEGAL OR EQUITABLE THEORY (CONTRACT, TORT OR OTHERWISE) UPON WHICH THE CLAIM IS BASED.

6. Approximation of Disclaimer and Damage Waiver IF THE DISCLAIMER AND DAMAGE WAIVER MENTIONED IN SECTION 4 AND SECTION 5 CANNOT BE GIVEN LEGAL EFFECT UNDER APPLICABLE LOCAL LAW, REVIEWING COURTS SHALL APPLY LOCAL LAW THAT MOST CLOSELY APPROXIMATES AN ABSOLUTE WAIVER OF ALL CIVIL LIABILITY IN CONNECTION WITH THE CONTRIBUTION.

7. Term 7.1 This Agreement shall come into effect upon Your acceptance of the terms and conditions.

7.2 In the event of a termination of this Agreement, sections 4, 5, 6, 7 and 8 shall survive such termination and shall remain in full force thereafter. For the avoidance of doubt, Contributions that are already licensed under a free and open source license at the date of the termination shall remain in full force after the termination of this Agreement.

8. Miscellaneous 8.1 This Agreement and all disputes, claims, actions, suits or other proceedings arising out of this agreement or relating in any way to it shall be governed by the laws of People's Republic of China excluding its private international law provisions.

8.2 This Agreement sets out the entire agreement between You and Us for Your Contributions to Us and overrides all other agreements or understandings.

8.3 If any provision of this Agreement is found void and unenforceable, such provision will be replaced to the extent possible with a provision that comes closest to the meaning of the original provision and that is enforceable. The terms and conditions set forth in this Agreement shall apply notwithstanding any failure of essential purpose of this Agreement or any limited remedy to the maximum extent possible under law.

8.4 You agree to notify Us of any facts or circumstances of which you become aware that would make this Agreement inaccurate in any respect.

8.5.7 Copyright Header Guide

ESP-IDF is released under the Apache License 2.0 with some additional third-party copyrighted code released under various licenses. For further information please refer to *the list of copyrights and licenses*.

This page explains how the source code should be properly marked with a copyright header. ESP-IDF uses the Software Package Data Exchange (SPDX) format which is short and can be easily read by humans or processed by automated tools for copyright checks.

How to Check the Copyright Headers

Please make sure you have installed the *pre-commit hooks* which contain a copyright header checker as well. The checker can suggest a header if it is not able to detect a properly formatted SPDX header.

What If the Checker's Suggestion Is Incorrect?

No automated checker (no matter how good is) can replace humans. So the developer's responsibility is to modify the offered header to be in line with the law and the license restrictions of the original code on which the work is based on. Certain licenses are not compatible between each other. Such corner cases will be covered by the following examples.

The checker can be configured with the `tools/ci/check_copyright_config.yaml` configuration file. Please check the options it offers and consider updating it in order to match the headers correctly.

Common Examples of Copyright Headers

The simplest case is when the code is not based on any licensed previous work, e.g., it was written completely from scratch. Such code can be decorated with the following copyright header and put under the license of ESP-IDF:

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Apache-2.0
 */
```

Less Restrictive Parts of ESP-IDF Some parts of ESP-IDF are deliberately under less restrictive licenses in order to ease their reuse in commercial closed source projects. This is the case for ESP-IDF examples which are in Public domain or under the Creative Commons Zero Universal (CC0) license. The following header can be used in such source files:

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Unlicense OR CC0-1.0
 */
```

The option allowing multiple licenses joined with the `OR` keyword from the above example can be achieved with the definition of multiple allowed licenses in the `tools/ci/check_copyright_config.yaml` configuration file. Please use this option with care and only selectively for a limited part of ESP-IDF.

Third Party Licenses Code licensed under different licenses, modified by Espressif Systems and included in ESP-IDF cannot be licensed under Apache License 2.0 not even if the checker suggests it. It is advised to keep the original copyright header and add an SPDX before it.

The following example is a suitable header for a code licensed under the "GNU General Public License v2.0 or later" held by John Doe with some additional modifications done by Espressif Systems:

```
/*
 * SPDX-FileCopyrightText: 1991 John Doe
 *
 * SPDX-License-Identifier: GPL-2.0-or-later
 *
 * SPDX-FileContributor: 2019-2023 Espressif Systems (Shanghai) CO LTD
 */
```

The licenses can be identified and the short SPDX identifiers can be found in the official SPDX license list. Other very common licenses are the GPL-2.0-only, the BSD-3-Clause, and the BSD-2-Clause.

In exceptional case, when a license is not present on the SPDX license list, it can be expressed by using the LicenseRef-[idString] custom license identifier, for example `LicenseRef-Special-License`. The full license text must be added into the `LICENSES` directory under `Special-License` filename.

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: LicenseRef-Special-License
 */
```

Dedicated `LicenseRef-Included` custom license identifier can be used to express a situation when the custom license is included directly in the source file.

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: LicenseRef-Included
 *
 * <Full custom license text>
 */
```

The configuration stored in `tools/ci/check_copyright_config.yaml` offers features useful for third party licenses:

- A different license can be defined for the files part of a third party library.
- The check for a selected set of files can be permanently disabled. Please use this option with care and only in cases when none of the other options are suitable.

8.5.8 ESP-IDF Tests with Pytest Guide

ESP-IDF provides a variety of testing mechanisms that runs directly on target ESP chips (referred to as **target test**). These target tests are typically integrated into an ESP-IDF project specifically designed for testing purposes (known as a **test app**). Similar to standard ESP-IDF projects, test apps follow the same build, flash, and monitoring procedures.

In target testing, a connected host (for instance, a PC) is typically required to trigger specific test cases, provide test data, and evaluate test results.

On the host side, ESP-IDF employs the pytest framework (alongside certain pytest plugins) to automate target testing. This guide delves into pytest in ESP-IDF, covering the following aspects:

1. Common concepts in ESP-IDF target testing.
2. Using the pytest framework in Python scripts for target testing automation.
3. ESP-IDF Continuous Integration (CI) target testing workflow.
4. Running target tests locally using pytest.
5. pytest tips and tricks.

Note: In ESP-IDF, we use the following pytest plugins by default:

- pytest-embedded with default services `esp,idf`
- pytest-rerunfailures
- pytest-ignore-test-results

All the concepts and usages introduced in this guide are based on the default behavior of these plugins, thus may not be available in vanilla pytest.

Important: This guide specifically targets ESP-IDF contributors. Some of the concepts, like the custom markers, may not be directly applicable to personal projects using the ESP-IDF SDK. For running pytest-embedded in personal projects, please refer to pytest-embedded documentation, and explore the provided examples.

Installation

All dependencies could be installed by running the ESP-IDF install script with the `--enable-pytest` argument:

```
$ install.sh --enable-pytest
```

Several mechanisms have been implemented to ensure the successful execution of the installation processes. If you encounter any issues during installation, please submit an issue report to our GitHub issue tracker.

Common Concepts

A **test app** is a set of binaries which are built from an IDF project that is used to test a particular feature of your project. Test apps are usually located under `${IDF_PATH}/examples`, `${IDF_PATH}/tools/test_apps`, and `${IDF_PATH}/components/<COMPONENT_NAME>/test_apps`.

A **Device under test (DUT)** is a set of ESP chip(s) which connect to a host (e.g., a PC). The host is responsible for flashing the apps to the DUT, triggering the test cases, and inspecting the test results.

A typical ESP-IDF project that contains a pytest script will have the following structure:

```
.
└── my_app/
    ├── main/
    │   └── ...
```

(continues on next page)

(continued from previous page)

```
    ├── CMakeLists.txt
    └── pytest_foo.py
```

Sometimes, for some multi-dut tests, one test case requires multiple test apps. In this case, the test app folder structure would be like this:

```
.
├── my_app_foo/
│   ├── main/
│   │   └── ...
│   └── CMakeLists.txt
├── my_app_bar/
│   ├── main/
│   │   └── ...
│   └── CMakeLists.txt
└── pytest_foo_bar.py
```

pytest in ESP-IDF

Single DUT Test Cases

Getting Started

```
@pytest.mark.esp32
@pytest.mark.esp32s2
@pytest.mark.generic
def test_hello_world(dut) -> None:
    dut.expect('Hello world!')
```

This is a simple test script that could run with the ESP-IDF getting-started example get-started/hello_world.

First two lines are the target markers:

- The `@pytest.mark.esp32` is a marker that indicates that this test case should be run on the ESP32.
- The `@pytest.mark.esp32s2` is a marker that indicates that this test case should be run on the ESP32-S2.

Note: If the test case can be run on all targets officially supported by ESP-IDF (call `idf.py --list-targets` for more details), you can use a special marker `supported_targets` to apply all of them in one line.

We also supports `preview_targets` and `all_targets` as special target markers (call `idf.py --list-targets --preview` for a full targets list including preview targets).

Next, we have the environment marker:

- The `@pytest.mark.generic` is a marker that indicates that this test case should be run on the `generic` board type.

Note: For the detailed explanation of the environment markers, please refer to ENV_MARKERS definition

Finally, we have the test function. With a `dut` fixture. In single-dut test cases, the `dut` fixture is an instance of `IdfDut` class, for multi-dut test cases, it is a tuple of `IdfDut` instances. For more details regarding the `IdfDut` class, please refer to pytest-embedded IdfDut API reference.

Same App With Different sdkconfig Files For some test cases, you may need to run the same app with different sdkconfig files. For detailed documentation regarding sdkconfig related concepts, please refer to idf-build-apps Documentation.

Here's a simple example that demonstrates how to run the same app with different sdkconfig files. Assume we have the following folder structure:

```
.
└── my_app/
    ├── main/
    │   └── ...
    ├── CMakeLists.txt
    ├── sdkconfig.ci.foo
    ├── sdkconfig.ci.bar
    └── pytest_foo.py
```

If the test case needs to run all supported targets with these two sdkconfig files, you can use the following code:

```
@pytest.mark.esp32
@pytest.mark.esp32s2
@pytest.mark.parametrize('config', [     # <-- parameterize the sdkconfig file
    'foo',                               # <-- run with sdkconfig.ci.foo
    'bar',                               # <-- run with sdkconfig.ci.bar
], indirect=True)                        # <-- `indirect=True` is required,␣
↪indicates this param is pre-calculated before other fixtures
def test_foo_bar(dut, config) -> None:
    if config == 'foo':
      dut.expect('This is from sdkconfig.ci.foo')
    elif config == 'bar':
      dut.expect('This is from sdkconfig.ci.bar')
```

All markers will impact the test case simultaneously. Overall, this test function would be replicated to 4 test cases:

- `test_foo_bar`, with esp32 target, and `sdkconfig.ci.foo` as the sdkconfig file
- `test_foo_bar`, with esp32 target, and `sdkconfig.ci.bar` as the sdkconfig file
- `test_foo_bar`, with esp32s2 target, and `sdkconfig.ci.foo` as the sdkconfig file
- `test_foo_bar`, with esp32s2 target, and `sdkconfig.ci.bar` as the sdkconfig file

Sometimes in the test script or the log file, you may see the following format:

- `esp32.foo.test_foo_bar`
- `esp32.bar.test_foo_bar`
- `esp32s2.foo.test_foo_bar`
- `esp32s2.bar.test_foo_bar`

We call this format the **test case ID**. The test case ID should be considered as the unique identifier of a test case. It is composed of the following parts:

- `esp32`: the target name
- `foo`: the config name
- `test_foo_bar`: the test function name

The test case ID is used to identify the test case in the JUnit report.

Note: Nearly all the CLI options of pytest-embedded supports parameterization. To see all supported CLI options, you may run `pytest --help` and check the `embedded-...` sections for vanilla pytest-embedded ones, and the `idf` sections for ESP-IDF specific ones.

Note: The target markers, like `@pytest.mark.esp32` and `@pytest.mark.esp32s2`, are actually syntactic sugar for parameterization. In fact they are defined as:

```
@pytest.mark.parametrize('target', [
    'esp32',
    'esp32s2',
], indirect=True)
```

Same App With Different sdkconfig Files, Different Targets For some test cases, you may need to run the same app with different sdkconfig files. These sdkconfig files supports different targets. We may use `pytest.param` to achieve this. Let's use the same folder structure as above.

```
@pytest.mark.parametrize('config', [
    pytest.param('foo', marks=[pytest.mark.esp32]),
    pytest.param('bar', marks=[pytest.mark.esp32s2]),
], indirect=True)
```

Now this test function would be replicated to 2 test cases (represented as test case IDs):

- `esp32.foo.test_foo_bar`
- `esp32s2.bar.test_foo_bar`

Testing Serial Output (Expecting) To ensure that test has executed successfully on target, the test script can test that serial output of the target using the `dut.expect()` function, for example:

```
def test_hello_world(dut) -> None:
    dut.expect('\d+')  # <-- `expect`ing from a regex
    dut.expect_exact('Hello world!')  # <-- `expect_exact`ly the string
```

The `dut.expect(...)` will first compile the expected string into regex, which in turn is then used to seek through the serial output until the compiled regex is matched, or until a timeout occurs.

Please pay extra attention to the expected string when it contains regex keyword characters (e.g., parentheses, square brackets). Alternatively, you may use `dut.expect_exact(...)` that will attempt to match the string without converting it into regex.

For more information regarding the different types of `expect` functions, please refer to the pytest-embedded Expecting documentation.

Multi-DUT Test Cases

Multi-Target Tests with the Same App In some cases a test may involve multiple targets running the same test app. Parameterize `count` to the number of DUTs you want to test with.

```
@pytest.mark.parametrize('count', [
    2,
], indirect=True)
@pytest.mark.parametrize('target', [
  'esp32|esp32s2',
  'esp32s3',
], indirect=True)
def test_hello_world(dut) -> None:
    dut[0].expect('Hello world!')
    dut[1].expect('Hello world!')
```

The `|` symbol in all parameterized items is used for separating the settings for each DUT. In this example, the test case would be tested with:

- esp32, esp32s2
- esp32s3, esp32s3

After setting the param `count` to 2, all the fixtures are changed into tuples.

Important: `count` is mandatory for multi-DUT tests.

Note: For detailed multi-dut parametrization documentation, please refer to pytest-embedded Multi-DUT documentation.

Warning: In some test scripts, you may see target markers like `@pytest.mark.esp32` and `@pytest.mark.esp32s2` used together with multi-DUT test cases. This is deprecated and should be replaced with the `target` parametrization.

For example,

```
@pytest.mark.esp32
@pytest.mark.esp32s2
@pytest.mark.parametrize('count', [
    2,
], indirect=True)
def test_hello_world(dut) -> None:
    dut[0].expect('Hello world!')
    dut[1].expect('Hello world!')
```

should be replaced with:

```
@pytest.mark.parametrize('count', [
    2,
], indirect=True)
@pytest.mark.parametrize('target', [
    'esp32',
    'esp32s2',
], indirect=True)
def test_hello_world(dut) -> None:
    dut[0].expect('Hello world!')
    dut[1].expect('Hello world!')
```

This could help avoid the ambiguity of the target markers when multi-DUT test cases are using different type of targets.

Multi-Target Tests with Different Apps In some cases, a test may involve multiple targets running different test apps (e.g., separate targets to act as master and slave). Usually in ESP-IDF, the folder structure would be like this:

```
.
├── master/
│   ├── main/
│   │   └── ...
│   └── CMakeLists.txt
├── slave/
│   ├── main/
│   │   └── ...
│   └── CMakeLists.txt
└── pytest_master_slave.py
```

In this case, we can parameterize the `app_path` to the path of the test apps you want to test with.

```
@pytest.mark.multi_dut_generic
@pytest.mark.parametrize('count', [
    2,
], indirect=True)
@pytest.mark.parametrize('app_path, target', [
    (f'{os.path.join(os.path.dirname(__file__), "master")}|{os.path.join(os.path.
↪dirname(__file__), "slave")}', 'esp32|esp32s2'),
    (f'{os.path.join(os.path.dirname(__file__), "master")}|{os.path.join(os.path.
↪dirname(__file__), "slave")}', 'esp32s2|esp32'),
```

(continues on next page)

(continued from previous page)

```
], indirect=True)
def test_master_slave(dut) -> None:
    master = dut[0]
    slave = dut[1]

    master.write('Hello world!')
    slave.expect_exact('Hello world!')
```

Note: When parametrizing two items, like `app_path, target` here, make sure you're passing a list of tuples to the `parametrize` decorator. Each tuple should contain the values for each item.

The test case here will be replicated to 2 test cases:

- dut-0, an ESP32, running app `master`, and dut-1, an ESP32-S2, running app `slave`
- dut-0, an ESP32-S2, running app `master`, and dut-1, an ESP32, running app `slave`

Test Cases with Unity Test Framework We use the Unity test framework in our unit tests. Overall, we have three types of test cases (Unity test framework):

- Normal test cases (single DUT)
- Multi-stage test cases (single DUT)
- Multi-device test cases (multi-DUT)

All single-DUT test cases (including normal test cases and multi-stage test cases) can be run using the following command:

```
def test_unity_single_dut(dut: IdfDut):
    dut.run_all_single_board_cases()
```

Using this command will skip all the test cases containing the `[ignore]` tag.

If you need to run a group of test cases, you may run:

```
def test_unity_single_dut(dut: IdfDut):
    dut.run_all_single_board_cases(group='psram')
```

It would trigger all test cases with the `[psram]` tag.

Warning: You may also see that there are some test scripts with the following statements, which are deprecated. Please use the suggested one as above.

```
def test_unity_single_dut(dut: IdfDut):
    dut.expect_exact('Press ENTER to see the list of tests')
    dut.write('*')
    dut.expect_unity_test_output()
```

We also provide a fixture `case_tester` to trigger all kinds of test cases easier. For example:

```
def test_unity_single_dut(case_tester):
    case_tester.run_all_normal_cases()        # to run all normal test cases
    case_tester.run_all_multi_dev_cases()     # to run all multi-device test cases
    case_tester.run_all_multi_stage_cases()   # to run all multi-stage test cases
```

For a full list of the available functions, please refer to pytest-embedded case_tester API reference.

Running Target Tests in CI

The workflow in CI is as follows:

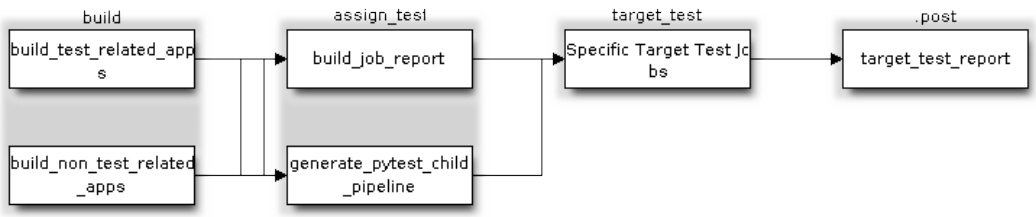

Fig. 4: Target Test Child Pipeline Workflow

All build jobs and target test jobs are generated automatically by our CI script tools/ci/dynamic_pipelines.

Build Jobs In CI, all ESP-IDF projects under `components`, `examples`, and `tools/test_apps`, are built with all supported targets and sdkconfig files. The binaries are built under `build_<target>_<config>`. For example

```
.
├── build_esp32_history/
│   └── ...
├── build_esp32_nohistory/
│   └── ...
├── build_esp32s2_history/
│   └── ...
├── ...
├── main/
├── CMakeLists.txt
├── sdkconfig.ci.history
├── sdkconfig.ci.nohistory
└── ...
```

There are two types of build jobs, `build_test_related_apps` and `build_non_test_related_apps`.

For `build_test_related_apps`, all the built binaries will be uploaded to our internal MinIO server. You may find the download link in the build report posted in the internal MR.

For `build_non_test_related_apps`, all the built binaries will be removed after the build job is finished. Only the build log files will be uploaded to our internal MinIO server. You may also find the download link in the build report posted in the internal MR.

Target Test Jobs In CI, all generated target test jobs are named according to the pattern "<targets> - <env_markers>". For example, single-dut test job `esp32 - generic`, or multi-dut test job `esp32,esp32 - multi_dut_generic`.

The binaries in the target test jobs are downloaded from our internal MinIO servers. For most of the test cases, only the files that are required by flash (like .bin files, flash_args files, etc) would be downloaded. For some test cases, like jtag test cases, .elf files are also downloaded.

Running Tests Locally

Installation First you need to install ESP-IDF with additional Python requirements:

```
$ cd $IDF_PATH
$ bash install.sh --enable-ci --enable-pytest
$ . ./export.sh
```

Build Directories By default, each test case looks for the required binary files in the following directories (in order):

- Directory set by `--build-dir` command line argument, if specified.
- `build_<target>_<sdkconfig>`
- `build_<target>`
- `build_<sdkconfig>`
- `build`

As long as one of the above directories exists, the test case uses that directory to flash the binaries. If none of the above directories exists, the test case fails with an error.

Test Your Test Script

Single-DUT Test Cases With `sdkconfig.defaults` This is the simplest use case. Let's take examples/get-started/hello_world as an example. Assume we're testing with a ESP32 board.

```
$ cd $IDF_PATH/examples/get-started/hello_world
$ idf.py set-target esp32 build
$ pytest --target esp32
```

Single-DUT Test Cases With `sdkconfig.ci.xxx` Some test cases may need to run with different sdkconfig files. Let's take examples/system/console/basic as an example. Assume we're testing with a ESP32 board, and test with `sdkconfig.ci.history`.

```
$ cd $IDF_PATH/examples/system/console/basic
$ idf.py -DSDKCONFIG_DEFAULTS='sdkconfig.defaults;sdkconfig.ci.history' -B build_
↪esp32_history set-target esp32 build
$ pytest --target esp32 -k "not nohistory"
```

Note: Here if we use `pytest --target esp32 -k history`, both test cases will be selected, since `pytest -k` will use string matching to filter the test cases.

If you want to build and test with all sdkconfig files at the same time, you should use our CI script as an helper script:

```
$ cd $IDF_PATH/examples/system/console/basic
$ python $IDF_PATH/tools/ci/ci_build_apps.py . --target esp32 -v --pytest-apps
$ pytest --target esp32
```

The app with `sdkconfig.ci.history` will be built in `build_esp32_history`, and the app with `sdkconfig.ci.nohistory` will be built in `build_esp32_nohistory`. `pytest --target esp32` will run tests on both apps.

Multi-DUT Test Cases Some test cases may need to run with multiple DUTs. Let's take examples/openthread as an example. The test case function looks like this:

```
@pytest.mark.parametrize(
    'config, count, app_path, target', [
        ('rcp|cli_h2|br', 3,
         f'{os.path.join(os.path.dirname(__file__), "ot_rcp")}'
         f'|{os.path.join(os.path.dirname(__file__), "ot_cli")}'
```

(continues on next page)

(continued from previous page)

```
        f'|{os.path.join(os.path.dirname(__file__), "ot_br")}',
        'esp32c6|esp32h2|esp32s3'),
    ],
    indirect=True,
)
def test_thread_connect(dut:Tuple[IdfDut, IdfDut, IdfDut]) -> None:
    ...
```

The test cases will run with

- ESP32-C6, flashed with `ot_rcp`
- ESP32-H2, flashed with `ot_cli`
- ESP32-S3, flashed with `ot_br`

Of course we can build the required binaries manually, but we can also use our CI script as an helper script:

```
$ cd $IDF_PATH/examples/openthread
$ python $IDF_PATH/tools/ci/ci_build_apps.py . --target all -v --pytest-apps -k␣
↪test_thread_connect
$ pytest --target esp32c6,esp32h2,esp32s3 -k test_thread_connect
```

Important: It is mandatory to list all the targets for multi-DUT test cases. Otherwise, the test case would fail with an error.

Debug CI Test Cases Sometimes you can't reproduce the CI test case failure locally. In this case, you may need to debug the test case with the binaries built in CI.

Run pytest with `--pipeline-id <pipeline_id>` to force pytest to download the binaries from CI. For example:

```
$ cd $IDF_PATH/examples/get-started/hello_world
$ pytest --target esp32 --pipeline-id 123456
```

Even if you have `build_esp32_default`, or `build` directory locally, pytest would still download the binaries from pipeline 123456 and place the binaries in `build_esp32_default`. Then run the test case with this binary.

Note: <pipeline_id> should be the parent pipeline id. You can copy it in your MR page.

Pytest Tips & Tricks

Custom Classes Usually, you may want to write a custom class under these conditions:

1. Add more reusable functions for a certain number of DUTs.
2. Add custom setup and teardown functions

This code example is taken from panic/conftest.py .

```
class PanicTestDut(IdfDut):
    ...

@pytest.fixture(scope='module')
def monkeypatch_module(request: FixtureRequest) -> MonkeyPatch:
    mp = MonkeyPatch()
    request.addfinalizer(mp.undo)
    return mp
```

(continues on next page)

(continued from previous page)

```
@pytest.fixture(scope='module', autouse=True)
def replace_dut_class(monkeypatch_module: MonkeyPatch) -> None:
    monkeypatch_module.setattr('pytest_embedded_idf.dut.IdfDut', PanicTestDut)
```

`monkeypatch_module` provides a module-scoped monkeypatch fixture.

`replace_dut_class` is a module-scoped autouse fixture. This function replaces the `IdfDut` class with your custom class.

Mark Flaky Tests Certain test cases are based on Ethernet or Wi-Fi. However, the test may be flaky due to networking issues. Thus, it is possible to mark a particular test case as flaky.

This code example is taken from pytest_esp_eth.py .

```
@pytest.mark.flaky(reruns=3, reruns_delay=5)
def test_esp_eth_ip101(dut: IdfDut) -> None:
    ...
```

This flaky marker means that if the test function failed, the test case would rerun for a maximum of 3 times with 5 seconds delay.

Mark Known Failures Sometimes, a test can consistently fail for the following reasons:

- The feature under test (or the test itself) has a bug.
- The test environment is unstable (e.g., due to network issues) leading to a high failure ratio.

Now you may mark this test case with marker xfail with a user-friendly readable reason.

This code example is taken from pytest_panic.py

```
@pytest.mark.xfail('config.getvalue("target") == "esp32s2"', reason='raised␣
↪IllegalInstruction instead')
def test_cache_error(dut: PanicTestDut, config: str, test_func_name: str) -> None:
```

This marker means that test is a known failure on the ESP32-S2.

Mark Nightly Run Test Cases Some test cases are only triggered in nightly run pipelines due to a lack of runners.

```
@pytest.mark.nightly_run
```

This marker means that the test case would only be run with env var `NIGHTLY_RUN` or `INCLUDE_NIGHTLY_RUN`.

Mark Temporarily Disabled in CI Some test cases which can pass locally may need to be temporarily disabled in CI due to a lack of runners.

```
@pytest.mark.temp_skip_ci(targets=['esp32', 'esp32s2'], reason='lack of runners')
```

This marker means that the test case could still be run locally with `pytest --target esp32`, but will not run in CI.

Add New Markers We are using two types of custom markers, target markers which indicate that the test cases should support this target, and env markers which indicate that the test cases should be assigned to runners with these tags in CI.

You can add new markers by adding one line under the conftest.py. If it is a target marker, it should be added into `TARGET_MARKERS`. If it is a marker that specifies a type of test environment, it should be added into `ENV_MARKERS`. The syntax should be: `<marker_name>: <marker_description>`.

Skip Auto Flash Binary Skipping auto-flash binary every time would be useful when you are debugging your test script.

You can call pytest with `--skip-autoflash y` to achieve it.

Record Statistics Sometimes you may need to record some statistics while running the tests, like the performance test statistics.

You can use record_xml_attribute fixture in your test script, and the statistics would be recorded as attributes in the JUnit report.

Logging System Sometimes you may need to add some extra logging lines while running the test cases.

You can use Python logging module to achieve this.

Here are some logging functions provided as fixtures,

log_performance

```
def test_hello_world(
    dut: IdfDut,
    log_performance: Callable[[str, object], None],
) -> None:
    log_performance('test', 1)
```

The above example would log the performance item with pre-defined format: `[performance][test]: 1` and record it under the `properties` tag in the JUnit report if `--junitxml <filepath>` is specified. The JUnit test case node would look like:

```
<testcase classname="examples.get-started.hello_world.pytest_hello_world" file=
↪"examples/get-started/hello_world/pytest_hello_world.py" line="13" name="esp32.
↪default.test_hello_world" time="8.389">
    <properties>
        <property name="test" value="1"/>
    </properties>
</testcase>
```

check_performance We provide C macros `TEST_PERFORMANCE_LESS_THAN` and `TEST_PERFORMANCE_GREATER_THAN` to log the performance item and check if the value is in the valid range. Sometimes the performance item value could not be measured in C code, so we also provide a Python function for the same purpose. Please note that using C macros is the preferred approach, since the Python function could not recognize the threshold values of the same performance item under different `#ifdef` blocks well.

```
def test_hello_world(
    dut: IdfDut,
    check_performance: Callable[[str, float, str], None],
) -> None:
    check_performance('RSA_2048KEY_PUBLIC_OP', 123, 'esp32')
    check_performance('RSA_2048KEY_PUBLIC_OP', 19001, 'esp32')
```

The above example would first get the threshold values of the performance item `RSA_2048KEY_PUBLIC_OP` from components/idf_test/include/idf_performance.h and the target-specific one components/idf_test/include/esp32/idf_performance_target.h, then check if the value reached the minimum limit or exceeded the maximum limit.

Let us assume the value of `IDF_PERFORMANCE_MAX_RSA_2048KEY_PUBLIC_OP` is 19000. so the first `check_performance` line would pass and the second one would fail with warning: `[Performance] RSA_2048KEY_PUBLIC_OP value is 19001, doesn\'t meet pass standard 19000.0`.

Chapter 9

ESP-IDF Versions

The ESP-IDF GitHub repository is updated regularly, especially the master branch where new development takes place.

For production use, there are also stable releases available.

9.1 Releases

The documentation for the current stable release version can always be found at this URL:

https://docs.espressif.com/projects/esp-idf/en/stable/

Documentation for the latest version (master branch) can always be found at this URL:

https://docs.espressif.com/projects/esp-idf/en/latest/

The full history of releases can be found on the GitHub repository Releases page. There you can find release notes, links to each version of the documentation, and instructions for obtaining each version.

9.2 Which Version Should I Start With?

- For production purposes, use the current stable version. Stable versions have been manually tested, and are updated with "bugfix releases" which fix bugs without changing other functionality (see *Versioning Scheme* for more details). Every stable release version can be found on the Releases page. Also refer to Compatibility Between ESP-IDF Releases and Revisions of Espressif SoCs to make sure the ESP-IDF version you selected is compatible with the chip revision you are going to produce with.
- For prototyping, experimentation or for developing new ESP-IDF features, use the latest version (master branch in Git). The latest version in the master branch has all the latest features and has passed automated testing, but has not been completely manually tested ("bleeding edge").
- If a required feature is not yet available in a stable release, but you do not want to use the master branch, it is possible to check out a pre-release version or a release branch. It is recommended to start from a stable version and then follow the instructions for *Updating to a Pre-Release Version* or *Updating to a Release Branch*.
- If you plan to use another project which is based on ESP-IDF, please check the documentation of that project to determine the version(s) of ESP-IDF it is compatible with.

See *Updating ESP-IDF* if you already have a local copy of ESP-IDF and wish to update it.

9.3 Versioning Scheme

ESP-IDF uses Semantic Versioning. This means that:

- Major Releases, like `v3.0`, add new functionality and may change functionality. This includes removing deprecated functionality.
  If updating to a new major release (for example, from `v2.1` to `v3.0`), some of your project's code may need updating and functionality may need to be re-tested. The release notes on the Releases page include lists of Breaking Changes to refer to.
- Minor Releases like `v3.1` add new functionality and fix bugs but will not change or remove documented functionality, or make incompatible changes to public APIs.
  If updating to a new minor release (for example, from `v3.0` to `v3.1`), your project's code does not require updating, but you should re-test your project. Pay particular attention to the items mentioned in the release notes on the Releases page.
- Bugfix Releases like `v3.0.1` only fix bugs and do not add new functionality.
  If updating to a new bugfix release (for example, from `v3.0` to `v3.0.1`), you do not need to change any code in your project, and you only need to re-test the functionality directly related to bugs listed in the release notes on the Releases page.

9.4 Support Periods

Each ESP-IDF major and minor release version has an associated support period. After this period, the release is End of Life and no longer supported.

The ESP-IDF Support Period Policy explains this in detail, and describes how the support periods for each release are determined.

Each release on the Releases page includes information about the support period for that particular release.

As a general guideline:

- If starting a new project, use the latest stable release.
- If you have a GitHub account, click the "Watch" button in the top-right of the Releases page and choose "Releases only". GitHub will notify you whenever a new release is available. Whenever a bug fix release is available for the version you are using, plan to update to it.
- If possible, periodically update the project to a new major or minor ESP-IDF version (for example, once a year.) The update process should be straightforward for Minor updates, but may require some planning and checking of the release notes for Major updates.
- Always plan to update to a newer release before the release you are using becomes End of Life.

Each ESP-IDF major and minor release (V4.1, V4.2, etc) is supported for 30 months after the initial stable release date.

Supported means that the ESP-IDF team will continue to apply bug fixes, security fixes, etc to the release branch on GitHub, and periodically make new bugfix releases as needed.

Support period is divided into "Service" and "Maintenance" period:

Period	Duration	Recommended for new projects?
Service	12 months	Yes
Maintenance	18 months	No

During the Service period, bugfixes releases are more frequent. In some cases, support for new features may be added during the Service period (this is reserved for features which are needed to meet particular regulatory requirements or standards for new products, and which carry a very low risk of introducing regressions.)

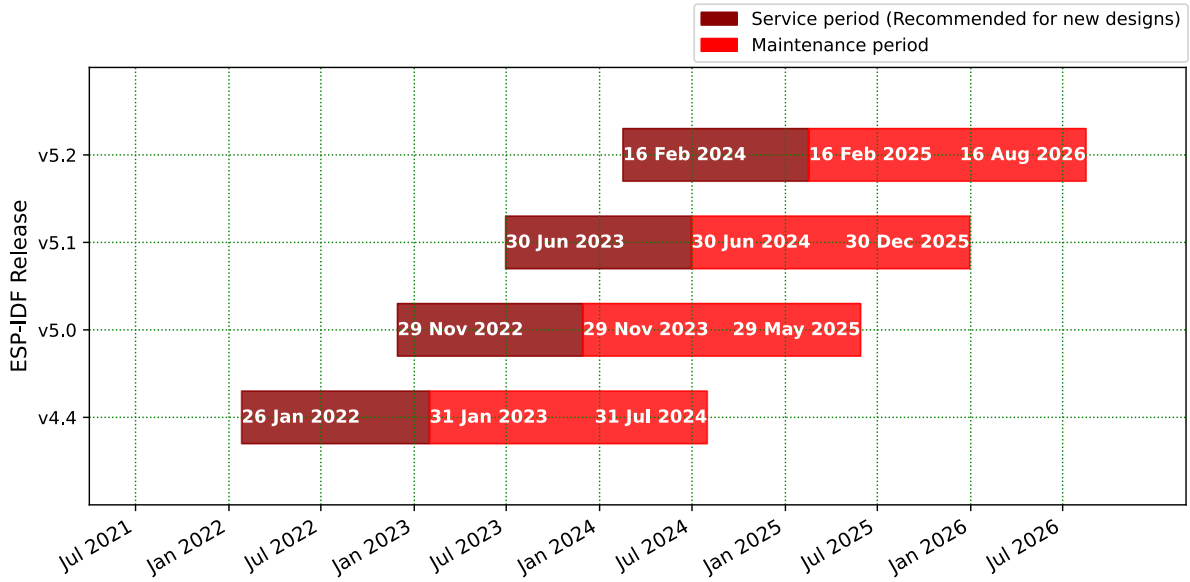
During the Maintenance period, the version is still supported but only bugfixes for high severity issues or security issues will be applied.

Using an "In Service" version is recommended when starting a new project.

Users are encouraged to upgrade all projects to a newer ESP-IDF release before the support period finishes and the release becomes End of Life (EOL). It is our policy to not continue fixing bugs in End of Life releases.

Pre-release versions (betas, previews, `-rc` and `-dev` versions, etc) are not covered by any support period. Sometimes a particular feature is marked as "Preview" in a release, which means it is also not covered by the support period.

The ESP-IDF Programming Guide has information about the different versions of ESP-IDF (major, minor, bugfix, etc).



9.5 Checking the Current Version

The local ESP-IDF version can be checked by using idf.py:

```
idf.py --version
```

The ESP-IDF version is also compiled into the firmware and can be accessed (as a string) via the macro `IDF_VER`. The default ESP-IDF bootloader will print the version on boot (the version information is not always updated if the code in the GitHub repo is updated, it only changes if there is a clean build or if that particular source file is recompiled).

If writing code that needs to support multiple ESP-IDF versions, the version can be checked at compile time using *compile-time macros*.

Examples of ESP-IDF versions:

Version String	Meaning
`v3.2-dev-306-gbeb3611ca`	Master branch pre-release. - `v3.2-dev` - in development for version 3.2. - `306` - number of commits after v3.2 development started. - `beb3611ca` - commit identifier.
`v3.0.2`	Stable release, tagged `v3.0.2`.
`v3.1-beta1-75-g346d6b0ea`	Beta version in development (on a *release branch*). - `v3.1-beta1` - pre-release tag. - `75` - number of commits after the pre-release beta tag was assigned. - `346d6b0ea` - commit identifier.
`v3.0.1-dirty`	Stable release, tagged `v3.0.1`. - `dirty` means that there are modifications in the local ESP-IDF directory.

9.6 Git Workflow

The development (Git) workflow of the Espressif ESP-IDF team is as follows:

- New work is always added on the master branch (latest version) first. The ESP-IDF version on `master` is always tagged with `-dev` (for "in development"), for example `v3.1-dev`.
- Changes are first added to an internal Git repository for code review and testing but are pushed to GitHub after automated testing passes.
- When a new version (developed on `master`) becomes feature complete and "beta" quality, a new branch is made for the release, for example `release/v3.1`. A pre-release tag is also created, for example `v3.1-beta1`. You can see a full list of branches and a list of tags on GitHub. Beta pre-releases have release notes which may include a significant number of Known Issues.
- As testing of the beta version progresses, bug fixes will be added to both the `master` branch and the release branch. New features for the next release may start being added to `master` at the same time.
- Once testing is nearly complete a new release candidate is tagged on the release branch, for example `v3.1-rc1`. This is still a pre-release version.
- If no more significant bugs are found or reported, then the final Major or Minor Version is tagged, for example `v3.1`. This version appears on the Releases page.
- As bugs are reported in released versions, the fixes will continue to be committed to the same release branch.
- Regular bugfix releases are made from the same release branch. After manual testing is complete, a bugfix release is tagged (i.e., `v3.1.1`) and appears on the Releases page.

9.7 Updating ESP-IDF

Updating ESP-IDF depends on which version(s) you wish to follow:

- *Updating to Stable Release* is recommended for production use.

- *Updating to Master Branch* is recommended for the latest features, development use, and testing.
- *Updating to a Release Branch* is a compromise between the first two.

Note: These guides assume that you already have a local copy of ESP-IDF cloned. To get one, check Step 2 in the *Getting Started* guide for any ESP-IDF version.

9.7.1 Updating to Stable Release

To update to a new ESP-IDF release (recommended for production use), this is the process to follow:

- Check the Releases page regularly for new releases.
- When a bugfix release for the version you are using is released (for example, if using `v3.0.1` and `v3.0.2` is released), check out the new bugfix version into the existing ESP-IDF directory.
- In Linux or macOS system, please run the following commands to update the local branch to vX.Y.Z:

```
cd $IDF_PATH
git fetch
git checkout vX.Y.Z
git submodule update --init --recursive
```

- In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.
- When major or minor updates are released, check the Release Notes on the releases page and decide if you want to update or to stay with your current release. Updating is via the same Git commands shown above.

Note: If you installed the stable release via zip file instead of using git, it might not be possible to update versions using the commands. In this case, update by downloading a new zip file and replacing the entire `IDF_PATH` directory with its contents.

9.7.2 Updating to a Pre-Release Version

It is also possible to `git checkout` a tag corresponding to a pre-release version or release candidate, the process is the same as *Updating to Stable Release*.

Pre-release tags are not always found on the Releases page. Consult the list of tags on GitHub for a full list. Caveats for using a pre-release are similar to *Updating to a Release Branch*.

9.7.3 Updating to Master Branch

Note: Using Master branch means living "on the bleeding edge" with the latest ESP-IDF code.

To use the latest version on the ESP-IDF master branch, this is the process to follow:

- In Linux or macOS system, please run the following commands to check out to the master branch locally:

```
cd $IDF_PATH
git checkout master
git pull
git submodule update --init --recursive
```

- In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.
- Periodically, re-run `git pull` to pull the latest version of master. Note that you may need to change your project or report bugs after updating your master branch.

- To switch from master to a release branch or stable version, run `git checkout` as shown in the other sections.

Important: It is strongly recommended to regularly run `git pull` and then `git submodule update --init --recursive` so a local copy of master does not get too old. Arbitrary old master branch revisions are effectively unsupportable "snapshots" that may have undocumented bugs. For a semi-stable version, try *Updating to a Release Branch* instead.

9.7.4 Updating to a Release Branch

In terms of stability, using a release branch is part-way between using the master branch and only using stable releases. A release branch is always beta quality or better, and receives bug fixes before they appear in each stable release.

You can find a list of branches on GitHub.

For example, in Linux or macOS system, you can execute the following commands to follow the branch for ESP-IDF v3.1, including any bugfixes for future releases like `v3.1.1`, etc:

```
cd $IDF_PATH
git fetch
git checkout release/v3.1
git pull
git submodule update --init --recursive
```

In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.

Each time you `git pull` this branch, ESP-IDF will be updated with fixes for this release.

Note: There is no dedicated documentation for release branches. It is recommended to use the documentation for the closest version to the branch which is currently checked out.

Chapter 10

Resources

10.1 PlatformIO

- *What Is PlatformIO?*
- *Installation*
- *Configuration*
- *Tutorials*
- *Project Examples*
- *Next Steps*

10.1.1 What Is PlatformIO?

PlatformIO is a cross-platform embedded development environment with out-of-the-box support for ESP-IDF.

Since ESP-IDF support within PlatformIO is not maintained by the Espressif team, please report any issues with PlatformIO directly to its developers in the official PlatformIO repositories.

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in the official PlatformIO documentation.

10.1.2 Installation

- PlatformIO IDE is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms.
- PlatformIO Core (CLI) is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services

10.1.3 Configuration

Please go through the official PlatformIO configuration guide for ESP-IDF.

10.1.4 Tutorials

- ESP-IDF and ESP32-DevKitC: debugging, unit testing, project analysis

10.1.5 Project Examples

Please check ESP-IDF page in the official PlatformIO documentation

10.1.6 Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Learn more about integrations with other IDEs or Text Editors
- Get help from PlatformIO community

10.2 CLion

10.2.1 What Is CLion?

CLion is a cross-platform integrated Development Environment (IDE) for C and C++ programming. CLion also provides dedicated support for ESP-IDF, allowing developers to seamlessly work with the ESP-IDF framework.

10.2.2 Installation

To install CLion, please follow the instructions provided in Install CLion for your operating system (Windows, macOS, or Linux).

10.2.3 Configuration

To configure an ESP-IDF project in CLion, please refer to the guide on Configure an ESP CMake project in CLion. This guide will walk you through the necessary steps to set up your project properly.

10.2.4 Resources

For more information about CLion and ESP-IDF integration, please refer to the following resource:

- CLion Documentation: The official documentation for CLion provides detailed information on various aspects of the IDE, including ESP-IDF integration.

10.3 VisualGDB

10.3.1 What Is VisualGDB?

VisualGDB is a powerful extension for Microsoft Visual Studio that provides advanced development tools and features for embedded systems, including support for the ESP-IDF framework. VisualGDB allows you to leverage the familiar and feature-rich Visual Studio environment for your ESP-IDF projects, enabling efficient coding, debugging, and deployment.

10.3.2 Installation

Please download and install VisualGDB by following the steps stated in VisualGDB download and installation.

10.3.3 Configuration

Creating Advanced ESP32 Projects with ESP-IDF provide basic steps about how to configure an ESP-IDF project in VisualGDB.

You can also refer to Advanced ESP-IDF Project Structure to get a more comprehensive impression for developing ESP-IDF projects using VisualGDB.

10.3.4 Resources

For more information about VisualGDB and ESP-IDF integration, refer to the following resources:

- VisualGDB Documentation: The official documentation for VisualGDB provides comprehensive guides and tutorials on using VisualGDB with ESP-IDF.

For inquiries related to these third-party tools, we recommend seeking assistance from the respective tool's support channels or user communities.

10.4 Useful Links

- The esp32.com forum is a place to ask questions and find community resources.
- Check the Issues section on GitHub if you find a bug or have a feature request. Please check existing Issues before opening a new one.
- A comprehensive collection of solutions, practical applications, components and drivers based on ESP-IDF is available in ESP IoT Solution repository. In most of cases descriptions are provided both in English and in 中文.
- To develop applications using Arduino platform, refer to Arduino core for the ESP32, ESP32-S2 and ESP32-C3.
- Several books have been written about ESP32 and they are listed on Espressif web site.
- If you're interested in contributing to ESP-IDF, please check the *Contributions Guide*.
- For additional ESP32-C3 product related information, please refer to documentation section of Espressif site.
- Download latest and previous versions of this documentation in PDF and HTML format.

Copyrights and Licenses

11.1 Software Copyrights

All original source code in this repository is Copyright (C) 2015-2023 Espressif Systems. This source code is licensed under the Apache License 2.0 as described in the file LICENSE.

Additional third party copyrighted code is included under the following licenses.

Where source code headers specify Copyright & License information, this information takes precedence over the summaries made here.

Some examples use external components which are not Apache licensed, please check the copyright description in each example source code.

11.1.1 Firmware Components

These third party libraries can be included into the application (firmware) produced by ESP-IDF.

- Newlib is licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB .
- Xtensa header files are Copyright (C) 2013 Tensilica Inc and are licensed under the MIT License as reproduced in the individual header files.
- Original parts of FreeRTOS (components/freertos) are Copyright (C) 2017 Amazon.com, Inc. or its affiliates, and are licensed under the MIT License, as described in license.txt .
- Original parts of LWIP (components/lwip) are Copyright (C) 2001, 2002 Swedish Institute of Computer Science and are licensed under the BSD License as described in COPYING file .
- wpa_supplicant, Copyright (C) 2003-2022 Jouni Malinen <j@w1.fi> and contributors and licensed under the BSD License.
- Fast PBKDF2 , Copyright (C) 2015 Joseph Birr-Pixton and licensed under CC0 Public Domain Dedication License.
- FreeBSD net80211, Copyright (C) 2004-2008 Sam Leffler, Errno Consulting and licensed under the BSD License.
- argtable3 argument parsing library, Copyright (C) 1998-2001,2003-2011,2013 Stewart Heitmann and licensed under 3-clause BSD license. argtable3 also includes the following software components. For details, please see argtable3 LICENSE file .
  - C Hash Table library, Copyright (C) 2002 Christopher Clark and licensed under 3-clause BSD License.
  - The Better String library, Copyright (C) 2014 Paul Hsieh and licensed under 3-clause BSD License.
  - TCL library, Copyright the Regents of the University of California, Sun Microsystems, Inc., Scriptics Corporation, ActiveState Corporation and other parties, and licensed under TCL/TK License.

- linenoise line editing library, Copyright (C) 2010-2014 Salvatore Sanfilippo, Copyright (C) 2010-2013 Pieter Noordhuis, licensed under 2-clause BSD License.
- FatFS library, Copyright (C) 2017 ChaN, is licensed under a BSD-style license .
- cJSON library, Copyright (C) 2009-2017 Dave Gamble and cJSON contributors, is licensed under MIT License as described in LICENSE file .
- micro-ecc library, Copyright (C) 2014 Kenneth MacKay, is licensed under 2-clause BSD License.
- Mbed TLS library, Copyright (C) 2006-2018 ARM Limited, is licensed under Apache License 2.0 as described in LICENSE file .
- SPIFFS library, Copyright (C) 2013-2017 Peter Andersson, is licensed under MIT License as described in LICENSE file .
- SD/MMC driver is derived from OpenBSD SD/MMC driver, Copyright (C) 2006 Uwe Stuehler, and is licensed under BSD License.
- ESP-MQTT Package (contiki-mqtt), Copyright (C) 2014 Stephen Robinson, MQTT-ESP - Tuan PM <tuanpm at live dot com> is licensed under Apache License 2.0 as described in LICENSE file .
- BLE Mesh is adapted from Zephyr Project, Copyright (C) 2017-2018 Intel Corporation and licensed under Apache License 2.0.
- mynewt-nimble, Copyright (C) 2015-2018 The Apache Software Foundation, is licensed under Apache License 2.0 as described in LICENSE file .
- TLSF allocator, Copyright (C) 2006-2016 Matthew Conte, and licensed under the BSD 3-clause license.
- openthread, Copyright (C) The OpenThread Authors, is licensed under BSD License as described in LICENSE file .
- UBSAN runtime , Copyright (C) 2016 Linaro Limited and Jiří Zárevúcky, licensed under the BSD 2-clause license.
- HTTP Parser is based on src/http/ngx_http_parse.c from NGINX copyright Igor Sysoev. Additional changes are licensed under the same terms as NGINX and Joyent, Inc. and other Node contributors. For details please check LICENSE file .
- SEGGER SystemView target-side library, Copyright (C) 1995-2021 SEGGER Microcontroller GmbH, is licensed under BSD 1-clause license.
- protobuf-c is Protocol Buffers implementation in C, Copyright (C) 2008-2022 Dave Benson and the protobuf-c authors. For details please check LICENSE file .
- CMock mock/stub generator for C, Copyright (C) 2007-14 Mike Karlesky, Mark VanderVoord, Greg Williams, is licensed under MIT License as described in LICENSE file .
- Unity Simple Unit Testing library, Copyright (C) 2007-23 Mike Karlesky, Mark VanderVoord, Greg Williams, is licensed under MIT License as described in LICENSE file .

11.1.2 Documentation

- HTML version of the ESP-IDF Programming Guide uses the Sphinx theme sphinx_idf_theme, which is Copyright (C) 2013-2020 Dave Snider, Read the Docs, Inc. & contributors, and Espressif Systems (Shanghai) CO., LTD. It is based on sphinx_rtd_theme. Both are licensed under MIT License.

11.2 ROM Source Code Copyrights

Espressif SoCs mask ROM hardware includes binaries compiled from portions of the following third party software:

- Newlib , licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB .
- Xtensa libhal, Copyright (C) Tensilica Inc and licensed under the MIT License (see below).
- TinyBasic Plus, Copyright (C) Mike Field & Scott Lawrence and licensed under the MIT License (see below).
- miniz, by Rich Geldreich - placed into the public domain.
- TJpgDec, Copyright (C) 2011 ChaN, all right reserved. See below for license.
- **Parts of Zephyr RTOS USB stack:**
  - DesignWare USB device driver, Copyright (C) 2016 Intel Corporation and licensed under Apache License 2.0.
  - Generic USB device driver, Copyright (C) 2006 Bertrik Sikken (bertrik@sikken.nl), 2016 Intel Corporation and licensed under BSD 3-clause license.

- USB descriptors functionality, Copyright (C) 2017 PHYTEC Messtechnik GmbH, 2017-2018 Intel Corporation and licensed under Apache License 2.0.
- USB DFU class driver, Copyright (C) 2015-2016 Intel Corporation, 2017 PHYTEC Messtechnik GmbH and licensed under BSD 3-clause license.
- USB CDC ACM class driver, Copyright (C) 2015-2016 Intel Corporation and licensed under Apache License 2.0.

11.3 Xtensa libhal MIT License

Copyright (C) 2003, 2006, 2010 Tensilica Inc.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

11.5 TJpgDec License

TJpgDec - Tiny JPEG Decompressor R0.01 (C) 2011 ChaN, is a generic JPEG decompressor module for tiny embedded systems.This is a free software that opened for education, research and commercial developments under license policy of following terms:

Copyright (C) 2011 ChaN, all right reserved.

- The TJpgDec module is a free software and there is NO WARRANTY.
- No restriction on use. You can use, modify and redistribute it for personal, non-profit or commercial products UNDER YOUR RESPONSIBILITY.
- Redistributions of source code must retain the above copyright notice.

Chapter 12

About

This is documentation of ESP-IDF, the framework to develop applications for ESP32-C3.

The ESP32-C3 is a 2.4 GHz Wi-Fi Bluetooth Low Energy combo SoC, which integrates a 32-bit RISC-V RV32IMC single-core processor.

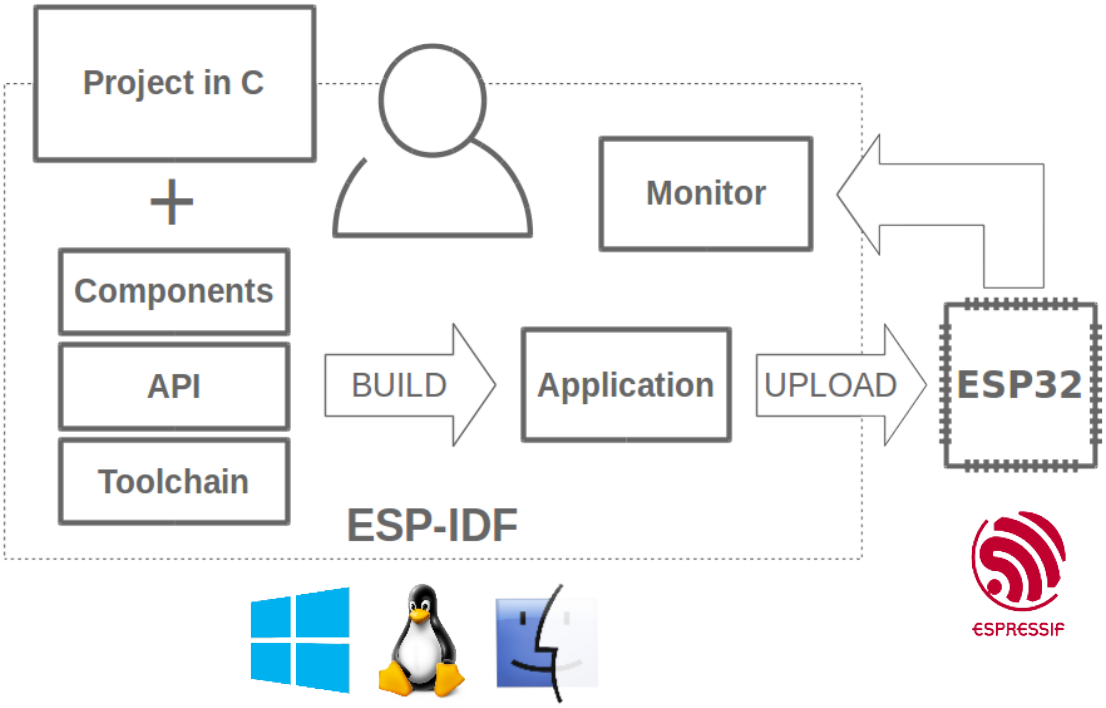

Fig. 1: Espressif IoT Integrated Development Framework

The ESP-IDF, Espressif IoT Development Framework, provides toolchain, API, components and workflows to develop applications for ESP32-C3 using Windows, Linux and macOS operating systems.

Chapter 13

Switch Between Languages

The ESP-IDF Programming Guide is now available in two languages. Please refer to the English version if there is any discrepancy.

- English
- Chinese

You can easily change from one language to another by clicking the language link you can find at the top of every document that has a translation.
