    TaskHandle_t xHandle = NULL;

    // Create the task without using any dynamic memory allocation.
xHandle = xTaskCreateStatic( vTaskCode, // Function that implements the task.
            "NAME", // Text name for the task.
            STACK_SIZE, // Stack size in words, not bytes.
            ( void * ) 1, // Parameter passed into the task.
            tskIDLE_PRIORITY, // Priority at which the task is created.
            xStack, // Array to use as the task's stack.
            &xTaskBuffer ); // Variable to hold the task's data...

    // puxStackBuffer and pxTaskBuffer were not NULL, so the task will have // been created, and xHandle will be the task's handle. Use the handle // to suspend the task.
    vTaskSuspend( xHandle );
}

Note: If configNUMBER_OF_CORES > 1, this function will create an unpinned task (see tskNO_AFFINITY for more details).

Note: If program uses thread local variables (ones specified with "__thread" keyword) then storage for them will be allocated on the task’s stack.
Parameters

- **pxTaskCode** - Pointer to the task entry function. Tasks must be implemented to never return (i.e. continuous loop).
- **pcName** - A descriptive name for the task. This is mainly used to facilitate debugging. The maximum length of the string is defined by configMAX_TASK_NAME_LEN in FreeRTOSConfig.h.
- **ulStackDepth** - The size of the task stack specified as the NUMBER OF BYTES. Note that this differs from vanilla FreeRTOS.
- **pvParameters** - Pointer that will be used as the parameter for the task being created.
- **uxPriority** - The priority at which the task will run.
- **puxStackBuffer** - Must point to a StackType_t array that has at least ulStackDepth indexes - the array will then be used as the task’s stack, removing the need for the stack to be allocated dynamically.
- **pxTaskBuffer** - Must point to a variable of type StaticTask_t, which will then be used to hold the task’s data structures, removing the need for the memory to be allocated dynamically.

Returns

If neither puxStackBuffer nor pxTaskBuffer are NULL, then the task will be created and a handle to the created task is returned. If either puxStackBuffer or pxTaskBuffer are NULL then the task will not be created and NULL is returned.

```c
void vTaskAllocateMPURegions(TaskHandle_t xTask, const MemoryRegion_t* const pxRegions) {
    Memory regions are assigned to a restricted task when the task is created by a call to xTaskCreateRestricted(). These regions can be redefined using vTaskAllocateMPURegions().
}
```

Example usage:

```c
// Define an array of MemoryRegion_t structures that configures an MPU region // allowing read/write access for 1024 bytes starting at the beginning of the // ucOneKByte array. The other two of the maximum 3 definable regions are // unused so set to zero.
static const MemoryRegion_t xAltRegions[portNUM_CONFIGURABLE_REGIONS] = {
    // Base address Length Parameters
    { ucOneKByte, 1024, portMPU_REGION_READ_WRITE },
    { 0, 0, 0 },
    { 0, 0, 0 }
};

void vATask(void *pvParameters) {
    // This task was created such that it has access to certain regions of // memory as defined by the MPU configuration. At some point it is // desired that these MPU regions are replaced with that defined in the // xAltRegions const struct above. Use a call to vTaskAllocateMPURegions() // for this purpose. NULL is used as the task handle to indicate that this // function should modify the MPU regions of the calling task.
    vTaskAllocateMPURegions(NULL, xAltRegions);

    // Now the task can continue its function, but from this point on can only // access its stack and the ucOneKByte array (unless any other statically // defined or shared regions have been declared elsewhere).
}
```

Parameters

- **xTask** - The handle of the task being updated.
- **pxRegions** - A pointer to a MemoryRegion_t structure that contains the new memory region definitions.
void \texttt{vTaskDelete} (\texttt{TaskHandle_t xTaskToDelete})

\texttt{INCLUDE_vTaskDelete} must be defined as 1 for this function to be available. See the configuration section for more information.

Remove a task from the RTOS real time kernel's management. The task being deleted will be removed from all ready, blocked, suspended and event lists.

NOTE: The idle task is responsible for freeing the kernel allocated memory from tasks that have been deleted. It is therefore important that the idle task is not starved of microcontroller processing time if your application makes any calls to \texttt{vTaskDelete}(). Memory allocated by the task code is not automatically freed, and should be freed before the task is deleted.

See the demo application file \texttt{death.c} for sample code that utilises \texttt{vTaskDelete}().

Example usage:

```
void \texttt{vOtherFunction} (\texttt{void})
{
    TaskHandle_t xHandle;

    // Create the task, storing the handle.
    xTaskCreate( \texttt{vTaskCode}, "NAME", \texttt{STACK_SIZE}, \texttt{NULL}, \texttt{tskIDLE_PRIORITY}, \&xHandle_~);

    // Use the handle to delete the task.
    vTaskDelete( xHandle );
}
```

\textbf{Parameters xTaskToDelete} – The handle of the task to be deleted. Passing NULL will cause the calling task to be deleted.

void \texttt{vTaskDelay} (const \texttt{TickType_t xTicksToDelay})

Delay a task for a given number of ticks. The actual time that the task remains blocked depends on the tick rate. The constant \texttt{portTICK\_PERIOD\_MS} can be used to calculate real time from the tick rate - with the resolution of one tick period.

\texttt{INCLUDE_vTaskDelay} must be defined as 1 for this function to be available. See the configuration section for more information.

\texttt{vTaskDelay}() specifies a time at which the task wishes to unblock relative to the time at which \texttt{vTaskDelay}() is called. For example, specifying a block period of 100 ticks will cause the task to unblock 100 ticks after \texttt{vTaskDelay}() is called. \texttt{vTaskDelay}() does not therefore provide a good method of controlling the frequency of a periodic task as the path taken through the code, as well as other task and interrupt activity, will affect the frequency at which \texttt{vTaskDelay}() gets called and therefore the time at which the task next executes. See \texttt{xTaskDelayUntil()} for an alternative API function designed to facilitate fixed frequency execution. It does this by specifying an absolute time (rather than a relative time) at which the calling task should unblock.

Example usage:

```
void \texttt{vTaskFunction} (\texttt{void \* pvParameters})
{
    // Block for 500ms.
    \texttt{const TickType_t xDelay} = 500 / \texttt{portTICK\_PERIOD\_MS};

    \texttt{for} (\texttt{;;})
    {
        // Simply toggle the LED every 500ms, blocking between each toggle.
        vToggleLED();
        \texttt{vTaskDelay( xDelay );}
    }
```

(continues on next page)
Parameters **xTicksToDelay** – The amount of time, in tick periods, that the calling task should block.

```c
BaseType_t xTaskDelayUntil (TickType_t *const pxPreviousWakeTime, const TickType_t xTimeIncrement)
```

INCLUDE_xTaskDelayUntil must be defined as 1 for this function to be available. See the configuration section for more information.

Delay a task until a specified time. This function can be used by periodic tasks to ensure a constant execution frequency.

This function differs from **vTaskDelay()** in one important aspect: **vTaskDelay()** will cause a task to block for the specified number of ticks from the time **vTaskDelay()** is called. It is therefore difficult to use **vTaskDelay()** by itself to generate a fixed execution frequency as the time between a task starting to execute and that task calling **vTaskDelay()** may not be fixed [the task may take a different path though the code between calls, or may get interrupted or preempted a different number of times each time it executes].

Whereas **vTaskDelay()** specifies a wake time relative to the time at which the function is called, **xTaskDelayUntil()** specifies the absolute (exact) time at which it wishes to unblock.

The macro **pdMS_TO_TICKS()** can be used to calculate the number of ticks from a time specified in milliseconds with a resolution of one tick period.

Example usage:

```c
// Perform an action every 10 ticks.
vTaskFunction( void * pvParameters )
{
    TickType_t xLastWakeTime;
    const TickType_t xFrequency = 10;
    BaseType_t xWasDelayed;

    // Initialise the xLastWakeTime variable with the current time.
    xLastWakeTime = xTaskGetTickCount();
    for(;; )
    {
        // Wait for the next cycle.
        xWasDelayed = xTaskDelayUntil( &xLastWakeTime, xFrequency );

        // Perform action here. xWasDelayed value can be used to determine
        // whether a deadline was missed if the code here took too long.
    }
}
```

Parameters

- **pxPreviousWakeTime** – Pointer to a variable that holds the time at which the task was last unblocked. The variable must be initialised with the current time prior to its first use (see the example below). Following this the variable is automatically updated within **xTaskDelayUntil()**.
- **xTimeIncrement** – The cycle time period. The task will be unblocked at time \(*\text{pxPreviousWakeTime} + \text{xTimeIncrement}\). Calling **xTaskDelayUntil** with the same **xTimeIncrement** parameter value will cause the task to execute with a fixed interface period.

Returns Value which can be used to check whether the task was actually delayed. Will be **pdTRUE** if the task was delayed and **pdFALSE** otherwise. A task will not be delayed if the next expected wake time is in the past.
**Chapter 2. API Reference**

**BaseType_t xTaskAbortDelay** *(TaskHandle_t xTask)*

INCLUDE_xTaskAbortDelay must be defined as 1 in FreeRTOSConfig.h for this function to be available.

A task will enter the Blocked state when it is waiting for an event. The event it is waiting for can be a temporal event (waiting for a time), such as when vTaskDelay() is called, or an event on an object, such as when xQueueReceive() or ulTaskNotifyTake() is called. If the handle of a task that is in the Blocked state is used in a call to xTaskAbortDelay() then the task will leave the Blocked state, and return from whichever function call placed the task into the Blocked state.

There is no ‘FromISR’ version of this function as an interrupt would need to know which object a task was blocked on in order to know which actions to take. For example, if the task was blocked on a queue the interrupt handler would then need to know if the queue was locked.

**Parameters**
- **xTask** – The handle of the task to remove from the Blocked state.

**Returns**
- If the task referenced by xTask was not in the Blocked state then pdFAIL is returned.
- Otherwise pdPASS is returned.

**UBaseType_t uxTaskPriorityGet** *(const TaskHandle_t xTask)*

INCLUDE_uxTaskPriorityGet must be defined as 1 for this function to be available. See the configuration section for more information.

Obtain the priority of any task.

**Example usage:**

```c
void vAFunction( void )
{
    TaskHandle_t xHandle;

    // Create a task, storing the handle.
    xTaskCreate( vTaskCode, "NAME", STACK_SIZE, NULL, tskIDLE_PRIORITY, &xHandle);

    // ...

    // Use the handle to obtain the priority of the created task.
    // It was created with tskIDLE_PRIORITY, but may have changed // it itself.
    if( uxTaskPriorityGet( xHandle ) != tskIDLE_PRIORITY )
    {
        // The task has changed it's priority.
    }

    // ...

    // Is our priority higher than the created task?
    if( uxTaskPriorityGet( xHandle ) < uxTaskPriorityGet( NULL ) )
    {
        // Our priority (obtained using NULL handle) is higher.
    }
}
```

**Parameters**
- **xTask** – Handle of the task to be queried. Passing a NULL handle results in the priority of the calling task being returned.

**Returns**
- The priority of xTask.

**UBaseType_t uxTaskPriorityGetFromISR** *(const TaskHandle_t xTask)*

A version of uxTaskPriorityGet() that can be used from an ISR.
**eTaskState eTaskGetState**(TaskHandle_t xTask)

INClude eTaskGetState must be defined as 1 for this function to be available. See the configuration section for more information.

Obtain the state of any task. States are encoded by the eTaskState enumerated type.

**Parameters**
- **xTask** - Handle of the task to be queried.

**Returns**
The state of xTask at the time the function was called. Note the state of the task might change between the function being called, and the functions return value being tested by the calling task.

**vTaskGetInfo**(TaskHandle_t xTask, TaskStatus_t *pxTaskStatus, BaseType_t xGetFreeStackSpace, eTaskState eState)

configUSE_TRACE_FACILITY must be defined as 1 for this function to be available. See the configuration section for more information.

Populates a TaskStatus_t structure with information about a task.

**Example usage:**

```c
void vAFunction( void )
{
    TaskHandle_t xHandle;
    TaskStatus_t xTaskDetails;

    // Obtain the handle of a task from its name.
    xHandle = xTaskGetHandle( "Task_Name" );

    // Check the handle is not NULL.
    configASSERT( xHandle );

    // Use the handle to obtain further information about the task.
    vTaskGetInfo( xHandle,
                  &xTaskDetails,
                  pdTRUE, // Include the high water mark in xTaskDetails.
                  eInvalid ); // Include the task state in xTaskDetails.
}
```

**Parameters**
- **xTask** - Handle of the task being queried. If xTask is NULL then information will be returned about the calling task.
- **pxTaskStatus** - A pointer to the TaskStatus_t structure that will be filled with information about the task referenced by the handle passed using the xTask parameter.
- **xGetFreeStackSpace** - The TaskStatus_t structure contains a member to report the stack high water mark of the task being queried. Calculating the stack high water mark takes a relatively long time, and can make the system temporarily unresponsive - so the xGetFreeStackSpace parameter is provided to allow the high water mark checking to be skipped. The high watermark value will only be written to the TaskStatus_t structure if xGetFreeStackSpace is not set to pdFALSE;
- **eState** - The TaskStatus_t structure contains a member to report the state of the task being queried. Obtaining the task state is not as fast as a simple assignment - so the eState parameter is provided to allow the state information to be omitted from the TaskStatus_t structure. To obtain state information then set eState to eInvalid - otherwise the value passed in eState will be reported as the task state in the TaskStatus_t structure.

**vTaskPrioritySet**(TaskHandle_t xTask, UBaseType_t uxNewPriority)

INClude vTaskPrioritySet must be defined as 1 for this function to be available. See the configuration section for more information.

Set the priority of any task.
A context switch will occur before the function returns if the priority being set is higher than the currently executing task.

Example usage:

```c
void vAFunction( void )
{
    TaskHandle_t xHandle;

    // Create a task, storing the handle.
    xTaskCreate( vTaskCode, "NAME", STACK_SIZE, NULL, tskIDLE_PRIORITY, &xHandle );

    // ...

    // Use the handle to raise the priority of the created task.
    vTaskPrioritySet( xHandle, tskIDLE_PRIORITY + 1 );

    // ...

    // Use a NULL handle to raise our priority to the same value.
    vTaskPrioritySet( NULL, tskIDLE_PRIORITY + 1 );
}
```

**Parameters**

- `xTask` – Handle to the task for which the priority is being set. Passing a NULL handle results in the priority of the calling task being set.
- `uxNewPriority` – The priority to which the task will be set.

void `vTaskSuspend` (TaskHandle_t xTaskToSuspend)

INCLUDE_vTaskSuspend must be defined as 1 for this function to be available. See the configuration section for more information.

Suspend any task. When suspended a task will never get any microcontroller processing time, no matter what its priority.

Calls to `vTaskSuspend` are not accumulative - i.e. calling `vTaskSuspend()` twice on the same task still only requires one call to `vTaskResume()` to ready the suspended task.

Example usage:

```c
void vAFunction( void )
{
    TaskHandle_t xHandle;

    // Create a task, storing the handle.
    xTaskCreate( vTaskCode, "NAME", STACK_SIZE, NULL, tskIDLE_PRIORITY, &xHandle );

    // ...

    // Use the handle to suspend the created task.
    vTaskSuspend( xHandle );

    // ...

    // The created task will not run during this period, unless
    // another task calls vTaskResume( xHandle ).

    // ...
}
```
//... 

// Suspend ourselves.
void vTaskSuspend( NULL );

// We cannot get here unless another task calls vTaskResume
// with our handle as the parameter.
}

**Parameters**

- **xTaskToSuspend** – Handle to the task being suspended. Passing a NULL handle will cause the calling task to be suspended.

**void vTaskResume (TaskHandle_t xTaskToResume)**

INCLUDE vTaskSuspend must be defined as 1 for this function to be available. See the configuration section for more information.

Resumes a suspended task.

A task that has been suspended by one or more calls to vTaskSuspend() will be made available for running again by a single call to vTaskResume().

Example usage:

```c
void vAFunction( void )
{
    TaskHandle_t xHandle;

    // Create a task, storing the handle.
    xTaskCreate( vTaskCode, "NAME", STACK_SIZE, NULL, tskIDLE_PRIORITY, &xHandle );

    //...

    // Use the handle to suspend the created task.
    vTaskSuspend( xHandle );

    //...

    // The created task will not run during this period, unless
    // another task calls vTaskResume( xHandle ).

    //...

    // Resume the suspended task ourselves.
    vTaskResume( xHandle );

    // The created task will once again get microcontroller processing
    // time in accordance with its priority within the system.
}
```

**Parameters**

- **xTaskToResume** – Handle to the task being readied.

**BaseType_t xTaskResumeFromISR (TaskHandle_t xTaskToResume)**

INCLUDE_xTaskResumeFromISR must be defined as 1 for this function to be available. See the configuration section for more information.

An implementation of vTaskResume() that can be called from within an ISR.
A task that has been suspended by one or more calls to vTaskSuspend() will be made available for running again by a single call to xTaskResumeFromISR().

xTaskResumeFromISR() should not be used to synchronise a task with an interrupt if there is a chance that the interrupt could arrive prior to the task being suspended - as this can lead to interrupts being missed. Use of a semaphore as a synchronisation mechanism would avoid this eventuality.

**Parameters** xTaskToResume – Handle to the task being readied.

**Returns** pdTRUE if resuming the task should result in a context switch, otherwise pdFALSE. This is used by the ISR to determine if a context switch may be required following the ISR.

```c
void vTaskSuspendAll (void)
{
    // Prevent the real time kernel swapping out the task.
    vTaskSuspendAll ();

    // Perform the operation here. There is no need to use critical sections as we have all the microcontroller processing time.
    // During this time interrupts will still operate and the kernel tick count will be maintained.
    // ...

    // The operation is complete. Restart the kernel.
    xTaskResumeAll ();
}
```

**BaseType_t xTaskResumeAll (void)**

Resumes scheduler activity after it was suspended by a call to vTaskSuspendAll().

xTaskResumeAll() only resumes the scheduler. It does not unsuspend tasks that were previously suspended by a call to vTaskSuspend().

Example usage:

```c

void vTask1 ( void * pvParameters )
{
    for ( ;; )
    {
        // Task code goes here.
        // ...
        // At some point the task wants to perform a long operation during which it does not want to get swapped out. It cannot use taskENTER_CRITICAL() / taskEXIT_CRITICAL() as the length of the operation may cause interrupts to be missed - including the ticks.
        // Prevent the real time kernel swapping out the task.
        vTaskSuspendAll ();

        // Perform the operation here. There is no need to use critical sections as we have all the microcontroller processing time.
        // During this time interrupts will still operate and the kernel tick count will be maintained.
        // ...

        // The operation is complete. Restart the kernel.
        xTaskResumeAll ();
    }
}
```
for(;;)
{
    // Task code goes here.
    // ...
    // At some point the task wants to perform a long operation during
    // which it does not want to get swapped out. It cannot use
    // taskENTER_CRITICAL() / taskEXIT_CRITICAL () as the length of the
    // operation may cause interrupts to be missed - including the
    // ticks.
    // Prevent the real time kernel swapping out the task.
    vTaskSuspendAll();
    // Perform the operation here. There is no need to use critical
    // sections as we have all the microcontroller processing time.
    // During this time interrupts will still operate and the real
    // time kernel tick count will be maintained.
    // ...
    // The operation is complete. Restart the kernel. We want to force
    // a context switch - but there is no point if resuming the scheduler
    // caused a context switch already.
    if(!xTaskResumeAll())
    {
        taskYIELD();
    }
}

Returns If resuming the scheduler caused a context switch then pdTRUE is returned, otherwise
dFALSe is returned.

TickType_t xTaskGetTickCount (void)

Returns The count of ticks since vTaskStartScheduler was called.

TickType_t xTaskGetTickCountFromISR (void)

This is a version of xTaskGetTickCount() that is safe to be called from an ISR - provided that TickType_t is
the natural word size of the microcontroller being used or interrupt nesting is either not supported or not being
used.

Returns The count of ticks since vTaskStartScheduler was called.

UBaseType_t uxTaskGetNumberOfTasks (void)

Returns The number of tasks that the real time kernel is currently managing. This includes all
ready, blocked and suspended tasks. A task that has been deleted but not yet freed by the idle
task will also be included in the count.

cchar *pcTaskGetName ( TaskHandle_t xTaskToQuery )

Returns The text (human readable) name of the task referenced by the handle xTaskToQuery. A
 task can query its own name by either passing in its own handle, or by setting xTaskToQuery
to NULL.

TaskHandle_t xTaskGetHandle ( const char *pcNameToQuery )

NOTE: This function takes a relatively long time to complete and should be used sparingly.
**Returns**
The handle of the task that has the human readable name pcNameToQuery. NULL is returned if no matching name is found. INCLUDE_xTaskGetHandle must be set to 1 in FreeRTOSConfig.h for pcTaskGetHandle() to be available.

_baseType_t xTaskGetStaticBuffers (TaskHandle_t xTask, StackType_t **ppuxStackBuffer, StaticTask_t **ppxTaskBuffer)_

Retrieve pointers to a statically created task’s data structure buffer and stack buffer. These are the same buffers that are supplied at the time of creation.

**Parameters**
- **xTask** – The task for which to retrieve the buffers.
- **ppuxStackBuffer** – Used to return a pointer to the task’s stack buffer.
- **ppxTaskBuffer** – Used to return a pointer to the task’s data structure buffer.

**Returns**
- pdTRUE if buffers were retrieved, pdFALSE otherwise.

_baseType_t uxTaskGetStackHighWaterMark (TaskHandle_t xTask)_

Returns the high water mark of the stack associated with xTask. That is, the minimum free stack space there has been (in words, so on a 32 bit machine a value of 1 means 4 bytes) since the task started. The smaller the returned number the closer the task has come to overflowing its stack.

uxTaskGetStackHighWaterMark() and uxTaskGetStackHighWaterMark2() are the same except for their return type. Using configSTACK_DEPTH_TYPE allows the user to determine the return type. It gets around the problem of the value overflowing on 8-bit types without breaking backward compatibility for applications that expect an 8-bit return type.

**Parameters**
- **xTask** – Handle of the task associated with the stack to be checked. Set xTask to NULL to check the stack of the calling task.

**Returns**
- The smallest amount of free stack space there has been (in words, so actual spaces on the stack rather than bytes) since the task referenced by xTask was created.

configSTACK_DEPTH_TYPE _uxTaskGetStackHighWaterMark2 (TaskHandle_t xTask)_

Returns the high water mark of the stack associated with xTask. That is, the minimum free stack space there has been (in words, so on a 32 bit machine a value of 1 means 4 bytes) since the task started. The smaller the returned number the closer the task has come to overflowing its stack.

uxTaskGetStackHighWaterMark() and uxTaskGetStackHighWaterMark2() are the same except for their return type. Using configSTACK_DEPTH_TYPE allows the user to determine the return type. It gets around the problem of the value overflowing on 8-bit types without breaking backward compatibility for applications that expect an 8-bit return type.

**Parameters**
- **xTask** – Handle of the task associated with the stack to be checked. Set xTask to NULL to check the stack of the calling task.

**Returns**
- The smallest amount of free stack space there has been (in words, so actual spaces on the stack rather than bytes) since the task referenced by xTask was created.

void vTaskSetApplicationTaskTag (TaskHandle_t xTask, TaskHookFunction_t pxHookFunction)_

Sets pxHookFunction to be the task hook function used by the task xTask. Passing xTask as NULL has the effect of setting the calling tasks hook function.

_TaskHookFunction_t xTaskGetApplicationTaskTag (TaskHandle_t xTask)_

Returns the pxHookFunction value assigned to the task xTask. Do not call from an interrupt service routine - call xTaskGetApplicationTaskTagFromISR() instead.

_TaskHookFunction_t xTaskGetApplicationTaskTagFromISR (TaskHandle_t xTask)_

Returns the pxHookFunction value assigned to the task xTask. Can be called from an interrupt service routine.
void vTaskSetThreadLocalStoragePointer (TaskHandle_t xTaskToSet, BaseType_t xIndex, void *pvValue)

Each task contains an array of pointers that is dimensioned by the configNUM_THREAD_LOCAL_STORAGE_POINTERS setting in FreeRTOSConfig.h. The kernel does not use the pointers itself, so the application writer can use the pointers for any purpose they wish. The following two functions are used to set and query a pointer respectively.

void *pvTaskGetThreadLocalStoragePointer (TaskHandle_t xTaskToQuery, BaseType_t xIndex)

void vApplicationGetIdleTaskMemory (StaticTask_t **ppxIdleTaskTCBBuffer, StackType_t **ppxIdleTaskStackBuffer, uint32_t *pulIdleTaskStackSize)

This function is used to provide a statically allocated block of memory to FreeRTOS to hold the Idle Task TCB. This function is required when configSUPPORT_STATIC_ALLOCATION is set. For more information see this URI: https://www.FreeRTOS.org/a00110.html#configSUPPORT_STATIC_ALLOCATION

Parameters
- ppxIdleTaskTCBBuffer – A handle to a statically allocated TCB buffer
- ppxIdleTaskStackBuffer – A handle to a statically allocated Stack buffer for the idle task
- pulIdleTaskStackSize – A pointer to the number of elements that will fit in the allocated stack buffer

BaseType_t xTaskCallApplicationTaskHook (TaskHandle_t xTask, void *pvParameter)

Calls the hook function associated with xTask. Passing xTask as NULL has the effect of calling the Running tasks (the calling task) hook function.

pvParameter is passed to the hook function for the task to interpret as it wants. The return value is the value returned by the task hook function registered by the user.

TaskHandle_t xTaskGetIdleTaskHandle (void)

xTaskGetIdleTaskHandle() is only available if INCLUDE_xTaskGetIdleTaskHandle is set to 1 in FreeRTOSConfig.h.

Simply returns the handle of the idle task of the current core. It is not valid to call xTaskGetIdleTaskHandle() before the scheduler has been started.

UBaseType_t uxTaskGetSystemState (TaskStatus_t *pxTaskStatusArray, const UBaseType_t uxArraySize, configRUN_TIME_COUNTER_TYPE *const pulTotalRunTime)

configUSE_TRACE_FACILITY must be defined as 1 in FreeRTOSConfig.h for uxTaskGetSystemState() to be available.

uxTaskGetSystemState() populates a TaskStatus_t structure for each task in the system. TaskStatus_t structures contain, among other things, members for the task handle, task name, task priority, task state, and total amount of run time consumed by the task. See the TaskStatus_t structure definition in this file for the full member list.

NOTE: This function is intended for debugging use only as its use results in the scheduler remaining suspended for an extended period.

Example usage:

```c
// This example demonstrates how a human readable table of run time stats
// information is generated from raw data provided by uxTaskGetSystemState().
// The human readable table is written to pcWriteBuffer.
void vTaskGetRunTimeStats ( char *pcWriteBuffer )
{
    TaskStatus_t pxTaskStatusArray;
    volatile UBaseType_t uxArraySize, x;
    configRUN_TIME_COUNTER_TYPE ulTotalRunTime, ulStatsAsPercentage;

    // Code for generating the human readable table...
}```
// Make sure the write buffer does not contain a string.
pcWriteBuffer = 0x00;

// Take a snapshot of the number of tasks in case it changes while this
// function is executing.
uxArraySize = uxTaskGetNumberOfTasks();

// Allocate a TaskStatus_t structure for each task. An array could be
// allocated statically at compile time.
pxTaskStatusArray = pvPortMalloc( uxArraySize * sizeof( TaskStatus_t ) );

if( pxTaskStatusArray != NULL )
{
    // Generate raw status information about each task.
    uxArraySize = uxTaskGetSystemState( pxTaskStatusArray, uxArraySize, &ulTotalRunTime );

    // For percentage calculations.
    ulTotalRunTime /= 100UL;

    // Avoid divide by zero errors.
    if( ulTotalRunTime > 0 )
    {
        // For each populated position in the pxTaskStatusArray array,
        // format the raw data as human readable ASCII data
        for( x = 0; x < uxArraySize; x++ )
        {
            // What percentage of the total run time has the task used?
            // This will always be rounded down to the nearest integer.
            // ulTotalRunTimeDiv100 has already been divided by 100.
            ulStatsAsPercentage = pxTaskStatusArray[ x ].ulRunTimeCounter - ulTotalRunTime;

            // If the percentage is zero here then the task has
            // consumed less than 1% of the total run time.
            if( ulStatsAsPercentage > 0UL )
            {
                sprintf( pcWriteBuffer, "%s\t%lu\t%lu\t%lu%%\n",...
                        pxTaskStatusArray[ x ].pcTaskName, pxTaskStatusArray[ x ].ulRuntimeCounter,
                        ulStatsAsPercentage );
            }
            else
            {
                // If the percentage is zero here then the task has
                // consumed less than 1% of the total run time.
                sprintf( pcWriteBuffer, "%s\t%lu\t<1%%\n",...
                        pxTaskStatusArray[ x ].pcTaskName, pxTaskStatusArray[ x ].ulRuntimeCounter );
            }

            pcWriteBuffer += strlen( (char *) pcWriteBuffer );
        }

    }

    // The array is no longer needed, free the memory it consumes.
    vPortFree( pxTaskStatusArray );
}

Parameters

- **pxTaskStatusArray** - A pointer to an array of TaskStatus_t structures. The array must contain at least one TaskStatus_t structure for each task that is under the control of the RTOS. The number of tasks under the control of the RTOS can be determined using the uxTaskGetNumberOfTasks() API function.
• **uxArraySize** - The size of the array pointed to by the pxTaskStatusArray parameter. The size is specified as the number of indexes in the array, or the number of TaskStatus_t structures contained in the array, not by the number of bytes in the array.

• **pulTotalRunTime** - If configGENERATE_RUN_TIME_STATS is set to 1 in FreeRTOSConfig.h then *pulTotalRunTime is set by uxTaskGetSystemState() to the total run time (as defined by the run time stats clock, see [https://www.FreeRTOS.org/RTOS-run-time-stats.html](https://www.FreeRTOS.org/RTOS-run-time-stats.html)) since the target booted. pulTotalRunTime can be set to NULL to omit the total run time information.

**Returns** The number of TaskStatus_t structures that were populated by uxTaskGetSystemState(). This should equal the number returned by the uxTaskGetNumberOfTasks() API function, but will be zero if the value passed in the uxArraySize parameter was too small.

```c
void vTaskList (char *pcWriteBuffer)
```

configUSE_TRACE_FACILITY and configUSE_STATS_FORMATTING_FUNCTIONS must both be defined as 1 for this function to be available. See the configuration section of the FreeRTOS.org website for more information.

**NOTE 1:** This function will disable interrupts for its duration. It is not intended for normal application runtime use but as a debug aid.

Lists all the current tasks, along with their current state and stack usage high water mark.

Tasks are reported as blocked (‘B’), ready (‘R’), deleted (‘D’) or suspended (‘S’).

**PLEASE NOTE:**

This function is provided for convenience only, and is used by many of the demo applications. Do not consider it to be part of the scheduler.

vTaskList() calls uxTaskGetSystemState(), then formats part of the uxTaskGetSystemState() output into a human readable table that displays task: names, states, priority, stack usage and task number. Stack usage specified as the number of unused StackType_t words stack can hold on top of stack - not the number of bytes.

vTaskList() has a dependency on the sprintf() C library function that might bloat the code size, use a lot of stack, and provide different results on different platforms. An alternative, tiny, third party, and limited functionality implementation of sprintf() is provided in many of the FreeRTOS/Demo sub-directories in a file called printf-stdarg.c (note printf-stdarg.c does not provide a full snprintf() implementation!).

It is recommended that production systems call uxTaskGetSystemState() directly to get access to raw stats data, rather than indirectly through a call to vTaskList().

**Parameters pcWriteBuffer** - A buffer into which the above mentioned details will be written, in ASCII form. This buffer is assumed to be large enough to contain the generated report. Approximately 40 bytes per task should be sufficient.

```c
void vTaskGetRunTimeStats (char *pcWriteBuffer)
```

configGENERATE_RUN_TIME_STATS and configUSE_STATS_FORMATTING_FUNCTIONS must both be defined as 1 for this function to be available. The application must also then provide definitions for portCONFIGURE_TIMER_FOR_RUN_TIME_STATS() and portGET_RUN_TIME_COUNTER_VALUE() to configure a peripheral timer/counter and return the timers current count value respectively. The counter should be at least 10 times the frequency of the tick count.

**NOTE 1:** This function will disable interrupts for its duration. It is not intended for normal application runtime use but as a debug aid.

Setting configGENERATE_RUN_TIME_STATS to 1 will result in a total accumulated execution time being stored for each task. The resolution of the accumulated time value depends on the frequency of the timer configured by the portCONFIGURE_TIMER_FOR_RUN_TIME_STATS() macro. Calling vTaskGetRunTimeStats() writes the total execution time of each task into a buffer, both as an absolute count value and as a percentage of the total system execution time.

**NOTE 2:**

This function is provided for convenience only, and is used by many of the demo applications. Do not consider it to be part of the scheduler.
vTaskGetRunTimeStats() calls uxTaskGetSystemState(), then formats part of the uxTaskGetSystemState() output into a human readable table that displays the amount of time each task has spent in the Running state in both absolute and percentage terms.

vTaskGetRunTimeStats() has a dependency on the sprintf() C library function that might bloat the code size, use a lot of stack, and provide different results on different platforms. An alternative, tiny, third party, and limited functionality implementation of sprintf() is provided in many of the FreeRTOS/Demo sub-directories in a file called printf-stdarg.c (note printf-stdarg.c does not provide a full snprintf() implementation!).

It is recommended that production systems call uxTaskGetSystemState() directly to get access to raw stats data, rather than indirectly through a call to vTaskGetRunTimeStats().

**Parameters**

`pcWriteBuffer` – A buffer into which the execution times will be written, in ASCII form. This buffer is assumed to be large enough to contain the generated report. Approximately 40 bytes per task should be sufficient.

**Returns**

The total run time of the idle task or the percentage of the total run time consumed by the idle task. This is the amount of time the idle task has actually been executing. The unit of time is dependent on the frequency configured using the portCONFIGURE_TIMER_FOR_RUN_TIME_STATS() and portGET_RUN_TIME_COUNTER_VALUE() macros. While uxTaskGetSystemState() and vTaskGetRunTimeStats() writes the total execution time of each task into a buffer, ulTaskGetIdleRunTimeCounter() returns the total execution time of just the idle task and ulTaskGetIdleRunTimePercent() returns the percentage of the CPU time used by just the idle task.

Note the amount of idle time is only a good measure of the slack time in a system if there are no other tasks executing at the idle priority, tickless idle is not used, and configIDLE_SHOULD_YIELD is set to 0.

**Note:** If configNUMBER_OF_CORES > 1, calling this function will query the idle task of the current core.
A notification sent to a task can optionally perform an action, such as update, overwrite or increment one of the task’s notification values. In that way task notifications can be used to send data to a task, or be used as light weight and fast binary or counting semaphores.

A notification sent to a task will remain pending until it is cleared by the task calling xTaskNotifyWaitIndexed() or ulTaskNotifyTakeIndexed() (or their un-indexed equivalents). If the task was already in the Blocked state to wait for a notification when the notification arrives then the task will automatically be removed from the Blocked state (unblocked) and the notification cleared.

A task can use xTaskNotifyWaitIndexed() to [optionally] block to wait for a notification to be pending, or ulTaskNotifyTakeIndexed() to [optionally] block to wait for a notification value to have a non-zero value. The task does not consume any CPU time while it is in the Blocked state.

NOTE Each notification within the array operates independently - a task can only block on one notification within the array at a time and will not be unblocked by a notification sent to any other array index.

Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. xTaskNotifyWait() is the original API function, and remains backward compatible by always operating on the notification value at index 0 in the array. Calling xTaskNotifyWait() is equivalent to calling xTaskNotifyWaitIndexed() with the uxIndexToWaitOn parameter set to 0.

Parameters

- **uxIndexToWaitOn** – The index within the calling task’s array of notification values on which the calling task will wait for a notification to be received. uxIndexToWaitOn must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. xTaskNotifyWait() does not have this parameter and always waits for notifications on index 0.
- **ulBitsToClearOnEntry** – Bits that are set in ulBitsToClearOnEntry value will be cleared in the calling task’s notification value before the task checks to see if any notifications are pending, and optionally blocks if no notifications are pending. Setting ulBitsToClearOnEntry to ULONG_MAX (if limits.h is included) or 0xffffffffUL (if limits.h is not included) will have the effect of resetting the task’s notification value to 0. Setting ulBitsToClearOnEntry to 0 will leave the task’s notification value unchanged.
- **ulBitsToClearOnExit** – If a notification is pending or received before the calling task exits the xTaskNotifyWait() function then the task’s notification value (see the xTaskNotify() API function) is passed out using the pulNotificationValue parameter. Then any bits that are set in ulBitsToClearOnExit will be cleared in the task’s notification value before any bits are cleared. Setting ulBitsToClearOnExit to ULONG_MAX (if limits.h is included) or 0xffffffffUL (if limits.h is not included) will have the effect of resetting the task’s notification value to 0 before the function exits. Setting ulBitsToClearOnExit to 0 will leave the task’s notification value unchanged when the function exits (in which case the value passed out in pulNotificationValue will match the task’s notification value).
- **pulNotificationValue** – Used to pass the task’s notification value out of the function. Note the value passed out will not be effected by the clearing of any bits caused by ulBitsToClearOnExit being non-zero.
- **xTicksToWait** – The maximum amount of time that the task should wait in the Blocked state for a notification to be received, should a notification not already be pending when xTaskNotifyWait() was called. The task will not consume any processing time while it is in the Blocked state. This is specified in kernel ticks, the macro pdMS_TO_TICKS(value_in_ms) can be used to convert a time specified in milliseconds to a time specified in ticks.

Returns If a notification was received (including notifications that were already pending when xTaskNotifyWait was called) then pdPASS is returned. Otherwise pdFAIL is returned.

void vTaskGenericNotifyGiveFromISR(TaskHandle_t xTaskToNotify, UBaseType_t uxIndexToNotify, BaseType_t *pxHigherPriorityTaskWoken)

A version of xTaskNotifyGiveIndexed() that can be called from an interrupt service routine (ISR).

configUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for this macro to be available.

Each task has a private array of “notification values” (or “notifications”), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

Events can be sent to a task using an intermediary object. Examples of such objects are queues, semaphores, mutexes and event groups. Task notifications are a method of sending an event directly to a task without the need for such an intermediary object.

A notification sent to a task can optionally perform an action, such as update, overwrite or increment one of the task’s notification values. In that way task notifications can be used to send data to a task, or be used as lightweight and fast binary or counting semaphores.

vTaskNotifyGiveIndexedFromISR() is intended for use when task notifications are used as light weight and faster binary or counting semaphore equivalents. Actual FreeRTOS semaphores are given from an ISR using the xSemaphoreGiveFromISR() API function, the equivalent action that instead uses a task notification is vTaskNotifyGiveIndexedFromISR().

When task notifications are being used as a binary or counting semaphore equivalent then the task being notified should wait for the notification using the uTaskNotifyTakeIndexed() API function rather than the xTaskNotifyWaitIndexed() API function.

NOTE Each notification within the array operates independently - a task can only block on one notification within the array at a time and will not be unblocked by a notification sent to any other array index.

Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. xTaskNotifyFromISR() is the original API function, and remains backward compatible by always operating on the notification value at index 0 within the array. Calling xTaskNotifyGiveFromISR() is equivalent to calling xTaskNotifyGiveIndexedFromISR() with the uxIndexToNotify parameter set to 0.

Parameters

- xTaskToNotify – The handle of the task being notified. The handle to a task can be returned from the xTaskCreate() API function used to create the task, and the handle of the currently running task can be obtained by calling xTaskGetCurrentTaskHandle().
- uxIndexToNotify – The index within the target task’s array of notification values to which the notification is to be sent. uxIndexToNotify must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. xTaskNotifyGiveFromISR() does not have this parameter and always sends notifications to index 0.
- pxHigherPriorityTaskWoken – vTaskNotifyGiveFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE if sending the notification caused the task to which the notification was sent to leave the Blocked state, and the unblocked task has a priority higher than the currently running task. If vTaskNotifyGiveFromISR() sets this value to pdTRUE then a context switch should be requested before the interrupt is exited. How a context switch is requested from an ISR is dependent on the port - see the documentation page for the port in use.

 BaseType_t xTaskGenericNotifyStateClear (TaskHandle_t xTask, UBBaseType_t uxIndexToClear)

configUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for these functions to be available.

Each task has a private array of “notification values” (or “notifications”), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

If a notification is sent to an index within the array of notifications then the notification at that index is said to be ‘pending’ until it is read or explicitly cleared by the receiving task. xTaskNotifyStateClearIndexed() is the function that clears a pending notification without reading the notification value. The notification value at the same array index is not altered. Set xTask to NULL to clear the notification state of the calling task.
Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. xTaskNotifyStateClear() is the original API function, and remains backward compatible by always operating on the notification value at index 0 within the array. Calling xTaskNotifyStateClear() is equivalent to calling xTaskNotifyStateClearIndexed() with the uxIndexToNotify parameter set to 0.

**Parameters**

- **xTask** – The handle of the RTOS task that will have a notification state cleared. Set xTask to NULL to clear a notification state in the calling task. To obtain a task’s handle create the task using xTaskCreate() and make use of the pxCreatedTask parameter, or create the task using xTaskCreateStatic() and store the returned value, or use the task’s name in a call to xTaskGetHandle().
- **uxIndexToClear** – The index within the target task’s array of notification values to act upon. For example, setting uxIndexToClear to 1 will clear the state of the notification at index 1 within the array. uxIndexToClear must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. ulTaskNotifyStateClear() does not have this parameter and always acts on the notification at index 0.

**Returns**

pdTRUE if the task’s notification state was set to eNotWaitingNotification, otherwise pdFALSE.

uint32_t ulTaskGenericNotifyValueClear(TaskHandle_t xTask, UBaseType_t uxIndexToClear, uint32_t ulBitsToClear)

configUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for these functions to be available.

Each task has a private array of “notification values” (or ‘notifications’), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

ulTaskNotifyValueClearIndexed() clears the bits specified by the ulBitsToClear bit mask in the notification value at array index uxIndexToClear of the task referenced by xTask.

Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. ulTaskNotifyValueClear() is the original API function, and remains backward compatible by always operating on the notification value at index 0 within the array. Calling ulTaskNotifyValueClear() is equivalent to calling ulTaskNotifyValueClearIndexed() with the uxIndexToClear parameter set to 0.

**Parameters**

- **xTask** – The handle of the RTOS task that will have bits in one of its notification values cleared. Set xTask to NULL to clear bits in a notification value in the calling task. To obtain a task’s handle create the task using xTaskCreate() and make use of the pxCreatedTask parameter, or create the task using xTaskCreateStatic() and store the returned value, or use the task’s name in a call to xTaskGetHandle().
- **uxIndexToClear** – The index within the target task’s array of notification values in which to clear the bits. uxIndexToClear must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. ulTaskNotifyValueClear() does not have this parameter and always clears bits in the notification value at index 0.
- **ulBitsToClear** – Bit mask of the bits to clear in the notification value of xTask. Set a bit to 1 to clear the corresponding bits in the task’s notification value. Set ulBitsToClear to 0xffffffff (UINT_MAX on 32-bit architectures) to clear the notification value to 0. Set ulBitsToClear to 0 to query the task’s notification value without clearing any bits.

**Returns**

The value of the target task’s notification value before the bits specified by ulBitsToClear were cleared.

void vTaskSetTimeOutState(TimeOut_t *const pxTimeOut)

Capture the current time for future use with xTaskCheckForTimeOut().
Parameters **pxTimeOut** – Pointer to a timeout object into which the current time is to be captured. The captured time includes the tick count and the number of times the tick count has overflowed since the system first booted.

**BaseType_t xTaskCheckForTimeOut** (TimeOut_t *const pxTimeOut, TickType_t *const pxTicksToWait)

Determines if pxTicksToWait ticks has passed since a time was captured using a call to vTaskSetTimeOutState(). The captured time includes the tick count and the number of times the tick count has overflowed.

Example Usage:

```c
size_t xUART_Receive( uint8_t *pucBuffer, size_t uxWantedBytes )
{
    size_t uxReceived = 0;
    TickType_t xTicksToWait = MAX_TIME_TO_WAIT;
    TimeOut_t xTimeOut;

    // Initialize xTimeOut. This records the time at which this function
    // was entered.
    vTaskSetTimeOutState( &xTimeOut );

    // Loop until the buffer contains the wanted number of bytes, or a
    // timeout occurs.
    while( UART_bytes_in_rx_buffer( pxUARTInstance ) < uxWantedBytes )
    {
        // The buffer didn't contain enough data so this task is going to
        // enter the Blocked state. Adjusting xTicksToWait to account for
        // any time that has been spent in the Blocked state within this
        // function so far to ensure the total amount of time spent in the
        // Blocked state does not exceed MAX_TIME_TO_WAIT.
        if( xTaskCheckForTimeOut( &xTimeOut, &xTicksToWait ) != pdFALSE )
        {
            // Timed out before the wanted number of bytes were available,
            // exit the loop.
            break;
        }

        // Wait for a maximum of xTicksToWait ticks to be notified that the
        // receive interrupt has placed more data into the buffer.
        ulTaskNotifyTake( pdTRUE, xTicksToWait );
    }

    // Attempt to read uxWantedBytes from the receive buffer into pucBuffer.
    // The actual number of bytes read (which might be less than
    // uxWantedBytes) is returned.
    uxReceived = UART_read_from_receive_buffer( pxUARTInstance, pucBuffer, uxWantedBytes );

    return uxReceived;
}  
```

(continues on next page)
See also:
https://www.FreeRTOS.org/xTaskCheckForTimeOut.html

Parameters

- **pxTimeOut** – The time status as captured previously using vTaskSetTimeOutState. If the timeout has not yet occurred, it is updated to reflect the current time status.
- **pxTicksToWait** – The number of ticks to check for timeout i.e. if pxTicksToWait ticks have passed since pxTimeOut was last updated (either by vTaskSetTimeOutState() or xTaskCheckForTimeOut()), the timeout has occurred. If the timeout has not occurred, pxTicksToWait is updated to reflect the number of remaining ticks.

**Returns**
If timeout has occurred, pdTRUE is returned. Otherwise pdFALSE is returned and pxTicksToWait is updated to reflect the number of remaining ticks.

BaseType_t xTaskCatchUpTicks (TickType_t xTicksToCatchUp)

This function corrects the tick count value after the application code has held interrupts disabled for an extended period resulting in tick interrupts having been missed.

This function is similar to vTaskStepTick(), however, unlike vTaskStepTick(), xTaskCatchUpTicks() may move the tick count forward past a time at which a task should be removed from the blocked state. That means tasks may have to be removed from the blocked state as the tick count is moved.

**Parameters**
- **xTicksToCatchUp** – The number of tick interrupts that have been missed due to interrupts being disabled. Its value is not computed automatically, so must be computed by the application writer.

**Returns**
- pdTRUE if moving the tick count forward resulted in a task leaving the blocked state and a context switch being performed. Otherwise pdFALSE.

**Structures**

struct xTASK_STATUS

Used with the uxTaskGetSystemState() function to return the state of each task in the system.

**Public Members**

*TaskHandle_t  xHandle*

The handle of the task to which the rest of the information in the structure relates.

*const char  *pcTaskName*

A pointer to the task’s name. This value will be invalid if the task was deleted since the structure was populated!

*UBaseType_t  xTaskNumber*

A number unique to the task.

*eTaskState  eCurrentState*

The state in which the task existed when the structure was populated.

*UBaseType_t  uxCurrentPriority*

The priority at which the task was running (may be inherited) when the structure was populated.
UBaseType_t uxBasePriority
The priority to which the task will return if the task’s current priority has been inherited to avoid unbounded priority inversion when obtaining a mutex. Only valid if configUSE_MUTEXES is defined as 1 in FreeRTOSConfig.h.

configRUN_TIME_COUNTER_TYPE ulRunTimeCounter
The total run time allocated to the task so far, as defined by the run time stats clock. See https://www.FreeRTOS.org/rtos-run-time-stats.html. Only valid when configGENERATE_RUN_TIME_STATS is defined as 1 in FreeRTOSConfig.h.

StackType_t *pxStackBase
Points to the lowest address of the task’s stack area.

configSTACK_DEPTH_TYPE usStackHighWaterMark
The minimum amount of stack space that has remained for the task since the task was created. The closer this value is to zero the closer the task has come to overflowing its stack.

BaseType_t xCoreID
Core this task is pinned to (0, 1, or tskNO_AFFINITY). If configNUMBER_OF_CORES == 1, this will always be 0.

Macros

tskIDLE_PRIORITY
Defines the priority used by the idle task. This must not be modified.

tskNO_AFFINITY
Macro representing and unpinned (i.e., “no affinity”) task in xCoreID parameters

taskYIELD()
Macro for forcing a context switch.

taskENTER_CRITICAL(x)
Macro to mark the start of a critical code region. Preemptive context switches cannot occur when in a critical region.

NOTE: This may alter the stack (depending on the portable implementation) so must be used with care!

taskENTER_CRITICAL_FROM_ISR()

taskENTER_CRITICAL_ISR(x)

taskEXIT_CRITICAL(x)
Macro to mark the end of a critical code region. Preemptive context switches cannot occur when in a critical region.

NOTE: This may alter the stack (depending on the portable implementation) so must be used with care!

taskEXIT_CRITICAL_FROM_ISR(x)

taskEXIT_CRITICAL_ISR(x)

taskDISABLE_INTERRUPTS()
Macro to disable all maskable interrupts.

taskENABLE_INTERRUPTS()
Macro to enable microcontroller interrupts.
taskSCHEDULER_SUSPENDED

Definitions returned by xTaskGetSchedulerState(). taskSCHEDULER_SUSPENDED is 0 to generate more optimal code when configASSERT() is defined as the constant is used in assert() statements.

taskSCHEDULER_NOT_STARTED

taskSCHEDULER_RUNNING

xTaskNotifyIndexed(xTaskToNotify, uxIndexToNotify, ulValue, eAction)

cfgUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for these functions to be available.

Sends a direct task notification to a task, with an optional value and action.

Each task has a private array of “notification values” (or ‘notifications’), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

Events can be sent to a task using an intermediary object. Examples of such objects are queues, semaphores, mutexes and event groups. Task notifications are a method of sending an event directly to a task without the need for such an intermediary object.

A notification sent to a task can optionally perform an action, such as update, overwrite or increment one of the task’s notification values. In that way task notifications can be used to send data to a task, or be used as light weight and fast binary or counting semaphores.

A task can use xTaskNotifyWaitIndexed() or ulTaskNotifyTakeIndexed() to [optionally] block to wait for a notification to be pending. The task does not consume any CPU time while it is in the Blocked state.

A notification sent to a task will remain pending until it is cleared by the task calling xTaskNotifyWaitIndexed() or ulTaskNotifyTakeIndexed() (or their un-indexed equivalents). If the task was already in the Blocked state to wait for a notification when the notification arrives then the task will automatically be removed from the Blocked state (unblocked) and the notification cleared.

NOTE Each notification within the array operates independently - a task can only block on one notification within the array at a time and will not be unblocked by a notification sent to any other array index.

Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. xTaskNotify() is the original API function, and remains backward compatible by always operating on the notification value at index 0 in the array. Calling xTaskNotify() is equivalent to calling xTaskNotifyIndexed() with the uxIndexToNotify parameter set to 0.

eSetBits - The target notification value is bitwise ORed with ulValue. xTaskNotifyIndexed() always returns pdPASS in this case.
eIncrement - The target notification value is incremented. ulValue is not used and xTaskNotifyIndexed() always returns pdPASS in this case.
eSetValueWithOverwrite - The target notification value is set to the value of ulValue, even if the task being notified had not yet processed the previous notification at the same array index (the task already had a notification pending at that index). xTaskNotifyIndexed() always returns pdPASS in this case.
eSetValueWithoutOverwrite - If the task being notified did not already have a notification pending at the same array index then the target notification value is set to ulValue and xTaskNotifyIndexed() will return pdPASS. If the task being notified already had a notification pending at the same array index then no action is performed and pdFAIL is returned.
Chapter 2. API Reference

eNoAction - The task receives a notification at the specified array index without the notification value at that index being updated. ulValue is not used and xTaskNotifyIndexed() always returns pdPASS in this case.

eNoAction - The task receives a notification at the specified array index without the notification value at that index being updated. ulValue is not used and xTaskNotifyIndexed() always returns pdPASS in this case.

pulPreviousNotificationValue - Can be used to pass out the subject task’s notification value before any bits are modified by the notify function.

Parameters

- **xTaskToNotify** – The handle of the task being notified. The handle to a task can be returned from the xTaskCreate() API function used to create the task, and the handle of the currently running task can be obtained by calling xTaskGetCurrentTaskHandle().

- **uxIndexToNotify** – The index within the target task’s array of notification values to which the notification is to be sent. uxIndexToNotify must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. xTaskNotify() does not have this parameter and always sends notifications to index 0.

- **ulValue** – Data that can be sent with the notification. How the data is used depends on the value of the eAction parameter.

- **eAction** – Specifies how the notification updates the task’s notification value, if at all. Valid values for eAction are as follows:

<table>
<thead>
<tr>
<th>eAction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eNoAction</td>
<td>The task receives a notification at the specified array index without the notification value at that index being updated. ulValue is not used and xTaskNotifyIndexed() always returns pdPASS in this case.</td>
</tr>
</tbody>
</table>

Returns

- **Dependent on the value of eAction. See the description of the eAction parameter.**

xTaskNotifyAndQueryIndexed(xTaskToNotify, uxIndexToNotify, ulValue, eAction, pulPreviousNotifyValue)

xTaskNotifyAndQueryIndexed() performs the same operation as xTaskNotifyIndexed() with the addition that it also returns the subject task’s prior notification value (the notification value at the time the function is called rather than when the function returns) in the additional pulPreviousNotifyValue parameter.

xTaskNotifyAndQuery() performs the same operation as xTaskNotify() with the addition that it also returns the subject task’s prior notification value (the notification value as it was at the time the function is called, rather than when the function returns) in the additional pulPreviousNotifyValue parameter.

xTaskNotifyIndexedFromISR(xTaskToNotify, uxIndexToNotify, ulValue, eAction, pxHigherPriorityTaskWoken)

configUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for these functions to be available.

A version of xTaskNotifyIndexed() that can be used from an interrupt service routine (ISR).

Each task has a private array of “notification values” (or ‘notifications’), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

Events can be sent to a task using an intermediary object. Examples of such objects are queues, semaphores, mutexes and event groups. Task notifications are a method of sending an event directly to a task without the need for such an intermediary object.

A notification sent to a task can optionally perform an action, such as update, overwrite or increment one of the task’s notification values. In that way task notifications can be used to send data to a task, or be used as light weight and fast binary or counting semaphores.

A task can use xTaskNotifyWaitIndexed() to [optionally] block to wait for a notification to be pending, or ulTaskNotifyTakeIndexed() to [optionally] block to wait for a notification value to have a non-zero value. The task does not consume any CPU time while it is in the Blocked state.

A notification sent to a task will remain pending until it is cleared by the task calling xTaskNotifyWaitIndexed() or ulTaskNotifyTakeIndexed() (or their un-indexed equivalents). If the task was already in the Blocked state to wait for a notification when the notification arrives then the task will automatically be removed from the Blocked state (unblocked) and the notification cleared.

**NOTE** Each notification within the array operates independently - a task can only block on one notification within the array at a time and will not be unblocked by a notification sent to any other array index.
Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. xTaskNotifyFromISR() is the original API function, and remains backward compatible by always operating on the notification value at index 0 within the array. Calling xTaskNotifyFromISR() is equivalent to calling xTaskNotifyIndexedFromISR() with the uxIndexToNotify parameter set to 0.

eSetBits - The task’s notification value is bitwise ORed with ulValue. xTaskNotify() always returns pdPASS in this case.
eIncrement - The task’s notification value is incremented. ulValue is not used and xTaskNotify() always returns pdPASS in this case.
eSetValueWithOverwrite - The task’s notification value is set to the value of ulValue, even if the task being notified had not yet processed the previous notification (the task already had a notification pending). xTaskNotify() always returns pdPASS in this case.
eSetValueWithoutOverwrite - If the task being notified did not already have a notification pending then the task’s notification value is set to ulValue and xTaskNotify() will return pdPASS. If the task being notified already had a notification pending then no action is performed and pdFAIL is returned.
eNoAction - The task receives a notification without its notification value being updated. ulValue is not used and xTaskNotify() always returns pdPASS in this case.

Parameters

- **uxIndexToNotify** - The index within the target task’s array of notification values to which the notification is to be sent. uxIndexToNotify must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. xTaskNotifyFromISR() does not have this parameter and always sends notifications to index 0.
- **xTaskToNotify** - The handle of the task being notified. The handle to a task can be returned from the xTaskCreate() API function used to create the task, and the handle of the currently running task can be obtained by calling xTaskGetCurrentTaskHandle().
- **ulValue** - Data that can be sent with the notification. How the data is used depends on the value of the eAction parameter.
- **eAction** - Specifies how the notification updates the task’s notification value, if at all. Valid values for eAction are as follows:
  - **pxHigherPriorityTaskWoken** - xTaskNotifyFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE if sending the notification caused the task to which the notification was sent to leave the Blocked state, and the unblocked task has a priority higher than the currently running task. If xTaskNotifyFromISR() sets this value to pdTRUE then a context switch should be requested before the interrupt is exited. How a context switch is requested is function dependent on the port - see the documentation page for the port in use.

Returns

Dependent on the value of eAction. See the description of the eAction parameter.

**xTaskNotifyAndQueryIndexedFromISR** (xTaskToNotify, uxIndexToNotify, ulValue, eAction, pulPreviousNotificationValue, pxHigherPriorityTaskWoken)

xTaskNotifyAndQueryIndexedFromISR() performs the same operation as xTaskNotifyIndexedFromISR() with the addition that it also returns the subject task’s prior notification value (the notification value at the time the function is called rather than at the time the function returns) in the additional pulPreviousNotificationValue parameter.

xTaskNotifyAndQueryFromISR() performs the same operation as xTaskNotifyFromISR() with the addition that it also returns the subject task’s prior notification value (the notification value at the time the function is called rather than at the time the function returns) in the additional pulPreviousNotificationValue parameter.

**xTaskNotifyWait** (ulBitsToClearOnEntry, ulBitsToClearOnExit, pulNotificationValue, xTicksToWait)
 portrays a direct-to-task notification to a particular index in the target task’s notification array in a manner similar to giving a counting semaphore.

configUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for these macros to be available.

Each task has a private array of “notification values” (or “notifications”), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

Events can be sent to a task using an intermediary object. Examples of such objects are queues, semaphores, mutexes and event groups. Task notifications are a method of sending an event directly to a task without the need for such an intermediary object.

A notification sent to a task can optionally perform an action, such as update, overwrite or increment one of the task’s notification values. In that way task notifications can be used to send data to a task, or be used as light weight and fast binary or counting semaphores.

xTaskNotifyGiveIndexed() is a helper macro intended for use when task notifications are used as light weight and faster binary or counting semaphore equivalents. Actual FreeRTOS semaphores are given using the xSemaphoreGive() API function, the equivalent action that instead uses a task notification is xTaskNotifyGiveIndexed().

When task notifications are being used as a binary or counting semaphore equivalent then the task being notified should wait for the notification using the ulTaskNotifyTakeIndexed() API function rather than the xTaskNotifyWaitIndexed() API function.

NOTE Each notification within the array operates independently - a task can only block on one notification within the array at a time and will not be unblocked by a notification sent to any other array index.

Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. xTaskNotifyGive() is the original API function, and remains backward compatible by always operating on the notification value at index 0 in the array. Calling xTaskNotifyGive() is equivalent to calling xTaskNotifyGiveIndexed() with the uxIndexToNotify parameter set to 0.

**Parameters**

- **xTaskToNotify** - The handle of the task being notified. The handle to a task can be returned from the xTaskCreate() API function used to create the task, and the handle of the currently running task can be obtained by calling xTaskGetCurrentTaskHandle().

- **uxIndexToNotify** - The index within the target task’s array of notification values to which the notification is to be sent. uxIndexToNotify must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. xTaskNotifyGive() does not have this parameter and always sends notifications to index 0.

**Returns**

xTaskNotifyGive() is a macro that calls xTaskNotify() with the eAction parameter set to eIncrement - so pdPASS is always returned.

**vTaskNotifyGiveFromISR** (xTaskToNotify, pxHigherPriorityTaskWoken)

**vTaskNotifyGiveIndexedFromISR** (xTaskToNotify, uxIndexToNotify, pxHigherPriorityTaskWoken)

**ulTaskNotifyTakeIndexed** (uxIndexToWaitOn, xClearCountOnExit, xTicksToWait)

Waits for a direct to task notification on a particular index in the calling task’s notification array in a manner similar to taking a counting semaphore.

configUSE_TASK_NOTIFICATIONS must be undefined or defined as 1 for this function to be available.
Each task has a private array of “notification values” (or ‘notifications’), each of which is a 32-bit unsigned integer (uint32_t). The constant configTASK_NOTIFICATION_ARRAY_ENTRIES sets the number of indexes in the array, and (for backward compatibility) defaults to 1 if left undefined. Prior to FreeRTOS V10.4.0 there was only one notification value per task.

Events can be sent to a task using an intermediary object. Examples of such objects are queues, semaphores, mutexes and event groups. Task notifications are a method of sending an event directly to a task without the need for such an intermediary object.

A notification sent to a task can optionally perform an action, such as update, overwrite or increment one of the task’s notification values. In that way task notifications can be used to send data to a task, or be used as light weight and fast binary or counting semaphores.

ulTaskNotifyTakeIndexed() is intended for use when a task notification is used as a faster and lighter weight binary or counting semaphore alternative. Actual FreeRTOS semaphores are taken using the xSemaphoreTake() API function, the equivalent action that instead uses a task notification is ulTaskNotifyTakeIndexed().

When a task is using its notification value as a binary or counting semaphore other tasks should send notifications to it using the xTaskNotifyGiveIndexed() macro, or xTaskNotifyIndex() function with the eAction parameter set to eIncDec.

ulTaskNotifyTakeIndexed() can either clear the task’s notification value at the array index specified by the uxIndexToWaitOn parameter to zero on exit, in which case the notification value acts like a binary semaphore, or decrement the notification value on exit, in which case the notification value acts like a counting semaphore.

A task can use ulTaskNotifyTakeIndexed() to [optionally] block to wait for a notification. The task does not consume any CPU time while it is in the Blocked state.

Where as xTaskNotifyWaitIndexed() will return when a notification is pending, ulTaskNotifyTakeIndexed() will return when the task’s notification value is not zero.

NOTE Each notification within the array operates independently - a task can only block on one notification within the array at a time and will not be unblocked by a notification sent to any other array index.

Backward compatibility information: Prior to FreeRTOS V10.4.0 each task had a single “notification value”, and all task notification API functions operated on that value. Replacing the single notification value with an array of notification values necessitated a new set of API functions that could address specific notifications within the array. ulTaskNotifyTake() is the original API function, and remains backward compatible by always operating on the notification value at index 0 in the array. Calling ulTaskNotifyTake() is equivalent to calling ulTaskNotifyTakeIndexed() with the uxIndexToWaitOn parameter set to 0.

**Parameters**

- **uxIndexToWaitOn** - The index within the calling task’s array of notification values on which the calling task will wait for a notification to be non-zero. uxIndexToWaitOn must be less than configTASK_NOTIFICATION_ARRAY_ENTRIES. xTaskNotifyTake() does not have this parameter and always waits for notifications on index 0.
- **xClearCountOnExit** - if xClearCountOnExit is pdFALSE then the task’s notification value is decremented when the function exits. In this way the notification value acts like a counting semaphore. If xClearCountOnExit is not pdFALSE then the task’s notification value is cleared to zero when the function exits. In this way the notification value acts like a binary semaphore.
- **xTicksToWait** - The maximum amount of time that the task should wait in the Blocked state for the task’s notification value to be greater than zero, should the count not already be greater than zero when ulTaskNotifyTake() was called. The task will not consume any processing time while it is in the Blocked state. This is specified in kernel ticks, the macro pdMS_TO_TICKS(value_in_ms) can be used to convert a time specified in milliseconds to a time specified in ticks.

**Returns** The task’s notification count before it is either cleared to zero or decremented (see the xClearCountOnExit parameter).

xTaskNotifyStateClear (xTask)
\textbf{xTaskNotifyStateClearIndexed} (xTask, uxIndexToClear)

\textbf{ulTaskNotifyValueClear} (xTask, ulBitsToClear)

\textbf{ulTaskNotifyValueClearIndexed} (xTask, uxIndexToClear, ulBitsToClear)

\textbf{Type Definitions}

typedef struct tskTaskControlBlock *\texttt{TaskHandle_t}

typedef BaseType_t (*\texttt{TaskHookFunction_t})(void*)

  Defines the prototype to which the application task hook function must conform.

typedef struct \texttt{xTASK_STATUS TaskStatus_t}

  Used with the uxTaskGetSystemState() function to return the state of each task in the system.

\textbf{Enumerations}

\textbf{enum eTaskState}

  Task states returned by eTaskGetState.

  \textit{Values:}

  \begin{itemize}
    \item \textbf{enumerator eRunning}
      A task is querying the state of itself, so must be running.
    \item \textbf{enumerator eReady}
      The task being queried is in a ready or pending ready list.
    \item \textbf{enumerator eBlocked}
      The task being queried is in the Blocked state.
    \item \textbf{enumerator eSuspended}
      The task being queried is in the Suspended state, or is in the Blocked state with an infinite time out.
    \item \textbf{enumerator eDeleted}
      The task being queried has been deleted, but its TCB has not yet been freed.
    \item \textbf{enumerator eInvalid}
      Used as an ‘invalid state’ value.
  \end{itemize}

\textbf{enum eNotifyAction}

  Actions that can be performed when vTaskNotify() is called.

  \textit{Values:}

  \begin{itemize}
    \item \textbf{enumerator eNoAction}
      Notify the task without updating its notify value.
    \item \textbf{enumerator eSetBits}
      Set bits in the task’s notification value.
  \end{itemize}
enumerator **eIncrement**
Increment the task’s notification value.

enumerator **eSetValueWithOverwrite**
Set the task’s notification value to a specific value even if the previous value has not yet been read by the task.

enumerator **eSetValueWithoutOverwrite**
Set the task’s notification value if the previous value has been read by the task.

enum **eSleepModeStatus**
Possible return values for eTaskConfirmSleepModeStatus().

**Values:**

enumerator **eAbortSleep**
A task has been made ready or a context switch pended since portSUPPRESS_TICKS_AND_SLEEP() was called - abort entering a sleep mode.

enumerator **eStandardSleep**
Enter a sleep mode that will not last any longer than the expected idle time.

Queue API

**Header File**
- components/freertos/FreeRTOS-Kernel/include/freertos/queue.h
- This header file can be included with:

```
#include "freertos/queue.h"
```

**Functions**

```
BaseType_t xQueueGenericSend(QueueHandle_t xQueue, const void *const pvItemToQueue, TickType_t xTicksToWait, const BaseType_t xCopyPosition)
```

It is preferred that the macros xQueueSend(), xQueueSendToFront() and xQueueSendToBack() are used in place of calling this function directly.

Post an item on a queue. The item is queued by copy, not by reference. This function must not be called from an interrupt service routine. See xQueueSendFromISR() for an alternative which may be used in an ISR.

Example usage:

```c
struct AMessage
{
    char ucMessageID;
    char ucData[ 20 ];
} xMessage;

uint32_t ulVar = 10UL;

void vATask( void *pvParameters )
{
    QueueHandle_t xQueue1, xQueue2;
}
```

(continues on next page)
struct AMessage *pxMessage;

// Create a queue capable of containing 10 uint32_t values.
xQueue1 = xQueueCreate( 10, sizeof( uint32_t ) );

// Create a queue capable of containing 10 pointers to AMessage structures. // These should be passed by pointer as they contain a lot of data.
xQueue2 = xQueueCreate( 10, sizeof( struct AMessage * ) );

// ...

if( xQueue1 != 0 )
{
    // Send an uint32_t. Wait for 10 ticks for space to become // available if necessary.
    if( xQueueGenericSend( xQueue1, ( void * ) &ulVar, ( TickType_t ) 10, __queueSEND_TO_BACK ) != pdPASS )
    {
        // Failed to post the message, even after 10 ticks.
    }
}

if( xQueue2 != 0 )
{
    // Send a pointer to a struct AMessage object. Don't block if the // queue is already full.
    pxMessage = & xMessage;
    xQueueGenericSend( xQueue2, ( void * ) &pxMessage, ( TickType_t ) 0, __queueSEND_TO_BACK );
}

// ... Rest of task code.

Parameters

- **xQueue** - The handle to the queue on which the item is to be posted.
- **pvItemToQueue** - A pointer to the item that is to be placed on the queue. The size of the items the queue will hold was defined when the queue was created, so this many bytes will be copied from pvItemToQueue into the queue storage area.
- **xTicksToWait** - The maximum amount of time the task should block waiting for space to become available on the queue, should it already be full. The call will return immediately if this is set to 0 and the queue is full. The time is defined in tick periods so the constant portTICK_PERIOD_MS should be used to convert to real time if this is required.
- **xCopyPosition** - Can take the value __queueSEND_TO_BACK__ to place the item at the back of the queue, or __queueSEND_TO_FRONT__ to place the item at the front of the queue (for high priority messages).

Returns

- pdTRUE if the item was successfully posted, otherwise errQUEUE_FULL.
- BaseType_t xQueuePeek (QueueHandle_t xQueue, void *const pvBuffer, TickType_t xTicksToWait)

Receive an item from a queue without removing the item from the queue. The item is received by copy so a buffer of adequate size must be provided. The number of bytes copied into the buffer was defined when the queue was created.

Successfully received items remain on the queue so will be returned again by the next call, or a call to xQueueReceive().

This macro must not be used in an interrupt service routine. See xQueuePeekFromISR() for an alternative that can be called from an interrupt service routine.
Example usage:

```c
struct AMessage
{
  char ucMessageID;
  char ucData[20];
} xMessage;

QueueHandle_t xQueue;

// Task to create a queue and post a value.
void vATask( void *pvParameters )
{
  struct AMessage *pxMessage;
  xQueue = xQueueCreate( 10, sizeof( struct AMessage * ) );
  if( xQueue == 0 )
  {
    // Failed to create the queue.
  }
  // ...
  // Send a pointer to a struct AMessage object. Don't block if the
  // queue is already full.
  pxMessage = &xMessage;
  xQueueSend( xQueue, ( void * ) &pxMessage, ( TickType_t ) 0 );
  // ... Rest of task code.
}

// Task to peek the data from the queue.
void vADifferentTask( void *pvParameters )
{
  struct AMessage *pxRxedMessage;
  if( xQueue != 0 )
  {
    // Peek a message on the created queue. Block for 10 ticks if a
    // message is not immediately available.
    if( xQueuePeek( xQueue, &pxRxedMessage, ( TickType_t ) 10 ) )
    {
      // pcRxedMessage now points to the struct AMessage variable posted
      // by vATask, but the item still remains on the queue.
    }
  }
  // ... Rest of task code.
}
```

Parameters

- **xQueue** - The handle to the queue from which the item is to be received.
- **pvBuffer** - Pointer to the buffer into which the received item will be copied.
- **xTicksToWait** - The maximum amount of time the task should block waiting for an item to receive should the queue be empty at the time of the call. The time is defined in tick periods so the constant portTICK_PERIOD_MS should be used to convert to real time if this is required. xQueuePeek() will return immediately if xTicksToWait is 0 and the queue is empty.

Returns

pdTRUE if an item was successfully received from the queue, otherwise pdFALSE.
BaseType_t xQueuePeekFromISR (QueueHandle_t xQueue, void *const pvBuffer)
A version of xQueuePeek() that can be called from an interrupt service routine (ISR).
Receive an item from a queue without removing the item from the queue. The item is received by copy so a buffer of adequate size must be provided. The number of bytes copied into the buffer was defined when the queue was created.
Successfully received items remain on the queue so will be returned again by the next call, or a call to xQueueReceive().

Parameters
• xQueue - The handle to the queue from which the item is to be received.
• pvBuffer - Pointer to the buffer into which the received item will be copied.

Returns
pdTRUE if an item was successfully received from the queue, otherwise pdFALSE.

BaseType_t xQueueReceive (QueueHandle_t xQueue, void *const pvBuffer, TickType_t xTicksToWait)
Receive an item from a queue. The item is received by copy so a buffer of adequate size must be provided. The number of bytes copied into the buffer was defined when the queue was created.
Successfully received items are removed from the queue.
This function must not be used in an interrupt service routine. See xQueueReceiveFromISR for an alternative that can.

Example usage:

```
struct AMessage
{
  char ucMessageID;
  char ucData[ 20 ];
} xMessage;
QueueHandle_t xQueue;

// Task to create a queue and post a value.
void vATask ( void *pvParameters )
{
  struct AMessage *pxMessage;

  // Create a queue capable of containing 10 pointers to AMessage structures.
  // These should be passed by pointer as they contain a lot of data.
  xQueue = xQueueCreate( 10, sizeof( struct AMessage * ) );
  if( xQueue == 0 )
  {
    // Failed to create the queue.
  }

  // ...

  // Send a pointer to a struct AMessage object. Don't block if the
  // queue is already full.
  pxMessage = & xMessage;
  xQueueSend( xQueue, ( void * ) &pxMessage, ( TickType_t ) 0 );

  // ... Rest of task code.
}

// Task to receive from the queue.
void vADifferentTask ( void *pvParameters )
{
  struct AMessage *pxRxedMessage;
```
if ( xQueue != 0 )
{
    // Receive a message on the created queue. Block for 10 ticks if a
    // message is not immediately available.
    if ( xQueueReceive ( xQueue, &pxRxedMessage, ( TickType_t ) 10 ) )
    {
        // pcRxedMessage now points to the struct AMessage variable posted
        // by vATask.
    }
}
// ... Rest of task code.

Parameters

• xQueue - The handle to the queue from which the item is to be received.
• pvBuffer - Pointer to the buffer into which the received item will be copied.
• xTicksToWait - The maximum amount of time the task should block waiting for an
  item to receive should the queue be empty at the time of the call. xQueueReceive() will
  return immediately if xTicksToWait is zero and the queue is empty. The time is defined
  in tick periods so the constant portTICK_PERIOD_MS should be used to convert to real
  time if this is required.

Returns pdTRUE if an item was successfully received from the queue, otherwise pdFALSE.

UBaseType_t uxQueueMessagesWaiting ( const QueueHandle_t xQueue )

Return the number of messages stored in a queue.

Parameters xQueue - A handle to the queue being queried.

Returns The number of messages available in the queue.

UBaseType_t uxQueueSpacesAvailable ( const QueueHandle_t xQueue )

Return the number of free spaces available in a queue. This is equal to the number of items that can be sent to
the queue before the queue becomes full if no items are removed.

Parameters xQueue - A handle to the queue being queried.

Returns The number of spaces available in the queue.

void vQueueDelete ( QueueHandle_t xQueue )

Delete a queue - freeing all the memory allocated for storing of items placed on the queue.

Parameters xQueue - A handle to the queue to be deleted.

BaseType_t xQueueGenericSendFromISR ( QueueHandle_t xQueue, const void * const pvItemToQueue,
                                        BaseType_t * const pxHigherPriorityTaskWoken, const
                                        BaseType_t xCopyPosition )

It is preferred that the macros xQueueSendFromISR(), xQueueSendToFrontFromISR() and xQueueSendTo-
BackFromISR() be used in place of calling this function directly. xQueueGiveFromISR() is an equivalent for
use by semaphores that don’t actually copy any data.

Post an item on a queue. It is safe to use this function from within an interrupt service routine.

Items are queued by copy not reference so it is preferable to only queue small items, especially when called
from an ISR. In most cases it would be preferable to store a pointer to the item being queued.

Example usage for buffered I/O (where the ISR can obtain more than one value per call):

```c
void vBufferISR ( void )
{
    char cIn;
}(continues on next page)```
// We have not woken a task at the start of the ISR.
xHigherPriorityTaskWokenByPost = pdFALSE;

// Loop until the buffer is empty.
do{
    // Obtain a byte from the buffer.
    cIn = portINPUT_BYTE( RX_REGISTER_ADDRESS );
    // Post each byte.
    xQueueGenericSendFromISR( xRxQueue, &cIn, &xHigherPriorityTaskWokenByPost, queueSEND_TO_BACK );
} while( portINPUT_BYTE( BUFFER_COUNT ) );

// Now the buffer is empty we can switch context if necessary. Note that the
// name of the yield function required is port specific.
if( xHigherPriorityTaskWokenByPost )
{
    portYIELD_FROM_ISR();
}

Parameters

- **xQueue** - The handle to the queue on which the item is to be posted.
- **pvItemToQueue** - A pointer to the item that is to be placed on the queue. The size of
  the items the queue will hold was defined when the queue was created, so this many bytes
  will be copied from pvItemToQueue into the queue storage area.
- **pxHigherPriorityTaskWoken** - xQueueGenericSendFromISR() will set *px-
  HigherPriorityTaskWoken to pdTRUE if sending to the queue caused a task to unblock,
  and the unblocked task has a priority higher than the currently running task. If xQueue-
  GenericSendFromISR() sets this value to pdTRUE then a context switch should be re-
  quested before the interrupt is exited.
- **xCopyPosition** - Can take the value queueSEND_TO_BACK to place the item at
  the back of the queue, or queueSEND_TO_FRONT to place the item at the front of the queue
  (for high priority messages).

Returns

pdTRUE if the data was successfully sent to the queue, otherwise errQUEUE_FULL.

BaseType_t xQueueGiveFromISR (QueueHandle_t xQueue, BaseType_t *const pxHigherPriorityTaskWoken)

BaseType_t xQueueReceiveFromISR (QueueHandle_t xQueue, void *const pvBuffer, BaseType_t *const
pxHigherPriorityTaskWoken)

Receive an item from a queue. It is safe to use this function from within an interrupt service routine.

Example usage:

```c
QueueHandle_t xQueue;

// Function to create a queue and post some values.
void vAFunction ( void *pvParameters )
{
    char cValueToPost;
    const TickType_t xTicksToWait = ( TickType_t )0xff;

    // Create a queue capable of containing 10 characters.
    xQueue = xQueueCreate( 10, sizeof( char ) );
```
if( xQueue == 0 )
{
   // Failed to create the queue.
}

//...

// Post some characters that will be used within an ISR. If the queue
// is full then this task will block for xTicksToWait ticks.
cValueToPost = 'a';
xQueueSend( xQueue, ( void * ) &cValueToPost, xTicksToWait );
cValueToPost = 'b';
xQueueSend( xQueue, ( void * ) &cValueToPost, xTicksToWait );

// ... keep posting characters ... this task may block when the queue
// becomes full.
cValueToPost = 'c';
xQueueSend( xQueue, ( void * ) &cValueToPost, xTicksToWait );
}

// ISR that outputs all the characters received on the queue.
void vISR_Routine( void )
{
  BaseType_t xTaskWokenByReceive = pdFALSE;
  char cRxedChar;

  while( xQueueReceiveFromISR( xQueue, ( void * ) &cRxedChar, &
                              xTaskWokenByReceive) )
  {
    // A character was received. Output the character now.
    vOutputCharacter( cRxedChar );

    // If removing the character from the queue woke the task that was
    // posting onto the queue xTaskWokenByReceive will have been set to
    // pdTRUE. No matter how many times this loop iterates only one
    // task will be woken.
  }

  if( xTaskWokenByReceive != ( char ) pdFALSE; 
  {
    taskYIELD();
  }
}

Parameters

• xQueue - The handle to the queue from which the item is to be received.
• pvBuffer - Pointer to the buffer into which the received item will be copied.
• pxHigherPriorityTaskWoken - A task may be blocked waiting for space to be-
    come available on the queue. If xQueueReceiveFromISR causes such a task to unblock
    *pxTaskWoken will get set to pdTRUE, otherwise *pxTaskWoken will remain unchanged.

Returns pdTRUE if an item was successfully received from the queue, otherwise pdFALSE.

BaseType_t xQueueIsQueueEmptyFromISR( const QueueHandle_t xQueue )

Queries a queue to determine if the queue is empty. This function should only be used in an ISR.

Parameters xQueue - The handle of the queue being queried

Returns pdFALSE if the queue is not empty, or pdTRUE if the queue is empty.

BaseType_t xQueueIsQueueFullFromISR( const QueueHandle_t xQueue )

Queries a queue to determine if the queue is full. This function should only be used in an ISR.
**Parameters**  
`xQueue` - The handle of the queue being queried  
`Returns`  
`pdFALSE` if the queue is not full, or `pdTRUE` if the queue is full.

**Parameters**  
`xQueue` - The handle of the queue being queried  
`Returns`  
The number of messages available in the queue.

**Returns**  
`pdFALSE` if the queue is not full, or `pdTRUE` if the queue is full.

**Parameters**  
`xQueue` - The handle of the queue being queried  
`Returns`  
`uxQueueMessagesWaitingFromISR()` can be called from an ISR. Return the number of messages stored in a queue.

**Parameters**  
`xQueue` - A handle to the queue being queried.

**Returns**  
The number of messages available in the queue.

**Parameters**  
`xQueue` - The handle of the queue being added to the registry. This is the handle returned by a call to `xQueueCreate()`. Semaphore and mutex handles can also be passed in here.

**Parameters**  
`pcQueueName` - The name to be associated with the handle. This is the name that the kernel aware debugger will display. The queue registry only stores a pointer to the string - so the string must be persistent (global or preferably in ROM/Flash), not on the stack.

**Parameters**  
`xQueue` - The handle of the queue being removed from the registry.

**Returns**  
If the queue is not in the registry then a pointer to the name of the queue is returned. If the queue is not in the registry then `NULL` is returned.

**Parameters**  
`xQueue` - The handle of the queue whose name will be returned.

**Returns**  
If the queue is in the registry then a pointer to the name of the queue is returned. If the queue is not in the registry then `NULL` is returned.

**Parameters**  
`uxEventQueueLength` - The handle of the queue being queried.

**Returns**  
A version of `uxQueueMessagesWaiting()` that can be called from an ISR. Return the number of messages stored in a queue.

**Parameters**  
A handle to the queue being queried.

**Returns**  
The number of messages available in the queue.

**Parameters**  
`xQueue` - A handle to the queue being queried.

**Returns**  
A version of `uxQueueMessagesWaiting()` that can be called from an ISR. Return the number of messages stored in a queue.

**Parameters**  
`xQueue` - A handle to the queue being queried.

**Returns**  
The number of messages available in the queue.

**Parameters**  
`xQueue` - The handle of the queue being added to the registry. This is the handle returned by a call to `xQueueCreate()`. Semaphore and mutex handles can also be passed in here.

**Parameters**  
`pcQueueName` - The name to be associated with the handle. This is the name that the kernel aware debugger will display. The queue registry only stores a pointer to the string - so the string must be persistent (global or preferably in ROM/Flash), not on the stack.

**Parameters**  
`xQueue` - The handle of the queue being removed from the registry.

**Returns**  
If the queue is not in the registry then a pointer to the name of the queue is returned. If the queue is not in the registry then `NULL` is returned.

**Parameters**  
`xQueue` - The handle of the queue being added to the registry. This is the handle returned by a call to `xQueueCreate()`. Semaphore and mutex handles can also be passed in here.

**Parameters**  
`pcQueueName` - The name to be associated with the handle. This is the name that the kernel aware debugger will display. The queue registry only stores a pointer to the string - so the string must be persistent (global or preferably in ROM/Flash), not on the stack.

**Parameters**  
`xQueue` - The handle of the queue being added to the registry. This is the handle returned by a call to `xQueueCreate()`. Semaphore and mutex handles can also be passed in here.

**Parameters**  
`pcQueueName` - The name to be associated with the handle. This is the name that the kernel aware debugger will display. The queue registry only stores a pointer to the string - so the string must be persistent (global or preferably in ROM/Flash), not on the stack.

**Returns**  
If the queue is not in the registry then a pointer to the name of the queue is returned. If the queue is not in the registry then `NULL` is returned.

**Parameters**  
`xQueue` - The handle of the queue being added to the registry. This is the handle returned by a call to `xQueueCreate()`. Semaphore and mutex handles can also be passed in here.

**Parameters**  
`pcQueueName` - The name to be associated with the handle. This is the name that the kernel aware debugger will display. The queue registry only stores a pointer to the string - so the string must be persistent (global or preferably in ROM/Flash), not on the stack.

**Parameters**  
`xQueue` - The handle of the queue being added to the registry. This is the handle returned by a call to `xQueueCreate()`. Semaphore and mutex handles can also be passed in here.

**Parameters**  
`pcQueueName` - The name to be associated with the handle. This is the name that the kernel aware debugger will display. The queue registry only stores a pointer to the string - so the string must be persistent (global or preferably in ROM/Flash), not on the stack.
Note 3: An additional 4 bytes of RAM is required for each space in a every queue added to a queue set. Therefore counting semaphores that have a high maximum count value should not be added to a queue set.

Note 4: A receive (in the case of a queue) or take (in the case of a semaphore) operation must not be performed on a member of a queue set unless a call to xQueueSelectFromSet() has first returned a handle to that set member.

**Parameters**

- `uxEventQueueLength` - Queue sets store events that occur on the queues and semaphores contained in the set. `uxEventQueueLength` specifies the maximum number of events that can be queued at once. To be absolutely certain that events are not lost `uxEventQueueLength` should be set to the total sum of the length of the queues added to the set, where binary semaphores and mutexes have a length of 1, and counting semaphores have a length set by their maximum count value. Examples:
  - If a queue set is to hold a queue of length 5, another queue of length 12, and a binary semaphore, then `uxEventQueueLength` should be set to `(5 + 12 + 1)`, or 18.
  - If a queue set is to hold three binary semaphores then `uxEventQueueLength` should be set to 
  - If a queue set is to hold a counting semaphore that has a maximum count of 5, and a counting semaphore that has a maximum count of 3, then `uxEventQueueLength` should be set to `(5 + 3)`, or 8.

**Returns**

If the queue set is created successfully then a handle to the created queue set is returned. Otherwise NULL is returned.

BaseType_t `xQueueAddToSet (QueueSetMemberHandle_t xQueueOrSemaphore, QueueSetHandle_t xQueueSet)`

Adds a queue or semaphore to a queue set that was previously created by a call to `xQueueCreateSet()`.

See FreeRTOS/Source/Demo/Common/Minimal/QueueSet.c for an example using this function.

Note 1: A receive (in the case of a queue) or take (in the case of a semaphore) operation must not be performed on a member of a queue set unless a call to `xQueueSelectFromSet()` has first returned a handle to that set member.

**Parameters**

- `xQueueOrSemaphore` - The handle of the queue or semaphore being added to the queue set (cast to an `QueueSetMemberHandle_t` type).
- `xQueueSet` - The handle of the queue set to which the queue or semaphore is being added.

**Returns**

If the queue or semaphore was successfully added to the queue set then `pdPASS` is returned. If the queue could not be successfully added to the queue set because it is already a member of a different queue set then `pdFAIL` is returned.

BaseType_t `xQueueRemoveFromSet (QueueSetMemberHandle_t xQueueOrSemaphore, QueueSetHandle_t xQueueSet)`

Removes a queue or semaphore from a queue set. A queue or semaphore can only be removed from a set if the queue or semaphore is empty.

See FreeRTOS/Source/Demo/Common/Minimal/QueueSet.c for an example using this function.

**Parameters**

- `xQueueOrSemaphore` - The handle of the queue or semaphore being removed from the queue set (cast to an `QueueSetMemberHandle_t` type).
- `xQueueSet` - The handle of the queue set in which the queue or semaphore is included.

**Returns**

If the queue or semaphore was successfully removed from the queue set then `pdPASS` is returned. If the queue was not in the queue set, or the queue (or semaphore) was not empty, then `pdFAIL` is returned.

`QueueSetMemberHandle_t xQueueSelectFromSet (QueueHandle_t xQueueSet, const TickType_t xTicksToWait)`

`xQueueSelectFromSet()` selects from the members of a queue set a queue or semaphore that either contains data (in the case of a queue) or is available to take (in the case of a semaphore). `xQueueSelectFromSet()`
effectively allows a task to block (pend) on a read operation on all the queues and semaphores in a queue set simultaneously.

See FreeRTOS/Source/Demo/Common/Minimal/QueueSet.c for an example using this function.

Note 1: See the documentation on https://www.FreeRTOS.org/RTOS-queue-sets.html for reasons why queue sets are very rarely needed in practice as there are simpler methods of blocking on multiple objects.

Note 2: Blocking on a queue set that contains a mutex will not cause the mutex holder to inherit the priority of the blocked task.

Note 3: A receive (in the case of a queue) or take (in the case of a semaphore) operation must not be performed on a member of a queue set unless a call to xQueueSelectFromSet() has first returned a handle to that set member.

**Parameters**

- `xQueueSet` – The queue set on which the task will (potentially) block.
- `xTicksToWait` – The maximum time, in ticks, that the calling task will remain in the Blocked state (with other tasks executing) to wait for a member of the queue set to be ready for a successful queue read or semaphore take operation.

**Returns**

xQueueSelectFromSet() will return the handle of a queue (cast to a QueueSetMemberHandle_t type) contained in the queue set that contains data, or the handle of a semaphore (cast to a QueueSetMemberHandle_t type) contained in the queue set that is available, or NULL if no such queue or semaphore exists before before the specified block time expires.

**Macros**

`xQueueCreate` (uxQueueLength, uxItemSize)

Creates a new queue instance, and returns a handle by which the new queue can be referenced.

Internally, within the FreeRTOS implementation, queues use two blocks of memory. The first block is used to hold the queue’s data structures. The second block is used to hold items placed into the queue. If a queue is created using xQueueCreate() then both blocks of memory are automatically dynamically allocated inside the xQueueCreate() function. (see https://www.FreeRTOS.org/a00111.html). If a queue is created using xQueueCreateStatic() then the application writer must provide the memory that will get used by the queue. xQueueCreateStatic() therefore allows a queue to be created without using any dynamic memory allocation.

**Example usage:**

```c
struct AMessage
{
    char ucMessageID;
    char ucData[20];
};

void vATask( void *pvParameters )
{
    QueueHandle_t xQueue1, xQueue2;

    // Create a queue capable of containing 10 uint32_t values.
    xQueue1 = xQueueCreate( 10, sizeof( uint32_t ) );
    if( xQueue1 == 0 )
    {
        // Queue was not created and must not be used.
    }

    // Create a queue capable of containing 10 pointers to AMessage structures.
```
// These should be passed by pointer as they contain a lot of data.

`xQueue2 = xQueueCreate( 10, sizeof( struct AMessage * ) );`

if( xQueue2 == 0 )
{
  // Queue was not created and must not be used.
}

// ... Rest of task code.

---

### Parameters

- `uxQueueLength` - The maximum number of items that the queue can contain.
- `uxItemSize` - The number of bytes each item in the queue will require. Items are queued by copy, not by reference, so this is the number of bytes that will be copied for each posted item. Each item on the queue must be the same size.

### Returns

If the queue is successfully created then a handle to the newly created queue is returned.

If the queue cannot be created then 0 is returned.

---

### `xQueueCreateStatic`(uxQueueLength, uxItemSize, pucQueueStorage, pxQueueBuffer)

Creates a new queue instance, and returns a handle by which the new queue can be referenced.

Internally, within the FreeRTOS implementation, queues use two blocks of memory. The first block is used to hold the queue’s data structures. The second block is used to hold items placed into the queue. If a queue is created using `xQueueCreate()` then both blocks of memory are automatically dynamically allocated inside the `xQueueCreate()` function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If a queue is created using `xQueueCreateStatic()` then the application writer must provide the memory that will get used by the queue. `xQueueCreateStatic()` therefore allows a queue to be created without using any dynamic memory allocation.

---

### Example usage:

```c
struct AMessage
{
  char ucMessageID;
  char ucData[ 20 ];
};

#define QUEUE_LENGTH 10
#define ITEM_SIZE sizeof( uint32_t )

// xQueueBuffer will hold the queue structure.
StaticQueue_t xQueueBuffer;

// ucQueueStorage will hold the items posted to the queue. Must be at least
// [(queue length) * ( queue item size)] bytes long.
uint8_t ucQueueStorage[ QUEUE_LENGTH * ITEM_SIZE ];

void vATask( void *pvParameters )
{
  QueueHandle_t xQueue1;

  // Create a queue capable of containing 10 uint32_t values.
  xQueue1 = xQueueCreate( QUEUE_LENGTH, // The number of items the queue can...
                           ITEM_SIZE     // The size of each item in the queue
                          & ucQueueStorage[ 0 ], // The buffer that will...
                          &xQueueBuffer ); // The buffer that will hold the...
```

---

(continues on next page)
The queue is guaranteed to be created successfully as no dynamic memory allocation is used. Therefore xQueue1 is now a handle to a valid queue.

... Rest of task code.

Parameters

- **uxQueueLength** - The maximum number of items that the queue can contain.
- **uxItemSize** - The number of bytes each item in the queue will require. Items are queued by copy, not by reference, so this is the number of bytes that will be copied for each posted item. Each item on the queue must be the same size.
- **pucQueueStorage** - If uxItemSize is not zero then pucQueueStorage must point to a uint8_t array that is at least large enough to hold the maximum number of items that can be in the queue at any one time - which is (uxQueueLength * uxItemsSize) bytes. If uxItemSize is zero then pucQueueStorage can be NULL.
- **pxQueueBuffer** - Must point to a variable of type StaticQueue_t, which will be used to hold the queue’s data structure.

Returns If the queue is created then a handle to the created queue is returned. If pxQueueBuffer is NULL then NULL is returned.

### xQueueGetStaticBuffers(xQueue, ppuQueueStorage, ppxStaticQueue)

Retrieve pointers to a statically created queue’s data structure buffer and storage area buffer. These are the same buffers that are supplied at the time of creation.

Parameters

- **xQueue** - The queue for which to retrieve the buffers.
- **ppuQueueStorage** - Used to return a pointer to the queue’s storage area buffer.
- **pxxStaticQueue** - Used to return a pointer to the queue’s data structure buffer.

Returns pdTRUE if buffers were retrieved, pdFALSE otherwise.

### xQueueSendToFront(xQueue, pvItemToQueue, xTicksToWait)

Post an item to the front of a queue. The item is queued by copy, not by reference. This function must not be called from an interrupt service routine. See xQueueSendFromISR() for an alternative which may be used in an ISR.

Example usage:

*struct AMessage
{
    char ucMessageID;
    char ucData[20];
} xMessage;*

*uint32_t ulVar = 10UL;*

*void vATask(void *pvParameters)*
{
    QueueHandle_t xQueue1, xQueue2;
    struct AMessage *pxMessage;

    // Create a queue capable of containing 10 uint32_t values.
    xQueue1 = xQueueCreate(10, sizeof(uint32_t));

    // Create a queue capable of containing 10 pointers to AMessage structures.
    // These should be passed by pointer as they contain a lot of data.
    xQueue2 = xQueueCreate(10, sizeof(struct AMessage *));*
// ...
if( xQueue1 != 0 )
{
    // Send an uint32_t. Wait for 10 ticks for space to become
    // available if necessary.
    if( xQueueSendToFront( xQueue1, ( void * ) &ulVar, ( TickType_t ) 10 ) !=
        pdPASS )
    {
        // Failed to post the message, even after 10 ticks.
    }
}
if( xQueue2 != 0 )
{
    // Send a pointer to a struct AMessage object. Don't block if the
    // queue is already full.
    pxMessage = & xMessage;
    xQueueSendToFront( xQueue2, ( void * ) pxMessage, ( TickType_t ) 0 );
    // ... Rest of task code.
}

Parameters

- **xQueue** - The handle to the queue on which the item is to be posted.
- **pvItemToQueue** - A pointer to the item that is to be placed on the queue. The size of
  the items the queue will hold was defined when the queue was created, so this many bytes
  will be copied from pvItemToQueue into the queue storage area.
- **xTicksToWait** - The maximum amount of time the task should block waiting for space
  to become available on the queue, should it already be full. The call will return immediately
  if this is set to 0 and the queue is full. The time is defined in tick periods so the constant
  portTICK_PERIOD_MS should be used to convert to real time if this is required.

Returns pdTRUE if the item was successfully posted, otherwise errQUEUE_FULL.

```c
xQueueSendToBack( xQueue, pvItemToQueue, xTicksToWait )
```

This is a macro that calls xQueueGenericSend().

Post an item to the back of a queue. The item is queued by copy, not by reference. This function must not be
called from an interrupt service routine. See xQueueSendFromISR () for an alternative which may be used in
an ISR.

Example usage:

```c
struct AMessage
{
    char ucMessageID;
    char ucData[ 20 ];
} xMessage;

uint32_t ulVar = 10UL;

void vATask( void *pvParameters )
{
    QueueHandle_t xQueue1, xQueue2;
    struct AMessage *pxMessage;
```
// Create a queue capable of containing 10 uint32_t values.
xQueue1 = xQueueCreate( 10, sizeof( uint32_t ) );

// Create a queue capable of containing 10 pointers to AMessage structures.
// These should be passed by pointer as they contain a lot of data.
xQueue2 = xQueueCreate( 10, sizeof( struct AMessage * ) );

// ...
if( xQueue1 != 0 )
{
    // Send an uint32_t. Wait for 10 ticks for space to become
    // available if necessary.
    if( xQueueSendToBack( xQueue1, ( void * ) &ulVar, ( TickType_t ) 10 ) != pdPASS )
    {
        // Failed to post the message, even after 10 ticks.
    }
}

if( xQueue2 != 0 )
{
    // Send a pointer to a struct AMessage object. Don’t block if the
    // queue is already full.
    pxMessage = & xMessage;
    xQueueSendToBack( xQueue2, ( void * ) &pxMessage, ( TickType_t ) 0 );
}

// ... Rest of task code.

Parameters

- xQueue - The handle to the queue on which the item is to be posted.
- pvItemToQueue - A pointer to the item that is to be placed on the queue. The size of
  the items the queue will hold was defined when the queue was created, so this many bytes
  will be copied from pvItemToQueue into the queue storage area.
- xTicksToWait - The maximum amount of time the task should block waiting for space
  to become available on the queue, should it already be full. The call will return immediately
  if this is set to 0 and the queue is full. The time is defined in tick periods so the constant
  portTICK_PERIOD_MS should be used to convert to real time if this is required.

Returns

pdTRUE if the item was successfully posted, otherwise errQUEUE_FULL.

xQueueSend(xQueue, pvItemToQueue, xTicksToWait)
This is a macro that calls xQueueGenericSend(). It is included for backward compatibility with versions of
FreeRTOS.org that did not include the xQueueSendToFront() and xQueueSendToBack() macros. It is equiva-
 lent to xQueueSendToBack().

Post an item on a queue. The item is queued by copy, not by reference. This function must not be called from
an interrupt service routine. See xQueueSendFromISR() for an alternative which may be used in an ISR.

Example usage:

struct AMessage
{
    char ucMessageID;
    char ucData[ 20 ];
} xMessage;
uint32_t ulVar = 10UL;

void vATask( void *pvParameters )
{
  QueueHandle_t xQueue1, xQueue2;
  struct AMessage *pxMessage;

  // Create a queue capable of containing 10 uint32_t values.
  xQueue1 = xQueueCreate( 10, sizeof( uint32_t ) );

  // Create a queue capable of containing 10 pointers to AMessage structures.
  xQueue2 = xQueueCreate( 10, sizeof( struct AMessage * ) );

  // ...
  if( xQueue1 != 0 )
  {
    // Send an uint32_t. Wait for 10 ticks for space to become
    // available if necessary.
    if( xQueueSend( xQueue1, ( void * ) &ulVar, ( TickType_t ) 10 ) != pdPASS_"
    { // Failed to post the message, even after 10 ticks.
    }
  }
  if( xQueue2 != 0 )
  {
    // Send a pointer to a struct AMessage object. Don't block if the
    // queue is already full.
    pxMessage = & xMessage;
    xQueueSend( xQueue2, ( void * ) &pxMessage, ( TickType_t ) 0 );
  }
  // ... Rest of task code.
}

Parameters
  • xQueue - The handle to the queue on which the item is to be posted.
  • pvItemToQueue - A pointer to the item that is to be placed on the queue. The size of
    the items the queue will hold was defined when the queue was created, so this many bytes
    will be copied from pvItemToQueue into the queue storage area.
  • xTicksToWait - The maximum amount of time the task should block waiting for space
    to become available on the queue, should it already be full. The call will return immediately
    if this is set to 0 and the queue is full. The time is defined in tick periods so the constant
    portTICK_PERIOD_MS should be used to convert to real time if this is required.

Returns pdTRUE if the item was successfully posted, otherwise errQUEUE_FULL.

xQueueOverwrite (xQueue, pvItemToQueue)

Only for use with queues that have a length of one - so the queue is either empty or full.
Post an item on a queue. If the queue is already full then overwrite the value held in the queue. The item is
queued by copy, not by reference.

This function must not be called from an interrupt service routine. See xQueueOverwriteFromISR () for an
alternative which may be used in an ISR.

Example usage:
void vFunction( void *pvParameters )
{
  QueueHandle_t xQueue;
  uint32_t ulVarToSend, ulValReceived;

  // Create a queue to hold one uint32_t value. It is strongly
  // recommended "not" to use xQueueOverwrite() on queues that can
  // contain more than one value, and doing so will trigger an assertion
  // if configASSERT() is defined.
  xQueue = xQueueCreate( 1, sizeof( uint32_t ) );

  // Write the value 10 to the queue using xQueueOverwrite().
  ulVarToSend = 10;
  xQueueOverwrite( xQueue, &ulVarToSend );

  // Peeking the queue should now return 10, but leave the value 10 in
  // the queue. A block time of zero is used as it is known that the
  // queue holds a value.
  ulValReceived = 0;
  xQueuePeek( xQueue, &ulValReceived, 0 );

  if( ulValReceived != 10 )
  {
    // Error unless the item was removed by a different task.
  }

  // The queue is still full. Use xQueueOverwrite() to overwrite the
  // value held in the queue with 100.
  ulVarToSend = 100;
  xQueueOverwrite( xQueue, &ulVarToSend );

  // This time read from the queue, leaving the queue empty once more.
  // A block time of 0 is used again.
  xQueueReceive( xQueue, &ulValReceived, 0 );

  // The value read should be the last value written, even though the
  // queue was already full when the value was written.
  if( ulValReceived != 100 )
  {
    // Error!
  }

  // ...
}

Parameters

- **xQueue** - The handle of the queue to which the data is being sent.
- **pvItemToQueue** - A pointer to the item that is to be placed on the queue. The size of
  the items the queue will hold was defined when the queue was created, so this many bytes
  will be copied from pvItemToQueue into the queue storage area.

Returns

xQueueOverwrite() is a macro that calls xQueueGenericSend(), and therefore has the
same return values as xQueueSendToFront(). However, pdPASS is the only value that can be
returned because xQueueOverwrite() will write to the queue even when the queue is already
full.

xQueueSendToFrontFromISR(xQueue, pvItemToQueue, pxHigherPriorityTaskWoken)
This is a macro that calls xQueueGenericSendToFrontFromISR().

Post an item to the front of a queue. It is safe to use this macro from within an interrupt service routine.

Items are queued by copy not reference so it is preferable to only queue small items, especially when called
from an ISR. In most cases it would be preferable to store a pointer to the item being queued.

Example usage for buffered IO (where the ISR can obtain more than one value per call):

```c
void vBufferISR( void )
{
    char cIn;
    BaseType_t xHigherPriorityTaskWoken;

    // We have not woken a task at the start of the ISR.
    xHigherPriorityTaskWoken = pdFALSE;

    // Loop until the buffer is empty.
    do
    {
        // Obtain a byte from the buffer.
        cIn = portINPUT_BYTE( RX_REGISTER_ADDRESS );

        // Post the byte.
        xQueueSendToFrontFromISR( xRxQueue, &cIn, &xHigherPriorityTaskWoken );
    } while( portINPUT_BYTE( BUFFER_COUNT ) );

    // Now the buffer is empty we can switch context if necessary.
    if( xHigherPriorityTaskWoken )
    {
        taskYIELD ();
    }
}
```

**Parameters**

- `xQueue` - The handle to the queue on which the item is to be posted.
- `pvItemToQueue` - A pointer to the item that is to be placed on the queue. The size of the items the queue will hold was defined when the queue was created, so this many bytes will be copied from `pvItemToQueue` into the queue storage area.
- `pxHigherPriorityTaskWoken` - `xQueueSendToFrontFromISR()` will set `pxHigherPriorityTaskWoken` to `pdTRUE` if sending to the queue caused a task to unblock, and the unblocked task has a priority higher than the currently running task. If `xQueueSendToFrontFromISR()` sets this value to `pdTRUE` then a context switch should be requested before the interrupt is exited.

**Returns**

- `pdTRUE` if the data was successfully sent to the queue, otherwise `errQUEUE_FULL`.

`xQueueSendToBackFromISR` (xQueue, pvItemToQueue, pxHigherPriorityTaskWoken)

This is a macro that calls `xQueueGenericSendFromISR()`.

Post an item to the back of a queue. It is safe to use this macro from within an interrupt service routine.

Items are queued by copy not reference so it is preferable to only queue small items, especially when called from an ISR. In most cases it would be preferable to store a pointer to the item being queued.

Example usage for buffered IO (where the ISR can obtain more than one value per call):

```c
void vBufferISR( void )
{
    char cIn;
    BaseType_t xHigherPriorityTaskWoken;

    // We have not woken a task at the start of the ISR.
    xHigherPriorityTaskWoken = pdFALSE;

    // ... (continues on next page)
// Loop until the buffer is empty.
do{
  // Obtain a byte from the buffer.
cIn = portINPUT_BYTE( RX_REGISTER_ADDRESS );
  // Post the byte.
xQueueSendToBackFromISR( xRxQueue, &cIn, &xHigherPriorityTaskWoken );
} while( portINPUT_BYTE( BUFFER_COUNT ) );

// Now the buffer is empty we can switch context if necessary.
if( xHigherPriorityTaskWoken ){
  taskYIELD();
}

Parameters

• **xQueue** – The handle to the queue on which the item is to be posted.
• **pvItemToQueue** – A pointer to the item that is to be placed on the queue. The size of the items the queue will hold was defined when the queue was created, so this many bytes will be copied from pvItemToQueue into the queue storage area.

• **pxHigherPriorityTaskWoken** – xQueueSendToBackFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE if sending to the queue caused a task to unblock, and the unblocked task has a priority higher than the currently running task. If xQueueSendToBackFromISR() sets this value to pdTRUE then a context switch should be requested before the interrupt is exited.

Returns pdTRUE if the data was successfully sent to the queue, otherwise errQUEUE_FULL.

**xQueueOverwriteFromISR** (xQueue, pvItemToQueue, pxHigherPriorityTaskWoken) A version of xQueueOverwrite() that can be used in an interrupt service routine (ISR).

Only for use with queues that can hold a single item - so the queue is either empty or full.

Post an item on a queue. If the queue is already full then overwrite the value held in the queue. The item is queued by copy, not by reference.

Example usage:

```c
QueueHandle_t xQueue;

void vFunction( void *pvParameters )
{
  // Create a queue to hold one uint32_t value. It is strongly
  // recommended *not* to use xQueueOverwriteFromISR() on queues that can
  // contain more than one value, and doing so will trigger an assertion
  // if configASSERT() is defined.
xQueue = xQueueCreate( 1, sizeof( uint32_t ) );
}

void vAnInterruptHandler( void )
{
  // xHigherPriorityTaskWoken must be set to pdFALSE before it is used.
  BaseType_t xHigherPriorityTaskWoken = pdFALSE;
  uint32_t ulVarToSend, ulValReceived;
```
// Write the value 10 to the queue using xQueueOverwriteFromISR().
ulVarToSend = 10;
xQueueOverwriteFromISR( xQueue, &ulVarToSend, &xHigherPriorityTaskWoken );

// The queue is full, but calling xQueueOverwriteFromISR() again will still
// pass because the value held in the queue will be overwritten with the
// new value.
ulVarToSend = 100;
xQueueOverwriteFromISR( xQueue, &ulVarToSend, &xHigherPriorityTaskWoken );

// Reading from the queue will now return 100.
// ...
xHigherPriorityTaskWoken = pdFALSE;

// Loop until the buffer is empty.
do {
    // Obtain a byte from the buffer.
    cIn = portINPUT_BYTE(RX_REGISTER_ADDRESS);

    // Post the byte.
    xQueueSendFromISR(xRxQueue, &cIn, &xHigherPriorityTaskWoken);
} while (portINPUT_BYTE(BUFFER_COUNT));

// Now the buffer is empty we can switch context if necessary.
if (xHigherPriorityTaskWoken) {
    // Actual macro used here is port specific.
    portYIELD_FROM_ISR();
}

Parameters

• xQueue – The handle to the queue on which the item is to be posted.
• pvItemToQueue – A pointer to the item that is to be placed on the queue. The size of
  the items the queue will hold was defined when the queue was created, so this many
  bytes will be copied from pvItemToQueue into the queue storage area.
• pxHigherPriorityTaskWoken – xQueueSendFromISR() will set *pxHigherPriorityTaskWoken
  to pdTRUE if sending to the queue caused a task to unblock, and the
  unblocked task has a priority higher than the currently running task. If xQueueSend-
  FromISR() sets this value to pdTRUE then a context switch should be requested before
  the interrupt is exited.

Returns

pdTRUE if the data was successfully sent to the queue, otherwise errQUEUE_FULL.

xQueueReset(xQueue)

Reset a queue back to its original empty state. The return value is now obsolete and is always set to pdPASS.

Type Definitions

typedef struct QueueDefinition *QueueHandle_t

typedef struct QueueDefinition *QueueSetHandle_t

Type by which queue sets are referenced. For example, a call to xQueueCreateSet() returns an QueueSet
variable that can then be used as a parameter to xQueueSelectFromSet(), xQueueAddToSet(), etc.

typedef struct QueueDefinition *QueueSetMemberHandle_t

Queue sets can contain both queues and semaphores, so the QueueSetMemberHandle_t is defined as a type to
be used where a parameter or return value can be either an QueueHandle_t or an SemaphoreHandle_t.

## Macros

**semBINARY_SEMAPHORE_QUEUE_LENGTH**

**semSEMAPHORE_QUEUE_ITEM_LENGTH**

**semGIVE_BLOCK_TIME**

### vSemaphoreCreateBinary(xSemaphore)

In many usage scenarios it is faster and more memory efficient to use a direct to task notification in place of a binary semaphore! [https://www.FreeRTOS.org/RTOS-task-notifications.html](https://www.FreeRTOS.org/RTOS-task-notifications.html)

This old vSemaphoreCreateBinary() macro is now deprecated in favour of the xSemaphoreCreateBinary() function. Note that binary semaphores created using the vSemaphoreCreateBinary() macro are created in a state such that the first call to ‘take’ the semaphore would pass, whereas binary semaphores created using xSemaphoreCreateBinary() are created in a state such that the the semaphore must first be ‘given’ before it can be ‘taken’.

Macro that implements a semaphore by using the existing queue mechanism. The queue length is 1 as this is a binary semaphore. The data size is 0 as we don’t want to actually store any data - we just want to know if the queue is empty or full.

This type of semaphore can be used for pure synchronisation between tasks or between an interrupt and a task. The semaphore need not be given back once obtained, so one task/interrupt can continuously ‘give’ the semaphore while another continuously ‘takes’ the semaphore. For this reason this type of semaphore does not use a priority inheritance mechanism. For an alternative that does use priority inheritance see xSemaphoreCreateMutex().

### Example usage:

```c
SemaphoreHandle_t xSemaphore = NULL;

void vATask( void * pvParameters )
{
    // Semaphore cannot be used before a call to vSemaphoreCreateBinary ().
    // This is a macro so pass the variable in directly.
    vSemaphoreCreateBinary( xSemaphore );

    if( xSemaphore != NULL )
    {
        // The semaphore was created successfully.
        // The semaphore can now be used.
    }
}
```

### Parameters

- **xSemaphore** – Handle to the created semaphore. Should be of type SemaphoreHandle_t.

### xSemaphoreCreateBinary()

Creates a new binary semaphore instance, and returns a handle by which the new semaphore can be referenced.

In many usage scenarios it is faster and more memory efficient to use a direct to task notification in place of a binary semaphore! [https://www.FreeRTOS.org/RTOS-task-notifications.html](https://www.FreeRTOS.org/RTOS-task-notifications.html)
Internally, within the FreeRTOS implementation, binary semaphores use a block of memory, in which the
semaphore structure is stored. If a binary semaphore is created using xSemaphoreCreateBinary() then the
required memory is automatically dynamically allocated inside the xSemaphoreCreateBinary() function. (see
https://www.FreeRTOS.org/a00111.html). If a binary semaphore is created using xSemaphoreCreateBina-
ryStatic() then the application writer must provide the memory. xSemaphoreCreateBinaryStatic() therefore
allows a binary semaphore to be created without using any dynamic memory allocation.

The old vSemaphoreCreateBinary() macro is now deprecated in favour of this xSemaphoreCreateBinary() function. Note that binary semaphores created using the vSemaphoreCreateBinary() macro are created in a
state such that the first call to ‘take’ the semaphore would pass, whereas binary semaphores created using
xSemaphoreCreateBinary() are created in a state such that the semaphore must first be ‘given’ before it
can be ‘taken’.

This type of semaphore can be used for pure synchronisation between tasks or between an interrupt and a
task. The semaphore need not be given back once obtained, so one task/interrupt can continuously ‘give’ the
semaphore while another continuously ‘takes’ the semaphore. For this reason this type of semaphore does not
use a priority inheritance mechanism. For an alternative that does use priority inheritance see xSemaphoreCre-
ateMutex().

Example usage:

```c
SemaphoreHandle_t xSemaphore = NULL;

void vATask( void * pvParameters )
{
    // Semaphore cannot be used before a call to xSemaphoreCreateBinary().
    // This is a macro so pass the variable in directly.
    xSemaphore = xSemaphoreCreateBinary();

    if( xSemaphore != NULL )
    {
        // The semaphore was created successfully.
        // The semaphore can now be used.
    }
}
```

**Returns** Handle to the created semaphore, or NULL if the memory required to hold the
semaphore’s data structures could not be allocated.

**xSemaphoreCreateBinaryStatic**(pxStaticSemaphore)

Creates a new binary semaphore instance, and returns a handle by which the new semaphore can be referenced.

NOTE: In many usage scenarios it is faster and more memory efficient to use a direct to task notification in
place of a binary semaphore! https://www.FreeRTOS.org/RTOS-task-notifications.html

Internally, within the FreeRTOS implementation, binary semaphores use a block of memory, in which the
semaphore structure is stored. If a binary semaphore is created using xSemaphoreCreateBinary() then the
required memory is automatically dynamically allocated inside the xSemaphoreCreateBinary() function. (see
https://www.FreeRTOS.org/a00111.html). If a binary semaphore is created using xSemaphoreCreateBina-
ryStatic() then the application writer must provide the memory. xSemaphoreCreateBinaryStatic() therefore
allows a binary semaphore to be created without using any dynamic memory allocation.

This type of semaphore can be used for pure synchronisation between tasks or between an interrupt and a
task. The semaphore need not be given back once obtained, so one task/interrupt can continuously ‘give’ the
semaphore while another continuously ‘takes’ the semaphore. For this reason this type of semaphore does not
use a priority inheritance mechanism. For an alternative that does use priority inheritance see xSemaphoreCre-
ateMutex().

Example usage:
SemaphoreHandle_t xSemaphore = NULL;
StaticSemaphore_t xSemaphoreBuffer;

void vATask( void * pvParameters )
{
    // Semaphore cannot be used before a call to xSemaphoreCreateBinary().
    // The semaphore's data structures will be placed in the xSemaphoreBuffer
    // variable, the address of which is passed into the function. The
    // function's parameter is not NULL, so the function will not attempt any
    // dynamic memory allocation, and therefore the function will not return
    // return NULL.
    xSemaphore = xSemaphoreCreateBinary( &xSemaphoreBuffer );

    // Rest of task code goes here.
}

Parameters

- **pxStaticSemaphore** – Must point to a variable of type StaticSemaphore_t, which will
  then be used to hold the semaphore’s data structure, removing the need for the memory
to be allocated dynamically.

Returns
If the semaphore is created then a handle to the created semaphore is returned. If
pxSemaphoreBuffer is NULL then NULL is returned.

xSemaphoreTake(xSemaphore, xBlockTime)

**Macro** to obtain a semaphore. The semaphore must have previously been created with a call to xSemaphoreCreateBinary(), xSemaphoreCreateMutex() or xSemaphoreCreateCounting().

Example usage:

```c
SemaphoreHandle_t xSemaphore = NULL;

// A task that creates a semaphore.
void vATask( void * pvParameters )
{
    // Create the semaphore to guard a shared resource.
    xSemaphore = xSemaphoreCreateBinary();
}

// A task that uses the semaphore.
void vAnotherTask( void * pvParameters )
{
    // ... Do other things.

    if( xSemaphore != NULL )
    {
        // See if we can obtain the semaphore. If the semaphore is not available
        // wait 10 ticks to see if it becomes free.
        if( xSemaphoreTake( xSemaphore, ( TickType_t ) 10 ) == pdTRUE )
        {
            // We were able to obtain the semaphore and can now access the
            // shared resource.

            // ...

            // We have finished accessing the shared resource. Release the
            // semaphore.
            xSemaphoreGive( xSemaphore );
        }
    }
    else
```
Parameters

- **xSemaphore** - A handle to the semaphore being taken - obtained when the semaphore was created.
- **xBlockTime** - The time in ticks to wait for the semaphore to become available. The macro portTICK_PERIOD_MS can be used to convert this to a real time. A block time of zero can be used to poll the semaphore. A block time of portMAX_DELAY can be used to block indefinitely (provided INCLUDE_vTaskSuspend is set to 1 in FreeRTOSConfig.h).

**Returns** pdTRUE if the semaphore was obtained. pdFALSE if xBlockTime expired without the semaphore becoming available.

### xSemaphoreTakeRecursive (xMutex, xBlockTime)

*Macro* to recursively obtain, or ‘take’, a mutex type semaphore. The mutex must have previously been created using a call to xSemaphoreCreateRecursiveMutex();

configUSE_RECURSIVE_MUTEXES must be set to 1 in FreeRTOSConfig.h for this macro to be available. This macro must not be used on mutexes created using xSemaphoreCreateMutex().

A mutex used recursively can be ‘taken’ repeatedly by the owner. The mutex doesn’t become available again until the owner has called xSemaphoreGiveRecursive() for each successful ‘take’ request. For example, if a task successfully ‘takes’ the same mutex 5 times then the mutex will not be available to any other task until it has also ‘given’ the mutex back exactly five times.

Example usage:

```c
SemaphoreHandle_t xMutex = NULL;

// A task that creates a mutex.
void vATask( void * pvParameters )
{
    // Create the mutex to guard a shared resource.
    xMutex = xSemaphoreCreateRecursiveMutex();
}

// A task that uses the mutex.
void vAnotherTask( void * pvParameters )
{
    // ... Do other things.
    if( xMutex != NULL )
    {
        // See if we can obtain the mutex. If the mutex is not available
        // wait 10 ticks to see if it becomes free.
        if( xSemaphoreTakeRecursive( xSemaphore, ( TickType_t ) 10 ) == pdTRUE )
        {
            // We were able to obtain the mutex and can now access the
            // shared resource.
            // ...
            // For some reason due to the nature of the code further calls to
            // xSemaphoreTakeRecursive() are made on the same mutex. In real
            // code these would not be just sequential calls as this would make
        }
    }
}
```

(continues on next page)
// no sense. Instead the calls are likely to be buried inside
// a more complex call structure.
xSemaphoreTakeRecursive( xMutex, ( TickType_t ) 10 );
xSemaphoreTakeRecursive( xMutex, ( TickType_t ) 10 );

// The mutex has now been 'taken' three times, so will not be
// available to another task until it has also been given back
// three times. Again it is unlikely that real code would have
// these calls sequentially, but instead buried in a more complex
// call structure. This is just for illustrative purposes.
xSemaphoreGiveRecursive( xMutex );
xSemaphoreGiveRecursive( xMutex );
xSemaphoreGiveRecursive( xMutex );

// Now the mutex can be taken by other tasks.
}
else
{
    // We could not obtain the mutex and can therefore not access
    // the shared resource safely.
}
}

Parameters

• xMutex - A handle to the mutex being obtained. This is the handle returned by
  xSemaphoreCreateRecursiveMutex();
• xBlockTime - The time in ticks to wait for the semaphore to become available. The
  macro portTICK_PERIOD_MS can be used to convert this to a real time. A block time
  of zero can be used to poll the semaphore. If the task already owns the semaphore then
  xSemaphoreTakeRecursive() will return immediately no matter what the value of xBlock-
  Time.

Returns pdTRUE if the semaphore was obtained. pdFALSE if xBlockTime expired without the
semaphore becoming available.

xSemaphoreGive( xSemaphore )

Macro to release a semaphore. The semaphore must have previously been created with a call to
xSemaphoreCreateBinary(), xSemaphoreCreateMutex() or xSemaphoreCreateCounting(). and obtained using xSemaphoreTake().

This macro must not be used from an ISR. See xSemaphoreGiveFromISR () for an alternative which can be
used from an ISR.

This macro must also not be used on semaphores created using xSemaphoreCreateRecursiveMutex().

Example usage:

SemaphoreHandle_t xSemaphore = NULL;

void vATask( void * pvParameters )
{
    // Create the semaphore to guard a shared resource.
    xSemaphore = vSemaphoreCreateBinary();
    
    if( xSemaphore != NULL )
    {
        if( xSemaphoreGive( xSemaphore ) != pdTRUE )
        {
            (continues on next page)
// We would expect this call to fail because we cannot give
// a semaphore without first "taking" it!

// Obtain the semaphore - don't block if the semaphore is not
// immediately available.
if (xSemaphoreTake(xSemaphore, (TickType_t)0)) {
    // We now have the semaphore and can access the shared resource.
    // ...
    // We have finished accessing the shared resource so can free the
    // semaphore.
    if (xSemaphoreGive(xSemaphore) != pdTRUE) {
        // We would not expect this call to fail because we must have
        // obtained the semaphore to get here.
    }
}

Parameters

• **xSemaphore** - A handle to the semaphore being released. This is the handle returned
when the semaphore was created.

Returns

pdTRUE if the semaphore was released. pdFALSE if an error occurred. Semaphores
are implemented using queues. An error can occur if there is no space on the queue to post a
message - indicating that the semaphore was not first obtained correctly.

**xSemaphoreGiveRecursive** (xMutex)

*Macro* to recursively release, or ‘give’ , a mutex type semaphore. The mutex must have previously been
created using a call to xSemaphoreCreateRecursiveMutex();

configUSE_RECURSIVE_MUTEXES must be set to 1 in FreeRTOSConfig.h for this macro to be available.

This macro must not be used on mutexes created using xSemaphoreCreateMutex().

A mutex used recursively can be ‘taken’ repeatedly by the owner. The mutex doesn’t become available
again until the owner has called xSemaphoreGiveRecursive() for each successful ‘take’ request. For example,
if a task successfully ‘takes’ the same mutex 5 times then the mutex will not be available to any other task
until it has also ‘given’ the mutex back exactly five times.

Example usage:

```c
SemaphoreHandle_t xMutex = NULL;

// A task that creates a mutex.
void vATask( void * pvParameters )
{
    // Create the mutex to guard a shared resource.
    xMutex = xSemaphoreCreateRecursiveMutex();
}

// A task that uses the mutex.
void vAnotherTask( void * pvParameters )
{
    // ... Do other things.
}
```

(continues on next page)
if( xMutex != NULL )
{
    // See if we can obtain the mutex. If the mutex is not available
    // wait 10 ticks to see if it becomes free.
    if( xSemaphoreTakeRecursive( xMutex, ( TickType_t ) 10 ) == pdTRUE )
    {
        // We were able to obtain the mutex and can now access the
        // shared resource.
        // ...
        // For some reason due to the nature of the code further calls to
        // xSemaphoreTakeRecursive() are made on the same mutex. In real
        // code these would not be just sequential calls as this would make
        // no sense. Instead the calls are likely to be buried inside
        // a more complex call structure.
        xSemaphoreTakeRecursive( xMutex, ( TickType_t ) 10 );
        xSemaphoreTakeRecursive( xMutex, ( TickType_t ) 10 );
        // The mutex has now been 'taken' three times, so will not be
        // available to another task until it has also been given back
        // three times. Again it is unlikely that real code would have
        // these calls sequentially, it would be more likely that the calls
        // to xSemaphoreGiveRecursive() would be called as a call stack
        // unwound. This is just for demonstrative purposes.
        xSemaphoreGiveRecursive( xMutex );
        xSemaphoreGiveRecursive( xMutex );
        xSemaphoreGiveRecursive( xMutex );
        // Now the mutex can be taken by other tasks.
    }
    else
    {
        // We could not obtain the mutex and can therefore not access
        // the shared resource safely.
    }
}

Parameters

• xMutex - A handle to the mutex being released, or ‘given’. This is the handle returned
  by xSemaphoreCreateMutex();

Returns pdTRUE if the semaphore was given.

xSemaphoreGiveFromISR( xSemaphore, pxHigherPriorityTaskWoken )

Macro to release a semaphore. The semaphore must have previously been created with a call to
xSemaphoreCreateBinary() or xSemaphoreCreateCounting().

Mutex type semaphores (those created using a call to xSemaphoreCreateMutex()) must not be used with this
macro.

This macro can be used from an ISR.

Example usage:

#define LONG_TIME 0xffff
#define TICKS_TO_WAIT 10
SemaphoreHandle_t xSemaphore = NULL;
// Repetitive task.
void vATask( void * pvParameters )
{
  for( ;; )
  {
    // We want this task to run every 10 ticks of a timer. The semaphore
    // was created before this task was started.

    // Block waiting for the semaphore to become available.
    if( xSemaphoreTake( xSemaphore, LONG_TIME ) == pdTRUE )
    {
      // It is time to execute.
      // ...

      // We have finished our task. Return to the top of the loop where
      // we will block on the semaphore until it is time to execute
      // again. Note when using the semaphore for synchronisation with an
      // ISR in this manner there is no need to 'give' the semaphore back.
    }
  }
}

// Timer ISR
void vTimerISR( void * pvParameters )
{
  static uint8_t ucLocalTickCount = 0;
  static BaseType_t xHigherPriorityTaskWoken;

  // A timer tick has occurred.
  // ... Do other time functions.

  // Is it time for vATask () to run?
  xHigherPriorityTaskWoken = pdFALSE;
  ucLocalTickCount += 1;
  if( ucLocalTickCount >= TICKS_TO_WAIT )
  {
    // Unblock the task by releasing the semaphore.
    xSemaphoreGiveFromISR( xSemaphore, &xHigherPriorityTaskWoken );

    // Reset the count so we release the semaphore again in 10 ticks time.
    ucLocalTickCount = 0;
  }

  if( xHigherPriorityTaskWoken != pdFALSE )
  {
    // We can force a context switch here. Context switching from an
    // ISR uses port specific syntax. Check the demo task for your port
    // to find the syntax required.
  }
}

Parameters
  • xSemaphore - A handle to the semaphore being released. This is the handle returned
    when the semaphore was created.
  • pxHigherPriorityTaskWoken - xSemaphoreGiveFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE if giving the semaphore caused a task to unblock, and the
    unblocked task has a priority higher than the currently running task. If xSemaphoreGiveFromISR() sets this value to pdTRUE then a context switch should be requested before
    the interrupt is exited.

Returns  pdTRUE if the semaphore was successfully given, otherwise errQUEUE_FULL.
**xSemaphoreTakeFromISR (xSemaphore, pxHigherPriorityTaskWoken)**

*Macro* to take a semaphore from an ISR. The semaphore must have previously been created with a call to xSemaphoreCreateBinary() or xSemaphoreCreateCounting().

Mutex type semaphores (those created using a call to xSemaphoreCreateMutex()) must not be used with this macro.

This macro can be used from an ISR, however taking a semaphore from an ISR is not a common operation. It is likely to only be useful when taking a counting semaphore when an interrupt is obtaining an object from a resource pool (when the semaphore count indicates the number of resources available).

**Parameters**

- **xSemaphore** - A handle to the semaphore being taken. This is the handle returned when the semaphore was created.
- **pxHigherPriorityTaskWoken** - `xSemaphoreTakeFromISR()` will set *pxHigherPriorityTaskWoken* to `pdTRUE` if taking the semaphore caused a task to unblock, and the unblocked task has a priority higher than the currently running task. If `xSemaphoreTakeFromISR()` sets this value to `pdTRUE` then a context switch should be requested before the interrupt is exited.

**Returns** `pdTRUE` if the semaphore was successfully taken, otherwise `pdFALSE`

**xSemaphoreCreateMutex ()**

Creates a new mutex type semaphore instance, and returns a handle by which the new mutex can be referenced.

Internally, within the FreeRTOS implementation, mutex semaphores use a block of memory, in which the mutex structure is stored. If a mutex is created using `xSemaphoreCreateMutex()` then the required memory is automatically dynamically allocated inside the `xSemaphoreCreateMutex()` function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If a mutex is created using `xSemaphoreCreateMutexStatic()` then the application writer must provide the memory. `xSemaphoreCreateMutexStatic()` therefore allows a mutex to be created without using any dynamic memory allocation.

Mutexes created using this function can be accessed using the `xSemaphoreTake()` and `xSemaphoreGive()` macros. The `xSemaphoreTakeRecursive()` and `xSemaphoreGiveRecursive()` macros must not be used.

This type of semaphore uses a priority inheritance mechanism so a task ‘taking’ a semaphore MUST ALWAYS ‘give’ the semaphore back once the semaphore it is no longer required.

Mutex type semaphores cannot be used from within interrupt service routines.

See `xSemaphoreCreateBinary()` for an alternative implementation that can be used for pure synchronisation (where one task or interrupt always ‘gives’ the semaphore and another always ‘takes’ the semaphore) and from within interrupt service routines.

**Example usage:**

```c
SemaphoreHandle_t xSemaphore;

void vATask( void * pvParameters )
{
    // Semaphore cannot be used before a call to xSemaphoreCreateMutex().
    // This is a macro so pass the variable in directly.
    xSemaphore = xSemaphoreCreateMutex();

    if( xSemaphore != NULL )
    {
        // The semaphore was created successfully.
        // The semaphore can now be used.
    }
}
```

**Returns** If the mutex was successfully created then a handle to the created semaphore is returned.

If there was not enough heap to allocate the mutex data structures then NULL is returned.
xSemaphoreCreateMutexStatic(pxMutexBuffer)

Creates a new mutex type semaphore instance, and returns a handle by which the new mutex can be referenced.

Internally, within the FreeRTOS implementation, mutex semaphores use a block of memory, in which the mutex structure is stored. If a mutex is created using xSemaphoreCreateMutex() then the required memory is automatically dynamically allocated inside the xSemaphoreCreateMutex() function. (see https://www.FreeRTOS.org/a00111.html). If a mutex is created using xSemaphoreCreateMutexStatic() then the application writer must provided the memory. xSemaphoreCreateMutexStatic() therefore allows a mutex to be created without using any dynamic memory allocation.

Mutexes created using this function can be accessed using the xSemaphoreTake() and xSemaphoreGive() macros. The xSemaphoreTakeRecursive() and xSemaphoreGiveRecursive() macros must not be used.

This type of semaphore uses a priority inheritance mechanism so a task ‘taking’ a semaphore MUST ALWAYS ‘give’ the semaphore back once the semaphore it is no longer required.

Mutex type semaphores cannot be used from within interrupt service routines.

See xSemaphoreCreateBinary() for an alternative implementation that can be used for pure synchronisation (where one task or interrupt always ‘gives’ the semaphore and another always ‘takes’ the semaphore) and from within interrupt service routines.

Example usage:

```c
SemaphoreHandle_t xSemaphore;
StaticSemaphore_t xMutexBuffer;

void vATask( void * pvParameters )
{
    // A mutex cannot be used before it has been created. xMutexBuffer is
    // into xSemaphoreCreateMutexStatic() so no dynamic memory allocation is
    // attempted.
    xSemaphore = xSemaphoreCreateMutexStatic( &xMutexBuffer );

    // As no dynamic memory allocation was performed, xSemaphore cannot be NULL,
    // so there is no need to check it.
}
```

Parameters
- **pxMutexBuffer** – Must point to a variable of type StaticSemaphore_t, which will be used to hold the mutex’s data structure, removing the need for the memory to be allocated dynamically.

Returns
If the mutex was successfully created then a handle to the created mutex is returned. If pxMutexBuffer was NULL then NULL is returned.

xSemaphoreCreateRecursiveMutex()

Creates a new recursive mutex type semaphore instance, and returns a handle by which the new recursive mutex can be referenced.

Internally, within the FreeRTOS implementation, recursive mutexes use a block of memory, in which the mutex structure is stored. If a recursive mutex is created using xSemaphoreCreateRecursiveMutex() then the required memory is automatically dynamically allocated inside the xSemaphoreCreateRecursiveMutex() function. (see https://www.FreeRTOS.org/a00111.html). If a recursive mutex is created using xSemaphoreCreateRecursiveMutexStatic() then the application writer must provide the memory that will get used by the mutex. xSemaphoreCreateRecursiveMutexStatic() therefore allows a recursive mutex to be created without using any dynamic memory allocation.

Mutexes created using this macro can be accessed using the xSemaphoreTakeRecursive() and xSemaphoreGiveRecursive() macros. The xSemaphoreTake() and xSemaphoreGive() macros must not be used.

A mutex used recursively can be ‘taken’ repeatedly by the owner. The mutex doesn’t become available again until the owner has called xSemaphoreGiveRecursive() for each successful ‘take’ request. For example,
if a task successfully ‘takes’ the same mutex 5 times then the mutex will not be available to any other task until it has also ‘given’ the mutex back exactly five times.

This type of semaphore uses a priority inheritance mechanism so a task ‘taking’ a semaphore MUST ALWAYS ‘give’ the semaphore back once the semaphore it is no longer required.

Mutex type semaphores cannot be used from within interrupt service routines.

See xSemaphoreCreateBinary() for an alternative implementation that can be used for pure synchronisation (where one task or interrupt always ‘gives’ the semaphore and another always ‘takes’ the semaphore) and from within interrupt service routines.

Example usage:

```c
SemaphoreHandle_t xSemaphore;

void vATask( void * pvParameters )
{
    // Semaphore cannot be used before a call to xSemaphoreCreateMutex().
    // This is a macro so pass the variable in directly.
    xSemaphore = xSemaphoreCreateRecursiveMutex();

    if( xSemaphore != NULL )
    {
        // The semaphore was created successfully.
        // The semaphore can now be used.
    }
}
```

Returns xSemaphore Handle to the created mutex semaphore. Should be of type SemaphoreHandle_t.

**xSemaphoreCreateRecursiveMutexStatic (pxStaticSemaphore)**

Creates a new recursive mutex type semaphore instance, and returns a handle by which the new recursive mutex can be referenced.

Internally, within the FreeRTOS implementation, recursive mutexes use a block of memory, in which the mutex structure is stored. If a recursive mutex is created using xSemaphoreCreateRecursiveMutex() then the required memory is automatically dynamically allocated inside the xSemaphoreCreateRecursiveMutex() function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If a recursive mutex is created using xSemaphoreCreateRecursiveMutexStatic() then the application writer must provide the memory that will get used by the mutex. xSemaphoreCreateRecursiveMutexStatic() therefore allows a recursive mutex to be created without using any dynamic memory allocation.

Mutexes created using this macro can be accessed using the xSemaphoreTakeRecursive() and xSemaphoreGiveRecursive() macros. The xSemaphoreTake() and xSemaphoreGive() macros must not be used.

A mutex used recursively can be ‘taken’ repeatedly by the owner. The mutex doesn’t become available again until the owner has called xSemaphoreGiveRecursive() for each successful ‘take’ request. For example, if a task successfully ‘takes’ the same mutex 5 times then the mutex will not be available to any other task until it has also ‘given’ the mutex back exactly five times.

This type of semaphore uses a priority inheritance mechanism so a task ‘taking’ a semaphore MUST ALWAYS ‘give’ the semaphore back once the semaphore it is no longer required.

Mutex type semaphores cannot be used from within interrupt service routines.

See xSemaphoreCreateBinary() for an alternative implementation that can be used for pure synchronisation (where one task or interrupt always ‘gives’ the semaphore and another always ‘takes’ the semaphore) and from within interrupt service routines.
Example usage:

```c
SemaphoreHandle_t xSemaphore;
StaticSemaphore_t xMutexBuffer;

void vATask( void * pvParameters )
{
    // A recursive semaphore cannot be used before it is created. Here a
    // recursive mutex is created using xSemaphoreCreateRecursiveMutexStatic().
    // The address of xMutexBuffer is passed into the function, and will hold
    // the mutexes data structures - so no dynamic memory allocation will be
    // attempted.
    xSemaphore = xSemaphoreCreateRecursiveMutexStatic( &xMutexBuffer );

    // As no dynamic memory allocation was performed, xSemaphore cannot be NULL,
    // so there is no need to check it.
}
```

**Parameters**

- **pxStaticSemaphore** – Must point to a variable of type StaticSemaphore_t, which will then be used to hold the recursive mutex’s data structure, removing the need for the memory to be allocated dynamically.

**Returns**

If the recursive mutex was successfully created then a handle to the created recursive mutex is returned. If pxStaticSemaphore was NULL then NULL is returned.

`xSemaphoreCreateCounting` *(uxMaxCount, uxInitialCount)*

Creates a new counting semaphore instance, and returns a handle by which the new counting semaphore can be referenced.

In many usage scenarios it is faster and more memory efficient to use a direct to task notification in place of a counting semaphore! [https://www.FreeRTOS.org/RTOS-task-notifications.html](https://www.FreeRTOS.org/RTOS-task-notifications.html)

Internally, within the FreeRTOS implementation, counting semaphores use a block of memory, in which the counting semaphore structure is stored. If a counting semaphore is created using `xSemaphoreCreateCounting()` then the required memory is automatically dynamically allocated inside the `xSemaphoreCreateCounting()` function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If a counting semaphore is created using `xSemaphoreCreateCountingStatic()` then the application writer can instead optionally provide the memory that will get used by the counting semaphore. `xSemaphoreCreateCountingStatic()` therefore allows a counting semaphore to be created without using any dynamic memory allocation.

Counting semaphores are typically used for two things:

1) Counting events.

In this usage scenario an event handler will ‘give’ a semaphore each time an event occurs (incrementing the semaphore count value), and a handler task will ‘take’ a semaphore each time it processes an event (decrementing the semaphore count value). The count value is therefore the difference between the number of events that have occurred and the number that have been processed. In this case it is desirable for the initial count value to be zero.

2) Resource management.

In this usage scenario the count value indicates the number of resources available. To obtain control of a resource a task must first obtain a semaphore - decrementing the semaphore count value. When the count value reaches zero there are no free resources. When a task finishes with the resource it ‘gives’ the semaphore back - incrementing the semaphore count value. In this case it is desirable for the initial count value to be equal to the maximum count value, indicating that all resources are free.

Example usage:
SemaphoreHandle_t xSemaphore;

void vATask ( void * pvParameters )
{
SemaphoreHandle_t xSemaphore = NULL;

// Semaphore cannot be used before a call to xSemaphoreCreateCounting().
// The max value to which the semaphore can count should be 10, and the
// initial value assigned to the count should be 0.
xSemaphore = xSemaphoreCreateCounting( 10, 0 );

if ( xSemaphore != NULL )
{
    // The semaphore was created successfully.
    // The semaphore can now be used.
}
}

Parameters

  • **uxMaxCount** – The maximum count value that can be reached. When the semaphore
            reaches this value it can no longer be ‘given’.
  • **uxInitialCount** – The count value assigned to the semaphore when it is created.

Returns

Handle to the created semaphore. Null if the semaphore could not be created.

xSemaphoreCreateCountingStatic (uxMaxCount, uxInitialCount, pxSemaphoreBuffer)

Creates a new counting semaphore instance, and returns a handle by which the new counting semaphore can
be referenced.

In many usage scenarios it is faster and more memory efficient to use a direct to task notification in place of a

Internally, within the FreeRTOS implementation, counting semaphores use a block of memory, in which the
counting semaphore structure is stored. If a counting semaphore is created using xSemaphoreCreateCounting() then the required memory is automatically dynamically allocated inside the xSemaphoreCreateCounting() function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If a counting semaphore is created using
xSemaphoreCreateCountingStatic() then the application writer must provide the memory. xSemaphoreCreateCountingStatic() therefore allows a counting semaphore to be created without using any dynamic memory allocation.

Counting semaphores are typically used for two things:

1) Counting events.

In this usage scenario an event handler will ‘give’ a semaphore each time an event occurs (incrementing the
semaphore count value), and a handler task will ‘take’ a semaphore each time it processes an event
(decrementing the semaphore count value). The count value is therefore the difference between the number of
events that have occurred and the number that have been processed. In this case it is desirable for the initial
count value to be zero.

2) Resource management.

In this usage scenario the count value indicates the number of resources available. To obtain control of a
resource a task must first obtain a semaphore - decrementing the semaphore count value. When the count value
reaches zero there are no free resources. When a task finishes with the resource it ‘gives’ the semaphore back
- incrementing the semaphore count value. In this case it is desirable for the initial count value to be equal to
the maximum count value, indicating that all resources are free.

Example usage:
SemaphoreHandle_t xSemaphore;
StaticSemaphore_t xSemaphoreBuffer;

void vATask( void * pvParameters )
{
SemaphoreHandle_t xSemaphore = NULL;

// Counting semaphore cannot be used before they have been created. Create
// a counting semaphore using xSemaphoreCreateCountingStatic(). The max
// value to which the semaphore can count is 10, and the initial value
// assigned to the count will be 0. The address of xSemaphoreBuffer is
// passed in and will be used to hold the semaphore structure, so no dynamic
// memory allocation will be used.
xSemaphore = xSemaphoreCreateCounting( 10, 0, &xSemaphoreBuffer );

// No memory allocation was attempted so xSemaphore cannot be NULL, so there
// is no need to check its value.
}

Parameters

• uxMaxCount – The maximum count value that can be reached. When the semaphore
  reaches this value it can no longer be ‘given’.
• uxInitialCount – The count value assigned to the semaphore when it is created.
• pxSemaphoreBuffer – Must point to a variable of type StaticSemaphore_t, which will
  then be used to hold the semaphore’s data structure, removing the need for the memory
  to be allocated dynamically.

Returns If the counting semaphore was successfully created then a handle to the created counting
semaphore is returned. If pxSemaphoreBuffer was NULL then NULL is returned.

vSemaphoreDelete( xSemaphore )

Delete a semaphore. This function must be used with care. For example, do not delete a mutex type semaphore
if the mutex is held by a task.

Parameters

• xSemaphore – A handle to the semaphore to be deleted.

xSemaphoreGetMutexHolder( xSemaphore )

If xMutex is indeed a mutex type semaphore, return the current mutex holder. If xMutex is not a mutex type
semaphore, or the mutex is available (not held by a task), return NULL.

Note: This is a good way of determining if the calling task is the mutex holder, but not a good way of deter-
mining the identity of the mutex holder as the holder may change between the function exiting and the returned
value being tested.

xSemaphoreGetMutexHolderFromISR( xSemaphore )

If xMutex is indeed a mutex type semaphore, return the current mutex holder. If xMutex is not a mutex type
semaphore, or the mutex is available (not held by a task), return NULL.

uxSemaphoreGetCount( xSemaphore )

If the semaphore is a counting semaphore then uxSemaphoreGetCount() returns its current count value. If the
semaphore is a binary semaphore then uxSemaphoreGetCount() returns 1 if the semaphore is available, and 0
if the semaphore is not available.

uxSemaphoreGetCountFromISR( xSemaphore )

semphr.h

UBaseType_t uxSemaphoreGetCountFromISR( SemaphoreHandle_t xSemaphore );

If the semaphore is a counting semaphore then uxSemaphoreGetCountFromISR() returns its current count
value. If the semaphore is a binary semaphore then uxSemaphoreGetCountFromISR() returns 1 if the
semaphore is available, and 0 if the semaphore is not available.
Chapter 2. API Reference

**xSemaphoreGetStaticBuffer** (xSemaphore, ppxSemaphoreBuffer)
Retrieve pointer to a statically created binary semaphore, counting semaphore, or mutex semaphore’s data structure buffer. This is the same buffer that is supplied at the time of creation.

**Parameters**
- **xSemaphore** - The semaphore for which to retrieve the buffer.
- **pxSemaphoreBuffer** - Used to return a pointer to the semaphore’s data structure buffer.

**Returns** pdTRUE if buffer was retrieved, pdFALSE otherwise.

**Type Definitions**

typedef QueueHandle_t SemaphoreHandle_t

**Timer API**

**Header File**
- components/freertos/FreeRTOS-Kernel/include/freertos/timers.h
- This header file can be included with:

```c
#include "freertos/timers.h"
```

**Functions**

**TimerHandle_t xTimerCreate** (const char *const pcTimerName, const TickType_t xTimerPeriodInTicks, const BaseType_t xAutoReload, void *const pvTimerID, TimerCallbackFunction_t pxCallbackFunction)

Creates a new software timer instance, and returns a handle by which the created software timer can be referenced.

Internally, within the FreeRTOS implementation, software timers use a block of memory, in which the timer data structure is stored. If a software timer is created using xTimerCreate() then the required memory is automatically dynamically allocated inside the xTimerCreate() function. (see https://www.FreeRTOS.org/a00111.html). If a software timer is created using xTimerCreateStatic() then the application writer must provide the memory that will get used by the software timer. xTimerCreateStatic() therefore allows a software timer to be created without using any dynamic memory allocation.

Timers are created in the dormant state. The xTimerStart(), xTimerReset(), xTimerStartFromISR(), xTimerResetFromISR(), xTimerChangePeriod() and xTimerChangePeriodFromISR() API functions can all be used to transition a timer into the active state.

**Example usage:**

```c
/* #define NUM_TIMERS 5 */

/* An array to hold handles to the created timers. */
TimerHandle_t xTimers[ NUM_TIMERS ];

/* An array to hold a count of the number of times each timer expires. */
int32_t lExpireCounters[ NUM_TIMERS ] = { 0 };

/* Define a callback function that will be used by multiple timer instances. */
/* The callback function does nothing but count the number of times the */
/* associated timer expires, and stop the timer once the timer has expired */
/* 10 times. */
void vTimerCallback( TimerHandle_t pxTimer )
```

(continues on next page)
* { int32_t lArrayIndex;
  const int32_t xMaxExpiryCountBeforeStopping = 10;
  
  // Optionally do something if the pxTimer parameter is NULL.
  configASSERT( pxTimer );
  
  // Which timer expired?
  lArrayIndex = ( int32_t ) pvTimerGetTimerID( pxTimer );

  // Increment the number of times that pxTimer has expired.
  lExpireCounters[ lArrayIndex ] += 1;

  // If the timer has expired 10 times then stop it from running.
  if( lExpireCounters[ lArrayIndex ] == xMaxExpiryCountBeforeStopping )
  {
    // Do not use a block time if calling a timer API function from a
    // timer callback function, as doing so could cause a deadlock!
    xTimerStop( pxTimer, 0 );
  }
  
  void main( void )
  {
    int32_t x;

    // Create then start some timers. Starting the timers before the
    // scheduler
    // has been started means the timers will start running immediately that
    // the scheduler starts.
    for( x = 0; x < NUM_TIMERS; x++ )
    {
      xTimers[ x ] = xTimerCreate("Timer", // Just a text
                               ( 100 * ( x + 1 ) ), // The timer
                               pdTRUE, // The timers
                               ( void * ) x, // Assign each
                               vTimerCallback // Each timer
                               );
      
      if( xTimers[ x ] == NULL )
      {
        // The timer was not created.
      }
      else
      {
        // Start the timer. No block time is specified, and even if one
        // was
        // it would be ignored because the scheduler has not yet been
        // started.
        if( xTimerStart( xTimers[ x ], 0 ) != pdPASS )
        {
          // The timer could not be set into the Active state.
        }
      }
    }
  }
Parameters

• pcTimerName – A text name that is assigned to the timer. This is done purely to assist debugging. The kernel itself only ever references a timer by its handle, and never by its name.

• xTimerPeriodInTicks – The timer period. The time is defined in tick periods so the constant portTICK_PERIOD_MS can be used to convert a time that has been specified in milliseconds. For example, if the timer must expire after 100 ticks, then xTimerPeriodInTicks should be set to 100. Alternatively, if the timer must expire after 500ms, then xPeriod can be set to (500 / portTICK_PERIOD_MS) provided configTICK_RATE_HZ is less than or equal to 1000. Time timer period must be greater than 0.

• xAutoReload – If xAutoReload is set to pdTRUE then the timer will expire repeatedly with a frequency set by the xTimerPeriodInTicks parameter. If xAutoReload is set to pdFALSE then the timer will be a one-shot timer and enter the dormant state after it expires.

• pvTimerID – An identifier that is assigned to the timer being created. Typically this would be used in the timer callback function to identify which timer expired when the same callback function is assigned to more than one timer.

• pxCallbackFunction – The function to call when the timer expires. Callback functions must have the prototype defined by TimerCallbackFunction_t, which is “void vCallbackFunction(TimerHandle_t xTimer);”.

Returns If the timer is successfully created then a handle to the newly created timer is returned. If the timer cannot be created because there is insufficient FreeRTOS heap remaining to allocate the timer structures then NULL is returned.

Example usage:

```
// Create tasks here.
//...

// Starting the scheduler will start the timers running as they have... already
// been set into the active state.
vTaskStartScheduler();

// Should not reach here.
for(;;);
```
// The buffer used to hold the software timer's data structure.
static StaticTimer_t xTimerBuffer;

// A variable that will be incremented by the software timer's callback
// function.
UBaseType_t uxVariableToIncrement = 0;

// A software timer callback function that increments a variable passed to
// it when the software timer was created. After the 5th increment the
// callback function stops the software timer.
static void prvTimerCallback( TimerHandle_t xExpiredTimer )
{
    UBaseType_t *pxVariableToIncrement;
    BaseType_t xReturned;

    // Obtain the address of the variable to increment from the timer ID.
    pxVariableToIncrement = ( UBaseType_t *) pvTimerGetTimerID( _
                                xExpiredTimer );

    // Increment the variable to show the timer callback has executed.
    ( *pxVariableToIncrement )++;

    // If this callback has executed the required number of times, stop the
    // timer.
    if( ( *pxVariableToIncrement == 5 )
        
        // This is called from a timer callback so must not block.
        xTimerStop( xExpiredTimer, staticDONT_BLOCK );
    
    
    
    
    
    void main( void )
    {
        // Create the software time. xTimerCreateStatic() has an extra parameter
        // than the normal xTimerCreate() API function. The parameter is a_
        // pointer
        // to the StaticTimer_t structure that will hold the software timer
        // structure. If the parameter is passed as NULL then the structure_
        // will be
        // allocated dynamically, just as if xTimerCreate() had been called.
        xTimer = xTimerCreateStatic( "T1", // Text name for the task.
                                  xTimerPeriod, // The period of the_
                                 timer in ticks.
                                  pdTRUE, // This is an auto-reload_
                                 timer.
                                  ( void * ) &uxVariableToIncrement, // A_
                                 variable incremented by the software timer's callback function
                                 prvTimerCallback, // The function to_
                                 execute when the timer expires.
                                 &xTimerBuffer ); // The buffer that will_
                                 hold the software timer structure.
        
        // The scheduler has not started yet so a block time is not used.
        xReturned = xTimerStart( xTimer, 0 );

        // ...
        // Create tasks here.
        // ...

        // (continues on next page)
Parameters

- **pcTimerName** – A text name that is assigned to the timer. This is done purely to assist debugging. The kernel itself only ever references a timer by its handle, and never by its name.
- **xTimerPeriodInTicks** – The timer period. The time is defined in tick periods so the constant portTICK_PERIOD_MS can be used to convert a time that has been specified in milliseconds. For example, if the timer must expire after 100 ticks, then xTimerPeriodInTicks should be set to 100. Alternatively, if the timer must expire after 500ms, then xPeriod can be set to \((500 / \text{portTICK_PERIOD_MS})\) provided configTICK_RATE_HZ is less than or equal to 1000. The timer period must be greater than 0.
- **xAutoReload** – If xAutoReload is set to pdTRUE then the timer will expire repeatedly with a frequency set by the xTimerPeriodInTicks parameter. If xAutoReload is set to pdFALSE then the timer will be a one-shot timer and enter the dormant state after it expires.
- **pvTimerID** – An identifier that is assigned to the timer being created. Typically this would be used in the timer callback function to identify which timer expired when the same callback function is assigned to more than one timer.
- **pxCallbackFunction** – The function to call when the timer expires. Callback functions must have the prototype defined by TimerCallbackFunction_t, which is “void vCallbackFunction(TimerHandle_t xTimer);”.
- **pxTimerBuffer** – Must point to a variable of type StaticTimer_t, which will be then be used to hold the software timer’s data structures, removing the need for the memory to be allocated dynamically.

Returns

If the timer is created then a handle to the created timer is returned. If pxTimerBuffer was NULL then NULL is returned.

`void *pvTimerGetTimerID(const TimerHandle_t xTimer)`

Returns the ID assigned to the timer.

IDs are assigned to timers using the pvTimerID parameter of the call to xTimerCreated() that was used to create the timer, and by calling the vTimerSetTimerID() API function.

If the same callback function is assigned to multiple timers then the timer ID can be used as time specific (timer local) storage.

Example usage:

See the xTimerCreate() API function example usage scenario.

**Parameters**

xTimer – The timer being queried.

**Returns**

The ID assigned to the timer being queried.

`void vTimerSetTimerID(TimerHandle_t xTimer, void *pvNewID)`

Sets the ID assigned to the timer.

IDs are assigned to timers using the pvTimerID parameter of the call to xTimerCreated() that was used to create the timer.
If the same callback function is assigned to multiple timers then the timer ID can be used as time specific (timer local) storage.

Example usage:

See the xTimerCreate() API function example usage scenario.

**Parameters**

- `xTimer` - The timer being updated.
- `pvNewID` - The ID to assign to the timer.

**Example usage:**

BaseType_t xTimerIsTimerActive(TimerHandle_t xTimer)

Queries a timer to see if it is active or dormant.

A timer will be dormant if: 1) It has been created but not started, or 2) It is an expired one-shot timer that has not been restarted.

Timers are created in the dormant state. The xTimerStart(), xTimerReset(), xTimerStartFromISR(), xTimerResetFromISR(), xTimerChangePeriod() and xTimerChangePeriodFromISR() API functions can all be used to transition a timer into the active state.

**Example usage:**

```c
/* // This function assumes xTimer has already been created.
 * void vAFunction( TimerHandle_t xTimer )
 * {
 *     if( xTimerIsTimerActive( xTimer ) != pdFALSE ) // or more simply and equivalently "if( xTimerIsTimerActive( xTimer ) )"
 *     {  
 *         // xTimer is active, do something.
 *     }
 *     else
 *     {  
 *         // xTimer is not active, do something else.
 *     }
 * }
 */
```

**Parameters**

- `xTimer` - The timer being queried.

**Returns**

`pdFALSE` will be returned if the timer is dormant. A value other than `pdFALSE` will be returned if the timer is active.

**TaskHandle_t xTimerGetTimerDaemonTaskHandle** *(void)*

Simply returns the handle of the timer service/daemon task. It it not valid to call xTimerGetTimerDaemonTaskHandle() before the scheduler has been started.

**BaseType_t xTimerPendFunctionCallFromISR** *(PendedFunction_t xFunctionToPend, void *pvParameter1, ulParameter2, BaseType_t *pxHigherPriorityTaskWoken)*

Used from application interrupt service routines to defer the execution of a function to the RTOS daemon task (the timer service task, hence this function is implemented in timers.c and is prefixed with ‘Timer’).

Ideally an interrupt service routine (ISR) is kept as short as possible, but sometimes an ISR either has a lot of processing to do, or needs to perform processing that is not deterministic. In these cases xTimerPendFunctionCallFromISR() can be used to defer processing of a function to the RTOS daemon task.

A mechanism is provided that allows the interrupt to return directly to the task that will subsequently execute the pended callback function. This allows the callback function to execute contiguously in time with the interrupt - just as if the callback had executed in the interrupt itself.
Example usage:

```c
/* // The callback function that will execute in the context of the daemon... */
/* void vProcessInterface( void *pvParameter1, uint32_t ulParameter2 ) */
{ /* BaseType_t xInterfaceToService; */
    /* // The interface that requires servicing is passed in the second */
    /* // parameter. The first parameter is not used in this case. */
    /* xInterfaceToService = ( BaseType_t ) ulParameter2; */
    /* ...Perform the processing here... */
}

/* // An ISR that receives data packets from multiple interfaces */
void vAnISR( void )
{ /* BaseType_t xInterfaceToService, xHigherPriorityTaskWoken; */
    /* // Query the hardware to determine which interface needs processing. */
    /* xInterfaceToService = prvCheckInterfaces(); */
    /* // The actual processing is to be deferred to a task. Request the */
    /* // vProcessInterface() callback function is executed, passing in the */
    /* // number of the interface that needs processing. The interface to */
    /* // service is passed in the second parameter. The first parameter is */
    /* // not used in this case. */
    /* xHigherPriorityTaskWoken = pdFALSE; */
    /* xTimerPendFunctionCallFromISR( vProcessInterface, NULL, ( uint32_t ) */
    /* xInterfaceToService, &xHigherPriorityTaskWoken ); */
    /* // If xHigherPriorityTaskWoken is now set to pdTRUE then a context */
    /* // switch should be requested. The macro used is port specific and will */
    /* // be either portYIELD_FROM_ISR() or portEND_SWITCHING_ISR() - refer to */
    /* // the documentation page for the port being used. */
    /* portYIELD_FROM_ISR( xHigherPriorityTaskWoken ); */
}
```

Parameters

- **xFunctionToPend** - The function to execute from the timer service/daemon task. The function must conform to the PendedFunction_t prototype.
- **pvParameter1** - The value of the callback function’s first parameter. The parameter has a void * type to allow it to be used to pass any type. For example, unsigned longs can be cast to a void *, or the void * can be used to point to a structure.
- **ulParameter2** - The value of the callback function’s second parameter.
- **pxHigherPriorityTaskWoken** - As mentioned above, calling this function will result in a message being sent to the timer daemon task. If the priority of the timer daemon task (which is set using configTIMER_TASK_PRIORITY in FreeRTOSConfig.h) is higher than the priority of the currently running task (the task the interrupt interrupted) then *pxHigherPriorityTaskWoken will be set to pdTRUE within xTimerPendFunctionCallFromISR(), indicating that a context switch should be requested before the interrupt exits. For that reason *pxHigherPriorityTaskWoken must be initialsed to pdFALSE. See the example code below.

Returns

`pdPASS` is returned if the message was successfully sent to the timer daemon task, otherwise `pdFALSE` is returned.
BaseType_t xTimerPendFunctionCall (PendedFunction_t xFunctionToPend, void *pvParameter1, uint32_t ulParameter2, TickType_t xTicksToWait)

Used to defer the execution of a function to the RTOS daemon task (the timer service task, hence this function is implemented in timers.c and is prefixed with ‘Timer’).

**Parameters**

- **xFunctionToPend** - The function to execute from the timer service/daemon task. The function must conform to the PendedFunction_t prototype.
- **pvParameter1** - The value of the callback function’s first parameter. The parameter has a void * type to allow it to be used to pass any type. For example, unsigned longs can be cast to a void *, or the void * can be used to point to a structure.
- **ulParameter2** - The value of the callback function’s second parameter.
- **xTicksToWait** - Calling this function will result in a message being sent to the timer daemon task on a queue. xTicksToWait is the amount of time the calling task should remain in the Blocked state (so not using any processing time) for space to become available on the timer queue if the queue is found to be full.

**Returns**

pdPASS is returned if the message was successfully sent to the timer daemon task, otherwise pdFALSE is returned.

const char *pcTimerGetName (TimerHandle_t xTimer)

Returns the name that was assigned to a timer when the timer was created.

**Parameters**

- **xTimer** - The handle of the timer being queried.

**Returns**

The name assigned to the timer specified by the xTimer parameter.

void vTimerSetReloadMode (TimerHandle_t xTimer, const BaseType_t xAutoReload)

Updates a timer to be either an auto-reload timer, in which case the timer automatically resets itself each time it expires, or a one-shot timer, in which case the timer will only expire once unless it is manually restarted.

**Parameters**

- **xTimer** - The handle of the timer being updated.
- **xAutoReload** - If xAutoReload is set to pdTRUE then the timer will expire repeatedly with a frequency set by the timer’s period (see the xTimerPeriodInTicks parameter of the xTimerCreate() API function). If xAutoReload is set to pdFALSE then the timer will be a one-shot timer and enter the dormant state after it expires.

BaseType_t xTimerGetReloadMode (TimerHandle_t xTimer)

Queries a timer to determine if it is an auto-reload timer, in which case the timer automatically resets itself each time it expires, or a one-shot timer, in which case the timer will only expire once unless it is manually restarted.

**Parameters**

- **xTimer** - The handle of the timer being queried.

**Returns**

If the timer is an auto-reload timer then pdTRUE is returned, otherwise pdFALSE is returned.

UBaseType_t uxTimerGetReloadMode (TimerHandle_t xTimer)

Queries a timer to determine if it is an auto-reload timer, in which case the timer automatically resets itself each time it expires, or a one-shot timer, in which case the timer will only expire once unless it is manually restarted.

**Parameters**

- **xTimer** - The handle of the timer being queried.

**Returns**

If the timer is an auto-reload timer then pdTRUE is returned, otherwise pdFALSE is returned.

TickType_t xTimerGetPeriod (TimerHandle_t xTimer)

Returns the period of a timer.

**Parameters**

- **xTimer** - The handle of the timer being queried.

**Returns**

The period of the timer in ticks.

TickType_t xTimerGetExpiryTime (TimerHandle_t xTimer)

Returns the time in ticks at which the timer will expire. If this is less than the current tick count then the expiry time has overflowed from the current time.
Parameters **xTimer** - The handle of the timer being queried.

Returns If the timer is running then the time in ticks at which the timer will next expire is returned. If the timer is not running then the return value is undefined.

```
BaseType_t xTimerGetStaticBuffer (TimerHandle_t xTimer, StaticTimer_t **ppxTimerBuffer)
```

Retrieve pointer to a statically created timer’s data structure buffer. This is the same buffer that is supplied at the time of creation.

Parameters
- **xTimer** - The timer for which to retrieve the buffer.
- **ppxTimerBuffer** - Used to return a pointer to the timers’s data structure buffer.

Returns `pdTRUE` if the buffer was retrieved, `pdFALSE` otherwise.

```
void vApplicationGetTimerTaskMemory (StaticTask_t **ppxTimerTaskTCBBuffer, StackType_t **ppxTimerTaskStackBuffer, uint32_t *pulTimerTaskStackSize)
```

This function is used to provide a statically allocated block of memory to FreeRTOS to hold the Timer Task TCB. This function is required when `configSUPPORT_STATIC_ALLOCATION` is set. For more information see this URI: [https://www.FreeRTOS.org/a00110.html#configSUPPORT_STATIC_ALLOCATION](https://www.FreeRTOS.org/a00110.html#configSUPPORT_STATIC_ALLOCATION)

Parameters
- **ppxTimerTaskTCBBuffer** - A handle to a statically allocated TCB buffer
- **ppxTimerTaskStackBuffer** - A handle to a statically allocated Stack buffer for the idle task
- **pulTimerTaskStackSize** - A pointer to the number of elements that will fit in the allocated stack buffer

**Macros**

```
xTimerStart (xTimer, xTicksToWait)
```

Timer functionality is provided by a timer service/daemon task. Many of the public FreeRTOS timer API functions send commands to the timer service task through a queue called the timer command queue. The timer command queue is private to the kernel itself and is not directly accessible to application code. The length of the timer command queue is set by the `configTIMER_QUEUE_LENGTH` configuration constant.

xTimerStart() starts a timer that was previously created using the xTimerCreate() API function. If the timer had already been started and was already in the active state, then xTimerStart() has equivalent functionality to the xTimerReset() API function.

Starting a timer ensures the timer is in the active state. If the timer is not stopped, deleted, or reset in the mean time, the callback function associated with the timer will get called ‘n’ ticks after xTimerStart() was called, where ‘n’ is the timers defined period.

It is valid to call xTimerStart() before the scheduler has been started, but when this is done the timer will not actually start until the scheduler is started, and the timers expiry time will be relative to when the scheduler is started, not relative to when xTimerStart() was called.

The `configUSE_TIMERS` configuration constant must be set to 1 for xTimerStart() to be available.

Example usage:

See the xTimerCreate() API function example usage scenario.

Parameters
- **xTimer** - The handle of the timer being started/restarted.
- **xTicksToWait** - Specifies the time, in ticks, that the calling task should be held in the Blocked state to wait for the start command to be successfully sent to the timer command queue, should the queue already be full when xTimerStart() was called. xTicksToWait is ignored if xTimerStart() is called before the scheduler is started.

Returns `pdFAIL` will be returned if the start command could not be sent to the timer command queue even after xTicksToWait ticks had passed. `pdPASS` will be returned if the command was successfully sent to the timer command queue. When the command is actually processed
will depend on the priority of the timer service/daemon task relative to other tasks in the system, although the timers expiry time is relative to when xTimerStart() is actually called. The timer service/daemon task priority is set by the configTIMER_TASK_PRIORITY configuration constant.

xTimerStop(xTimer, xTicksToWait)

Timer functionality is provided by a timer service/daemon task. Many of the public FreeRTOS timer API functions send commands to the timer service task through a queue called the timer command queue. The length of the timer command queue is set by the configTIMER_QUEUE_LENGTH configuration constant.

xTimerStop() stops a timer that was previously started using either of the xTimerStart(), xTimerReset(), xTimerStartFromISR(), xTimerResetFromISR(), xTimerChangePeriod() or xTimerChangePeriodFromISR() API functions.

Stopping a timer ensures the timer is not in the active state.

The configUSE_TIMERS configuration constant must be set to 1 for xTimerStop() to be available.

Example usage:

See the xTimerCreate() API function example usage scenario.

Parameters

- **xTimer** - The handle of the timer being stopped.
- **xTicksToWait** - Specifies the time, in ticks, that the calling task should be held in the Blocked state to wait for the stop command to be successfully sent to the timer command queue, should the queue already be full when xTimerStop() was called. xTicksToWait is ignored if xTimerStop() is called before the scheduler is started.

Returns pdFAIL will be returned if the stop command could not be sent to the timer command queue even after xTicksToWait ticks had passed. pdPASS will be returned if the command was successfully sent to the timer command queue. When the command is actually processed will depend on the priority of the timer service/daemon task relative to other tasks in the system. The timer service/daemon task priority is set by the configTIMER_TASK_PRIORITY configuration constant.

xTimerChangePeriod(xTimer, xNewPeriod, xTicksToWait)

Timer functionality is provided by a timer service/daemon task. Many of the public FreeRTOS timer API functions send commands to the timer service task through a queue called the timer command queue. The length of the timer command queue is set by the configTIMER_QUEUE_LENGTH configuration constant.

xTimerChangePeriod() changes the period of a timer that was previously created using the xTimerCreate() API function.

xTimerChangePeriod() can be called to change the period of an active or dormant state timer.

The configUSE_TIMERS configuration constant must be set to 1 for xTimerChangePeriod() to be available.

Example usage:

```c
/* // This function assumes xTimer has already been created. If the timer
  // referenced by xTimer is already active when it is called, then the timer
  // is deleted. If the timer referenced by xTimer is not active when it is
  // called, then the period of the timer is set to 500ms and the timer is
  // started.

  void vAFunction( TimerHandle_t xTimer )
  {
    if( xTimerIsTimerActive( xTimer ) != pdFALSE ) // or more simply and_
        // equivalently "if( xTimerIsTimerActive( xTimer ) )"
      {
```
Chapter 2. API Reference

(continued from previous page)

```c
* // xTimer is already active - delete it.
* xTimerDelete( xTimer );
* }
* else
* {  
* // xTimer is not active, change its period to 500ms. This will also
* // cause the timer to start. Block for a maximum of 100 ticks if the
* // change period command cannot immediately be sent to the timer
* // command queue.
* if( xTimerChangePeriod( xTimer, 500 / portTICK_PERIOD_MS, 100 ) == pdPASS )
* {  
* // The command was successfully sent.
* }
* else
* {  
* // The command could not be sent, even after waiting for 100
* // ticks
* // to pass. Take appropriate action here.
* }
* }
* }
* }
```

Parameters

- **xTimer** - The handle of the timer that is having its period changed.
- **xNewPeriod** - The new period for xTimer. Timer periods are specified in tick periods, so the constant portTICK_PERIOD_MS can be used to convert a time that has been specified in milliseconds. For example, if the timer must expire after 100 ticks, then xNewPeriod should be set to 100. Alternatively, if the timer must expire after 500 ms, then xNewPeriod can be set to (500 / portTICK_PERIOD_MS) provided configTICK_RATE_HZ is less than or equal to 1000.
- **xTicksToWait** - Specifies the time, in ticks, that the calling task should be held in the Blocked state to wait for the change period command to be successfully sent to the timer command queue, should the queue already be full when xTimerChangePeriod() was called. xTicksToWait is ignored if xTimerChangePeriod() is called before the scheduler is started.

Returns

pdFAIL will be returned if the change period command could not be sent to the timer command queue even after xTicksToWait ticks had passed. pdPASS will be returned if the command was successfully sent to the timer command queue. When the command is actually processed will depend on the priority of the timer service/daemon task relative to other tasks in the system. The timer service/daemon task priority is set by the configTIMER_TASK_PRIORITY configuration constant.

### xTimerDelete(xTimer, xTicksToWait)

Timer functionality is provided by a timer service/daemon task. Many of the public FreeRTOS timer API functions send commands to the timer service task through a queue called the timer command queue. The timer command queue is private to the kernel itself and is not directly accessible to application code. The length of the timer command queue is set by the configTIMER_QUEUE_LENGTH configuration constant.

xTimerDelete() deletes a timer that was previously created using the xTimerCreate() API function.

The configUSE_TIMERS configuration constant must be set to 1 for xTimerDelete() to be available.

Example usage:

See the xTimerChangePeriod() API function example usage scenario.

Parameters
• **xTimer** - The handle of the timer being deleted.
• **xTicksToWait** - Specifies the time, in ticks, that the calling task should be held in the Blocked state to wait for the delete command to be successfully sent to the timer command queue, should the queue already be full when xTimerDelete() was called. xTicksToWait is ignored if xTimerDelete() is called before the scheduler is started.

**Returns**  
`pdFAIL` will be returned if the delete command could not be sent to the timer command queue even after `xTicksToWait` ticks had passed. `pdPASS` will be returned if the command was successfully sent to the timer command queue. When the command is actually processed will depend on the priority of the timer service/daemon task relative to other tasks in the system. The timer service/daemon task priority is set by the `configTIMER_TASK_PRIORITY` configuration constant.

**xTimerReset** (xTimer, xTicksToWait)  
Timer functionality is provided by a timer service/daemon task. Many of the public FreeRTOS timer API functions send commands to the timer service task through a queue called the timer command queue. The timer command queue is private to the kernel itself and is not directly accessible to application code. The length of the timer command queue is set by the `configTIMER_QUEUE_LENGTH` configuration constant.

xTimerReset() re-starts a timer that was previously created using the xTimerCreate() API function. If the timer had already been started and was already in the active state, then xTimerReset() will cause the timer to re-evaluate its expiry time so that it is relative to when xTimerReset() was called. If the timer was in the dormant state then xTimerReset() has equivalent functionality to the xTimerStart() API function.

Resetting a timer ensures the timer is in the active state. If the timer is not stopped, deleted, or reset in the mean time, the callback function associated with the timer will get called `m` ticks after xTimerReset() was called, where `n` is the timers defined period.

It is valid to call xTimerReset() before the scheduler has been started, but when this is done the timer will not actually start until the scheduler is started, and the timers expiry time will be relative to when the scheduler is started, not relative to when xTimerReset() was called.

The `configUSE_TIMERS` configuration constant must be set to 1 for xTimerReset() to be available.

**Example usage:**

```c
* // When a key * is pressed, an LCD back-light * is switched on. If 5 seconds...--pass
* // without a key being pressed, then the LCD back-light * is switched off. In
* // this case, the timer * is a one-shot timer.
* * TimerHandle_t xBacklightTimer = NULL;
* *
* // The callback function assigned to the one-shot timer. In this case the
* // parameter is not used.
* void vBacklightTimerCallback( TimerHandle_t pxTimer )
* {
*     // The timer expired, therefore 5 seconds must have passed since a key
*     // was pressed. Switch off the LCD back-light.
*     vSetBacklightState( BACKLIGHT_OFF );
* }
* *
* // The key press event handler.
* void vKeyPressEventHandler( char cKey )
* {
*     // Ensure the LCD back-light * is on, then reset the timer that * is
*     // responsible for turning the back-light off after 5 seconds of
*     // key inactivity. Wait 10 ticks for the command to be successfully sent
*     // if it cannot be sent immediately.
*     vSetBacklightState( BACKLIGHT_ON );
*     if( xTimerReset( xBacklightTimer, 100 ) != pdPASS )
*         {
*             // Command was not successfully sent, reset the timer
*             // and wait for the command to be sent again.
*             vSetBacklightState( BACKLIGHT_OFF );
*             if( xTimerReset( xBacklightTimer, 100 ) != pdPASS )
*                 {
*                     // Command is still not being sent, do nothing.
*                     // In this example, we could consider waiting for a
*                     // longer period before trying again.
*                 }
*         }
* }
```

(continues on next page)
The reset command was not executed successfully. Take appropriate action here.

Perform the rest of the key processing here.

```c
void main( void )
{
    int32_t x;
    // Create then start the one-shot timer that is responsible for turning the back-light off if no keys are pressed within a 5 second period.
    xBacklightTimer = xTimerCreate( "BacklightTimer", 5000 / portTICK_PERIOD_MS, pdFALSE, 0, vBacklightTimerCallback );
    // Just a text name, not used by the kernel.
    if( xBacklightTimer == NULL )
    {
        // The timer was not created.
    }
    else
    {
        // Start the timer. No block time is specified, and even if one was it would be ignored because the scheduler has not yet been started.
        if( xTimerStart( xBacklightTimer, 0 ) != pdPASS )
        {
            // The timer could not be set into the Active state.
        }
        // Starting the scheduler will start the timer running as it has already been set into the active state.
        vTaskStartScheduler();
        // Should not reach here.
        for( ;; );
    }
}
```

**Parameters**
- `xTimer` - The handle of the timer being reset/started/restarted.
- `xTicksToWait` - Specifies the time, in ticks, that the calling task should be held in the Blocked state to wait for the reset command to be successfully sent to the timer command queue, should the queue already be full when xTimerReset() was called. xTicksToWait is ignored if xTimerReset() is called before the scheduler is started.

**Returns** `pdFAIL` will be returned if the reset command could not be sent to the timer command queue even after xTicksToWait ticks had passed. `pdPASS` will be returned if the command
was successfully sent to the timer command queue. When the command is actually processed
will depend on the priority of the timer service/daemon task relative to other tasks in the sys-
tem, although the timers expiry time is relative to when xTimerStart() is actually called. The
timer service/daemon task priority is set by the configTIMER_TASK_PRIORITY configura-
tion constant.

**xTimerStartFromISR** (xTimer, pxHigherPriorityTaskWoken)

A version of xTimerStart() that can be called from an interrupt service routine.

Example usage:

```c
* // This scenario assumes xBacklightTimer has already been created. When a
* // key *is* pressed, an LCD back-light *is* switched on. If 5 seconds *pass
* // without a key being pressed, then the LCD back-light *is* switched off. In
* // this case, the timer *is* a one-shot timer, and *unlike* the example given *for
* // the xTimerReset() function, the key press event handler *is* an interrupt
* // service routine.
* // The callback function assigned to the one-shot timer. In this case the
* // parameter *is not* used.
* void vBacklightTimerCallback( TimerHandle_t pxTimer )
* {
*   // The timer expired, therefore 5 seconds must have passed since a key
*   // was pressed. Switch off the LCD back-light.
*   vSetBacklightState( BACKLIGHT_OFF );
* }
* // The key press interrupt service routine.
* void vKeyPressEventInterruptHandler( void )
* {
*   BaseType_t xHigherPriorityTaskWoken = pdFALSE;
*   // Ensure the LCD back-light *is* on, then restart the timer that *is
*   // responsible *for* turning the back-light off after 5 seconds of
*   // key inactivity. This *is* an interrupt service routine so can only
*   // call FreeRTOS API functions that end in "FromISR".
*   vSetBacklightState( BACKLIGHT_ON );
*   // xTimerStartFromISR() or xTimerResetFromISR() could be called here
*   // *as* both cause the timer to re-calculate its expiry time.
*   // xHigherPriorityTaskWoken was initialised to pdFALSE when it was
*   // declared *(in this function).
*   if( xTimerStartFromISR( xBacklightTimer, &xHigherPriorityTaskWoken ) !=
*      pdPASS )
*   {
*     // The start command was *not* executed successfully. Take appropriate
*     // action here.
*   }
*   // Perform the rest of the key processing here.
*   // If xHigherPriorityTaskWoken equals pdTRUE, then a context switch
*   // should be performed. The syntax required to perform a context switch
*   // *from inside* an ISR varies *from* port *to* port, and *from* compiler to
*   // compiler. Inspect the demos *for* the port you are using to find the
*   // actual syntax required.
*   if( xHigherPriorityTaskWoken != pdFALSE )
*   {
*     // Call the interrupt safe *yield* function here (actual function
*     // depends on the FreeRTOS port being used).
*   }
* (continues on next page)
Parameters

- **xTimer** - The handle of the timer being started/restarted.
- **pxHigherPriorityTaskWoken** - The timer service/daemon task spends most of its time in the Blocked state, waiting for messages to arrive on the timer command queue. Calling `xTimerStartFromISR()` writes a message to the timer command queue, so has the potential to transition the timer service/daemon task out of the Blocked state. If calling `xTimerStartFromISR()` causes the timer service/daemon task to leave the Blocked state, and the timer service/daemon task has a priority equal to or greater than the currently executing task (the task that was interrupted), then `*pxHigherPriorityTaskWoken` will get set to `pdTRUE` internally within the `xTimerStartFromISR()` function. If `xTimerStartFromISR()` sets this value to `pdTRUE` then a context switch should be performed before the interrupt exits.

**Returns**

- `pdFAIL` will be returned if the start command could not be sent to the timer command queue.
- `pdPASS` will be returned if the command was successfully sent to the timer command queue. When the command is actually processed will depend on the priority of the timer service/daemon task relative to other tasks in the system, although the timers expiry time is relative to when `xTimerStartFromISR()` is actually called. The timer service/daemon task priority is set by the `configTIMER_TASK_PRIORITY` configuration constant.

### xTimerStopFromISR (xTimer, pxHigherPriorityTaskWoken)

A version of `xTimerStop()` that can be called from an interrupt service routine.

**Example usage:**

```c
/* // This scenario assumes xTimer has already been created and started. When
// an interrupt occurs, the timer should be simply stopped.

/* // The interrupt service routine that stops the timer.
void vAnExampleInterruptServiceRoutine( void )
{
    BaseType_t xHigherPriorityTaskWoken = pdFALSE;
    /* The interrupt has occurred - simply stop the timer.
    */
    if( xTimerStopFromISR( xTimer, &xHigherPriorityTaskWoken ) != pdPASS )
    {
        // The stop command was not executed successfully. Take appropriate
        // action here.
    }

    /* // If xHigherPriorityTaskWoken equals pdTRUE, then a context switch
    // should be performed. The syntax required to perform a context switch
    // from inside an ISR varies from port to port, and from compiler to
    // compiler. Inspect the demos for the port you are using to find the
    // actual syntax required.
    */
    if( xHigherPriorityTaskWoken != pdFALSE )
    {
        // Call the interrupt safe yield function here (actual function
        // depends on the FreeRTOS port being used).
    }
*/
```
Parameters

- **xTimer** - The handle of the timer being stopped.
- **pxHigherPriorityTaskWoken** - The timer service/daemon task spends most of its
time in the Blocked state, waiting for messages to arrive on the timer command queue. Calling
xTimerStopFromISR() writes a message to the timer command queue, so has the
potential to transition the timer service/daemon task out of the Blocked state. If calling
xTimerStopFromISR() causes the timer service/daemon task to leave the Blocked
state, and the timer service/ daemon task has a priority equal to or greater than the cur-
tently executing task (the task that was interrupted), then *pxHigherPriorityTaskWoken
will get set to pdTRUE internally within the xTimerStopFromISR() function. If xTimer-
StopFromISR() sets this value to pdTRUE then a context switch should be performed
before the interrupt exits.

Returns

pdFAIL will be returned if the stop command could not be sent to the timer command
queue. pdPASS will be returned if the command was successfully sent to the timer command
queue. When the command is actually processed will depend on the priority of the timer ser-
vice/daemon task relative to other tasks in the system. The timer service/daemon task priority
is set by the configTIMER_TASK_PRIORITY configuration constant.

**xTimerChangePeriodFromISR** (xTimer, xNewPeriod, pxHigherPriorityTaskWoken)

A version of xTimerChangePeriod() that can be called from an interrupt service routine.

Example usage:

```c
/* // This scenario assumes xTimer has already been created and started. When
* // an interrupt occurs, the period of xTimer should be changed to 500ms.
* */
* /* // The interrupt service routine that changes the period of xTimer.
* void vAnExampleInterruptServiceRoutine( void ) {
*     BaseType_t xHigherPriorityTaskWoken = pdFALSE;
*     
*     // The interrupt has occurred - change the period of xTimer to 500ms.
*     xHigherPriorityTaskWoken was set to pdFALSE where it was defined
*     // (within this function). As this is an interrupt service routine, only
*     // FreeRTOS API functions that end in "FromISR" can be used.
*     if( xTimerChangePeriodFromISR( xTimer, &xHigherPriorityTaskWoken ) !=
*                 pdPASS ) {
*         // The command to change the timers period was not executed
*         // successfully. Take appropriate action here.
*     }
*     
*     // If xHigherPriorityTaskWoken equals pdTRUE, then a context switch
*     // should be performed. The syntax required to perform a context switch
*     // from inside an ISR varies from port to port, and from compiler to
*     // compiler. Inspect the demos for the port you are using to find the
*     // actual syntax required.
*     if( xHigherPriorityTaskWoken != pdFALSE ) {
*         // Call the interrupt safe yield function here (actual function
*         // depends on the FreeRTOS port being used).
*     }
* }
*/
```

Parameters

- **xTimer** - The handle of the timer that is having its period changed.
- **xNewPeriod** - The new period for xTimer. Timer periods are specified in tick periods,
so the constant portTICK_PERIOD_MS can be used to convert a time that has been spec-
ified in milliseconds. For example, if the timer must expire after 100 ticks, then xNewPeriod should be set to 100. Alternatively, if the timer must expire after 500ms, then xNewPeriod can be set to \((500/\text{portTICK\_PERIOD\_MS})\) provided \text{configTICK\_RATE\_HZ}\ is less than or equal to 1000.

- \textbf{pxHigherPriorityTaskWoken} - The timer service/daemon task spends most of its time in the Blocked state, waiting for messages to arrive on the timer command queue. Calling \text{xTimerChangePeriodFromISR()} writes a message to the timer command queue, so has the potential to transition the timer service/daemon task out of the Blocked state. If calling \text{xTimerChangePeriodFromISR()} causes the timer service/daemon task to leave the Blocked state, and the timer service/daemon task has a priority equal to or greater than the currently executing task (the task that was interrupted), then \*pxHigherPriorityTaskWoken will get set to pdTRUE internally within the \text{xTimerChangePeriodFromISR()} function. If \text{xTimerChangePeriodFromISR()} sets this value to pdTRUE then a context switch should be performed before the interrupt exits.

\textbf{Returns} - pdFAIL will be returned if the command to change the timers period could not be sent to the timer command queue. pdPASS will be returned if the command was successfully sent to the timer command queue. When the command is actually processed will depend on the priority of the timer service/daemon task relative to other tasks in the system. The timer service/daemon task priority is set by the \text{configTIMER\_TASK\_PRIORITY} configuration constant.

\textbf{xTimerResetFromISR}(\text{TxTimer, pxHigherPriorityTaskWoken})

A version of \text{xTimerReset()} that can be called from an interrupt service routine.

Example usage:

```c
/* // This scenario assumes xBacklightTimer has already been created. When a */ /* // key is pressed, an LCD back-light is switched on. If 5 seconds pass */ /* // without a key being pressed, then the LCD back-light is switched off. In */ /* // this case, the timer is a one-shot timer, and unlike the example given for */ /* // the xTimerReset() function, the key press event handler is an interrupt */ /* // service routine. */ /* */ /* // The callback function assigned to the one-shot timer. In this case the */ /* // parameter is not used. */ void vBacklightTimerCallback( TimerHandle_t pxTimer )
{
    /* // The timer expired, therefore 5 seconds must have passed since a key */ /* // was pressed. Switch off the LCD back-light. */ vSetBacklightState( BACKLIGHT_OFF );
}
/* */
/* // The key press interrupt service routine. */ void vKeyPressEventInterruptHandler( void )
{
    BaseType_t xHigherPriorityTaskWoken = pdFALSE;

    /* // Ensure the LCD back-light is on, then reset the timer that is */ /* // responsible for turning the back-light off after 5 seconds of */ /* // key inactivity. This is an interrupt service routine so can only */ /* // call FreeRTOS API functions that end in "FromISR". */ vSetBacklightState( BACKLIGHT_ON );

    /* // xTimerStartFromISR() or xTimerResetFromISR() could be called here */ /* // as both cause the timer to re-calculate its expiry time. */ /* // xHigherPriorityTaskWoken was initialised to pdFALSE when it was */ /* // declared in this function. */ if( xTimerResetFromISR( xBacklightTimer, &xHigherPriorityTaskWoken ) != pdPASS )

(continues on next page)
The reset command was not executed successfully. Take appropriate action here.

// If xHigherPriorityTaskWoken equals pdTRUE, then a context switch should be performed. The syntax required to perform a context switch from inside an ISR varies from port to port, and from compiler to compiler. Inspect the demos for the port you are using to find the actual syntax required.

if (xHigherPriorityTaskWoken != pdFALSE)
{
    // Call the interrupt safe yield function here (actual function depends on the FreeRTOS port being used).
}

Parameters

- **xTimer** - The handle of the timer that is to be started, reset, or restarted.
- **pxHigherPriorityTaskWoken** - The timer service/daemon task spends most of its time in the Blocked state, waiting for messages to arrive on the timer command queue. Calling xTimerResetFromISR() writes a message to the timer command queue, so has the potential to transition the timer service/daemon task out of the Blocked state. If calling xTimerResetFromISR() causes the timer service/daemon task to leave the Blocked state, and the timer service/daemon task has a priority equal to or greater than the currently executing task (the task that was interrupted), then *pxHigherPriorityTaskWoken will get set to pdTRUE internally within the xTimerResetFromISR() function. If xTimerResetFromISR() sets this value to pdTRUE then a context switch should be performed before the interrupt exits.

Returns

- pdFAIL will be returned if the reset command could not be sent to the timer command queue. pdPASS will be returned if the command was successfully sent to the timer command queue. When the command is actually processed will depend on the priority of the timer service/daemon task relative to other tasks in the system, although the timers expiry time is relative to when xTimerResetFromISR() is actually called. The timer service/daemon task priority is set by the configTIMER_TASK_PRIORITY configuration constant.

Type Definitions

typedef struct tmrTimerControl *TimerHandle_t

typedef void (*TimerCallbackFunction_t)(TimerHandle_t xTimer)

Defines the prototype to which timer callback functions must conform.

typedef void (*PendedFunction_t)(void*, uint32_t)

Defines the prototype to which functions used with the xTimerPendFunctionCallFromISR() function must conform.

Event Group API

Header File

- components/freertos/FreeRTOS-Kernel/include/freertos/event_groups.h
- This header file can be included with:
#include "freertos/event_groups.h"

## Functions

**EventGroupHandle_t xEventGroupCreate (void)**

Create a new event group.

Internally, within the FreeRTOS implementation, event groups use a [small] block of memory, in which the event group’s structure is stored. If an event groups is created using xEventGroupCreate() then the required memory is automatically dynamically allocated inside the xEventGroupCreate() function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If an event group is created using xEventGroupCreateStatic() then the application writer must instead provide the memory that will get used by the event group. xEventGroupCreateStatic() therefore allows an event group to be created without using any dynamic memory allocation.

Although event groups are not related to ticks, for internal implementation reasons the number of bits available for use in an event group is dependent on the configUSE_16_BIT_TICKS setting in FreeRTOSConfig.h. If configUSE_16_BIT_TICKS is 1 then each event group contains 8 usable bits (bit 0 to bit 7). If configUSE_16_BIT_TICKS is set to 0 then each event group has 24 usable bits (bit 0 to bit 23). The EventBits_t type is used to store event bits within an event group.

**Example usage:**

```c
// Declare a variable to hold the created event group.
EventGroupHandle_t xCreatedEventGroup;

// Attempt to create the event group.
xCreatedEventGroup = xEventGroupCreate();

// Was the event group created successfully?
if( xCreatedEventGroup == NULL )
{
    // The event group was not created because there was insufficient
    // FreeRTOS heap available.
}
else
{
    // The event group was created.
}
```

**Returns** If the event group was created then a handle to the event group is returned. If there was insufficient FreeRTOS heap available to create the event group then NULL is returned. See [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)

**EventGroupHandle_t xEventGroupCreateStatic (StaticEventGroup_t *pxEventGroupBuffer)**

Create a new event group.

Internally, within the FreeRTOS implementation, event groups use a [small] block of memory, in which the event group’s structure is stored. If an event groups is created using xEventGroupCreate() then the required memory is automatically dynamically allocated inside the xEventGroupCreate() function. (see [https://www.FreeRTOS.org/a00111.html](https://www.FreeRTOS.org/a00111.html)). If an event group is created using xEventGroupCreateStatic() then the application writer must instead provide the memory that will get used by the event group. xEventGroupCreateStatic() therefore allows an event group to be created without using any dynamic memory allocation.

Although event groups are not related to ticks, for internal implementation reasons the number of bits available for use in an event group is dependent on the configUSE_16_BIT_TICKS setting in FreeRTOSConfig.h. If configUSE_16_BIT_TICKS is 1 then each event group contains 8 usable bits (bit 0 to bit 7). If configUSE_16_BIT_TICKS is set to 0 then each event group has 24 usable bits (bit 0 to bit 23). The EventBits_t type is used to store event bits within an event group.
StaticEventGroup_t is a publicly accessible structure that has the same size and alignment requirements as the real event group structure. It is provided as a mechanism for applications to know the size of the event group (which is dependent on the architecture and configuration file settings) without breaking the strict data hiding policy by exposing the real event group internals. This StaticEventGroup_t variable is passed into the xSemaphoreCreateEventGroupStatic() function and is used to store the event group’s data structures.

Example usage:

```c
StaticEventGroup_t xEventGroupBuffer;
```

// Create the event group without dynamically allocating any memory.

```c
xEventGroup = xEventGroupCreateStatic( &xEventGroupBuffer );
```

### Parameters pxEventGroupBuffer

pxEventGroupBuffer must point to a variable of type StaticEventGroup_t, which will be then be used to hold the event group’s data structures, removing the need for the memory to be allocated dynamically.

### Returns

If the event group was created then a handle to the event group is returned. If pxEventGroupBuffer was NULL then NULL is returned.

```
EventBits_t xEventGroupWaitBits( EventGroupHandle_t xEventGroup, const EventBits_t uxBitsToWaitFor, const BaseType_t xClearOnExit, const BaseType_t xWaitForAllBits, TickType_t xTicksToWait )
```

[Potentially] block to wait for one or more bits to be set within a previously created event group.

This function cannot be called from an interrupt.

Example usage:

```c
#define BIT_0 ( 1 << 0 )
#define BIT_4 ( 1 << 4 )

void aFunction( EventGroupHandle_t xEventGroup )
{
    EventBits_t uxBits;
    const TickType_t xTicksToWait = 100 / portTICK_PERIOD_MS;

    // Wait a maximum of 100ms for either bit 0 or bit 4 to be set within the event group. Clear the bits before exiting.
    uxBits = xEventGroupWaitBits( xEventGroup, BIT_0 | BIT_4, pdTRUE, // BIT_0 and BIT_4 should be cleared before returning.
                                  BIT_0 | BIT_4, // The bits within the event group to wait for.
                                  pdFALSE, // Don't wait for both bits, either bit will do.
                                  xTicksToWait );  // Wait a maximum of 100ms for either bit to be set.

    if( ( uxBits & ( BIT_0 | BIT_4 ) ) == ( BIT_0 | BIT_4 ) )
    {
        // xEventGroupWaitBits() returned because both bits were set.
    }
    else if( ( uxBits & BIT_0 ) != 0 )
    {
        // xEventGroupWaitBits() returned because just BIT_0 was set.
    }
    else if( ( uxBits & BIT_4 ) != 0 )
```

(continues on next page)
 Parameters

• **xEventGroup** – The event group in which the bits are being tested. The event group must have previously been created using a call to xEventGroupCreate().

• **uxBitsToWaitFor** – A bitwise value that indicates the bit or bits to test inside the event group. For example, to wait for bit 0 and/or bit 2 set uxBitsToWaitFor to 0x05. To wait for bits 0 and/or bit 1 and/or bit 2 set uxBitsToWaitFor to 0x07. Etc.

• **xClearOnExit** – If xClearOnExit is set to pdTRUE then any bits within uxBitsToWaitFor that are set within the event group will be cleared before xEventGroupWaitBits() returns if the wait condition was met (if the function returns for a reason other than a timeout). If xClearOnExit is set to pdFALSE then the bits set in the event group are not altered when the call to xEventGroupWaitBits() returns.

• **xWaitForAllBits** – If xWaitForAllBits is set to pdTRUE then xEventGroupWaitBits() will return when either all the bits in uxBitsToWaitFor are set or the specified block time expires. If xWaitForAllBits is set to pdFALSE then xEventGroupWaitBits() will return when any one of the bits set in uxBitsToWaitFor is set or the specified block time expires. The block time is specified by the xTicksToWait parameter.

• **xTicksToWait** – The maximum amount of time (specified in ‘ticks’) to wait for one/all (depending on the xWaitForAllBits value) of the bits specified by uxBitsToWaitFor to become set. A value of portMAX_DELAY can be used to block indefinitely (provided INCLUDE_vTaskSuspend is set to 1 in FreeRTOSConfig.h).

**Returns**
The value of the event group at the time either the bits being waited for became set, or the block time expired. Test the return value to know which bits were set. If xEventGroupWaitBits() returned because its timeout expired then not all the bits being waited for will be set. If xEventGroupWaitBits() returned because the bits it was waiting for were set then the returned value is the event group value before any bits were automatically cleared in the case that xClearOnExit parameter was set to pdTRUE.

```c
EventBits_t xEventGroupClearBits( EventGroupHandle_t xEventGroup, const EventBits_t uxBitsToClear )
```
Clear bits within an event group. This function cannot be called from an interrupt.

Example usage:

```c
#define BIT_0 ( 1 << 0 )
#define BIT_4 ( 1 << 4 )

void aFunction( EventGroupHandle_t xEventGroup )
{
    EventBits_t uxBits;

    // Clear bit 0 and bit 4 in xEventGroup.
    uxBits = xEventGroupClearBits( xEventGroup, BIT_0 | BIT_4 ); // The bits being cleared.
    if( ( uxBits & ( BIT_0 | BIT_4 ) ) == ( BIT_0 | BIT_4 ) )
    {
        // xEventGroupWaitBits() returned because just BIT_4 was set.
    }
    else
    {
        // xEventGroupWaitBits() returned because xTicksToWait ticks passed without either BIT_0 or BIT_4 becoming set.
    }
}
```
// Both bit 0 and bit 4 were set before xEventGroupClearBits() was called. Both will now be clear (not set).
}
else if ( uxBits & BIT_0 ) != 0 )
{
    // Bit 0 was set before xEventGroupClearBits() was called. It will now be clear.
}
else if ( uxBits & BIT_4 ) != 0 )
{
    // Bit 4 was set before xEventGroupClearBits() was called. It will now be clear.
}
else
{
    // Neither bit 0 nor bit 4 were set in the first place.
}

Parameters

- **xEventGroup** – The event group in which the bits are to be cleared.
- **uxBitsToClear** – A bitwise value that indicates the bit or bits to clear in the event group. For example, to clear bit 3 only, set uxBitsToClear to 0x08. To clear bit 3 and bit 0 set uxBitsToClear to 0x09.

Returns

The value of the event group before the specified bits were cleared.

**EventBits_t xEventGroupSetBits (EventGroupHandle_t xEventGroup, const EventBits_t uxBitsToSet)_sockMemPoolHandle_t xSockMemPool, const sockMemHandle_t uxSockMemPool)***

Set bits within an event group. This function cannot be called from an interrupt. **xEventGroupSetBits-FromISR()** is a version that can be called from an interrupt.

Setting bits in an event group will automatically unblock tasks that are blocked waiting for the bits.

Example usage:

```c
#define BIT_0 ( 1 << 0 )
#define BIT_4 ( 1 << 4 )

void aFunction( EventGroupHandle_t xEventGroup )
{
    EventBits_t uxBits;

    // Set bit 0 and bit 4 in xEventGroup.
    uxBits = xEventGroupSetBits(
        xEventGroup,   // The event group being updated.
        BIT_0 | BIT_4 );// The bits being set.

    if( ( uxBits & ( BIT_0 | BIT_4 ) ) == ( BIT_0 | BIT_4 ) )
    {
        // Both bit 0 and bit 4 remained set when the function returned.
    }
    else if( ( uxBits & BIT_0 ) != 0 )
    {
        // Bit 0 remained set when the function returned, but bit 4 was cleared. It might be that bit 4 was cleared automatically as a task that was waiting for bit 4 was removed from the Blocked state.
    }
    else if( ( uxBits & BIT_4 ) != 0 )
    {
```
// Bit 4 remained set when the function returned, but bit 0 was
// cleared. It might be that bit 0 was cleared automatically as a
// task that was waiting for bit 0 was removed from the Blocked
// state.
}
else
{
    // Neither bit 0 nor bit 4 remained set. It might be that a task
    // was waiting for both of the bits to be set, and the bits were
    // cleared as the task left the Blocked state.
}
}

Parameters

- `xEventGroup` - The event group in which the bits are to be set.
- `uxBitsToSet` - A bitwise value that indicates the bit or bits to set. For example, to set
  bit 3 only, set `uxBitsToSet` to 0x08. To set bit 3 and bit 0 set `uxBitsToSet` to 0x09.

Returns

The value of the event group at the time the call to `xEventGroupSetBits()` returns. There
are two reasons why the returned value might have the bits specified by the `uxBitsToSet` pa-
rameter cleared. First, if setting a bit results in a task that was waiting for the bit leaving the
blocked state then it is possible the bit will be cleared automatically (see the `xClearBitOnExit
parameter of `xEventGroupWaitBits()`). Second, any unblocked (or otherwise Ready state) task
that has a priority above that of the task that called `xEventGroupSetBits()` will execute and may
change the event group value before the call to `xEventGroupSetBits()` returns.

`EventBits_t xEventGroupSync(const EventGroupHandle_t xEventGroup, const EventBits_t uxBitsToSet, const EventBits_t uxBitsToWaitFor, TickType_t xTicksToWait)`

Atomically set bits within an event group, then wait for a combination of bits to be set within the same event
group. This functionality is typically used to synchronise multiple tasks, where each task has to wait for the
other tasks to reach a synchronisation point before proceeding.

This function cannot be used from an interrupt.

The function will return before its block time expires if the bits specified by the `uxBitsToWait` parameter are
set, or become set within that time. In this case all the bits specified by `uxBitsToWait` will be automatically
cleared before the function returns.

Example usage:

```c
// Bits used by the three tasks.
#define TASK_0_BIT ( 1 << 0 )
#define TASK_1_BIT ( 1 << 1 )
#define TASK_2_BIT ( 1 << 2 )

#define ALL_SYNC_BITS ( TASK_0_BIT | TASK_1_BIT | TASK_2_BIT )

// Use an event group to synchronise three tasks. It is assumed this event
// group has already been created elsewhere.

EventGroupHandle_t xEventBits;

void vTask0( void *pvParameters )
{
    EventBits_t uxReturn;
    TickType_t xTicksToWait = 100 / portTICK_PERIOD_MS;

    for( ;; )
    {
        // Perform task functionality here.
```
// Set bit 0 in the event flag to note this task has reached the
// sync point. The other two tasks will set the other two bits defined
// by ALL_SYNC_BITS. All three tasks have reached the synchronisation
// point when all the ALL_SYNC_BITS are set. Wait a maximum of 100ms
// for this to happen.
uxReturn = xEventGroupSync( xEventBits, TASK_0_BIT, ALL_SYNC_BITS, _
                           xTicksToWait );

if( ( uxReturn & ALL_SYNC_BITS ) == ALL_SYNC_BITS )
{
    // All three tasks reached the synchronisation point before the call
    // to xEventGroupSync() timed out.
}
}
}

void vTask1( void *pvParameters )
{
    for( ;; )
    {
        // Perform task functionality here.
        // Set bit 1 in the event flag to note this task has reached the
        // synchronisation point. The other two tasks will set the other two
        // bits defined by ALL_SYNC_BITS. All three tasks have reached the
        // synchronisation point when all the ALL_SYNC_BITS are set. Wait
        // indefinitely for this to happen.
        xEventGroupSync( xEventBits, TASK_1_BIT, ALL_SYNC_BITS, portMAX_DELAY );

        // xEventGroupSync() was called with an indefinite block time, so
        // this task will only reach here if the synchronisation was made by all
        // three tasks, so there is no need to test the return value.
    }
}

void vTask2( void *pvParameters )
{
    for( ;; )
    {
        // Perform task functionality here.
        // Set bit 2 in the event flag to note this task has reached the
        // synchronisation point. The other two tasks will set the other two
        // bits defined by ALL_SYNCBITS. All three tasks have reached the
        // synchronisation point when all the ALL_SYNC_BITS are set. Wait
        // indefinitely for this to happen.
        xEventGroupSync( xEventBits, TASK_2_BIT, ALL_SYNC_BITS, portMAX_DELAY );

        // xEventGroupSync() was called with an indefinite block time, so
        // this task will only reach here if the synchronisation was made by all
        // three tasks, so there is no need to test the return value.
    }
}

**Parameters**

- **xEventGroup** – The event group in which the bits are being tested. The event group must have previously been created using a call to xEventGroupCreate().
- **uxBitsToSet** – The bits to set in the event group before determining if, and possibly waiting for, all the bits specified by the uxBitsToWait parameter are set.
- **uxBitsToWaitFor** – A bitwise value that indicates the bit or bits to test inside the event
group. For example, to wait for bit 0 and bit 2 set uxBitsToWaitFor to 0x05. To wait for bits 0 and bit 1 and bit 2 set uxBitsToWaitFor to 0x07. Etc.

* `xTicksToWait` - The maximum amount of time (specified in ‘ticks’) to wait for all of the bits specified by `uxBitsToWaitFor` to become set.

**Returns** The value of the event group at the time either the bits being waited for became set, or the block time expired. Test the return value to know which bits were set. If `xEventGroupSync()` returned because its timeout expired then not all the bits being waited for will be set. If `xEventGroupSync()` returned because all the bits it was waiting for were set then the returned value is the event group value before any bits were automatically cleared.

`EventBits_t xEventGroupGetBitsFromISR (EventGroupHandle_t xEventGroup)`
A version of `xEventGroupGetBits()` that can be called from an ISR.

**Parameters** `xEventGroup` - The event group being queried.

**Returns** The event group bits at the time `xEventGroupGetBitsFromISR()` was called.

`void vEventGroupDelete (EventGroupHandle_t xEventGroup)`
Delete an event group that was previously created by a call to `xEventGroupCreate()`. Tasks that are blocked on the event group will be unblocked and obtain 0 as the event group’s value.

**Parameters** `xEventGroup` - The event group being deleted.

`BaseType_t xEventGroupGetStaticBuffer (EventGroupHandle_t xEventGroup, StaticEventGroup_t **ppxEventGroupBuffer)`
Retrieve a pointer to a statically created event groups’ data structure buffer. It is the same buffer that is supplied at the time of creation.

**Parameters**

* `xEventGroup` - The event group for which to retrieve the buffer.
* `ppxEventGroupBuffer` - Used to return a pointer to the event groups’ data structure buffer.

**Returns** `pdTRUE` if the buffer was retrieved, `pdFALSE` otherwise.

**Macros**

`xEventGroupClearBitsFromISR (xEventGroup, uxBitsToClear)`
A version of `xEventGroupClearBits()` that can be called from an interrupt.

Setting bits in an event group is not a deterministic operation because there are an unknown number of tasks that may be waiting for the bit or bits being set. FreeRTOS does not allow nondeterministic operations to be performed while interrupts are disabled, so protects event groups that are accessed from tasks by suspending the scheduler rather than disabling interrupts. As a result event groups cannot be accessed directly from an interrupt service routine. Therefore `xEventGroupClearBitsFromISR()` sends a message to the timer task to have the clear operation performed in the context of the timer task.

**Example usage:**

```c
#define BIT_0 ( 1 << 0 )
#define BIT_4 ( 1 << 4 )

// An event group which it is assumed has already been created by a call to
// xEventGroupCreate().
EventGroupHandle_t xEventGroup;

void anInterruptHandler( void )
{
    // Clear bit 0 and bit 4 in xEventGroup.
    xResult = xEventGroupClearBitsFromISR( xEventGroup, // The event group being updated. 
                                             BIT_0 | BIT_4 ); // The bits being set.
}
```

(continues on next page)
if (xResult == pdPASS)
{
    // The message was posted successfully.
    portYIELD_FROM_ISR(pdTRUE);
}

Note: If this function returns pdPASS then the timer task is ready to run and a
portYIELD_FROM_ISR(pdTRUE) should be executed to perform the needed clear on the event group. This
behavior is different from xEventGroupSetBitsFromISR because the parameter xHigherPriorityTaskWoken
is not present.

Parameters
• xEventGroup – The event group in which the bits are to be cleared.
• uxBitsToClear – A bitwise value that indicates the bit or bits to clear. For example,
  to clear bit 3 only, set uxBitsToClear to 0x08. To clear bit 3 and bit 0 set uxBitsToClear
to 0x09.

Returns If the request to execute the function was posted successfully then pdPASS is returned,
otherwise pdFALSE is returned. pdFALSE will be returned if the timer service queue was
full.

Example usage:

```c
#define BIT_0 ( 1 << 0 )
#define BIT_4 ( 1 << 4 )

// An event group which it is assumed has already been created by a call to
// xEventGroupCreate().
EventGroupHandle_t xEventGroup;

void anInterruptHandler( void )
{
    BaseType_t xHigherPriorityTaskWoken, xResult;

    // xHigherPriorityTaskWoken must be initialised to pdFALSE.
    xHigherPriorityTaskWoken = pdFALSE;

    // Set bit 0 and bit 4 in xEventGroup.
    xResult = xEventGroupSetBitsFromISR(
        xEventGroup,  // The event group being updated.
        BIT_0 | BIT_4  // The bits being set.
        &xHigherPriorityTaskWoken );

    // Was the message posted successfully?
    if (xResult == pdPASS)
    {
        // If xHigherPriorityTaskWoken is now set to pdTRUE then a context
```
Parameters:

- \texttt{xEventGroup} -- The event group in which the bits are to be set.
- \texttt{uxBitsToSet} -- A bitwise value that indicates the bit or bits to set. For example, to set bit 3 only, set \texttt{uxBitsToSet} to 0x08. To set bit 3 and bit 0 set \texttt{uxBitsToSet} to 0x09.
- \texttt{pxHigherPriorityTaskWoken} -- As mentioned above, calling this function will result in a message being sent to the timer daemon task. If the priority of the timer daemon task is higher than the priority of the currently running task (the task the interrupt interrupted) then \texttt{pxHigherPriorityTaskWoken} will be set to \texttt{pdTRUE} by \texttt{xEventGroupSetBitsFromISR()}, indicating that a context switch should be requested before the interrupt exits. For that reason \texttt{pxHigherPriorityTaskWoken} must be initialised to \texttt{pdFALSE}. See the example code below.

Returns: If the request to execute the function was posted successfully then \texttt{pdPASS} is returned, otherwise \texttt{pdFALSE} is returned. \texttt{pdFALSE} will be returned if the timer service queue was full.

\texttt{xEventGroupGetBits(xEventGroup)}

Returns the current value of the bits in an event group. This function cannot be used from an interrupt.

Parameters:

- \texttt{xEventGroup} -- The event group being queried.

Returns: The event group bits at the time \texttt{xEventGroupGetBits()} was called.

Type Definitions:

typedef struct EventGroupDef_t \texttt{EventGroupHandle_t}\n
typedef TickType_t \texttt{EventBits_t}\n
Stream Buffer API

Header File:

- \texttt{components/freertos/FreeRTOS-Kernel/include/freertos/stream_buffer.h}
- This header file can be included with:

\begin{verbatim}
#include "freertos/stream_buffer.h"
\end{verbatim}

Functions:

\texttt{BaseType_t xStreamBufferGetStaticBuffers (StreamBufferHandle_t xStreamBuffer, uint8_t **ppucStreamBufferStorageArea, StaticStreamBuffer_t **ppxStaticStreamBuffer)}

Retrieve pointers to a statically created stream buffer’s data structure buffer and storage area buffer. These are the same buffers that are supplied at the time of creation.

Parameters:

- \texttt{xStreamBuffer} -- The stream buffer for which to retrieve the buffers.
- \texttt{ppucStreamBufferStorageArea} -- Used to return a pointer to the stream buffer’s storage area buffer.
• **ppxStaticStreamBuffer** – Used to return a pointer to the stream buffer’s data structure buffer.

**Returns**  pdTRUE if buffers were retrieved, pdFALSE otherwise.

```c
size_t xStreamBufferSend( StreamBufferHandle_t xStreamBuffer, const void *pvTxData, size_t xDataLengthBytes, TickType_t xTicksToWait )
```

Sends bytes to a stream buffer. The bytes are copied into the stream buffer.

: Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as `xStreamBufferSend()`) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as `xStreamBufferReceive()`) inside a critical section and set the receive block time to 0.

Use `xStreamBufferSend()` to write to a stream buffer from a task. Use `xStreamBufferSendFromISR()` to write to a stream buffer from an interrupt service routine (ISR).

**Example use:**

```c
void vAFunction( StreamBufferHandle_t xStreamBuffer )
{
    size_t xBytesSent;
    uint8_t ucArrayToSend[] = { 0, 1, 2, 3 };
    char *pcStringToSend = "String to send";
    const TickType_t x100ms = pdMS_TO_TICKS( 100 );

    // Send an array to the stream buffer, blocking for a maximum of 100ms to
    // wait for enough space to be available in the stream buffer.
    xBytesSent = xStreamBufferSend( xStreamBuffer, ( void * ) ucArrayToSend, ...
                                         sizeof( ucArrayToSend ) , x100ms );

    if( xBytesSent != sizeof( ucArrayToSend ) )
    {
        // The call to xStreamBufferSend() times out before there was enough
        // space in the buffer for the data to be written, but it did
        // successfully write xBytesSent bytes.

    }

    // Send the string to the stream buffer. Return immediately if there is not
    // enough space in the buffer.
    xBytesSent = xStreamBufferSend( xStreamBuffer, ( void * ) pcStringToSend, ...
                                         strlen( pcStringToSend ) , 0 );

    if( xBytesSent != strlen( pcStringToSend ) )
    {
        // The entire string could not be added to the stream buffer because
        // there was not enough free space in the buffer, but xBytesSent bytes
        // were sent. Could try again to send the remaining bytes.
    }
}
```

**Parameters**

- **xStreamBuffer** – The handle of the stream buffer to which a stream is being sent.
- **pvTxData** – A pointer to the buffer that holds the bytes to be copied into the stream buffer.
- **xDataLengthBytes** – The maximum number of bytes to copy from pvTxData into the stream buffer.
• **xTicksToWait** - The maximum amount of time the task should remain in the Blocked state to wait for enough space to become available in the stream buffer, should the stream buffer contain too little space to hold the other xDataLengthBytes bytes. The block time is specified in tick periods, so the absolute time it represents is dependent on the tick frequency. The macro pdMS_TO_TICKS() can be used to convert a time specified in milliseconds into a time specified in ticks. Setting xTicksToWait to portMAX_DELAY will cause the task to wait indefinitely (without timing out), provided INCLUDE_vTaskSuspend is set to 1 in FreeRTOSConfig.h. If a task times out before it can write all xDataLengthBytes into the buffer it will still write as many bytes as possible. A task does not use any CPU time when it is in the blocked state.

**Returns** The number of bytes written to the stream buffer. If a task times out before it can write all xDataLengthBytes into the buffer it will still write as many bytes as possible.

```c
size_t xStreamBufferSendFromISR (StreamBufferHandle_t xStreamBuffer, const void *pvTxData, size_t xDataLengthBytes, BaseType_t *const pxHigherPriorityTaskWoken)
```

Interrupt safe version of the API function that sends a stream of bytes to the stream buffer.

: Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as xStreamBufferSend()) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as xStreamBufferReceive()) inside a critical section and set the receive block time to 0.

Use xStreamBufferSend() to write to a stream buffer from a task. Use xStreamBufferSendFromISR() to write to a stream buffer from an interrupt service routine (ISR).

Example use:

```c
// A stream buffer that has already been created.
StreamBufferHandle_t xStreamBuffer;

void vAnInterruptServiceRoutine( void )
{
    size_t xBytesSent;
    char *pcStringToSend = "String to send";
    BaseType_t xHigherPriorityTaskWoken = pdFALSE; // Initialised to pdFALSE.

    // Attempt to send the string to the stream buffer.
    xBytesSent = xStreamBufferSendFromISR( xStreamBuffer,
                                           ( void * ) pcStringToSend,
                                           strlen( pcStringToSend ),
                                           &xHigherPriorityTaskWoken );

    if( xBytesSent != strlen( pcStringToSend ) )
    {
        // There was not enough free space in the stream buffer for the entire
        // string to be written, ut xBytesSent bytes were written.
    }

    // If xHigherPriorityTaskWoken was set to pdTRUE inside
    // xStreamBufferSendFromISR() then a task that has a priority above the
    // priority of the currently executing task was unblocked and a context
    // switch should be performed to ensure the ISR returns to the unblocked
    // task. In most FreeRTOS ports this is done by simply passing
    // xHigherPriorityTaskWoken into portYIELD_FROM_ISR(), which will test the
```

(continues on next page)
(continued from previous page)

```c
// variables value, and perform the context switch if necessary. Check the
// documentation for the port in use for port specific instructions.
portYIELD_FROM_ISR( xHigherPriorityTaskWoken );
```

### Parameters
- **xStreamBuffer** - The handle of the stream buffer to which a stream is being sent.
- **pvTxData** - A pointer to the data that is to be copied into the stream buffer.
- **xDataLengthBytes** - The maximum number of bytes to copy from pvTxData into the stream buffer.
- **pxHigherPriorityTaskWoken** - It is possible that a stream buffer will have a task blocked on it waiting for data. Calling xStreamBufferSendFromISR() can make data available, and so cause a task that was waiting for data to leave the Blocked state. If calling xStreamBufferSendFromISR() causes a task to leave the Blocked state, and the unblocked task has a priority higher than the currently executing task (the task that was interrupted), then, internally, xStreamBufferSendFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE. If xStreamBufferSendFromISR() sets this value to pdTRUE, then normally a context switch should be performed before the interrupt is exited. This will ensure that the interrupt returns directly to the highest priority Ready state task. *pxHigherPriorityTaskWoken should be set to pdFALSE before it is passed into the function. See the example code below for an example.

### Returns
The number of bytes actually written to the stream buffer, which will be less than xDataLengthBytes if the stream buffer didn’t have enough free space for all the bytes to be written.

```c
size_t xStreamBufferReceive ( StreamBufferHandle_t xStreamBuffer, void* pvRxData, size_t xBufferLengthBytes, TickType_t xTicksToWait )
```

Receives bytes from a stream buffer.

- Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as xStreamBufferSend()) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as xStreamBufferReceive()) inside a critical section and set the receive block time to 0.

Use xStreamBufferReceive() to read from a stream buffer from a task. Use xStreamBufferReceiveFromISR() to read from a stream buffer from an interrupt service routine (ISR).

#### Example use:

```c
void vAFunction( StreamBuffer_t xStreamBuffer )
{
  uint8_t ucRxData[ 20 ];
  size_t xReceivedBytes;
  const TickType_t xBlockTime = pdMS_TO_TICKS( 20 );

  // Receive up to another sizeof( ucRxData ) bytes from the stream buffer.
  // Wait in the Blocked state (so not using any CPU processing time) for a
  // maximum of 100ms for the full sizeof( ucRxData ) number of bytes to be
  // available.
  xReceivedBytes = xStreamBufferReceive( xStreamBuffer,
    ( void * ) ucRxData,
    sizeof( ucRxData ),
    xBlockTime );
```

(continues on next page)
if( xReceivedBytes > 0 )
{
    // A ucRxData contains another xReceivedBytes bytes of data, which can
    // be processed here....
}

Parameters

- **xStreamBuffer** - The handle of the stream buffer from which bytes are to be received.
- **pvRxData** - A pointer to the buffer into which the received bytes will be copied.
- **xBufferLengthBytes** - The length of the buffer pointed to by the pvRxData parameter. This sets the maximum number of bytes to receive in one call. xStreamBufferReceive will return as many bytes as possible up to a maximum set by xBufferLengthBytes.
- **xTicksToWait** - The maximum amount of time the task should remain in the Blocked state to wait for data to become available if the stream buffer is empty. xStreamBufferReceive() will return immediately if xTicksToWait is zero. The block time is specified in tick periods, so the absolute time it represents is dependent on the tick frequency. The macro pdMS_TO_TICKS() can be used to convert a time specified in milliseconds into a time specified in ticks. Setting xTicksToWait to portMAX_DELAY will cause the task to wait indefinitely (without timing out), provided INCLUDE_vTaskSuspend is set to 1 in FreeRTOSConfig.h. A task does not use any CPU time when it is in the Blocked state.

Returns

The number of bytes actually read from the stream buffer, which will be less than xBufferLengthBytes if the call to xStreamBufferReceive() timed out before xBufferLengthBytes were available.

```c
size_t xStreamBufferReceiveFromISR( StreamBufferHandle_t xStreamBuffer, void *pvRxData, size_t xBufferLengthBytes, BaseType_t *const pxHigherPriorityTaskWoken)
```

An interrupt safe version of the API function that receives bytes from a stream buffer.

Use xStreamBufferReceive() to read bytes from a stream buffer from a task. Use xStreamBufferReceiveFromISR() to read bytes from a stream buffer from an interrupt service routine (ISR).

Example use:

```c
// A stream buffer that has already been created.
StreamBuffer_t xStreamBuffer;

void vAnInterruptServiceRoutine( void )
{
    uint8_t ucRxData[ 20 ];
    size_t xReceivedBytes;
    BaseType_t xHigherPriorityTaskWoken = pdFALSE; // Initialised to pdFALSE.

    // Receive the next stream from the stream buffer.
    xReceivedBytes = xStreamBufferReceiveFromISR( xStreamBuffer,
                                                 ( void * ) ucRxData,
                                                 sizeof( ucRxData ),
                                                 &xHigherPriorityTaskWoken );

    if( xReceivedBytes > 0 )
    {
        // ucRxData contains xReceivedBytes read from the stream buffer.
        // Process the stream here....
    }
```
// If xHigherPriorityTaskWoken was set to pdTRUE inside
// xStreamBufferReceiveFromISR() then a task that has a priority above the
// priority of the currently executing task was unblocked and a context
// switch should be performed to ensure the ISR returns to the unblocked
// task. In most FreeRTOS ports this is done by simply passing
// xHigherPriorityTaskWoken into portYIELD_FROM_ISR(), which will test the
// variables value, and perform the context switch if necessary. Check the
// documentation for the port in use for port specific instructions.
portYIELD_FROM_ISR( xHigherPriorityTaskWoken );

Parameters
- **xStreamBuffer** – The handle of the stream buffer from which a stream is being received.
- **pvRxData** – A pointer to the buffer into which the received bytes are copied.
- **xBUFFER_LENGTH_BYTES** – The length of the buffer pointed to by the pvRxData parameter. This sets the maximum number of bytes to receive in one call. xStreamBufferReceive will return as many bytes as possible up to a maximum set by xBUFFER_LENGTH_BYTES.
- **pxHigherPriorityTaskWoken** – It is possible that a stream buffer will have a task blocked on it waiting for space to become available. Calling xStreamBufferReceiveFromISR() can make space available, and so cause a task that is waiting for space to leave the Blocked state. If calling xStreamBufferReceiveFromISR() causes a task to leave the Blocked state, and the unblocked task has a priority higher than the currently executing task (the task that was interrupted), then, internally, xStreamBufferReceiveFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE. If xStreamBufferReceiveFromISR() sets this value to pdTRUE, then normally a context switch should be performed before the interrupt is exited. That will ensure the interrupt returns directly to the highest priority Ready state task. *pxHigherPriorityTaskWoken should be set to pdFALSE before it is passed into the function. See the code example below for an example.

Returns
- The number of bytes read from the stream buffer, if any.

```c
void vStreamBufferDelete ( StreamBufferHandle_t xStreamBuffer )

Deletes a stream buffer that was previously created using a call to xStreamBufferCreate() or xStreamBufferCreateStatic(). If the stream buffer was created using dynamic memory (that is, by xStreamBufferCreate()), then the allocated memory is freed.

A stream buffer handle must not be used after the stream buffer has been deleted.

Parameters
- **xStreamBuffer** – The handle of the stream buffer to be deleted.

```c
BaseType_t xStreamBufferIsFull ( StreamBufferHandle_t xStreamBuffer )

Queries a stream buffer to see if it is full. A stream buffer is full if it does not have any free space, and therefore cannot accept any more data.

Parameters
- **xStreamBuffer** – The handle of the stream buffer being queried.

Returns
- If the stream buffer is full then pdTRUE is returned. Otherwise pdFALSE is returned.

```c
BaseType_t xStreamBufferIsEmpty ( StreamBufferHandle_t xStreamBuffer )

Queries a stream buffer to see if it is empty. A stream buffer is empty if it does not contain any data.

Parameters
- **xStreamBuffer** – The handle of the stream buffer being queried.

Returns
- If the stream buffer is empty then pdTRUE is returned. Otherwise pdFALSE is returned.

```c
BaseType_t xStreamBufferReset ( StreamBufferHandle_t xStreamBuffer )

Resets a stream buffer to its initial, empty, state. Any data that was in the stream buffer is discarded. A stream buffer can only be reset if there are no tasks blocked waiting to either send to or receive from the stream buffer.

Parameters
- **xStreamBuffer** – The handle of the stream buffer being reset.
Returns If the stream buffer is reset then pdPASS is returned. If there was a task blocked waiting to send to or read from the stream buffer then the stream buffer is not reset and pdFAIL is returned.

`size_t xStreamBufferSpacesAvailable(StreamBufferHandle_t xStreamBuffer)`
Queries a stream buffer to see how much free space it contains, which is equal to the amount of data that can be sent to the stream buffer before it is full.

**Parameters**
- `xStreamBuffer` - The handle of the stream buffer being queried.

**Returns**
- The number of bytes that can be written to the stream buffer before the stream buffer would be full.

`size_t xStreamBufferBytesAvailable(StreamBufferHandle_t xStreamBuffer)`
Queries a stream buffer to see how much data it contains, which is equal to the number of bytes that can be read from the stream buffer before the stream buffer would be empty.

**Parameters**
- `xStreamBuffer` - The handle of the stream buffer being queried.

**Returns**
- The number of bytes that can be read from the stream buffer before the stream buffer would be empty.

`BaseType_t xStreamBufferSetTriggerLevel(StreamBufferHandle_t xStreamBuffer, size_t xTriggerLevel)`
A stream buffer’s trigger level is the number of bytes that must be in the stream buffer before a task that is blocked on the stream buffer to wait for data is moved out of the blocked state. For example, if a task is blocked on a read of an empty stream buffer that has a trigger level of 1 then the task will be unblocked when a single byte is written to the buffer or the task’s block time expires. As another example, if a task is blocked on a read of an empty stream buffer that has a trigger level of 10 then the task will not be unblocked until the stream buffer contains at least 10 bytes or the task’s block time expires. If a reading task’s block time expires before the trigger level is reached then the task will still receive however many bytes are actually available. Setting a trigger level of 0 will result in a trigger level of 1 being used. It is not valid to specify a trigger level that is greater than the buffer size.

A trigger level is set when the stream buffer is created, and can be modified using `xStreamBufferSetTriggerLevel()`.

**Parameters**
- `xStreamBuffer` - The handle of the stream buffer being updated.
- `xTriggerLevel` - The new trigger level for the stream buffer.

**Returns**
- If `xTriggerLevel` was less than or equal to the stream buffer’s length then the trigger level will be updated and pdTRUE is returned. Otherwise pdFALSE is returned.

`BaseType_t xStreamBufferSendCompletedFromISR(StreamBufferHandle_t xStreamBuffer, BaseType_t *pxHigherPriorityTaskWoken)`
For advanced users only.

The sbSEND_COMPLETED() macro is called from within the FreeRTOS APIs when data is sent to a message buffer or stream buffer. If there was a task that was blocked on the message or stream buffer waiting for data to arrive then the sbSEND_COMPLETED() macro sends a notification to the task to remove it from the Blocked state. xStreamBufferSendCompletedFromISR() does the same thing. It is provided to enable application writers to implement their own version of sbSEND_COMPLETED(), and MUST NOT BE USED AT ANY OTHER TIME.

See the example implemented in FreeRTOS/Demo/Minimal/MessageBufferAMP.c for additional information.

**Parameters**
- `xStreamBuffer` - The handle of the stream buffer to which data was written.
- `pxHigherPriorityTaskWoken` - *pxHigherPriorityTaskWoken should be initialised to pdFALSE before it is passed into xStreamBufferSendCompletedFromISR(). If calling xStreamBufferSendCompletedFromISR() removes a task from the Blocked state, and the task has a priority above the priority of the currently running task, then *pxHigherPriorityTaskWoken will get set to pdTRUE indicating that a context switch should be performed before exiting the ISR.
Returns If a task was removed from the Blocked state then pdTRUE is returned. Otherwise pdFALSE is returned.

BaseType_t xStreamBufferReceiveCompletedFromISR (StreamBufferHandle_t xStreamBuffer, BaseType_t *pxHigherPriorityTaskWoken)

For advanced users only.

The sbRECEIVE_COMPLETED() macro is called from within the FreeRTOS APIs when data is read out of a message buffer or stream buffer. If there was a task that was blocked on the message or stream buffer waiting for data to arrive then the sbRECEIVE_COMPLETED() macro sends a notification to the task to remove it from the Blocked state. xStreamBufferReceiveCompletedFromISR() does the same thing. It is provided to enable application writers to implement their own version of sbRECEIVE_COMPLETED(), and MUST NOT BE USED AT ANY OTHER TIME.

See the example implemented in FreeRTOS/Demo/Minimal/MessageBufferAMP.c for additional information.

Parameters

• xStreamBuffer – The handle of the stream buffer from which data was read.
• pxHigherPriorityTaskWoken – *pxHigherPriorityTaskWoken should be initialised to pdFALSE before it is passed into xStreamBufferReceiveCompletedFromISR(). If calling xStreamBufferReceiveCompletedFromISR() removes a task from the Blocked state, and the task has a priority above the priority of the currently running task, then *pxHigherPriorityTaskWoken will get set to pdTRUE indicating that a context switch should be performed before exiting the ISR.

Returns If a task was removed from the Blocked state then pdTRUE is returned. Otherwise pdFALSE is returned.

Macros

xStreamBufferCreateWithCallback (xBufferSizeBytes, xTriggerLevelBytes, pxSendCompletedCallback, pxReceiveCompletedCallback)

Creates a new stream buffer using dynamically allocated memory. See xStreamBufferCreateStatic() for a version that uses statically allocated memory (memory that is allocated at compile time).

configSUPPORT_DYNAMIC_ALLOCATION must be set to 1 or left undefined in FreeRTOSConfig.h for xStreamBufferCreate() to be available.

Example use:

```
void vAFunction( void )
{
StreamBufferHandle_t xStreamBuffer;
const size_t xStreamBufferSizeBytes = 100, xTriggerLevel = 10;

// Create a stream buffer that can hold 100 bytes. The memory used to hold
// both the stream buffer structure and the data in the stream buffer is
// allocated dynamically.
xStreamBuffer = xStreamBufferCreate( xStreamBufferSizeBytes, xTriggerLevel );

if( xStreamBuffer == NULL )
{
    // There was not enough heap memory space available to create the
    // stream buffer.
}
else
{
    // The stream buffer was created successfully and can now be used.
}
}
```
• **xBufferSizeBytes** — The total number of bytes the stream buffer will be able to hold at any one time.

• **xTriggerLevelBytes** — The number of bytes that must be in the stream buffer before a task that is blocked on the stream buffer to wait for data is moved out of the blocked state. For example, if a task is blocked on a read of an empty stream buffer that has a trigger level of 1 then the task will be unblocked when a single byte is written to the buffer or the task’s block time expires. As another example, if a task is blocked on a read of an empty stream buffer that has a trigger level of 10 then the task will not be unblocked until the stream buffer contains at least 10 bytes or the task’s block time expires. If a reading task’s block time expires before the trigger level is reached then the task will still receive however many bytes are actually available. Setting a trigger level of 0 will result in a trigger level of 1 being used. It is not valid to specify a trigger level that is greater than the buffer size.

• **pxSendCompletedCallback** — Callback invoked when number of bytes at least equal to trigger level is sent to the stream buffer. If the parameter is NULL, it will use the default implementation provided by sbSEND_COMPLETED macro. To enable the callback, configUSE_SB_COMPLETED_CALLBACK must be set to 1 in FreeRTOSConfig.h.

• **pxReceiveCompletedCallback** — Callback invoked when more than zero bytes are read from a stream buffer. If the parameter is NULL, it will use the default implementation provided by sbRECEIVE_COMPLETED macro. To enable the callback, configUSE_SB_COMPLETED_CALLBACK must be set to 1 in FreeRTOSConfig.h.

**Returns** If NULL is returned, then the stream buffer cannot be created because there is insufficient heap memory available for FreeRTOS to allocate the stream buffer data structures and storage area. A non-NULL value being returned indicates that the stream buffer has been created successfully - the returned value should be stored as the handle to the created stream buffer.

```c
xStreamBufferCreateStaticWithCallback (xBufferSizeBytes, xTriggerLevelBytes, pucStreamBufferStorageArea, pxStaticStreamBuffer, pxSendCompletedCallback, pxReceiveCompletedCallback)
```

Creates a new stream buffer using statically allocated memory. See xStreamBufferCreate() for a version that uses dynamically allocated memory.

configSUPPORT_STATIC_ALLOCATION must be set to 1 in FreeRTOSConfig.h for xStreamBufferCreateStatic() to be available.

**Example use:**

```c
// Used to dimension the array used to hold the streams. The available space // will actually be one less than this, so 999. #define STORAGE_SIZE_BYTES 1000

// Defines the memory that will actually hold the streams within the stream // buffer.
static uint8_t ucStorageBuffer[ STORAGE_SIZE_BYTES ];

// The variable used to hold the stream buffer structure.
StaticStreamBuffer_t xStreamBufferStruct;

void MyFunction( void )
{
    StreamBufferHandle_t xStreamBuffer;
    const size_t xTriggerLevel = 1;

    xStreamBuffer = xStreamBufferCreateStatic( sizeof( ucStorageBuffer ),
    xTriggerLevel,
    ucStorageBuffer,
    &xStreamBufferStruct );
}
```

(continues on next page)
// As neither the pucStreamBufferStorageArea or pxStaticStreamBuffer parameters were NULL, xStreamBuffer will not be NULL, and can be used to reference the created stream buffer in other stream buffer API calls.

// Other code that uses the stream buffer can go here.

```c
}
```

### Parameters

- **xBufferSizeBytes** - The size, in bytes, of the buffer pointed to by the pucStreamBufferStorageArea parameter.
- **xTriggerLevelBytes** - The number of bytes that must be in the stream buffer before a task that is blocked on the stream buffer to wait for data is moved out of the blocked state. For example, if a task is blocked on a read of an empty stream buffer that has a trigger level of 1 then the task will be unblocked when a single byte is written to the buffer or the task’s block time expires. As another example, if a task is blocked on a read of an empty stream buffer that has a trigger level of 10 then the task will not be unblocked until the stream buffer contains at least 10 bytes or the task’s block time expires. If a reading task’s block time expires before the trigger level is reached then the task will still receive however many bytes are actually available. Setting a trigger level of 0 will result in a trigger level of 1 being used. It is not valid to specify a trigger level that is greater than the buffer size.
- **pucStreamBufferStorageArea** - Must point to a uint8_t array that is at least xBufferSizeBytes big. This is the array to which streams are copied when they are written to the stream buffer.
- **pxStaticStreamBuffer** - Must point to a variable of type StaticStreamBuffer_t, which will be used to hold the stream buffer’s data structure.
- **pxSendCompletedCallback** - Callback invoked when number of bytes at least equal to trigger level is sent to the stream buffer. If the parameter is NULL, it will use the default implementation provided by sbSEND.Completed.CALLBACK macro. To enable the callback, configUSE_SB_COMPLETED.CALLBACK must be set to 1 in FreeRTOSConfig.h.
- **pxReceiveCompletedCallback** - Callback invoked when more than zero bytes are read from a stream buffer. If the parameter is NULL, it will use the default implementation provided by sbRECEIVE.Completed.CALLBACK macro. To enable the callback, configUSE_SB_COMPLETED.CALLBACK must be set to 1 in FreeRTOSConfig.h.

### Returns

If the stream buffer is created successfully then a handle to the created stream buffer is returned. If either pucStreamBufferStorageArea or pxStaticStreamBuffer are NULL then NULL is returned.

### Type Definitions

```c
typedef struct StreamBufferDef_t *StreamBufferHandle_t

typedef void (StreamBufferCallbackFunction_t(StreamBufferHandle_t xStreamBuffer, BaseType_t xIsInsideISR, BaseType_t *const pxHigherPriorityTaskWoken))
```

Type used as a stream buffer’s optional callback.

### Message Buffer API

### Header File

- components/freertos/FreeRTOS-Kernel/include/freertos/message_buffer.h
- This header file can be included with:

```c
#include "freertos/message_buffer.h"
```

## Macros

### xMessageBufferCreateWithCallback

```c
xMessageBufferCreateWithCallback (xBuffSizeBytes, pxSendCompletedCallback,
                                  pxReceiveCompletedCallback)
```

Creates a new message buffer using dynamically allocated memory. See xMessageBufferCreateStatic() for a version that uses statically allocated memory (memory that is allocated at compile time).

`configSUPPORT_DYNAMIC_ALLOCATION` must be set to 1 or left undefined in FreeRTOSConfig.h for xMessageBufferCreate() to be available.

### Example use:

```c
void vAFunction ( void )
{
    MessageBufferHandle_t xMessageBuffer;
    const size_t xMessageBufferSizeBytes = 100;

    // Create a message buffer that can hold 100 bytes. The memory used to hold
    // both the message buffer structure and the messages themselves is allocated
    // dynamically. Each message added to the buffer consumes an additional 4
    // bytes which are used to hold the length of the message.
    xMessageBuffer = xMessageBufferCreate ( xMessageBufferSizeBytes );

    if ( xMessageBuffer == NULL )
    {
        // There was not enough heap memory space available to create the
        // message buffer.
    }
    else
    {
        // The message buffer was created successfully and can now be used.
    }
```

### Parameters

- **xBuffSizeBytes** - The total number of bytes (not messages) the message buffer will be able to hold at any one time. When a message is written to the message buffer an additional `sizeof( size_t )` bytes are also written to store the message's length. `sizeof( size_t )` is typically 4 bytes on a 32-bit architecture, so on most 32-bit architectures a 10 byte message will take up 14 bytes of message buffer space.

- **pxSendCompletedCallback** - Callback invoked when a send operation to the message buffer is complete. If the parameter is NULL or `xMessageBufferCreate()` is called without the parameter, then it will use the default implementation provided by `sbSEND_COMPLETED` macro. To enable the callback, `configUSE_SB_COMPLETED_CALLBACK` must be set to 1 in FreeRTOSConfig.h.

- **pxReceiveCompletedCallback** - Callback invoked when a receive operation from the message buffer is complete. If the parameter is NULL or `xMessageBufferCreate()` is called without the parameter, it will use the default implementation provided by `sbRECEIVE_COMPLETED` macro. To enable the callback, `configUSE_SB_COMPLETED_CALLBACK` must be set to 1 in FreeRTOSConfig.h.

### Returns

If NULL is returned, then the message buffer cannot be created because there is insufficient heap memory available for FreeRTOS to allocate the message buffer data structures and storage area. A non-NULL value being returned indicates that the message buffer has been created successfully - the returned value should be stored as the handle to the created message buffer.
**xMessageBufferCreateStaticWithCallback** \( \text{xBufferSizeBytes, pucMessageBufferStorageArea, pxStaticMessageBuffer, pxSendCompletedCallback, pxReceiveCompletedCallback} \)

Creates a new message buffer using statically allocated memory. See `xMessageBufferCreate()` for a version that uses dynamically allocated memory.

**Example use:**

```c
// Used to dimension the array used to hold the messages. The available space will actually be one less than this, so 999.
#define STORAGE_SIZE_BYTES 1000

// Defines the memory that will actually hold the messages within the message buffer.
static uint8_t ucStorageBuffer[ STORAGE_SIZE_BYTES ];

// The variable used to hold the message buffer structure.
StaticMessageBuffer_t xMessageBufferStruct;

void MyFunction( void )
{
    MessageBufferHandle_t xMessageBuffer;

    xMessageBuffer = xMessageBufferCreateStatic( sizeof( ucStorageBuffer ), ucStorageBuffer, &xMessageBufferStruct );

    // As neither the pucMessageBufferStorageArea or pxStaticMessageBuffer parameters were NULL, xMessageBuffer will not be NULL, and can be used to reference the created message buffer in other message buffer API calls.
    // Other code that uses the message buffer can go here.
}
```

**Parameters**

- **xBufferSizeBytes** – The size, in bytes, of the buffer pointed to by the `pucMessageBufferStorageArea` parameter. When a message is written to the message buffer an additional `sizeof(size_t)` bytes are also written to store the message’s length. `sizeof(size_t)` is typically 4 bytes on a 32-bit architecture, so on most 32-bit architecture a 10 byte message will take up 14 bytes of message buffer space. The maximum number of bytes that can be stored in the message buffer is actually `(xBufferSizeBytes - 1)`.

- **pucMessageBufferStorageArea** – Must point to a `uint8_t` array that is at least `xBufferSizeBytes` big. This is the array to which messages are copied when they are written to the message buffer.

- **pxStaticMessageBuffer** – Must point to a variable of type `StaticMessageBuffer_t`, which will be used to hold the message buffer’s data structure.

- **pxSendCompletedCallback** – Callback invoked when a new message is sent to the message buffer. If the parameter is NULL or `xMessageBufferCreate()` is called without the parameter, then it will use the default implementation provided by `shSEND_COMPLETED` macro. To enable the callback, configuration `USE_SB_COMPLETED_CALLBACK` must be set to 1 in `FreeRTOSConfig.h`.

- **pxReceiveCompletedCallback** – Callback invoked when a message is read from a message buffer. If the parameter is NULL or `xMessageBufferCreate()` is called without the parameter, it will use the default implementation provided by `shRECEIVE_COMPLETED` macro. To enable the callback, configuration `USE_SB_COMPLETED_CALLBACK` must be set to 1 in `FreeRTOSConfig.h`.

**Returns**

If the message buffer is created successfully then a handle to the created message buffer is returned. If either `pucMessageBufferStorageArea` or `pxStaticmessageBuffer` are NULL then NULL is returned.
**Chapter 2. API Reference**

**xMessageBufferGetStaticBuffers** (xMessageBuffer, ppucMessageBufferStorageArea, ppxStaticMessageBuffer)

Retrieve pointers to a statically created message buffer’s data structure buffer and storage area buffer. These are the same buffers that are supplied at the time of creation.

**Parameters**

- **xMessageBuffer** – The message buffer for which to retrieve the buffers.
- **ppucMessageBufferStorageArea** – Used to return a pointer to the message buffer’s storage area buffer.
- **ppxStaticMessageBuffer** – Used to return a pointer to the message buffer’s data structure buffer.

**Returns**

- pdTRUE if buffers were retrieved, pdFALSE otherwise.

**xMessageBufferSend** (xMessageBuffer, pvTxData, xDataLengthBytes, xTicksToWait)

Sends a discrete message to the message buffer. The message can be any length that fits within the buffer’s free space, and is copied into the buffer.

: Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as xMessageBufferSend()) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as xMessageBufferRead()) inside a critical section and set the receive block time to 0.

Use xMessageBufferSend() to write to a message buffer from a task. Use xMessageBufferSendFromISR() to write to a message buffer from an interrupt service routine (ISR).

**Example use:**

```c
void vAFunction( MessageBufferHandle_t xMessageBuffer )
{
    size_t xBytesSent;
    uint8_t ucArrayToSend[] = { 0, 1, 2, 3 };
    char *pcStringToSend = "String to send";
    const TickType_t x100ms = pdMS_TO_TICKS( 100 );

    // Send an array to the message buffer, blocking for a maximum of 100ms to
    // wait for enough space to be available in the message buffer.
    xBytesSent = xMessageBufferSend( xMessageBuffer, ( void * ) ucArrayToSend, _
                                     sizeof( ucArrayToSend ), x100ms );

    if( xBytesSent != sizeof( ucArrayToSend ) )
    {
        // The call to xMessageBufferSend() times out before there was enough
        // space in the buffer for the data to be written.
    }

    // Send the string to the message buffer. Return immediately if there is
    // not enough space in the buffer.
    xBytesSent = xMessageBufferSend( xMessageBuffer, ( void * ) pcStringToSend, _
                                      strlen( pcStringToSend ), 0 );

    if( xBytesSent != strlen( pcStringToSend ) )
    {
        // The string could not be added to the message buffer because there was
        // not enough free space in the buffer.
    }
}
```
Parameters

• **xMessageBuffer** – The handle of the message buffer to which a message is being sent.
• **pvTxData** – A pointer to the message that is to be copied into the message buffer.
• **xDataLengthBytes** – The length of the message. That is, the number of bytes to copy from pvTxData into the message buffer. When a message is written to the message buffer an additional sizeof(size_t) bytes are also written to store the message’s length. sizeof(size_t) is typically 4 bytes on a 32-bit architecture, so on most 32-bit architecture setting xDataLengthBytes to 20 will reduce the free space in the message buffer by 24 bytes (20 bytes of message data and 4 bytes to hold the message length).
• **xTicksToWait** – The maximum amount of time the calling task should remain in the Blocked state to wait for enough space to become available in the message buffer, should the message buffer have insufficient space when xMessageBufferSend() is called. The calling task will never block if xTicksToWait is zero. The block time is specified in tick intervals, so the absolute time it represents is dependent on the tick frequency. The macro pdMS_TO_TICKS() can be used to convert a time specified in milliseconds into a time specified in ticks. Setting xTicksToWait to portMAX_DELAY will cause the task to wait indefinitely (without timing out), provided INCLUDE_vTaskSuspend is set to 1 in FreeRTOSConfig.h. Tasks do not use any CPU time when they are in the Blocked state.

Returns

The number of bytes written to the message buffer. If the call to xMessageBufferSend() times out before there was enough space to write the message into the message buffer then zero is returned. If the call did not time out then xDataLengthBytes is returned.

*xMessageBufferSendFromISR*(xMessageBuffer, pvTxData, xDataLengthBytes, pxHigherPriorityTaskWoken)

Interrupt safe version of the API function that sends a discrete message to the message buffer. The message can be any length that fits within the buffer’s free space, and is copied into the buffer.

: Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as xMessageBufferSend()) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as xMessageBufferRead()) inside a critical section and set the receive block time to 0.

Use xMessageBufferSend() to write to a message buffer from a task. Use xMessageBufferSendFromISR() to write to a message buffer from an interrupt service routine (ISR).

Example use:

```c
// A message buffer that has already been created.
MessageBufferHandle_t xMessageBuffer;

void vAnInterruptServiceRoutine( void )
{
    size_t xBytesSent;
    char* pcStringToSend = "String to send";
    BaseType_t xHigherPriorityTaskWoken = pdFALSE; // Initialised to pdFALSE.

    // Attempt to send the string to the message buffer.
    xBytesSent = xMessageBufferSendFromISR( xMessageBuffer,
                                        ( void* ) pcStringToSend,
                                        strlen( pcStringToSend ),
                                        xHigherPriorityTaskWoken );

    if( xBytesSent != strlen( pcStringToSend ) )
    {
        // Code here....
    }
```

(continues on next page)
// The string could not be added to the message buffer because there was
// not enough free space in the buffer.
{
}

// If xHigherPriorityTaskWoken was set to pdTRUE inside
// xMessageBufferSendFromISR() then a task that has a priority above the
// priority of the currently executing task was unblocked and a context
// switch should be performed to ensure the ISR returns to the unblocked
// task. In most FreeRTOS ports this is done by simply passing
// xHigherPriorityTaskWoken into portYIELD_FROM_ISR(), which will test the
// variables value, and perform the context switch if necessary. Check the
// documentation for the port in use for port specific instructions.
portYIELD_FROM_ISR(xHigherPriorityTaskWoken);
}

Parameters

• **xMessageBuffer** – The handle of the message buffer to which a message is being sent.
• **pvTxData** – A pointer to the message that is to be copied into the message buffer.
• **xDataLengthBytes** – The length of the message. That is, the number of bytes to copy from pvTxData into the message buffer. When a message is written to the message buffer an additional sizeof (size_t) bytes are also written to store the message’s length. sizeof (size_t) is typically 4 bytes on a 32-bit architecture, so on most 32-bit architecture setting xDataLengthBytes to 20 will reduce the free space in the message buffer by 24 bytes (20 bytes of message data and 4 bytes to hold the message length).
• **pxHigherPriorityTaskWoken** – It is possible that a message buffer will have a task blocked on it waiting for data. Calling xMessageBufferSendFromISR() can make data available, and so cause a task that was waiting for data to leave the Blocked state. If calling xMessageBufferSendFromISR() causes a task to leave the Blocked state, and the unblocked task has a priority higher than the currently executing task (the task that was interrupted), then, internally, xMessageBufferSendFromISR() will set *pxHigherPriorityTaskWoken to pdTRUE. If xMessageBufferSendFromISR() sets this value to pdTRUE, then normally a context switch should be performed before the interrupt is exited. This will ensure that the interrupt returns directly to the highest priority Ready state task. *pxHigherPriorityTaskWoken should be set to pdFALSE before it is passed into the function. See the code example below for an example.

Returns The number of bytes actually written to the message buffer. If the message buffer didn’t have enough free space for the message to be stored then 0 is returned, otherwise xDataLengthBytes is returned.

**xMessageBufferReceive** (xMessageBuffer, pvRxData, xBufferLengthBytes, xTicksToWait)

Receives a discrete message from a message buffer. Messages can be of variable length and are copied out of the buffer.

: Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as xMessageBufferSend()) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as xMessageBufferRead()) inside a critical section and set the receive block time to 0.

Use xMessageBufferReceive() to read from a message buffer from a task. Use xMessageBufferReceiveFromISR() to read from a message buffer from an interrupt service routine (ISR).

Example use:
```c
void vAPFunction( MessageBuffer_t xMessageBuffer )
{
    uint8_t ucRxData[ 20 ];
    size_t xReceivedBytes;
    const TickType_t xBlockTime = pdMS_TO_TICKS( 20 );

    // Receive the next message from the message buffer. Wait in the Blocked
    // state (so not using any CPU processing time) for a maximum of 100ms for
    // a message to become available.
    xReceivedBytes = xMessageBufferReceive( xMessageBuffer,
                                          ( void * ) ucRxData,
                                          sizeof( ucRxData ),
                                          xBlockTime );

    if( xReceivedBytes > 0 )
    {
        // A ucRxData contains a message that is xReceivedBytes long. Process
        // the message here....
    }
}
```

**Parameters**

- **xMessageBuffer** – The handle of the message buffer from which a message is being received.
- **pvRxData** – A pointer to the buffer into which the received message is to be copied.
- **xBufferLengthBytes** – The length of the buffer pointed to by the pvRxData parameter. This sets the maximum length of the message that can be received. If xBufferLengthBytes is too small to hold the next message then the message will be left in the message buffer and 0 will be returned.
- **xTicksToWait** – The maximum amount of time the task should remain in the Blocked state to wait for a message, should the message buffer be empty. xMessageBufferReceive() will return immediately if xTicksToWait is zero and the message buffer is empty. The block time is specified in tick periods, so the absolute time it represents is dependent on the tick frequency. The macro pdMS_TO_TICKS() can be used to convert a time specified in milliseconds into a time specified in ticks. Setting xTicksToWait to portMAX_DELAY will cause the task to wait indefinitely (without timing out), provided INCLUDE_vTaskSuspend is set to 1 in FreeRTOSConfig.h. Tasks do not use any CPU time when they are in the Blocked state.

**Returns** The length, in bytes, of the message read from the message buffer, if any. If xMessageBufferReceive() times out before a message became available then zero is returned. If the length of the message is greater than xBufferLengthBytes then the message will be left in the message buffer and zero is returned.

**xMessageBufferReceiveFromISR** (xMessageBuffer, pvRxData, xBufferLengthBytes, pxHigherPriorityTaskWoken)

An interrupt safe version of the API function that receives a discrete message from a message buffer. Messages can be of variable length and are copied out of the buffer.

: Uniquely among FreeRTOS objects, the stream buffer implementation (so also the message buffer implementation, as message buffers are built on top of stream buffers) assumes there is only one task or interrupt that will write to the buffer (the writer), and only one task or interrupt that will read from the buffer (the reader). It is safe for the writer and reader to be different tasks or interrupts, but, unlike other FreeRTOS objects, it is not safe to have multiple different writers or multiple different readers. If there are to be multiple different writers then the application writer must place each call to a writing API function (such as xMessageBufferSend()) inside a critical section and set the send block time to 0. Likewise, if there are to be multiple different readers then the application writer must place each call to a reading API function (such as xMessageBufferRead()) inside a critical section and set the receive block time to 0.

Use xMessageBufferReceive() to read from a message buffer from a task. Use xMessageBufferReceiver-
FromISR() to read from a message buffer from an interrupt service routine (ISR).

Example use:

```c
// A message buffer that has already been created.
MessageBuffer_t xMessageBuffer;

void vAnInterruptServiceRoutine( void )
{
    uint8_t ucRxData[ 20 ];
    size_t xReceivedBytes;
    BaseType_t xHigherPriorityTaskWoken = pdFALSE; // Initialised to pdFALSE.

    // Receive the next message from the message buffer.
    xReceivedBytes = xMessageBufferReceiveFromISR( xMessageBuffer,
        ( void * ) ucRxData,
        sizeof( ucRxData ),
        &xHigherPriorityTaskWoken );
    if( xReceivedBytes > 0 )
    {
        // A ucRxData contains a message that is xReceivedBytes long. Process
        // the message here....
    }

    // If xHigherPriorityTaskWoken was set to pdTRUE inside
    // xMessageBufferReceiveFromISR() then a task that has a priority above the
    // priority of the currently executing task was unblocked and a context
    // switch should be performed to ensure the ISR returns to the unblocked
    // task. In most FreeRTOS ports this is done by simply passing
    // xHigherPriorityTaskWoken into portYIELD_FROM_ISR(), which will test the
    // variables value, and perform the context switch if necessary. Check the
    // documentation for the port in use for port specific instructions.
    portYIELD_FROM_ISR( xHigherPriorityTaskWoken );
}
```

**Parameters**
- `xMessageBuffer` – The handle of the message buffer from which a message is being received.
- `pvRxData` – A pointer to the buffer into which the received message is to be copied.
- `xBufferLengthBytes` – The length of the buffer pointed to by the `pvRxData` parameter. This sets the maximum length of the message that can be received. If `xBufferLengthBytes` is too small to hold the next message then the message will be left in the message buffer and 0 will be returned.
- `pxHigherPriorityTaskWoken` – It is possible that a message buffer will have a task blocked on it waiting for space to become available. Calling `xMessageBufferReceiveFromISR()` can make space available, and so cause a task that is waiting for space to leave the Blocked state. If calling `xMessageBufferReceiveFromISR()` causes a task to leave the Blocked state, and the unblocked task has a priority higher than the currently executing task (the task that was interrupted), then, internally, `xMessageBufferReceiveFromISR()` will set `pxHigherPriorityTaskWoken` to `pdTRUE`. If `xMessageBufferReceiveFromISR()` sets this value to `pdTRUE`, then normally a context switch should be performed before the interrupt is exited. That will ensure the interrupt returns directly to the highest priority Ready state task. `pxHigherPriorityTaskWoken` should be set to `pdFALSE` before it is passed into the function. See the code example below for an example.

**Returns** The length, in bytes, of the message read from the message buffer, if any.

---

`vMessageBufferDelete(xMessageBuffer)`

Deletes a message buffer that was previously created using a call to `xMessageBufferCreate()` or `xMessage-`
BufferCreateStatic(). If the message buffer was created using dynamic memory (that is, by xMessageBufferCreate()), then the allocated memory is freed.

A message buffer handle must not be used after the message buffer has been deleted.

**Parameters**
- `xMessageBuffer` – The handle of the message buffer to be deleted.

**xMessageBufferIsFull (xMessageBuffer)**
Tests to see if a message buffer is full. A message buffer is full if it cannot accept any more messages, of any size, until space is made available by a message being removed from the message buffer.

**Parameters**
- `xMessageBuffer` – The handle of the message buffer being queried.

**Returns**
- `pdTRUE` if the message buffer referenced by `xMessageBuffer` is full then `pdTRUE` is returned.
- Otherwise `pdFALSE` is returned.

**xMessageBufferIsEmpty (xMessageBuffer)**
Tests to see if a message buffer is empty (does not contain any messages).

**Parameters**
- `xMessageBuffer` – The handle of the message buffer being queried.

**Returns**
- `pdTRUE` if the message buffer referenced by `xMessageBuffer` is empty then `pdTRUE` is returned.
- Otherwise `pdFALSE` is returned.

**xMessageBufferReset (xMessageBuffer)**
Resets a message buffer to its initial empty state, discarding any message it contained.

A message buffer can only be reset if there are no tasks blocked on it.

**Parameters**
- `xMessageBuffer` – The handle of the message buffer being reset.

**Returns**
- `pdPASS` if the message buffer was reset then `pdPASS` is returned.
- If the message buffer could not be reset because either there was a task blocked on the message queue to wait for space to become available, or to wait for a message to be available, then `pdFAIL` is returned.

**xMessageBufferSpaceAvailable (xMessageBuffer)**

```c
size_t xMessageBufferSpaceAvailable( MessageBufferHandle_t xMessageBuffer );
```

Returns the number of bytes of free space in the message buffer.

**Parameters**
- `xMessageBuffer` – The handle of the message buffer being queried.

**Returns**
- The number of bytes that can be written to the message buffer before the message buffer would be full. When a message is written to the message buffer an additional `sizeof(size_t)` bytes are also written to store the message’s length. `sizeof(size_t)` is typically 4 bytes on a 32-bit architecture, so if `xMessageBufferSpaceAvailable()` returns 10, then the size of the largest message that can be written to the message buffer is 6 bytes.

**xMessageBufferSpacesAvailable (xMessageBuffer)**

**xMessageBufferNextLengthBytes (xMessageBuffer)**
Returns the length (in bytes) of the next message in a message buffer. Useful if `xMessageBufferReceive()` returned 0 because the size of the buffer passed into `xMessageBufferReceive()` was too small to hold the next message.

**Parameters**
- `xMessageBuffer` – The handle of the message buffer being queried.

**Returns**
- The length (in bytes) of the next message in the message buffer, or 0 if the message buffer is empty.
**xMessageBufferSendCompletedFromISR** (xMessageBuffer, pxHigherPriorityTaskWoken)

For advanced users only.

The sbSEND_COMPLETED() macro is called from within the FreeRTOS APIs when data is sent to a message buffer or stream buffer. If there was a task that was blocked on the message or stream buffer waiting for data to arrive then the sbSEND_COMPLETED() macro sends a notification to the task to remove it from the Blocked state. xMessageBufferSendCompletedFromISR() does the same thing. It is provided to enable application writers to implement their own version of sbSEND_COMPLETED(), and MUST NOT BE USED AT ANY OTHER TIME.

See the example implemented in FreeRTOS/Demo/Minimal/MessageBufferAMP.c for additional information.

**Parameters**

- **xMessageBuffer** – The handle of the stream buffer to which data was written.
- **pxHigherPriorityTaskWoken** – *pxHigherPriorityTaskWoken should be initialised to pdFALSE before it is passed into xMessageBufferSendCompletedFromISR(). If calling xMessageBufferSendCompletedFromISR() removes a task from the Blocked state, and the task has a priority above the priority of the currently running task, then *pxHigherPriorityTaskWoken will get set to pdTRUE indicating that a context switch should be performed before exiting the ISR.

**Returns**

If a task was removed from the Blocked state then pdTRUE is returned. Otherwise pdFALSE is returned.

**xMessageBufferReceiveCompletedFromISR** (xMessageBuffer, pxHigherPriorityTaskWoken)

For advanced users only.

The sbRECEIVE_COMPLETED() macro is called from within the FreeRTOS APIs when data is read out of a message buffer or stream buffer. If there was a task that was blocked on the message or stream buffer waiting for data to arrive then the sbRECEIVE_COMPLETED() macro sends a notification to the task to remove it from the Blocked state. xMessageBufferReceiveCompletedFromISR() does the same thing. It is provided to enable application writers to implement their own version of sbRECEIVE_COMPLETED(), and MUST NOT BE USED AT ANY OTHER TIME.

See the example implemented in FreeRTOS/Demo/Minimal/MessageBufferAMP.c for additional information.

**Parameters**

- **xMessageBuffer** – The handle of the stream buffer from which data was read.
- **pxHigherPriorityTaskWoken** – *pxHigherPriorityTaskWoken should be initialised to pdFALSE before it is passed into xMessageBufferReceiveCompletedFromISR(). If calling xMessageBufferReceiveCompletedFromISR() removes a task from the Blocked state, and the task has a priority above the priority of the currently running task, then *pxHigherPriorityTaskWoken will get set to pdTRUE indicating that a context switch should be performed before exiting the ISR.

**Returns**

If a task was removed from the Blocked state then pdTRUE is returned. Otherwise pdFALSE is returned.

**Type Definitions**

```c
typedef StreamBufferHandle_t MessageBufferHandle_t
```

Type by which message buffers are referenced. For example, a call to xMessageBufferCreate() returns an MessageBufferHandle_t variable that can then be used as a parameter to xMessageBufferSend(), xMessageBufferReceive(), etc. Message buffer is essentially built as a stream buffer hence its handle is also set to same type as a stream buffer handle.

**2.10.13 FreeRTOS (Supplemental Features)**
ESP-IDF provides multiple features to supplement the features offered by FreeRTOS. These supplemental features are available on all FreeRTOS implementations supported by ESP-IDF (i.e., ESP-IDF FreeRTOS and Amazon SMP FreeRTOS). This document describes these supplemental features and is split into the following sections:

Contents

- FreeRTOS (Supplemental Features)
  - Overview
  - Ring Buffers
  - ESP-IDF Tick and Idle Hooks
  - TLSP Deletion Callbacks
  - IDF Additional API
  - Component Specific Properties
- API Reference

Overview

ESP-IDF adds various new features to supplement the capabilities of FreeRTOS as follows:

- **Ring buffers**: Ring buffers provide a FIFO buffer that can accept entries of arbitrary lengths.
- **ESP-IDF Tick and Idle Hooks**: ESP-IDF provides multiple custom tick interrupt hooks and idle task hooks that are more numerous and more flexible when compared to FreeRTOS tick and idle hooks.
- **Thread Local Storage Pointer (TLSP) Deletion Callbacks**: TLSP Deletion callbacks are run automatically when a task is deleted, thus allowing users to clean up their TLSPs automatically.
- **IDF Additional API**: ESP-IDF specific functions added to augment the features of FreeRTOS.
- **Component Specific Properties**: Currently added only one component specific property ORIG_INCLUDE_PATH.

Ring Buffers

FreeRTOS provides stream buffers and message buffers as the primary mechanisms to send arbitrarily sized data between tasks and ISRs. However, FreeRTOS stream buffers and message buffers have the following limitations:

- Strictly single sender and single receiver
- Data is passed by copy
- Unable to reserve buffer space for a deferred send (i.e., send acquire)

Therefore, ESP-IDF provides a separate ring buffer implementation to address the issues above.

ESP-IDF ring buffers are strictly FIFO buffers that supports arbitrarily sized items. Ring buffers are a more memory efficient alternative to FreeRTOS queues in situations where the size of items is variable. The capacity of a ring buffer is not measured by the number of items it can store, but rather by the amount of memory used for storing items.

The ring buffer provides APIs to send an item, or to allocate space for an item in the ring buffer to be filled manually by the user. For efficiency reasons, **items are always retrieved from the ring buffer by reference**. As a result, all retrieved items **must also be returned** to the ring buffer by using vRingbufferReturnItem() or vRingbufferReturnItemFromISR(), in order for them to be removed from the ring buffer completely.

The ring buffers are split into the three following types:

- **No-Split buffers** guarantee that an item is stored in contiguous memory and does not attempt to split an item under any circumstances. Use No-Split buffers when items must occupy contiguous memory. **Only this buffer type allows reserving buffer space for deferred sending.** Refer to the documentation of the functions xRingbufferSendAcquire() and xRingbufferSendComplete() for more details.

- **Allow-Split buffers** allow an item to be split in two parts when wrapping around the end of the buffer if there is enough space at the tail and the head of the buffer combined to store the item. Allow-Split buffers are more memory efficient than No-Split buffers but can return an item in two parts when retrieving.
**Byte buffers** do not store data as separate items. All data is stored as a sequence of bytes, and any number of bytes can be sent or retrieved each time. Use byte buffers when separate items do not need to be maintained, e.g., a byte stream.

**Note:** No-Split buffers and Allow-Split buffers always store items at 32-bit aligned addresses. Therefore, when retrieving an item, the item pointer is guaranteed to be 32-bit aligned. This is useful especially when you need to send some data to the DMA.

**Note:** Each item stored in No-Split or Allow-Split buffers requires an additional 8 bytes for a header. Item sizes are also rounded up to a 32-bit aligned size, i.e., multiple of 4 bytes. However the true item size is recorded within the header. The sizes of No-Split and Allow-Split buffers will also be rounded up when created.

**Usage** The following example demonstrates the usage of `xRingbufferCreate()` and `xRingbufferSend()` to create a ring buffer and then send an item to it:

```c
#include "freertos/ringbuf.h"
static char tx_item[] = "test_item";
...

//Create ring buffer
RingbufHandle_t buf_handle;
buf_handle = xRingbufferCreate(1028, RINGBUF_TYPE_NOSPLIT);
if (buf_handle == NULL) {
  printf("Failed to create ring buffer\n");
}

//Send an item
UBaseType_t res = xRingbufferSend(buf_handle, tx_item, sizeof(tx_item), pdMS_TO_TICKS(1000));
if (res != pdTRUE) {
  printf("Failed to send item\n");
}
```

The following example demonstrates the usage of `xRingbufferSendAcquire()` and `xRingbufferSendComplete()` instead of `xRingbufferSend()` to acquire memory on the ring buffer (of type `RINGBUF_TYPE_NOSPLIT`) and then send an item to it. This adds one more step, but allows getting the address of the memory to write to, and writing to the memory yourself.

```c
#include "freertos/ringbuf.h"
#include "soc/lldesc.h"

typedef struct {
  lldesc_t dma_desc;
  uint8_t buf[1];
} dma_item_t;

#define DMA_ITEM_SIZE(N) (sizeof(lldesc_t)+(((N)+3)&(~3)))
...

//Retrieve space for DMA descriptor and corresponding data buffer
//This has to be done with SendAcquire, or the address may be different when we copy
dma_item_t item;
UBaseType_t res = xRingbufferSendAcquire(buf_handle, &item, DMA_ITEM_SIZE(buffer_size), pdMS_TO_TICKS(1000));
```

(continues on next page)
if (res != pdTRUE) {
    printf("Failed to acquire memory for item\n");
}
item->dma_desc = (lldesc_t) {
    .size = buffer_size,
    .length = buffer_size,
    .eof = 0,
    .owner = 1,
    .buf = &item->buf,
};
//Actually send to the ring buffer for consumer to use
res = xRingbufferSendComplete(buf_handle, item);
if (res != pdTRUE) {
    printf("Failed to send item\n");
}

The following example demonstrates retrieving and returning an item from a No-Split ring buffer using xRingbufferReceive() and vRingbufferReturnItem()

...  
//Receive an item from no-split ring buffer
size_t item_size;
char *item = (char *)xRingbufferReceive(buf_handle, &item_size, pdMS_TO_TICKS(1000));

//Check received item
if (item != NULL) {
    //Print item
    for (int i = 0; i < item_size; i++) {
        printf("%c", item[i]);
    }
    printf("\n");
    //Return Item
    vRingbufferReturnItem(buf_handle, (void *)item);
} else {
    //Failed to receive item
    printf("Failed to receive item\n");
}

The following example demonstrates retrieving and returning an item from an Allow-Split ring buffer using xRingbufferReceiveSplit() and vRingbufferReturnItem()

...  
//Receive an item from allow-split ring buffer
size_t item_size1, item_size2;
char *item1, *item2;
BaseType_t ret = xRingbufferReceiveSplit(buf_handle, (void **)item1, (void**)item2, &item_size1, &item_size2, pdMS_TO_TICKS(1000));

//Check received item
if (ret == pdTRUE && item1 != NULL) {
    for (int i = 0; i < item_size1; i++) {
        printf("%c", item1[i]);
    }
    vRingbufferReturnItem(buf_handle, (void *)item1);
    //Check if item was split
    if (item2 != NULL) {
        for (int i = 0; i < item_size2; i++) {
            printf("%c", item2[i]);
    }
}
The following example demonstrates retrieving and returning an item from a byte buffer using `xRingbufferReceiveUpTo()` and `vRingbufferReturnItem()`:

```c
//Receive data from byte buffer
size_t item_size;
char *item = (char *)xRingbufferReceiveUpTo(buf_handle, &item_size, pdMS_TO_TICKS(1000), sizeof(tx_item));

//Check received data
if (item != NULL) {
    //Print item
    for (int i = 0; i < item_size; i++) {
        printf("%c", item[i]);
    }
    printf("\n");
    //Return Item
    vRingbufferReturnItem(buf_handle, (void *)item);
} else {
    //Failed to receive item
    printf("Failed to receive item\n");
}
```

For ISR safe versions of the functions used above, call `xRingbufferSendFromISR()`, `xRingbufferReceiveFromISR()`, `xRingbufferReceiveSplitFromISR()`, `xRingbufferReceiveUpToFromISR()`, and `vRingbufferReturnItemFromISR()`.

**Note:** Two calls to `RingbufferReceive[UpTo][FromISR]()` are required if the bytes wraps around the end of the ring buffer.

### Sending to Ring Buffer

The following diagrams illustrate the differences between No-Split and Allow-Split buffers as compared to byte buffers with regard to sending items or data. The diagrams assume that three items of sizes 18, 3, and 27 bytes are sent respectively to a buffer of 128 bytes:

![Sending items to No-Split or Allow-Split ring buffers](image)

Fig. 37: Sending items to No-Split or Allow-Split ring buffers

For No-Split and Allow-Split buffers, a header of 8 bytes precedes every data item. Furthermore, the space occupied by each item is **rounded up to the nearest 32-bit aligned size** in order to maintain overall 32-bit alignment.
However, the true size of the item is recorded inside the header which will be returned when the item is retrieved. Referring to the diagram above, the 18, 3, and 27 byte items are **rounded up to 20, 4, and 28 bytes** respectively. An 8 byte header is then added in front of each item.

Referring to the diagram above, the 18, 3, and 27 byte items are sequentially written to the byte buffer and **merged into a single item of 48 bytes**.

**Using SendAcquire and SendComplete** Items in No-Split buffers are acquired (by SendAcquire) in strict FIFO order and must be sent to the buffer by SendComplete for the data to be accessible by the consumer. Multiple items can be sent or acquired without calling SendComplete, and the items do not necessarily need to be completed in the order they were acquired. However, the receiving of data items must occur in FIFO order, therefore not calling SendComplete for the earliest acquired item prevents the subsequent items from being received.

The following diagrams illustrate what will happen when SendAcquire and SendComplete do not happen in the same order. At the beginning, there is already a data item of 16 bytes sent to the ring buffer. Then SendAcquire is called to acquire space of 20, 8, 24 bytes on the ring buffer.

After that, we fill (use) the buffers, and send them to the ring buffer by SendComplete in the order of 8, 24, 20. When 8 bytes and 24 bytes data are sent, the consumer still can only get the 16 bytes data item. Hence, if SendComplete is not called for the 20 bytes, it will not be available, nor will the data items following the 20 bytes item.

When the 20 bytes item is finally completed, all the 3 data items can be received now, in the order of 20, 8, 24 bytes, right after the 16 bytes item existing in the buffer at the beginning.

Allow-Split buffers and byte buffers do not allow using SendAcquire or SendComplete since acquired buffers are required to be complete (not wrapped).

**Wrap Around** The following diagrams illustrate the differences between No-Split, Allow-Split, and byte buffers when a sent item requires a wrap around. The diagrams assume a buffer of 128 bytes with 56 bytes of free space that wraps around and a sent item of 28 bytes.
Chapter 2. API Reference

Fig. 40: Wraparound in No-Split buffers

No-Split buffers only store an item in continuous free space and do not split an item under any circumstances. When the free space at the tail of the buffer is insufficient to completely store the item and its header, the free space at the tail will be marked as dummy data. The buffer will then wrap around and store the item in the free space at the head of the buffer.

Referring to the diagram above, the 16 bytes of free space at the tail of the buffer is insufficient to store the 28 byte item. Therefore, the 16 bytes is marked as dummy data and the item is written to the free space at the head of the buffer instead.

Fig. 41: Wraparound in Allow-Split buffers

Allow-Split buffers will attempt to split the item into two parts when the free space at the tail of the buffer is insufficient to store the item data and its header. Both parts of the split item will have their own headers, therefore incurring an extra 8 bytes of overhead.

Referring to the diagram above, the 16 bytes of free space at the tail of the buffer is insufficient to store the 28 byte item. Therefore, the item is split into two parts (8 and 20 bytes) and written as two parts to the buffer.

Note: Allow-Split buffers treat both parts of the split item as two separate items, therefore call xRingbufferReceiveSplit() instead of xRingbufferReceive() to receive both parts of a split item in a thread safe manner.

Fig. 42: Wraparound in byte buffers

Byte buffers store as much data as possible into the free space at the tail of buffer. The remaining data will then be stored in the free space at the head of the buffer. No overhead is incurred when wrapping around in byte buffers.

Referring to the diagram above, the 16 bytes of free space at the tail of the buffer is insufficient to completely store the 28 bytes of data. Therefore, the 16 bytes of free space is filled with data, and the remaining 12 bytes are written...
to the free space at the head of the buffer. The buffer now contains data in two separate continuous parts, and each continuous part is treated as a separate item by the byte buffer.

**Retrieving/Returning** The following diagrams illustrate the differences between No-Split and Allow-Split buffers as compared to byte buffers in retrieving and returning data:

Items in No-Split buffers and Allow-Split buffers are retrieved in strict FIFO order and must be returned for the occupied space to be freed. Multiple items can be retrieved before returning, and the items do not necessarily need to be returned in the order they were retrieved. However, the freeing of space must occur in FIFO order, therefore not returning the earliest retrieved item prevents the space of subsequent items from being freed.

Referring to the diagram above, the 16, 20, and 8 byte items are retrieved in FIFO order. However, the items are not returned in the order they were retrieved. First, the 20 byte item is returned followed by the 8 byte and the 16 byte items. The space is not freed until the first item, i.e., the 16 byte item is returned.

Byte buffers do not allow multiple retrievals before returning (every retrieval must be followed by a return before another retrieval is permitted). When using `xRingbufferReceive()` or `xRingbufferReceiveFromISR()`, all continuous stored data will be retrieved. `xRingbufferReceiveUpTo()` or `xRingbufferReceiveUpToFromISR()` can be used to restrict the maximum number of bytes retrieved. Since every retrieval must be followed by a return, the space is freed as soon as the data is returned.

Referring to the diagram above, the 38 bytes of continuous stored data at the tail of the buffer is retrieved, returned, and freed. The next call to `xRingbufferReceive()` or `xRingbufferReceiveFromISR()` then wraps around and does the same to the 30 bytes of continuous stored data at the head of the buffer.

**Ring Buffers with Queue Sets** Ring buffers can be added to FreeRTOS queue sets using `xRingbufferAddToQueueSetRead()` such that every time a ring buffer receives an item or data, the queue set is notified. Once
added to a queue set, every attempt to retrieve an item from a ring buffer should be preceded by a call to `xQueueSelectFromSet()`. To check whether the selected queue set member is the ring buffer, call `xRingbufferCanRead()`.

The following example demonstrates queue set usage with ring buffers:

```c
#include "freertos/queue.h"
#include "freertos/ringbuf.h"
...

//Create ring buffer and queue set
RingbufHandle_t buf_handle = xRingbufferCreate(1028, RINGBUF_TYPE_NOSPLIT);
QueueSetHandle_t queue_set = xQueueCreateSet(3);

//Add ring buffer to queue set
if (xRingbufferAddToQueueSetRead(buf_handle, queue_set) != pdTRUE) {
    printf("Failed to add to queue set\n");
}
...

//Block on queue set
QueueSetMemberHandle_t member = xQueueSelectFromSet(queue_set, pdMS_TO_TICKS(1000));

//Check if member is ring buffer
if (member != NULL && xRingbufferCanRead(buf_handle, member) == pdTRUE) {
    //Member is ring buffer, receive item from ring buffer
    size_t item_size;
    char *item = (char *)xRingbufferReceive(buf_handle, &item_size, 0);
    //Handle item...
} else { ...
}
```

**Ring Buffers with Static Allocation** The `xRingbufferCreateStatic()` can be used to create ring buffers with specific memory requirements (such as a ring buffer being allocated in external RAM). All blocks of memory used by a ring buffer must be manually allocated beforehand, then passed to the `xRingbufferCreateStatic()` to be initialized as a ring buffer. These blocks include the following:

- The ring buffer’s data structure of type `StaticRingbuffer_t`.
- The ring buffer’s storage area of size `xBufferSize`. Note that `xBufferSize` must be 32-bit aligned for No-Split and Allow-Split buffers.

The manner in which these blocks are allocated depends on the users requirements (e.g., all blocks being statically declared, or dynamically allocated with specific capabilities such as external RAM).

**Note:** When deleting a ring buffer created via `xRingbufferCreateStatic()`, the function `vRingbufferDelete()` will not free any of the memory blocks. This must be done manually by the user after `vRingbufferDelete()` is called.

The code snippet below demonstrates a ring buffer being allocated entirely in external RAM.

```c
#include "freertos/ringbuf.h"
#include "freertos/semphr.h"
#include "esp_heap_caps.h"
```
```
#define BUFFER_SIZE 400 //32-bit aligned size
#define BUFFER_TYPE RINGBUF_TYPE_NOSPLIT
...

//Allocate ring buffer data structure and storage area into external RAM
StaticRingbuffer_t *buffer_struct = (StaticRingbuffer_t *)heap_caps_malloc(sizeof(StaticRingbuffer_t), MALLOC_CAP_SPIRAM);
uint8_t *buffer_storage = (uint8_t *)heap_caps_malloc(sizeof(uint8_t) * BUFFER_SIZE, MALLOC_CAP_SPIRAM);

//Create a ring buffer with manually allocated memory
RingbufHandle_t handle = xRingbufferCreateStatic(BUFFER_SIZE, BUFFER_TYPE, buffer_, storage, buffer_struct);
...

//Delete the ring buffer after used
vRingbufferDelete(handle);

//Manually free all blocks of memory
free(buffer_struct);
free(buffer_storage);
```

**ESP-IDF Tick and Idle Hooks**

FreeRTOS allows applications to provide a tick hook and an idle hook at compile time:

- FreeRTOS tick hook can be enabled via the `CONFIG_FREERTOS_USE_TICK_HOOK` option. The application must provide the `void vApplicationTickHook( void )` callback.
- FreeRTOS idle hook can be enabled via the `CONFIG_FREERTOS_USE_IDLE_HOOK` option. The application must provide the `void vApplicationIdleHook( void )` callback.

However, the FreeRTOS tick hook and idle hook have the following drawbacks:

- The FreeRTOS hooks are registered at compile time
- Only one of each hook can be registered
- On multi-core targets, the FreeRTOS hooks are symmetric, meaning each core’s tick interrupt and idle tasks ends up calling the same hook

Therefore, ESP-IDF tick and idle hooks are provided to supplement the features of FreeRTOS tick and idle hooks. The ESP-IDF hooks have the following features:

- The hooks can be registered and deregistered at run-time
- Multiple hooks can be registered (with a maximum of 8 hooks of each type per core)
- On multi-core targets, the hooks can be asymmetric, meaning different hooks can be registered to each core

ESP-IDF hooks can be registered and deregistered using the following APIs:

- For tick hooks:
  - Register using `esp_register_freertos_tick_hook()` or `esp_register_freertos_tick_hook_for_cpu()`
  - Deregister using `esp_deregister_freertos_tick_hook()` or `esp_deregister_freertos_tick_hook_for_cpu()`
- For idle hooks:
  - Register using `esp_register_freertos_idle_hook()` or `esp_register_freertos_idle_hook_for_cpu()`
  - Deregister using `esp_deregister_freertos_idle_hook()` or `esp_deregister_freertos_idle_hook_for_cpu()`
Note: The tick interrupt stays active while the cache is disabled, therefore any tick hook (FreeRTOS or ESP-IDF) functions must be placed in internal RAM. Please refer to the SPI flash API documentation for more details.

TLSP Deletion Callbacks

Vanilla FreeRTOS provides a Thread Local Storage Pointers (TLSP) feature. These are pointers stored directly in the Task Control Block (TCB) of a particular task. TLSPs allow each task to have its own unique set of pointers to data structures. Vanilla FreeRTOS expects users to:

- set a task’s TLSPs by calling `vTaskSetThreadLocalStoragePointer()` after the task has been created.
- get a task’s TLSPs by calling `pvTaskGetThreadLocalStoragePointer()` during the task’s lifetime.
- free the memory pointed to by the TLSPs before the task is deleted.

However, there can be instances where users may want the freeing of TLSP memory to be automatic. Therefore, ESP-IDF provides the additional feature of TLSP deletion callbacks. These user-provided deletion callbacks are called automatically when a task is deleted, thus allowing the TLSP memory to be cleaned up without needing to add the cleanup logic explicitly to the code of every task.

The TLSP deletion callbacks are set in a similar fashion to the TLSPs themselves.

- `vTaskSetThreadLocalStoragePointerAndDelCallback()` sets both a particular TLSP and its associated callback.
- Calling the Vanilla FreeRTOS function `vTaskSetThreadLocalStoragePointer()` simply sets the TLSP’s associated Deletion Callback to `NULL`, meaning that no callback is called for that TLSP during task deletion.

When implementing TLSP callbacks, users should note the following:

- The callback must never attempt to block or yield and critical sections should be kept as short as possible.
- The callback is called shortly before a deleted task’s memory is freed. Thus, the callback can either be called from `vTaskDelete()` itself, or from the idle task.

IDF Additional API

The `freertos/esp_additions/include/freertos/idf_additions.h` header contains FreeRTOS-related helper functions added by ESP-IDF. Users can include this header via `#include "freertos/idf_additions.h"`.

Component Specific Properties

Besides standard component variables that are available with basic cmake build properties, FreeRTOS component also provides arguments (only one so far) for simpler integration with other modules:

- `ORIG_INCLUDE_PATH` - contains an absolute path to freertos root include folder. Thus instead of `#include "freertos/FreeRTOS.h"` you can refer to headers directly: `#include "FreeRTOS.h"`.

API Reference

Ring Buffer API

Header File

- `components/esp_ringbuf/include/freertos/ringbuf.h`
- This header file can be included with:
#include "freertos/ringbuf.h"

- This header file is a part of the API provided by the esp_ringbuf component. To declare that your component depends on esp_ringbuf, add the following to your CMakeLists.txt:

```
REQUIRES esp_ringbuf
```
or

```
PRIV_REQUIRES esp_ringbuf
```

## Functions

### RingbufHandle_t xRingbufferCreate

Create a ring buffer.

**Parameters**
- `xBuffersize` - [in] Size of the buffer in bytes. Note that items require space for a header in no-split/allow-split buffers
- `xBufferType` - [in] Type of ring buffer, see documentation.

**Returns**
A handle to the created ring buffer, or NULL in case of error.

### RingbufHandle_t xRingbufferCreateNoSplit

Create a ring buffer of type RINGBUF_TYPE_NOSPLIT for a fixed item size.

This API is similar to xRingbufferCreate(), but it will internally allocate additional space for the headers.

**Parameters**
- `xItemSize` - [in] Size of each item to be put into the ring buffer
- `xItemNum` - [in] Maximum number of items the buffer needs to hold simultaneously

**Returns**
A RingbufHandle_t handle to the created ring buffer, or NULL in case of error.

### RingbufHandle_t xRingbufferCreateStatic

Create a ring buffer but manually provide the required memory.

**Note:** xBuffersize of no-split/allow-split buffers MUST be 32-bit aligned.

**Parameters**
- `xBuffersize` - [in] Size of the buffer in bytes.
- `xBufferType` - [in] Type of ring buffer, see documentation
- `pucRingbufferStorage` - [in] Pointer to the ring buffer’s storage area. Storage area must have the same size as specified by xBuffersize
- `pxStaticRingbuffer` - [in] Pointer to a struct of type StaticRingbuffer_t which will be used to hold the ring buffer’s data structure

**Returns**
A handle to the created ring buffer

### BaseType_t xRingbufferSend

Insert an item into the ring buffer.

Attempt to insert an item into the ring buffer. This function will block until enough free space is available or until it times out.
Note: For no-split/allow-split ring buffers, the actual size of memory that the item will occupy will be rounded up to the nearest 32-bit aligned size. This is done to ensure all items are always stored in 32-bit aligned fashion.

Note: For no-split/allow-split buffers, an xItemSize of 0 will result in an item with no data being set (i.e., item only contains the header). For byte buffers, an xItemSize of 0 will simply return pdTRUE without copying any data.

Parameters
- xRingbuffer -[in] Ring buffer to insert the item into
- pvItem -[in] Pointer to data to insert. NULL is allowed if xItemSize is 0.
- xItemSize -[in] Size of data to insert.
- xTicksToWait -[in] Ticks to wait for room in the ring buffer.

Returns
- pdTRUE if succeeded
- pdFALSE on time-out or when the data is larger than the maximum permissible size of the buffer

BaseType_t xRingbufferSendFromISR(RingbufHandle_t xRingbuffer, const void *pvItem, size_t xItemSize, BaseType_t *pxHigherPriorityTaskWoken)

Insert an item into the ring buffer in an ISR.

Attempt to insert an item into the ring buffer from an ISR. This function will return immediately if there is insufficient free space in the buffer.

Note: For no-split/allow-split ring buffers, the actual size of memory that the item will occupy will be rounded up to the nearest 32-bit aligned size. This is done to ensure all items are always stored in 32-bit aligned fashion.

Note: For no-split/allow-split buffers, an xItemSize of 0 will result in an item with no data being set (i.e., item only contains the header). For byte buffers, an xItemSize of 0 will simply return pdTRUE without copying any data.

Parameters
- xRingbuffer -[in] Ring buffer to insert the item into
- pvItem -[in] Pointer to data to insert. NULL is allowed if xItemSize is 0.
- xItemSize -[in] Size of data to insert.
- pxHigherPriorityTaskWoken -[out] Value pointed to will be set to pdTRUE if the function woke up a higher priority task.

Returns
- pdTRUE if succeeded
- pdFALSE when the ring buffer does not have space.

BaseType_t xRingbufferSendAcquire(RingbufHandle_t xRingbuffer, void **ppvItem, size_t xItemSize, TickType_t xTicksToWait)

Acquire memory from the ring buffer to be written to by an external source and to be sent later.

Attempt to allocate buffer for an item to be sent into the ring buffer. This function will block until enough free space is available or until it times out.

The item, as well as the following items SendAcquire or Send after it, will not be able to be read from the ring buffer until this item is actually sent into the ring buffer.

Note: Only applicable for no-split ring buffers now, the actual size of memory that the item will occupy will
be rounded up to the nearest 32-bit aligned size. This is done to ensure all items are always stored in 32-bit aligned fashion.

**Note:** An xItemSize of 0 will result in a buffer being acquired, but the buffer will have a size of 0.

**Parameters**
- `xRingbuffer` - [in] Ring buffer to allocate the memory
- `ppvItem` - [out] Double pointer to memory acquired (set to NULL if no memory were retrieved)
- `xItemSize` - [in] Size of item to acquire.
- `xTicksToWait` - [in] Ticks to wait for room in the ring buffer.

**Returns**
- pdTRUE if succeeded
- pdFALSE on time-out or when the data is larger than the maximum permissible size of the buffer

BaseType_t `xRingbufferSendComplete` (RingbufHandle_t xRingbuffer, void *pvItem)
Actually send an item into the ring buffer allocated before by `xRingbufferSendAcquire`.

**Note:** Only applicable for no-split ring buffers. Only call for items allocated by `xRingbufferSendAcquire`.

**Parameters**
- `xRingbuffer` - [in] Ring buffer to insert the item into
- `pvItem` - [in] Pointer to item in allocated memory to insert.

**Returns**
- pdTRUE if succeeded
- pdFALSE if fail for some reason.

void *`xRingbufferReceive` (RingbufHandle_t xRingbuffer, size_t *pxItemSize, TickType_t xTicksToWait)
Retrieve an item from the ring buffer.

Attempt to retrieve an item from the ring buffer. This function will block until an item is available or until it times out.

**Note:** A call to vRingbufferReturnItem() is required after this to free the item retrieved.

**Note:** It is possible to receive items with a pxItemSize of 0 on no-split/allow split buffers.

**Parameters**
- `xRingbuffer` - [in] Ring buffer to retrieve the item from
- `pxItemSize` - [out] Pointer to a variable to which the size of the retrieved item will be written.
- `xTicksToWait` - [in] Ticks to wait for items in the ring buffer.

**Returns**
- Pointer to the retrieved item on success; *pxItemSize filled with the length of the item.
- NULL on timeout, *pxItemSize is untouched in that case.

void *`xRingbufferReceiveFromISR` (RingbufHandle_t xRingbuffer, size_t *pxItemSize)
Retrieve an item from the ring buffer in an ISR.
Attempt to retrieve an item from the ring buffer. This function returns immediately if there are no items available for retrieval.

**Note:** A call to `vRingbufferReturnItemFromISR()` is required after this to free the item retrieved.

**Note:** Byte buffers do not allow multiple retrievals before returning an item

**Note:** Two calls to `RingbufferReceiveFromISR()` are required if the bytes wrap around the end of the ring buffer.

**Note:** It is possible to receive items with a `pxItemSize` of 0 on no-split/allow split buffers.

### Parameters

- `xRingbuffer` - [in] Ring buffer to retrieve the item from
- `pxItemSize` - [out] Pointer to a variable to which the size of the retrieved item will be written.

### Returns

- Pointer to the retrieved item on success; `*pxItemSize` filled with the length of the item.
- NULL when the ring buffer is empty, `*pxItemSize` is untouched in that case.

```c
BaseType_t xRingbufferReceiveSplit(RingbufHandle_t xRingbuffer, void **ppvHeadItem, void **ppvTailItem, size_t *pxHeadItemSize, size_t *pxTailItemSize, TickType_t xTicksToWait)
```

Retrieve a split item from an allow-split ring buffer. Attempt to retrieve a split item from an allow-split ring buffer. If the item is not split, only a single item is retrieved. If the item is split, both parts will be retrieved. This function will block until an item is available or until it times out.

**Note:** Call(s) to `vRingbufferReturnItem()` is required after this to free up the item(s) retrieved.

**Note:** This function should only be called on allow-split buffers

**Note:** It is possible to receive items with a `pxItemSize` of 0 on allow split buffers.

### Parameters

- `xRingbuffer` - [in] Ring buffer to retrieve the item from
- `ppvHeadItem` - [out] Double pointer to first part (set to NULL if no items were retrieved)
- `ppvTailItem` - [out] Double pointer to second part (set to NULL if item is not split)
- `pxHeadItemSize` - [out] Pointer to size of first part (unmodified if no items were retrieved)
- `pxTailItemSize` - [out] Pointer to size of second part (unmodified if item is not split)
- `xTicksToWait` - [in] Ticks to wait for items in the ring buffer.

### Returns

- `pdTRUE` if an item (split or unsplit) was retrieved
- `pdFALSE` when no item was retrieved
BaseType_t xRingbufferReceiveSplitFromISR (RingbufHandle_t xRingbuffer, void **ppvHeadItem, void **ppvTailItem, size_t *pxHeadItemSize, size_t *pxTailItemSize)

Retrieve a split item from an allow-split ring buffer in an ISR.

Attempt to retrieve a split item from an allow-split ring buffer. If the item is not split, only a single item is retrieved. If the item is split, both parts will be retrieved. This function returns immediately if there are no items available for retrieval.

**Note:** Calls to vRingbufferReturnItemFromISR() is required after this to free up the item(s) retrieved.

**Note:** This function should only be called on allow-split buffers.

**Note:** It is possible to receive items with a pxItemSize of 0 on allow split buffers.

**Parameters**
- **xRingbuffer** – [in] Ring buffer to retrieve the item from
- **ppvHeadItem** – [out] Double pointer to first part (set to NULL if no items were retrieved)
- **ppvTailItem** – [out] Double pointer to second part (set to NULL if item is not split)
- **pxHeadItemSize** – [out] Pointer to size of first part (unmodified if no items were retrieved)
- **pxTailItemSize** – [out] Pointer to size of second part (unmodified if item is not split)

**Returns**
- pdTRUE if an item (split or unsplit) was retrieved
- pdFALSE when no item was retrieved

void *xRingbufferReceiveUpTo (RingbufHandle_t xRingbuffer, size_t *pxItemSize, TickType_t xTicksToWait, size_t xMaxSize)

Retrieve bytes from a byte buffer, specifying the maximum amount of bytes to retrieve.

Attempt to retrieve data from a byte buffer whilst specifying a maximum number of bytes to retrieve. This function will block until there is data available for retrieval or until it times out.

**Note:** A call to vRingbufferReturnItem() is required after this to free up the data retrieved.

**Note:** This function should only be called on byte buffers.

**Note:** Byte buffers do not allow multiple retrievals before returning an item.

**Note:** Two calls to RingbufferReceiveUpTo() are required if the bytes wrap around the end of the ring buffer.

**Parameters**
- **xRingbuffer** – [in] Ring buffer to retrieve the item from
- **pxItemSize** – [out] Pointer to a variable to which the size of the retrieved item will be written.
- **xTicksToWait** – [in] Ticks to wait for items in the ring buffer.
- **xMaxSize** – [in] Maximum number of bytes to return.
Returns

- Pointer to the retrieved item on success; *pxItemSize filled with the length of the item.
- NULL on timeout, *pxItemSize is untouched in that case.

void *xRingbufferReceiveUpToFromISR (RingbufHandle_t xRingbuffer, size_t *pxItemSize, size_t xMaxSize)

Retrieve bytes from a byte buffer, specifying the maximum amount of bytes to retrieve. Call this from an ISR. Attempt to retrieve bytes from a byte buffer whilst specifying a maximum number of bytes to retrieve. This function will return immediately if there is no data available for retrieval.

Note: A call to vRingbufferReturnItemFromISR() is required after this to free up the data received.

Note: This function should only be called on byte buffers

Note: Byte buffers do not allow multiple retrievals before returning an item

Parameters

- xRingbuffer –[in] Ring buffer to retrieve the item from
- pxItemSize –[out] Pointer to a variable to which the size of the retrieved item will be written.
- xMaxSize –[in] Maximum number of bytes to return. Size of 0 simply returns NULL.

Returns

- Pointer to the retrieved item on success; *pxItemSize filled with the length of the item.
- NULL when the ring buffer is empty, *pxItemSize is untouched in that case.

void vRingbufferReturnItem (RingbufHandle_t xRingbuffer, void *pvItem)

Return a previously-retrieved item to the ring buffer.

Note: If a split item is retrieved, both parts should be returned by calling this function twice

Parameters

- xRingbuffer –[in] Ring buffer the item was retrieved from
- pvItem –[in] Item that was received earlier

void vRingbufferReturnItemFromISR (RingbufHandle_t xRingbuffer, void *pvItem, BaseType_t *pxHigherPriorityTaskWoken)

Return a previously-retrieved item to the ring buffer from an ISR.

Note: If a split item is retrieved, both parts should be returned by calling this function twice

Parameters

- xRingbuffer –[in] Ring buffer the item was retrieved from
- pvItem –[in] Item that was received earlier
- pxHigherPriorityTaskWoken –[out] Value pointed to will be set to pdTRUE if the function woke up a higher priority task.
void `vRingbufferDelete(RingbufHandle_t xRingbuffer)`
Delete a ring buffer.

**Note:** This function will not deallocate any memory if the ring buffer was created using `xRingbufferCreateStatic()`.Deallocation must be done manually by the user.

**Parameters**
- `xRingbuffer`  
  Ring buffer to delete

`size_t xRingbufferGetMaxItemSize(RingbufHandle_t xRingbuffer)`
Get maximum size of an item that can be placed in the ring buffer.

**Note:** The max item size for a no-split buffer is limited to `((buffer_size/2)-header_size)`. This limit is imposed so that an item of max item size can always be sent to an empty no-split buffer regardless of the internal positions of the buffer’s read/write/free pointers.

**Parameters**
- `xRingbuffer`  
  Ring buffer to query

`size_t xRingbufferGetCurFreeSize(RingbufHandle_t xRingbuffer)`
Get current free size available for an item/data in the buffer.

**Note:** An empty no-split buffer has a max current free size for an item that is limited to `((buffer_size/2)-header_size)`. See API reference for `xRingbufferGetMaxItemSize()`.

**Warning:** This API is not thread safe. So, if multiple threads are accessing the same ring buffer, it is the application’s responsibility to ensure atomic access to this API and the subsequent Send

**Parameters**
- `xRingbuffer`  
  Ring buffer to query

**Returns**
- `pdTRUE` on success, `pdFALSE` otherwise

`static inline BaseType_t xRingbufferAddToQueueSetRead(RingbufHandle_t xRingbuffer, QueueSetHandle_t xQueueSet)`
Add the ring buffer to a queue set. Notified when data has been written to the ring buffer.

This function adds the ring buffer to a queue set, thus allowing a task to block on multiple queues/ring buffers. The queue set is notified when the new data becomes available to read on the ring buffer.

**Parameters**
- `xRingbuffer`  
  Ring buffer to add to the queue set
- `xQueueSet`  
  Queue set to add the ring buffer to

**Returns**
- `pdTRUE` on success, `pdFALSE` otherwise

`static inline BaseType_t xRingbufferCanRead(RingbufHandle_t xRingbuffer, QueueSetMemberHandle_t xMember)`
Check if the selected queue set member is a particular ring buffer.

This API checks if queue set member returned from `xQueueSelectFromSet()` is a particular ring buffer. If so, this indicates the ring buffer has items waiting to be retrieved.
Parameters
• \texttt{xRingbuffer} \[\text{in}] \text{Ring buffer to check}
• \texttt{xMember} \[\text{in}] \text{Member returned from xQueueSelectFromSet}

Returns
• \texttt{pdTRUE} when selected set member is the ring buffer
• \texttt{pdFALSE} otherwise.

BaseType_t \texttt{xRingbufferRemoveFromQueueSetRead} \ (\ RingbufHandle_t \ xRingbuffer, \ QueueSetHandle_t \ xQueueSet) 

Remove the ring buffer from a queue set.

This function removes a ring buffer from a queue set. The ring buffer must have been previously added to the queue set using \texttt{xRingbufferAddToQueueSetRead}().

Parameters
• \texttt{xRingbuffer} \[\text{in}] \text{Ring buffer to remove from the queue set}
• \texttt{xQueueSet} \[\text{in}] \text{Queue set to remove the ring buffer from}

Returns
• \texttt{pdTRUE} on success
• \texttt{pdFALSE} otherwise

void \texttt{vRingbufferGetInfo} \ (\ RingbufHandle_t \ xRingbuffer, \ UBaseType_t* \uxFree, \ UBaseType_t* \uxRead, \ UBaseType_t* \uxWrite, \ UBaseType_t* \uxAcquire, \ UBaseType_t* \uxItemsWaiting) 

Get information about ring buffer status.

Get information of a ring buffer’s current status such as free/read/write/acquire pointer positions, and number of items waiting to be retrieved. Arguments can be set to NULL if they are not required.

Parameters
• \texttt{xRingbuffer} \[\text{in}] \text{Ring buffer to remove from the queue set}
• \texttt{uxFree} \[\text{out}] \text{Pointer used to store free pointer position}
• \texttt{uxRead} \[\text{out}] \text{Pointer used to store read pointer position}
• \texttt{uxWrite} \[\text{out}] \text{Pointer used to store write pointer position}
• \texttt{uxAcquire} \[\text{out}] \text{Pointer used to store acquire pointer position}
• \texttt{uxItemsWaiting} \[\text{out}] \text{Pointer used to store number of items (bytes for byte buffer) waiting to be retrieved}

void \texttt{xRingbufferPrintInfo} \ (\ RingbufHandle_t \ xRingbuffer) 

Debugging function to print the internal pointers in the ring buffer.

Parameters \texttt{xRingbuffer} \[\text{Ring buffer to show}

BaseType_t \texttt{xRingbufferGetStaticBuffer} \ (\ RingbufHandle_t \ xRingbuffer, \ uint8_t* \ ppucRingbufferStorage, \ StaticRingbuffer_t* \ ppxStaticRingbuffer) 

Retrieve the pointers to a statically created ring buffer.

Parameters
• \texttt{xRingbuffer} \[\text{in}] \text{Ring buffer}
• \texttt{ppucRingbufferStorage} \[\text{out}] \text{Used to return a pointer to the queue’s storage area buffer}
• \texttt{ppxStaticRingbuffer} \[\text{out}] \text{Used to return a pointer to the queue’s data structure buffer}

Returns \texttt{pdTRUE} if buffers were retrieved, \texttt{pdFALSE} otherwise.

\texttt{RingbufHandle_t xRingbufferCreateWithCaps} \ (\ size_t \ xBufferSize, \ RingbufferType_t \ xBufferType, \ UBaseType_t \ uxMemoryCaps) 

Creates a ring buffer with specific memory capabilities.

This function is similar to \texttt{xRingbufferCreate()}, except that it allows the memory allocated for the ring buffer to have specific capabilities (e.g., MALLOC\_CAP\_INTERNAL).
Chapter 2. API Reference

**Note:** A queue created using this function must only be deleted using vRingbufferDeleteWithCaps()

### Parameters
- **xBuffersize**  
  - **[in]** Size of the buffer in bytes
- **xBuffertype**  
  - **[in]** Type of ring buffer, see documentation.
- **uxMemoryCaps**  
  - **[in]** Memory capabilities of the queue’s memory (see esp_heap_caps.h)

### Returns
Handle to the created ring buffer or NULL on failure.

```c
void vRingbufferDeleteWithCaps(RingbufHandle_t xRingbuffer)
```

Deletes a ring buffer previously created using xRingbufferCreateWithCaps()

### Parameters
- **xRingbuffer**  
  - Ring buffer

### Structures

```c
struct xSTATIC_RINGBUFFER
```

Struct that is equivalent in size to the ring buffer’s data structure.

The contents of this struct are not meant to be used directly. This structure is meant to be used when creating a statically allocated ring buffer where this struct is of the exact size required to store a ring buffer’s control data structure.

### Type Definitions

```c
typedef void *RingbufHandle_t
```

Type by which ring buffers are referenced. For example, a call to xRingbufferCreate() returns a RingbufHandle_t variable that can then be used as a parameter to xRingbufferSend(), xRingbufferReceive(), etc.

```c
typedef struct xSTATIC_RINGBUFFER StaticRingbuffer_t
```

Struct that is equivalent in size to the ring buffer’s data structure.

The contents of this struct are not meant to be used directly. This structure is meant to be used when creating a statically allocated ring buffer where this struct is of the exact size required to store a ring buffer’s control data structure.

### Enumerations

```c
enum RingbufferType_t
```

### Values:

- **enumerator RINGBUF_TYPE_NOSPLIT**
  
  No-split buffers will only store an item in contiguous memory and will never split an item. Each item requires an 8 byte overhead for a header and will always internally occupy a 32-bit aligned size of space.

- **enumerator RINGBUF_TYPE_ALLOWSPLIT**
  
  Allow-split buffers will split an item into two parts if necessary in order to store it. Each item requires an 8 byte overhead for a header, splitting incurs an extra header. Each item will always internally occupy a 32-bit aligned size of space.

- **enumerator RINGBUF_TYPE_BYTEBUF**
  
  Byte buffers store data as a sequence of bytes and do not maintain separate items, therefore byte buffers have no overhead. All data is stored as a sequence of byte and any number of bytes can be sent or retrieved each time.
enumerator `RINGBUF_TYPE_MAX`

**Hooks API**

**Header File**
- `components/esp_system/include/esp_freertos_hooks.h`
- This header file can be included with:

  ```c
  #include "esp_freertos_hooks.h"
  ```

**Functions**

`esp_err_t esp_register_freertos_idle_hook_for_cpu(esp_freertos_idle_cb_t new_idle_cb, UBaseType_t cpuid)`

Register a callback to be called from the specified core’s idle hook. The callback should return true if it should be called by the idle hook once per interrupt (or FreeRTOS tick), and return false if it should be called repeatedly as fast as possible by the idle hook.

**Warning:** Idle callbacks MUST NOT, UNDER ANY CIRCUMSTANCES, CALL A FUNCTION THAT MIGHT BLOCK.

**Parameters**
- `new_idle_cb` - [in] Callback to be called
- `cpuid` - [in] id of the core

**Returns**
- ESP_OK: Callback registered to the specified core’s idle hook
- ESP_ERR_NO_MEM: No more space on the specified core’s idle hook to register callback
- ESP_ERR_INVALID_ARG: cpuid is invalid

`esp_err_t esp_register_freertos_idle_hook(esp_freertos_idle_cb_t new_idle_cb)`

Register a callback to the idle hook of the core that calls this function. The callback should return true if it should be called by the idle hook once per interrupt (or FreeRTOS tick), and return false if it should be called repeatedly as fast as possible by the idle hook.

**Warning:** Idle callbacks MUST NOT, UNDER ANY CIRCUMSTANCES, CALL A FUNCTION THAT MIGHT BLOCK.

**Parameters**
- `new_idle_cb` - [in] Callback to be called

**Returns**
- ESP_OK: Callback registered to the calling core’s idle hook
- ESP_ERR_NO_MEM: No more space on the calling core’s idle hook to register callback

`esp_err_t esp_register_freertos_tick_hook_for_cpu(esp_freertos_tick_cb_t new_tick_cb, UBaseType_t cpuid)`

Register a callback to be called from the specified core’s tick hook.

**Parameters**
- `new_tick_cb` - [in] Callback to be called
- `cpuid` - [in] id of the core

**Returns**
- ESP_OK: Callback registered to specified core’s tick hook
• ESP_ERR_NO_MEM: No more space on the specified core’s tick hook to register the callback
• ESP_ERR_INVALID_ARG: cpuid is invalid

```c
esp_err_t esp_register_freertos_tick_hook (esp_freertos_tick_cb_t new_tick_cb)
```

Register a callback to be called from the calling core’s tick hook.

**Parameters**
- `new_tick_cb` [in] Callback to be called

**Returns**
- ESP_OK: Callback registered to the calling core’s tick hook
- ESP_ERR_NO_MEM: No more space on the calling core’s tick hook to register the callback

```c
void esp_deregister_freertos_idle_hook_for_cpu (esp_freertos_idle_cb_t old_idle_cb, UBaseType_t cpuid)
```

Unregister an idle callback from the idle hook of the specified core.

**Parameters**
- `old_idle_cb` [in] Callback to be unregistered
- `cpuid` [in] id of the core

```c
void esp_deregister_freertos_idle_hook (esp_freertos_idle_cb_t old_idle_cb)
```

Unregister an idle callback. If the idle callback is registered to the idle hooks of both cores, the idle hook will be unregistered from both cores.

**Parameters**
- `old_idle_cb` [in] Callback to be unregistered

```c
void esp_deregister_freertos_tick_hook_for_cpu (esp_freertos_tick_cb_t old_tick_cb, UBaseType_t cpuid)
```

Unregister a tick callback from the tick hook of the specified core.

**Parameters**
- `old_tick_cb` [in] Callback to be unregistered
- `cpuid` [in] id of the core

```c
void esp_deregister_freertos_tick_hook (esp_freertos_tick_cb_t old_tick_cb)
```

Unregister a tick callback. If the tick callback is registered to the tick hooks of both cores, the tick hook will be unregistered from both cores.

**Parameters**
- `old_tick_cb` [in] Callback to be unregistered

**Type Definitions**

```c
typedef bool (*esp_freertos_idle_cb_t)(void)

typedef void (*esp_freertos_tick_cb_t)(void)
```

**Additional API**

**Header File**

- `components/freertos/esp_additions/include/freertos/idf_additions.h`
- This header file can be included with:

```c
#include "freertos/idf_additions.h"
```
Functions

BaseType_t xTaskCreatePinnedToCore(TaskFunction_t pxTaskCode, const char *const pcName, const uint32_t ulStackDepth, void *const pvParameters, UBaseType_t uxPriority, TaskHandle_t *const pxCreatedTask, const BaseType_t xCoreID)

Create a new task that is pinned to a particular core.

This function is similar to xTaskCreate(), but allows the creation of a pinned task. The task’s pinned core is specified by the xCoreID argument. If xCoreID is set to tskNO_AFFINITY, then the task is unpinned and can run on any core.

Note: If (configNUM_CORES == 1), xCoreID is ignored.

Parameters

• pxTaskCode - Pointer to the task entry function.
• pcName - A descriptive name for the task.
• ulStackDepth - The size of the task stack specified as the NUMBER OF BYTES. Note that this differs from vanilla FreeRTOS.
• pvParameters - Pointer that will be used as the parameter for the task being created.
• uxPriority - The priority at which the task should run.
• pxCreatedTask - Used to pass back a handle by which the created task can be referenced.
• xCoreID - The core to which the task is pinned to, or tskNO_AFFINITY if the task has no core affinity

Returns pdPASS if the task was successfully created and added to a ready list, otherwise an error code defined in the file projdefs.h

TaskHandle_t xTaskCreateStaticPinnedToCore(TaskFunction_t pxTaskCode, const char *const pcName, const uint32_t ulStackDepth, void *const pvParameters, UBaseType_t uxPriority, StackType_t *const puxStackBuffer, StaticTask_t *const pxTaskBuffer, const BaseType_t xCoreID)

Create a new static task that is pinned to a particular core.

This function is similar to xTaskCreateStatic(), but allows the creation of a pinned task. The task’s pinned core is specified by the xCoreID argument. If xCoreID is set to tskNO_AFFINITY, then the task is unpinned and can run on any core.

Note: If (configNUM_CORES == 1), xCoreID is ignored.

Parameters

• pxTaskCode - Pointer to the task entry function.
• pcName - A descriptive name for the task.
• ulStackDepth - The size of the task stack specified as the NUMBER OF BYTES. Note that this differs from vanilla FreeRTOS.
• pvParameters - Pointer that will be used as the parameter for the task being created.
• uxPriority - The priority at which the task should run.
• puxStackBuffer - Must point to a StackType_t array that has at least ulStackDepth indexes
• pxTaskBuffer - Must point to a variable of type StaticTask_t, which will then be used to hold the task’s data structures.
• xCoreID - The core to which the task is pinned to, or tskNO_AFFINITY if the task has no core affinity

Returns The task handle if the task was created, NULL otherwise.
Chapter 2. API Reference

BaseType_t xTaskGetCoreID (TaskHandle_t xTask)
Get the current core ID of a particular task.

Helper function to get the core ID of a particular task. If the task is pinned to a particular core, the core ID is returned. If the task is not pinned to a particular core, tskNO_AFFINITY is returned.

If CONFIG_FREEERTOS_UNICORE is enabled, this function simply returns 0.
[refactor-todo] See if this needs to be deprecated (IDF-8145)(IDF-8164)

Note: If CONFIG_FREEERTOS_SMP is enabled, please call vTaskCoreAffinityGet() instead.

Note: In IDF FreerTOS when configNUMBER_OF_CORES == 1, this function will always return 0.

Parameters  
- xTask : The task to query

Returns  
- The task’s core ID or tskNO_AFFINITY

TaskHandle_t xTaskGetIdleTaskHandleForCore (BaseType_t xCoreID)
Get the handle of idle task for the given core.
[refactor-todo] See if this needs to be deprecated (IDF-8145)

Note: If CONFIG_FREEERTOS_SMP is enabled, please call xTaskGetIdleTaskHandle() instead.

Parameters  
- xCoreID : The core to query

Returns  
- Handle of the idle task for the queried core

TaskHandle_t xTaskGetCurrentTaskHandleForCore (BaseType_t xCoreID)
Get the handle of the task currently running on a certain core.
Because of the nature of SMP processing, there is no guarantee that this value will still be valid on return and should only be used for debugging purposes.
[refactor-todo] See if this needs to be deprecated (IDF-8145)

Note: If CONFIG_FREEERTOS_SMP is enabled, please call xTaskGetCurrentTaskHandleCPU() instead.

Parameters  
- xCoreID : The core to query

Returns  
- Handle of the current task running on the queried core

uint8_t* pxTaskGetStackStart (TaskHandle_t xTask)
Returns the start of the stack associated with xTask.
Returns the lowest stack memory address, regardless of whether the stack grows up or down.
[refactor-todo] Change return type to StackType_t (IDF-8158)

Parameters  
- xTask : Handle of the task associated with the stack returned. Set xTask to NULL to return the stack of the calling task.

Returns  
- A pointer to the start of the stack.

void vTaskSetThreadLocalStoragePointerAndDelCallback (TaskHandle_t xTaskToSet, BaseType_t xIndex, void *pvValue, TlsDeleteCallbackFunction_t pvDelCallback)
Set local storage pointer and deletion callback.

Each task contains an array of pointers that is dimensioned by the configNUM_THREAD_LOCAL_STORAGE_POINTERS setting in FreeRTOSConfig.h. The kernel does not use the pointers itself, so the application writer can use the pointers for any purpose they wish.

Local storage pointers set for a task can reference dynamically allocated resources. This function is similar to vTaskSetThreadLocalStoragePointer, but provides a way to release these resources when the task gets deleted. For each pointer, a callback function can be set. This function will be called when task is deleted, with the local storage pointer index and value as arguments.

**Parameters**
- **xTaskToSet** – Task to set thread local storage pointer for
- **xIndex** – The index of the pointer to set, from 0 to configNUM_THREAD_LOCAL_STORAGE_POINTERS - 1.
- **pvValue** – Pointer value to set.
- **pvDelCallback** – Function to call to dispose of the local storage pointer when the task is deleted.

```c
BaseType_t xTaskCreatePinnedToCoreWithCaps(TaskFunction_t pvTaskCode, const char* const pcName, const configSTACK_DEPTH_TYPE usStackDepth, void* const pvParameters, UBaseType_t uxPriority, TaskHandle_t* const pvCreatedTask, const BaseType_t xCoreID, UBaseType_t uxMemoryCaps)
```

Creates a pinned task where its stack has specific memory capabilities.

This function is similar to xTaskCreatePinnedToCore(), except that it allows the memory allocated for the task’s stack to have specific capabilities (e.g., MALLOC_CAP_SPIRAM).

However, the specified capabilities will NOT apply to the task’s TCB as a TCB must always be in internal RAM.

**Parameters**
- **pvTaskCode** – Pointer to the task entry function
- **pcName** – A descriptive name for the task
- **usStackDepth** – The size of the task stack specified as the number of bytes
- **pvParameters** – Pointer that will be used as the parameter for the task being created.
- **uxPriority** – The priority at which the task should run.
- **pvCreatedTask** – Used to pass back a handle by which the created task can be referenced.
- **xCOREID** – Core to which the task is pinned to, or tskNO_AFFINITY if unpinned.
- **uxMemoryCaps** – Memory capabilities of the task stack’s memory (see esp_heap_caps.h)

**Returns**
- pdPASS if the task was successfully created and added to a ready list, otherwise an error code defined in the file projdefs.h

```c
static inline BaseType_t xTaskCreateWithCaps(TaskFunction_t pvTaskCode, const char *const pcName, configSTACK_DEPTH_TYPE usStackDepth, void *const pvParameters, UBaseType_t uxPriority, TaskHandle_t *pvCreatedTask, UBaseType_t uxMemoryCaps)
```

Creates a task where its stack has specific memory capabilities.

This function is similar to xTaskCreate(), except that it allows the memory allocated for the task’s stack to have specific capabilities (e.g., MALLOC_CAP_SPIRAM).

However, the specified capabilities will NOT apply to the task’s TCB as a TCB must always be in internal RAM.

**Note:** A task created using this function must only be deleted using vTaskDeleteWithCaps()
Chapter 2. API Reference

Parameters

- `pvTaskCode` - Pointer to the task entry function
- `pcName` - A descriptive name for the task
- `usStackDepth` - The size of the task stack specified as the number of bytes
- `pvParameters` - Pointer that will be used as the parameter for the task being created.
- `uxPriority` - The priority at which the task should run.
- `pvCreatedTask` - Used to pass back a handle by which the created task can be referenced.
- `uxMemoryCaps` - Memory capabilities of the task stack’s memory (see esp_heap_caps.h)

Returns `pdPASS` if the task was successfully created and added to a ready list, otherwise an error code defined in the file projdefs.h

```c
void vTaskDeleteWithCaps (TaskHandle_t xTaskToDelete)
```

Deletes a task previously created using `xTaskCreateWithCaps()` or `xTaskCreatePinnedToCoreWithCaps()`.

Parameters

- `xTaskToDelete` - A handle to the task to be deleted.

```c
QueueHandle_t xQueueCreateWithCaps (UBaseType_t uxQueueLength, UBaseType_t uxItemSize,
                                     UBaseType_t uxMemoryCaps)
```

Creates a queue with specific memory capabilities.

This function is similar to `xQueueCreate()`, except that it allows the memory allocated for the queue to have specific capabilities (e.g., `MALLOC_CAP_INTERNAL`).

Note: A queue created using this function must only be deleted using `vQueueDeleteWithCaps()`.

```c
void vQueueDeleteWithCaps (QueueHandle_t xQueue)
```

Deletes a queue previously created using `xQueueCreateWithCaps()`.

Parameters

- `xQueue` - A handle to the queue to be deleted.

```c
static inline SemaphoreHandle_t xSemaphoreCreateBinaryWithCaps (UBaseType_t uxMemoryCaps)
```

Creates a binary semaphore with specific memory capabilities.

This function is similar to `vSemaphoreCreateBinary()`, except that it allows the memory allocated for the binary semaphore to have specific capabilities (e.g., `MALLOC_CAP_INTERNAL`).

Note: A binary semaphore created using this function must only be deleted using `vSemaphoreDeleteWithCaps()`.

```c
static inline SemaphoreHandle_t xSemaphoreCreateCountingWithCaps (UBaseType_t uxMaxCount,
                                                                  UBaseType_t uxInitialCount,
                                                                  UBaseType_t uxMemoryCaps)
```

Creates a counting semaphore with specific memory capabilities.
This function is similar to xSemaphoreCreateCounting(), except that it allows the memory allocated for the counting semaphore to have specific capabilities (e.g., MALLOC_CAP_INTERNAL).

**Note:** A counting semaphore created using this function must only be deleted using vSemaphoreDeleteWithCaps().

**Parameters**
- `uxMaxCount` - The maximum count value that can be reached.
- `uxInitialCount` - The count value assigned to the semaphore when it is created.
- `uxMemoryCaps` - Memory capabilities of the counting semaphore’s memory (see esp_heap_caps.h)

**Returns** Handle to the created counting semaphore or NULL on failure.

static inline `SemaphoreHandle_t xSemaphoreCreateMutexWithCaps (UBaseType_t uxMemoryCaps)`

Creates a mutex semaphore with specific memory capabilities.

This function is similar to xSemaphoreCreateMutex(), except that it allows the memory allocated for the mutex semaphore to have specific capabilities (e.g., MALLOC_CAP_INTERNAL).

**Note:** A mutex semaphore created using this function must only be deleted using vSemaphoreDeleteWithCaps().

**Parameters** `uxMemoryCaps` - Memory capabilities of the mutex semaphore’s memory (see esp_heap_caps.h)

**Returns** Handle to the created mutex semaphore or NULL on failure.

static inline `SemaphoreHandle_t xSemaphoreCreateRecursiveMutexWithCaps (UBaseType_t uxMemoryCaps)`

Creates a recursive mutex with specific memory capabilities.

This function is similar to xSemaphoreCreateRecursiveMutex(), except that it allows the memory allocated for the recursive mutex to have specific capabilities (e.g., MALLOC_CAP_INTERNAL).

**Note:** A recursive mutex created using this function must only be deleted using vSemaphoreDeleteWithCaps().

**Parameters** `uxMemoryCaps` - Memory capabilities of the recursive mutex’s memory (see esp_heap_caps.h)

**Returns** Handle to the created recursive mutex or NULL on failure.

void `vSemaphoreDeleteWithCaps (SemaphoreHandle_t xSemaphore)`

Deletes a semaphore previously created using one of the xSemaphoreCreate***WithCaps() functions.

**Parameters** `xSemaphore` - A handle to the semaphore to be deleted.

static inline `StreamBufferHandle_t xStreamBufferCreateWithCaps (size_t xBufferSizeBytes, size_t xTriggerLevelBytes, UBaseType_t uxMemoryCaps)`

Creates a stream buffer with specific memory capabilities.

This function is similar to xStreamBufferCreate(), except that it allows the memory allocated for the stream buffer to have specific capabilities (e.g., MALLOC_CAP_INTERNAL).

**Note:** A stream buffer created using this function must only be deleted using vStreamBufferDeleteWithCaps().
Chapter 2. API Reference

Parameters
- **xBufferSizeBytes** - The total number of bytes the stream buffer will be able to hold at any one time.
- **xTriggerLevelBytes** - The number of bytes that must be in the stream buffer before unblocking
- **uxMemoryCaps** - Memory capabilities of the stream buffer’s memory (see esp_heap_caps.h)

Returns Handle to the created stream buffer or NULL on failure.

static inline void **vStreamBufferDeleteWithCaps** (StreamBufferHandle_t xStreamBuffer)
Deletes a stream buffer previously created using xStreamBufferCreateWithCaps()

Parameters **xStreamBuffer** - A handle to the stream buffer to be deleted.

static inline MessageBufferHandle_t **xMessageBufferCreateWithCaps** (size_t xBufferSizeBytes,
UBaseType_t uxMemoryCaps)
Creates a message buffer with specific memory capabilities.
This function is similar to xMessageBufferCreate(), except that it allows the memory allocated for the message buffer to have specific capabilities (e.g., MALLOC_CAP_INTERNAL).

**Note:** A message buffer created using this function must only be deleted using vMessageBufferDeleteWithCaps()

Parameters
- **xBufferSizeBytes** - The total number of bytes (not messages) the message buffer will be able to hold at any one time.
- **uxMemoryCaps** - Memory capabilities of the message buffer’s memory (see esp_heap_caps.h)

Returns Handle to the created message buffer or NULL on failure.

static inline void **vMessageBufferDeleteWithCaps** (MessageBufferHandle_t xMessageBuffer)
Deletes a stream buffer previously created using xMessageBufferCreateWithCaps()

Parameters **xMessageBuffer** - A handle to the message buffer to be deleted.

**EventGroupHandle_t** **xEventGroupCreateWithCaps** (UBaseType_t uxMemoryCaps)
Creates an event group with specific memory capabilities.
This function is similar to xEventGroupCreate(), except that it allows the memory allocated for the event group to have specific capabilities (e.g., MALLOC_CAP_INTERNAL).

**Note:** An event group created using this function must only be deleted using vEventGroupDeleteWithCaps()

Parameters **uxMemoryCaps** - Memory capabilities of the event group’s memory (see esp_heap_caps.h)

Returns Handle to the created event group or NULL on failure.

void **vEventGroupDeleteWithCaps** (EventGroupHandle_t xEventGroup)
Deletes an event group previously created using xEventGroupCreateWithCaps()

Parameters **xEventGroup** - A handle to the event group to be deleted.

**Type Definitions**

typedef void (*TlsDeleteCallbackFunction_t)(int, void*)
Prototype of local storage pointer deletion callback.
2.10.14 Heap Memory Allocation

Stack and Heap

ESP-IDF applications use the common computer architecture patterns of stack (dynamic memory allocated by program control flow), heap (dynamic memory allocated by function calls), and static memory (memory allocated at compile time).

Because ESP-IDF is a multi-threaded RTOS environment, each RTOS task has its own stack. By default, each of these stacks is allocated from the heap when the task is created. See xTaskCreateStatic() for the alternative where stacks are statically allocated.

Because ESP32 uses multiple types of RAM, it also contains multiple heaps with different capabilities. A capabilities-based memory allocator allows apps to make heap allocations for different purposes.

For most purposes, the C Standard Library’s malloc() and free() functions can be used for heap allocation without any special consideration. However, in order to fully make use of all of the memory types and their characteristics, ESP-IDF also has a capabilities-based heap memory allocator. If you want to have a memory with certain properties (e.g., DMA-Capable Memory or executable-memory), you can create an OR-mask of the required capabilities and pass that to heap_caps_malloc().

Memory Capabilities

The ESP32 contains multiple types of RAM:

- DRAM (Data RAM) is memory that is connected to CPU’s data bus and is used to hold data. This is the most common kind of memory accessed as a heap.
- IRAM (Instruction RAM) is memory that is connected to the CPU’s instruction bus and usually holds executable data only (i.e., instructions). If accessed as generic memory, all accesses must be aligned to 32-Bit Accessible Memory.
- D/IRAM is RAM that is connected to CPU’s data bus and instruction bus, thus can be used either Instruction or Data RAM.

For more details on these internal memory types, see Memory Types.

It is also possible to connect external SPI RAM to the ESP32. The external RAM is integrated into the ESP32’s memory map via the cache, and accessed similarly to DRAM.

All DRAM memory is single-byte accessible, thus all DRAM heaps possess the MALLOC_CAP_8BIT capability. Users can call heap_caps_get_free_size(MALLOC_CAP_8BIT) to get the free size of all DRAM heaps.

If ran out of MALLOC_CAP_8BIT, the users can use MALLOC_CAP_IRAM_8BIT instead. In that case, IRAM can still be used as a “reserve” pool of internal memory if the users only access it in a 32-bit aligned manner, or if they enable CONFIG_ESP32_IRAM_AS_8BIT_ACCESSIBLE_MEMORY).

When calling malloc(), the ESP-IDF malloc() internally calls heap_caps_malloc_default(size). This will allocate memory with the capability MALLOC_CAP_DEFAULT, which is byte-addressable.

Because malloc() uses the capabilities-based allocation system, memory allocated using heap_caps_malloc() can be freed by calling the standard free() function.

Available Heap

DRAM At startup, the DRAM heap contains all data memory that is not statically allocated by the app. Reducing statically-allocated buffers increases the amount of available free heap.

To find the amount of statically allocated memory, use the idf.py size command.
Chapter 2. API Reference

**Note:** See the **DRAM (Data RAM)** section for more details about the DRAM usage limitations.

**Note:** At runtime, the available heap DRAM may be less than calculated at compile time, because, at startup, some memory is allocated from the heap before the FreeRTOS scheduler is started (including memory for the stacks of initial FreeRTOS tasks).

**IRAM**  At startup, the IRAM heap contains all instruction memory that is not used by the app executable code. The `idf.py size` command can be used to find the amount of IRAM used by the app.

**D/IRAM** Some memory in the ESP32 is available as either DRAM or IRAM. If memory is allocated from a D/IRAM region, the free heap size for both types of memory will decrease.

**Heap Sizes**  At startup, all ESP-IDF apps log a summary of all heap addresses (and sizes) at level Info:

```plaintext
I (252) heap_init: Initializing. RAM available for dynamic allocation:
I (259) heap_init: At 3FFAE6E0 len 00001920 (6 KiB): DRAM
I (265) heap_init: At 3FFB2ECC len 0002D138 (180 KiB): DRAM
I (272) heap_init: At 3FFE0440 len 00003AE0 (14 KiB): D/IRAM
I (278) heap_init: At 3FFE4350 len 0001BCB0 (111 KiB): D/IRAM
I (284) heap_init: At 4008944C len 00016BB4 (90 KiB): IRAM
```

**Finding Available Heap**  See **Heap Information**.

**Special Capabilities**

**DMA-Capable Memory**  Use the `MALLOC_CAP_DMA` flag to allocate memory which is suitable for use with hardware DMA engines (for example SPI and I2S). This capability flag excludes any external PSRAM.

**32-Bit Accessible Memory**  If a certain memory structure is only addressed in 32-bit units, for example, an array of ints or pointers, it can be useful to allocate it with the `MALLOC_CAP_32BIT` flag. This also allows the allocator to give out IRAM memory, which is sometimes unavailable for a normal `malloc()` call. This can help to use all the available memory in the ESP32.

Please note that on ESP32 series chips, `MALLOC_CAP_32BIT` cannot be used for storing floating-point variables. This is because `MALLOC_CAP_32BIT` may return instruction RAM and the floating-point assembly instructions on ESP32 cannot access instruction RAM.

Memory allocated with `MALLOC_CAP_32BIT` can only be accessed via 32-bit reads and writes, any other type of access will generate a fatal LoadStoreError exception.

**External SPI Memory**  When `external RAM` is enabled, external SPI RAM under 4 MiB in size can be allocated using standard `malloc` calls, or via `heap_caps_malloc(MALLOC_CAP_SPIRAM)`, depending on the configuration. See **Configuring External RAM** for more details.

To use the region above the 4 MiB limit, you can use the `himem API`.
Chapter 2. API Reference

Thread Safety

Heap functions are thread-safe, meaning they can be called from different tasks simultaneously without any limitations.

It is technically possible to call `malloc`, `free`, and related functions from interrupt handler (ISR) context (see Calling Heap-Related Functions from ISR). However, this is not recommended, as heap function calls may delay other interrupts. It is strongly recommended to refactor applications so that any buffers used by an ISR are pre-allocated outside of the ISR. Support for calling heap functions from ISRs may be removed in a future update.

Calling Heap-Related Functions from ISR

The following functions from the heap component can be called from the interrupt handler (ISR):

- `heap_caps_malloc()`
- `heap_caps_malloc_default()`
- `heap_caps_realloc_default()`
- `heap_caps_malloc_prefer()`
- `heap_caps_realloc_prefer()`
- `heap_caps_malloc_prefer()`
- `heap_caps_free()`
- `heap_caps_realloc()`
- `heap_caps_calloc()`
- `heap_caps_aligned_alloc()`
- `heap_caps_aligned_free()`

**Note:** However, this practice is strongly discouraged.

Heap Tracing & Debugging

The following features are documented on the Heap Memory Debugging page:

- **Heap Information** (free space, etc.)
- **Heap Allocation and Free Function Hooks**
- **Heap Corruption Detection**
- **Heap Tracing** (memory leak detection, monitoring, etc.)

Implementation Notes

Knowledge about the regions of memory in the chip comes from the “SoC” component, which contains memory layout information for the chip, and the different capabilities of each region. Each region’s capabilities are prioritized, so that (for example) dedicated DRAM and IRAM regions are used for allocations ahead of the more versatile D/IRAM regions.

Each contiguous region of memory contains its own memory heap. The heaps are created using the `multi_heap` functionality. `multi_heap` allows any contiguous region of memory to be used as a heap.

The heap capabilities allocator uses knowledge of the memory regions to initialize each individual heap. Allocation functions in the heap capabilities API will find the most appropriate heap for the allocation based on desired capabilities, available space, and preferences for each region’s use, and then calling `multi_heap_malloc()` for the heap situated in that particular region.

Calling `free()` involves finding the particular heap corresponding to the freed address, and then call `multi_heap_free()` on that particular `multi_heap` instance.
API Reference - Heap Allocation

Header File
- components/heap/include/esp_heap_caps.h
- This header file can be included with:

```c
#include "esp_heap_caps.h"
```

Functions
- `esp_err_t heap_caps_register_failed_alloc_callback (esp_alloc_failed_hook_t callback)`
  registers a callback function to be invoked if a memory allocation operation fails

  **Parameters callback** — caller defined callback to be invoked

  **Returns** ESP_OK if callback was registered.

- `void *heap_caps_malloc (size_t size, uint32_t caps)`
  Allocate a chunk of memory which has the given capabilities.
  Equivalent semantics to libc malloc(), for capability-aware memory.

  **Parameters**
  - `size` — Size, in bytes, of the amount of memory to allocate
  - `caps` — Bitwise OR of MALLOC_CAP_* flags indicating the type of memory to be returned

  **Returns** A pointer to the memory allocated on success, NULL on failure

- `void heap_caps_free (void *ptr)`
  Free memory previously allocated via heap_caps_malloc() or heap_caps_realloc().
  Equivalent semantics to libc free(), for capability-aware memory.

  In IDF, free(p) is equivalent to heap_caps_free(p).

  **Parameters**
  - `ptr` — Pointer to memory previously returned from heap_caps_malloc() or heap_caps_realloc(). Can be NULL.

- `void *heap_caps_realloc (void *ptr, size_t size, uint32_t caps)`
  Reallocate memory previously allocated via heap_caps_malloc() or heap_caps_realloc().
  Equivalent semantics to libc realloc(), for capability-aware memory.

  In IDF, realloc(p, s) is equivalent to heap_caps_realloc(p, s, MALLOC_CAP_8BIT).

  ‘caps’ parameter can be different to the capabilities that any original ‘ptr’ was allocated with. In this way, realloc can be used to ‘move’ a buffer if necessary to ensure it meets a new set of capabilities.

  **Parameters**
  - `ptr` — Pointer to previously allocated memory, or NULL for a new allocation.
  - `size` — Size of the new buffer requested, or 0 to free the buffer.
  - `caps` — Bitwise OR of MALLOC_CAP_* flags indicating the type of memory desired for the new allocation.

  **Returns** Pointer to a new buffer of size ‘size’ with capabilities ‘caps’, or NULL if allocation failed.

- `void *heap_caps_aligned_alloc (size_t alignment, size_t size, uint32_t caps)`
  Allocate an aligned chunk of memory which has the given capabilities.
  Equivalent semantics to libc aligned_alloc(), for capability-aware memory.

  **Parameters**
  - `alignment` — How the pointer received needs to be aligned must be a power of two
  - `size` — Size, in bytes, of the amount of memory to allocate
  - `caps` — Bitwise OR of MALLOC_CAP_* flags indicating the type of memory to be returned
Returns A pointer to the memory allocated on success, NULL on failure

```c
void heap_caps_aligned_free(void *ptr)
```

Used to deallocate memory previously allocated with heap_caps_aligned_alloc.

**Note:** This function is deprecated, please consider using heap_caps_free() instead

**Parameters**
- `ptr` - Pointer to the memory allocated

```c
void *heap_caps_aligned_calloc(size_t alignment, size_t n, size_t size, uint32_t caps)
```

Allocate an aligned chunk of memory which has the given capabilities. The initialized value in the memory is set to zero.

**Parameters**
- `alignment` - How the pointer received needs to be aligned must be a power of two
- `n` - Number of continuing chunks of memory to allocate
- `size` - Size, in bytes, of a chunk of memory to allocate
- `caps` - Bitwise OR of MALLOC_CAP_* flags indicating the type of memory to be returned

**Returns** A pointer to the memory allocated on success, NULL on failure

```c
void *heap_caps_calloc(size_t n, size_t size, uint32_t caps)
```

Allocate a chunk of memory which has the given capabilities. The initialized value in the memory is set to zero.

Equivalent semantics to libc malloc(), for capability-aware memory.

In IDF, `calloc(p)` is equivalent to `heap_caps_calloc(p, MALLOC_CAP_8BIT)`.

**Parameters**
- `n` - Number of continuing chunks of memory to allocate
- `size` - Size, in bytes, of a chunk of memory to allocate
- `caps` - Bitwise OR of MALLOC_CAP_* flags indicating the type of memory to be returned

**Returns** A pointer to the memory allocated on success, NULL on failure

```c
size_t heap_caps_get_total_size(uint32_t caps)
```

Get the total size of all the regions that have the given capabilities.

This function takes all regions capable of having the given capabilities allocated in them and adds up the total space they have.

**Parameters**
- `caps` - Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

**Returns** Total size in bytes

```c
size_t heap_caps_get_free_size(uint32_t caps)
```

Get the total free size of all the regions that have the given capabilities.

This function takes all regions capable of having the given capabilities allocated in them and adds up the free space they have.

**Note:** Note that because of heap fragmentation it is probably not possible to allocate a single block of memory of this size. Use `heap_caps_get_largest_free_block()` for this purpose.

**Parameters**
- `caps` - Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

**Returns** Amount of free bytes in the regions
size_t heap_caps_get_minimum_free_size (uint32_t caps)

Get the total minimum free memory of all regions with the given capabilities.

This adds all the low watermarks of the regions capable of delivering the memory with the given capabilities.

**Note:** Note the result may be less than the global all-time minimum available heap of this kind, as “low watermarks” are tracked per-region. Individual regions’ heaps may have reached their “low watermarks” at different points in time. However, this result still gives a “worst case” indication for all-time minimum free heap.

**Parameters caps** – Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

**Returns** Amount of free bytes in the regions

size_t heap_caps_get_largest_free_block (uint32_t caps)

Get the largest free block of memory able to be allocated with the given capabilities.

Returns the largest value of s for which heap_caps_malloc(s, caps) will succeed.

**Parameters caps** – Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

**Returns** Size of the largest free block in bytes.

void heap_caps_get_info (multi_heap_info_t *info, uint32_t caps)

Get heap info for all regions with the given capabilities.

Calls multi_heap_info() on all heaps which share the given capabilities. The information returned is an aggregate across all matching heaps. The meanings of fields are the same as defined for multi_heap_info_t, except that minimum_free_bytes has the same caveats described in heap_caps_get_minimum_free_size().

**Parameters**
- *info – Pointer to a structure which will be filled with relevant heap metadata.
- *caps – Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

void heap_caps_print_heap_info (uint32_t caps)

Print a summary of all memory with the given capabilities.

Calls multi_heap_info on all heaps which share the given capabilities, and prints a two-line summary for each, then a total summary.

**Parameters caps** – Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

bool heap_caps_check_integrity_all (bool print_errors)

Check integrity of all heap memory in the system.

Calls multi_heap_check on all heaps. Optionally print errors if heaps are corrupt.

Calling this function is equivalent to calling heap_caps_check_integrity with the caps argument set to MALLOC_CAP_INVALID.

**Note:** Please increase the value of CONFIG_ESP_INT_WDT_TIMEOUT_MS when using this API with PSRAM enabled.

**Parameters print_errors** – Print specific errors if heap corruption is found.

**Returns** True if all heaps are valid, False if at least one heap is corrupt.

bool heap_caps_check_integrity (uint32_t caps, bool print_errors)

Check integrity of all heaps with the given capabilities.

Calls multi_heap_check on all heaps which share the given capabilities. Optionally print errors if the heaps are corrupt.
See also `heap_caps_check_integrity_all` to check all heap memory in the system and `heap_caps_check_integrity_addr` to check memory around a single address.

**Note:** Please increase the value of `CONFIG_ESP_INT_WDT_TIMEOUT_MS` when using this API with PSRAM capability flag.

### Parameters
- `caps` - Bitwise OR of `MALLOC_CAP_*` flags indicating the type of memory
- `print_errors` - Print specific errors if heap corruption is found.

### Returns
True if all heaps are valid, False if at least one heap is corrupt.

```cpp
bool heap_caps_check_integrity_addr(intptr_t addr, bool print_errors)
```

Check integrity of heap memory around a given address.

This function can be used to check the integrity of a single region of heap memory, which contains the given address.

This can be useful if debugging heap integrity for corruption at a known address, as it has a lower overhead than checking all heap regions. Note that if the corrupt address moves around between runs (due to timing or other factors) then this approach won’t work, and you should call `heap_caps_check_integrity` or `heap_caps_check_integrity_all` instead.

**Note:** The entire heap region around the address is checked, not only the adjacent heap blocks.

### Parameters
- `addr` - Address in memory. Check for corruption in region containing this address.
- `print_errors` - Print specific errors if heap corruption is found.

### Returns
True if the heap containing the specified address is valid, False if at least one heap is corrupt or the address doesn’t belong to a heap region.

```cpp
void heap_caps_malloc_extmem_enable(size_t limit)
```

Enable `malloc()` in external memory and set limit below which `malloc()` attempts are placed in internal memory.

When external memory is in use, the allocation strategy is to initially try to satisfy smaller allocation requests with internal memory and larger requests with external memory. This sets the limit between the two, as well as generally enabling allocation in external memory.

**Parameters**
- `limit` - Limit, in bytes.

```cpp
void* heap_caps_malloc_prefer(size_t size, size_t num, ...)
```

Allocate a chunk of memory as preference in decreasing order.

**Attention** The variable parameters are bitwise OR of `MALLOC_CAP_*` flags indicating the type of memory. This API prefers to allocate memory with the first parameter. If failed, allocate memory with the next parameter. It will try in this order until allocating a chunk of memory successfully or fail to allocate memories with any of the parameters.

### Parameters
- `size` - Size, in bytes, of the amount of memory to allocate
- `num` - Number of variable parameters

### Returns
A pointer to the memory allocated on success, NULL on failure.

```cpp
void* heap_caps_realloc_prefer(void* ptr, size_t size, size_t num, ...)
```

Reallocate a chunk of memory as preference in decreasing order.

**Parameters**
Chapter 2. API Reference

- **ptr** – Pointer to previously allocated memory, or NULL for a new allocation.
- **size** – Size of the new buffer requested, or 0 to free the buffer.
- **num** – Number of variable parameters

**Returns** Pointer to a new buffer of size `size`, or NULL if allocation failed.

```c
void *heap_caps_calloc_prefer(size_t n, size_t size, size_t num, ...)
```

Allocate a chunk of memory as preference in decreasing order.

**Parameters**
- **n** – Number of continuing chunks of memory to allocate
- **size** – Size, in bytes, of a chunk of memory to allocate
- **num** – Number of variable parameters

**Returns** A pointer to the memory allocated on success, NULL on failure

```c
void heap_caps_dump(uint32_t caps)
```

Dump the full structure of all heaps with matching capabilities.

Prints a large amount of output to serial (because of locking limitations, the output bypasses stdout/stderr).

For each (variable sized) block in each matching heap, the following output is printed on a single line:

- Block address (the data buffer returned by malloc is 4 bytes after this if heap debugging is set to Basic, or 8 bytes otherwise).
- Data size (the data size may be larger than the size requested by malloc, either due to heap fragmentation or because of heap debugging level).
- Address of next block in the heap.
- If the block is free, the address of the next free block is also printed.

**Parameters** `caps` – Bitwise OR of MALLOC_CAP_* flags indicating the type of memory

```c
void heap_caps_dump_all(void)
```

Dump the full structure of all heaps.

Covers all registered heaps. Prints a large amount of output to serial.

Output is the same as for heap_caps_dump.

```c
size_t heap_caps_get_allocated_size(void *ptr)
```

Return the size that a particular pointer was allocated with.

**Note:** The app will crash with an assertion failure if the pointer is not valid.

**Parameters** `ptr` – Pointer to currently allocated heap memory. Must be a pointer value previously returned by heap_caps_malloc, malloc, calloc, etc. and not yet freed.

**Returns** Size of the memory allocated at this block.

**Macros**

**HEAP_IRAM_ATTR**

**MALLOC_CAP_EXEC**

Flags to indicate the capabilities of the various memory systems.

Memory must be able to run executable code

**MALLOC_CAP_32BIT**

Memory must allow for aligned 32-bit data accesses.
MALLOC_CAP_8BIT
Memory must allow for 8/16/32-bit data accesses.

MALLOC_CAP_DMA
Memory must be able to accessed by DMA.

MALLOC_CAP_PID2
Memory must be mapped to PID2 memory space (PIDs are not currently used)

MALLOC_CAP_PID3
Memory must be mapped to PID3 memory space (PIDs are not currently used)

MALLOC_CAP_PID4
Memory must be mapped to PID4 memory space (PIDs are not currently used)

MALLOC_CAP_PID5
Memory must be mapped to PID5 memory space (PIDs are not currently used)

MALLOC_CAP_PID6
Memory must be mapped to PID6 memory space (PIDs are not currently used)

MALLOC_CAP_PID7
Memory must be mapped to PID7 memory space (PIDs are not currently used)

MALLOC_CAP_SPIRAM
Memory must be in SPI RAM.

MALLOC_CAP_INTERNAL
Memory must be internal; specifically it should not disappear when flash/spiram cache is switched off.

MALLOC_CAP_DEFAULT
Memory can be returned in a non-capability-specific memory allocation (e.g. malloc(), calloc()) call.

MALLOC_CAP_IRAM_8BIT
Memory must be in IRAM and allow unaligned access.

MALLOC_CAP_RETENTION
Memory must be able to accessed by retention DMA.

MALLOC_CAP_RTCRAM
Memory must be in RTC fast memory.

MALLOC_CAP_TCM
Memory must be in TCM memory.

MALLOC_CAP_INVALID
Memory can’t be used / list end marker.
**Type Definitions**

typedef void (*esp_alloc_failed_hook_t)(size_t size, uint32_t caps, const char *function_name)

callback called when an allocation operation fails, if registered

- **Param size** in bytes of failed allocation
- **Param caps** capabilities requested of failed allocation
- **Param function_name** function which generated the failure

**API Reference - Initialisation**

**Header File**

- components/heap/include/esp_heap_caps_init.h
- This header file can be included with:

  ```
  #include "esp_heap_caps_init.h"
  ```

**Functions**

```c
void heap_caps_init (void)
```

Initialize the capability-aware heap allocator.

This is called once in the IDF startup code. Do not call it at other times.

```c
void heap_caps_enable_nonos_stack_heaps (void)
```

Enable heap(s) in memory regions where the startup stacks are located.

On startup, the pro/app CPUs have a certain memory region they use as stack, so we cannot do allocations in the regions these stack frames are. When FreeRTOS is completely started, they do not use that memory anymore and heap(s) there can be enabled.

```c
esp_err_t heap_caps_add_region (intptr_t start, intptr_t end)
```

Add a region of memory to the collection of heaps at runtime.

Most memory regions are defined in soc_memory_layout.c for the SoC, and are registered via heap_caps_init(). Some regions can’t be used immediately and are later enabled via heap_caps_enable_nonos_stack_heaps().

Call this function to add a region of memory to the heap at some later time.

This function does not consider any of the “reserved” regions or other data in soc_memory_layout, caller needs to consider this themselves.

All memory within the region specified by start & end parameters must be otherwise unused.

The capabilities of the newly registered memory will be determined by the start address, as looked up in the regions specified in soc_memory_layout.c.

Use heap_caps_add_region_with_caps() to register a region with custom capabilities.

**Note:** Please refer to following example for memory regions allowed for addition to heap based on an existing region (address range for demonstration purpose only):

| Existing region: 0x1000 <-> 0x3000 |
|------------------|------------------|
| New region:      0x1000 <-> 0x3000 (Allowed) |
| New region:      0x1000 <-> 0x2000 (Allowed) |
| New region:      0x0000 <-> 0x1000 (Allowed) |
| New region:      0x3000 <-> 0x4000 (Allowed) |
| New region:      0x0000 <-> 0x2000 (NOT Allowed) |
| New region:      0x0000 <-> 0x4000 (NOT Allowed) |
| New region:      0x1000 <-> 0x4000 (NOT Allowed) |
| New region:      0x2000 <-> 0x4000 (NOT Allowed) |
Parameters

- **start** – Start address of new region.
- **end** – End address of new region.

Returns ESP_OK on success, ESP_ERR_INVALID_ARG if a parameter is invalid, ESP_ERR_NOT_FOUND if the specified start address doesn’t reside in a known region, or any error returned by heap_caps_add_region_with_caps().

```c
esp_err_t heap_caps_add_region_with_caps(const uint32_t caps[], intptr_t start, intptr_t end)
```

Add a region of memory to the collection of heaps at runtime, with custom capabilities.

Similar to heap_caps_add_region(), only custom memory capabilities are specified by the caller.

### Note:
Please refer to following example for memory regions allowed for addition to heap based on an existing region (address range for demonstration purpose only):

<table>
<thead>
<tr>
<th>Existing region:</th>
<th>0x1000 &lt;&gt; 0x3000</th>
</tr>
</thead>
<tbody>
<tr>
<td>New region:</td>
<td>0x1000 &lt;&gt; 0x3000 (Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x1000 &lt;&gt; 0x2000 (Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x0000 &lt;&gt; 0x1000 (Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x3000 &lt;&gt; 0x4000 (Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x0000 &lt;&gt; 0x2000 (NOT Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x0000 &lt;&gt; 0x4000 (NOT Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x1000 &lt;&gt; 0x4000 (NOT Allowed)</td>
</tr>
<tr>
<td>New region:</td>
<td>0x2000 &lt;&gt; 0x4000 (NOT Allowed)</td>
</tr>
</tbody>
</table>

### Parameters

- **caps** – Ordered array of capability masks for the new region, in order of priority. Must have length SOC_MEMORY_TYPE_NO_PRIOS. Does not need to remain valid after the call returns.
- **start** – Start address of new region.
- **end** – End address of new region.

### Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if a parameter is invalid
- ESP_ERR_NO_MEM if no memory to register new heap.
- ESP_ERR_INVALID_SIZE if the memory region is too small to fit a heap
- ESP_FAIL if region overlaps the start and/or end of an existing region

---

### API Reference - Multi-Heap API

(Note: The multi-heap API is used internally by the heap capabilities allocator. Most ESP-IDF programs never need to call this API directly.)

### Header File

- components/heap/include/multi_heap.h

This header file can be included with:

```c
#include "multi_heap.h"
```

### Functions

```c
void *multi_heap_aligned_alloc(multi_heap_handle_t heap, size_t size, size_t alignment)
```

allocate a chunk of memory with specific alignment

### Parameters

- **heap** – Handle to a registered heap.
### Chapter 2. API Reference

- **size** - size in bytes of memory chunk
- **alignment** - how the memory must be aligned

**Returns**
- Pointer to the memory allocated, NULL on failure

```c
void *multi_heap_malloc (multi_heap_handle_t heap, size_t size)
```

malloc() a buffer in a given heap

Semantics are the same as standard malloc(), only the returned buffer will be allocated in the specified heap.

**Parameters**
- **heap** - Handle to a registered heap.
- **size** - Size of desired buffer.

**Returns**
- Pointer to new memory, or NULL if allocation fails.

```c
void multi_heap_aligned_free (multi_heap_handle_t heap, void *p)
```

free() a buffer aligned in a given heap.

**Note:** This function is deprecated, consider using multi_heap_free() instead

**Parameters**
- **heap** - Handle to a registered heap.
- **p** - NULL, or a pointer previously returned from multi_heap_aligned_alloc() for the same heap.

```c
void multi_heap_free (multi_heap_handle_t heap, void *p)
```

free() a buffer in a given heap.

Semantics are the same as standard free(), only the argument ‘p’ must be NULL or have been allocated in the specified heap.

**Parameters**
- **heap** - Handle to a registered heap.
- **p** - NULL, or a pointer previously returned from multi_heap_malloc() or multi_heap_realloc() for the same heap.

```c
void *multi_heap_realloc (multi_heap_handle_t heap, void *p, size_t size)
```

realloc() a buffer in a given heap.

Semantics are the same as standard realloc(), only the argument ‘p’ must be NULL or have been allocated in the specified heap.

**Parameters**
- **heap** - Handle to a registered heap.
- **p** - NULL, or a pointer previously returned from multi_heap_malloc() or multi_heap_realloc() for the same heap.
- **size** - Desired new size for buffer.

**Returns**
- New buffer of ‘size’ containing contents of ‘p’, or NULL if reallocation failed.

```c
size_t multi_heap_get_allocated_size (multi_heap_handle_t heap, void *p)
```

Return the size that a particular pointer was allocated with.

**Parameters**
- **heap** - Handle to a registered heap.
- **p** - NULL, or a pointer previously returned from multi_heap_malloc() or multi_heap_realloc() for the same heap.

**Returns**
- Size of the memory allocated at this block. May be more than the original size argument, due to padding and minimum block sizes.

```c
multi_heap_handle_t multi_heap_register (void *start, size_t size)
```

Register a new heap for use.

This function initialises a heap at the specified address, and returns a handle for future heap operations.
There is no equivalent function for deregistering a heap - if all blocks in the heap are free, you can immediately start using the memory for other purposes.

**Parameters**
- **start** – Start address of the memory to use for a new heap.
- **size** – Size (in bytes) of the new heap.

**Returns** Handle of a new heap ready for use, or NULL if the heap region was too small to be initialised.

```c
void multi_heap_set_lock(multi_heap_handle_t heap, void *lock)
```

Associate a private lock pointer with a heap.

The lock argument is supplied to the MULTI_HEAP_LOCK() and MULTI_HEAP_UNLOCK() macros, defined in multi_heap_platform.h.

The lock in question must be recursive.

When the heap is first registered, the associated lock is NULL.

**Parameters**
- **heap** – Handle to a registered heap.
- **lock** – Optional pointer to a locking structure to associate with this heap.

```c
void multi_heap_dump(multi_heap_handle_t heap)
```

Dump heap information to stdout.

For debugging purposes, this function dumps information about every block in the heap to stdout.

**Parameters**
- **heap** – Handle to a registered heap.

```c
bool multi_heap_check(multi_heap_handle_t heap, bool print_errors)
```

Check heap integrity.

Walks the heap and checks all heap data structures are valid. If any errors are detected, an error-specific message can be optionally printed to stderr. Print behaviour can be overridden at compile time by defining MULTI_CHECK_FAIL__PRINTF in multi_heap_platform.h.

**Note:** This function is not thread-safe as it sets a global variable with the value of print_errors.

**Parameters**
- **heap** – Handle to a registered heap.
- **print_errors** – If true, errors will be printed to stderr.

**Returns** true if heap is valid, false otherwise.

```c
size_t multi_heap_free_size(multi_heap_handle_t heap)
```

Return free heap size.

Returns the number of bytes available in the heap.

Equivalent to the total_free_bytes member returned by multi_heap_get_heap_info().

Note that the heap may be fragmented, so the actual maximum size for a single malloc() may be lower. To know this size, see the largest_free_block member returned by multi_heap_get_heap_info().

**Parameters**
- **heap** – Handle to a registered heap.

**Returns** Number of free bytes.

```c
size_t multi_heap_minimum_free_size(multi_heap_handle_t heap)
```

Return the lifetime minimum free heap size.

Equivalent to the minimum_free_bytes member returned by multi_heap_get_info().

Returns the lifetime “low watermark” of possible values returned from multi_free_heap_size(), for the specified heap.
Chapter 2. API Reference

Parameters heap – Handle to a registered heap.
Returns Number of free bytes.

void multi_heap_get_info (multi_heap_handle_t heap, multi_heap_info_t *info)
Return metadata about a given heap.
Fills a multi_heap_info_t structure with information about the specified heap.

Parameters
• heap – Handle to a registered heap.
• info – Pointer to a structure to fill with heap metadata.

Structures

struct multi_heap_info_t
Structure to access heap metadata via multi_heap_get_info.

Public Members

size_t total_free_bytes
Total free bytes in the heap. Equivalent to multi_free_heap_size().

size_t total_allocated_bytes
Total bytes allocated to data in the heap.

size_t largest_free_block
Size of the largest free block in the heap. This is the largest malloc-able size.

size_t minimum_free_bytes
Lifetime minimum free heap size. Equivalent to multi_minimum_free_heap_size().

size_t allocated_blocks
Number of (variable size) blocks allocated in the heap.

size_t free_blocks
Number of (variable size) free blocks in the heap.

size_t total_blocks
Total number of (variable size) blocks in the heap.

Type Definitions

typedef struct multi_heap_info *multi_heap_handle_t
Opaque handle to a registered heap.

2.10.15 Memory Management for MMU Supported Memory
Introduction

ESP32 Memory Management Unit (MMU) is relatively simple. It can do memory address translation between physical memory addresses and virtual memory addresses. So CPU can access physical memories via virtual addresses. There are multiple types of virtual memory addresses, which have different capabilities.

ESP-IDF provides a memory mapping driver that manages the relation between these physical memory addresses and virtual memory addresses, so as to achieve some features such as reading from SPI flash via a pointer.

Memory mapping driver is actually a capabilities-based virtual memory address allocator that allows applications to make virtual memory address allocations for different purposes. In the following chapters, we call this driver esp_mmap driver.

ESP-IDF also provides a memory synchronization driver which can be used for potential memory desynchronization scenarios.

Physical Memory Types

Memory mapping driver currently supports mapping to following physical memory type(s):

- SPI flash

Virtual Memory Capabilities

- MMU_MEM_CAP_EXEC: This capability indicates that the virtual memory address has the execute permission. Note this permission scope is within the MMU hardware.
- MMU_MEM_CAP_READ: This capability indicates that the virtual memory address has the read permission. Note this permission scope is within the MMU hardware.
- MMU_MEM_CAP_WRITE: This capability indicates that the virtual memory address has the write permission. Note this permission scope is within the MMU hardware.
- MMU_MEM_CAP_32BIT: This capability indicates that the virtual memory address allows for 32 bits or multiples of 32 bits access.
- MMU_MEM_CAP_8BIT: This capability indicates that the virtual memory address allows for 8 bits or multiples of 8 bits access.

8 MB external memory addresses (from 0x40400000 to 0x40C00000) which have the MMU_MEM_CAP_EXEC and MMU_MEM_CAP_READ capabilities are not available for users to allocate, due to hardware limitations.

You can call esp_mmu_map_get_max_consecutive_free_block_size() to know the largest consecutive mappable block size with certain capabilities.

Memory Management Drivers

Driver Concept

Terminology The virtual memory pool is made up with one or multiple virtual memory regions, see below figure:

- A virtual memory pool stands for the whole virtual address range that can be mapped to physical memory.
A virtual memory region is a range of virtual address with same attributes.
A virtual memory block is a piece of virtual address range that is dynamically mapped.
A slot is the virtual address range between two virtual memory blocks.
A physical memory block is a piece of physical address range that is to-be-mapped or already mapped to a virtual memory block.
Dynamical mapping is done by calling esp_mmap driver API esp_mmu_map(). This API maps the given physical memory block to a virtual memory block which is allocated by the esp_mmap driver.

Relation Between Memory Blocks

When mapping a physical memory block A, block A can have one of the following relations with another previously mapped physical memory block B:

- Enclosed: block A is completely enclosed within block B, see figure below:

![Enclosed](image1)

- Identical: block A is completely the same as block B, see figure below:

![Identical](image2)

Note that esp_mmap driver considers the identical scenario the same as the enclosed scenario.

- Overlapped: block A is overlapped with block B, see figure below:

![Overlapped](image3)

There is a special condition, when block A entirely encloses block B, see figure below:

![Enclosed](image4)
Chapter 2. API Reference

Note that esp_mmap driver considers this scenario **the same as the overlapped scenario**.

**Driver Behaviour**

**Memory Map**  You can call `esp_mmu_map()` to do a dynamical mapping. This API can allocate a certain size of virtual memory block according to the virtual memory capabilities you selected, then map this virtual memory block to the physical memory block as you requested. The esp_mmap driver supports mapping to one or more types of physical memory, so you should specify the physical memory target when mapping.

By default, physical memory blocks and virtual memory blocks are one-to-one mapped. This means, when calling `esp_mmu_map()`:

- If it is the enclosed scenario, this API will return an `ESP_ERR_INVALID_STATE`. The `out_ptr` will be assigned to the start virtual memory address of the previously mapped one which encloses the to-be-mapped one.
- If it is the identical scenario, this API will behaves exactly the same as the enclosed scenario.
- If it is the overlapped scenario, this API will by default return an `ESP_ERR_INVALID_ARG`. This means, esp_mmap driver by default does not allow mapping a physical memory address to multiple virtual memory addresses.

Specially, you can use `ESP_MMU_MMAP_FLAG_PADDR_SHARED`. This flag stands for one-to-multiple mapping between a physical address and multiple virtual addresses:

- If it is the overlapped scenario, this API will allocate a new virtual memory block as requested, then map to the given physical memory block.

**Memory Unmap**  You can call `esp_mmu_unmap()` to unmap a previously mapped memory block. This API returns an `ESP_ERR_NOT_FOUND` if you are trying to unmap a virtual memory block that is not mapped to any physical memory block yet.

**Memory Address Conversion**  The esp_mmap driver provides two helper APIs to do the conversion between virtual memory address and physical memory address:

- `esp_mmu_vaddr_to_paddr()` converts virtual address to physical address.
- `esp_mmu_paddr_to_vaddr()` converts physical address to virtual address.

**Memory Synchronization**  MMU supported physical memories can be accessed by one or multiple methods.

SPI flash can be accessed by SPI1 (ESP-IDF esp_flash driver APIs), or by pointers. ESP-IDF esp_flash driver APIs have already considered the memory synchronization, so users do not need to worry about this.

PSRAM can be accessed by pointers, hardware guarantees the data consistency when PSRAM is only accessed via pointers.
Chapter 2. API Reference

Thread Safety

APIs in `esp_mmu_map.h` are not guaranteed to be thread-safe.

APIs in `esp_cache.h` are guaranteed to be thread-safe.

API Reference

API Reference - ESP MMAP Driver

Header File

- components/esp_mm/include/esp_mmu_map.h
- This header file can be included with:

```c
#include "esp_mmu_map.h"
```

- This header file is a part of the API provided by the `esp_mm` component. To declare that your component depends on `esp_mm`, add the following to your CMakeLists.txt:

```cmake
REQUIRES esp_mm
```

or

```cmake
PRIV_REQUIRES esp_mm
```

Functions

`esp_err_t esp_mmu_map(esp_paddr_t paddr_start, size_t size, mmu_target_t target, mmu_mem_caps_t caps, int flags, void** out_ptr)`

Map a physical memory block to external virtual address block, with given capabilities.

**Note:** This API does not guarantee thread safety

Parameters

- `paddr_start` - [in] Start address of the physical memory block
- `size` - [in] Size to be mapped. Size will be rounded up by to the nearest multiple of MMU page size
- `target` - [in] Physical memory target you’re going to map to, see `mmu_target_t`
- `caps` - [in] Memory capabilities, see `mmu_mem_caps_t`
- `flags` - [in] Mmap flags
- `out_ptr` - [out] Start address of the mapped virtual memory

Returns

- `ESP_OK`
- `ESP_ERR_INVALID_ARG`: Invalid argument, see printed logs
- `ESP_ERR_NOT_SUPPORTED`: Only on ESP32, PSRAM is not a supported physical memory target
- `ESP_ERR_NOT_FOUND`: No enough size free block to use
- `ESP_ERR_NO_MEM`: Out of memory, this API will allocate some heap memory for internal usage
- `ESP_ERR_INVALID_STATE`: Paddr is mapped already, this API will return corresponding vaddr_start of the previously mapped block. Only to-be-mapped paddr block is totally enclosed by a previously mapped block will lead to this error. (Identical scenario will be-have similarly) new_block_start new_block_end !—&#8212; New Block —&#8212;1 —&#8212;1 —&#8212;1 —&#8212;1 block_start block_end
**esp_err_t esp_mmu_unmap**(void *ptr)

Unmap a previously mapped virtual memory block.

**Note:** This API does not guarantee thread safety

**Parameters**
- **ptr** - [in] Start address of the virtual memory

**Returns**
- ESP_OK
- ESP_ERR_INVALID_ARG: Null pointer
- ESP_ERR_NOT_FOUND: Vaddr is not in external memory, or it’s not mapped yet

**esp_err_t esp_mmu_map_get_max_consecutive_free_block_size**(mmu_mem_caps_t caps,
mmu_target_t target,
size_t *out_len)

Get largest consecutive free external virtual memory block size, with given capabilities and given physical target.

**Parameters**
- **caps** - [in] Bitwise OR of MMU_MEM_CAP_* flags indicating the memory block
- **target** - [in] Physical memory target you’re going to map to, see mmu_target_t.
- **out_len** - [out] Largest free block length, in bytes.

**Returns**
- ESP_OK
- ESP_ERR_INVALID_ARG: Invalid arguments, could be null pointer

**esp_err_t esp_mmu_map_dump_mapped_blocks**(FILE *stream)

Dump all the previously mapped blocks

**Note:** This API shall not be called from an ISR.

**Note:** This API does not guarantee thread safety

**Parameters**
- **stream** - stream to print information to; use stdout or stderr to print to the console; use fmemopen/open_memstream to print to a string buffer.

**Returns**
- ESP_OK

**esp_err_t esp_mmu_vaddr_to_paddr**(void *vaddr,
esp_paddr_t *out_paddr,
mwu_target_t *out_target)

Convert virtual address to physical address.

**Parameters**
- **vaddr** - [in] Virtual address
- **out_paddr** - [out] Physical address
- **out_target** - [out] Physical memory target, see mmu_target_t

**Returns**
- ESP_OK
- ESP_ERR_INVALID_ARG: Null pointer, or vaddr is not within external memory
- ESP_ERR_NOT_FOUND: Vaddr is not mapped yet

**esp_err_t esp_mmu_paddr_to_vaddr**(esp_paddr_t paddr,
mwu_target_t target,
mwu_vaddr_t type,
void **out_vaddr)

Convert physical address to virtual address.

**Parameters**
- **paddr** - [in] Physical address
Chapter 2. API Reference

• **target** - [in] Physical memory target, see `mmu_target_t`
• **type** - [in] Virtual address type, could be either instruction or data
• **out_vaddr** - [out] Virtual address

**Returns**
• ESP_OK
• ESP_ERR_INVALID_ARG: Null pointer
• ESP_ERR_NOT_FOUND: Paddr is not mapped yet

```c
esp_err_t esp_mmu_paddr_find_caps(const esp_paddr_t paddr, mmu_mem_caps_t*out_caps)
```

If the physical address is mapped, this API will provide the capabilities of the virtual address where the physical address is mapped to.

**Note:** Only return value is ESP_OK (which means physically address is successfully mapped), then caps you get make sense.

**Note:** This API only check one page (see `CONFIG_MMU_PAGE_SIZE`), starting from the `paddr`

**Parameters**
• **paddr** - [in] Physical address
• **out_caps** - [out] Bitwise OR of MMU_MEM_CAP_* flags indicating the capabilities of a virtual address where the physical address is mapped to.

**Returns**
• ESP_OK: Physical address successfully mapped.
• ESP_ERR_INVALID_ARG: Null pointer
• ESP_ERR_NOT_FOUND: Physical address is not mapped successfully.

**Macros**

```c
ESP_MMU_MMAP_FLAG_PADDR_SHARED
```

Share this mapping.

MMU Memory Mapping Driver APIs for MMU supported memory

Driver Backgrounds:

**Type Definitions**

```c
typedef uint32_t esp_paddr_t
```

Physical memory type.

### 2.10.16 Heap Memory Debugging

**Overview**

ESP-IDF integrates tools for requesting heap information, heap corruption detection, and heap tracing. These can help track down memory-related bugs.

For general information about the heap memory allocator, see [Heap Memory Allocation](#).
Heap Information

To obtain information about the state of the heap, call the following functions:

- `heap_caps_get_free_size()` can be used to return the current free memory for different memory capabilities.
- `heap_caps_get_largest_free_block()` can be used to return the largest free block in the heap, which is also the largest single allocation currently possible. Tracking this value and comparing it to the total free heap allows you to detect heap fragmentation.
- `heap_caps_get_minimum_free_size()` can be used to track the heap “low watermark” since boot.
- `heap_caps_get_info()` returns a `multi_heap_info_t` structure, which contains the information from the above functions, plus some additional heap-specific data (number of allocations, etc.).
- `heap_caps_print_heap_info()` prints a summary of the information returned by `heap_caps_get_info()` to stdout.
- `heap_caps_dump()` and `heap_caps_dump_all()` output detailed information about the structure of each block in the heap. Note that this can be a large amount of output.

Heap Allocation and Free Function Hooks

Heap allocation and free detection hooks allow you to be notified of every successful allocation and free operation:

- Providing a definition of `esp_heap_trace_alloc_hook()` allows you to be notified of every successful memory allocation operation
- Providing a definition of `esp_heap_trace_free_hook()` allows you to be notified of every successful memory-free operations

This feature can be enabled by setting the `CONFIG_HEAP_USE_HOOKS` option. `esp_heap_trace_alloc_hook()` and `esp_heap_trace_free_hook()` have weak declarations (e.g., `__attribute__((weak))`), thus it is not necessary to provide declarations for both hooks. Given that it is technically possible to allocate and free memory from an ISR (though strongly discouraged from doing so), the `esp_heap_trace_alloc_hook()` and `esp_heap_trace_free_hook()` can potentially be called from an ISR.

It is not recommended to perform (or call API functions to perform) blocking operations or memory allocation/free operations in the hook functions. In general, the best practice is to keep the implementation concise and leave the heavy computation outside of the hook functions.

The example below shows how to define the allocation and free function hooks:

```c
#include "esp_heap_caps.h"

void esp_heap_trace_alloc_hook(void* ptr, size_t size, uint32_t caps)
{
    ...
}

void esp_heap_trace_free_hook(void* ptr)
{
    ...
}

void app_main()
{
    ...
}
```

Heap Corruption Detection

Heap corruption detection allows you to detect various types of heap memory errors:

- Out-of-bound writes & buffer overflows
• Writes to freed memory
• Reads from freed or uninitialized memory

Assertions The heap implementation (heap/multi_heap.c, etc.) includes numerous assertions that will fail if the heap memory is corrupted. To detect heap corruption most effectively, ensure that assertions are enabled in the project configuration via the CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL option.

If a heap integrity assertion fails, a line will be printed like CORRUPT HEAP: multi_heap.c:225 detected at 0x3ffbb71c. The memory address printed is the address of the heap structure that has corrupt content.

It is also possible to manually check heap integrity by calling heap_caps_check_integrity_all() or related functions. This function checks all of the requested heap memory for integrity and can be used even if assertions are disabled. If the integrity checks detects an error, it will print the error along with the address(es) of corrupt heap structures.

Memory Allocation Failed Hook Users can use heap_caps_register_failed_alloc_callback() to register a callback that is invoked every time an allocation operation fails.

Additionally, users can enable the CONFIG_HEAP_ABORT_WHEN_ALLOCATION_FAILS, which will automatically trigger a system abort if any allocation operation fails.

The example below shows how to register an allocation failure callback:

```c
#include "esp_heap_caps.h"

void heap_caps_alloc_failed_hook(size_t requested_size, uint32_t caps, const char *function_name) {
    printf("%s was called but failed to allocate %d bytes with 0x%X capabilities. \n", function_name, requested_size, caps);
}

void app_main() {
    ...
    esp_err_t error = heap_caps_register_failed_alloc_callback(heap_caps_alloc_failed_hook);
    ...
    void *ptr = heap_caps_malloc(allocation_size, MALLOC_CAP_DEFAULT);
    ...
}
```

Finding Heap Corruption Memory corruption can be one of the hardest classes of bugs to find and fix, as the source of the corruption could be completely unrelated to the symptoms of the corruption. Here are some tips:

• A crash with a CORRUPT HEAP: message usually includes a stack trace, but this stack trace is rarely useful. The crash is the symptom of memory corruption when the system realizes the heap is corrupt. But usually, the corruption happens elsewhere and earlier in time.
• Increasing the heap memory debugging Configuration level to “Light impact” or “Comprehensive” gives you a more accurate message with the first corrupt memory address.
• Adding regular calls to heap_caps_check_integrity_all() or heap_caps_check_integrity_addr() in your code helps you pin down the exact time that the corruption happened. You can move these checks around to “close in on” the section of code that corrupted the heap.
• Based on the memory address that has been corrupted, you can use JTAG debugging to set a watchpoint on this address and have the CPU halt when it is written to.
• If you do not have JTAG, but you do know roughly when the corruption happens, set a watchpoint in software just beforehand via esp_cpu_set_watchpoint(). A fatal exception will occur when the watchpoint triggers. The following is an example of how to use the function - esp_cpu_set_watchpoint(0, (void *)addr, 4, ESP_WATCHPOINT_STORE). Note that watchpoints are per-CPU and are set...
on the current running CPU only. So if you do not know which CPU is corrupting memory, call this function on both CPUs.

- For buffer overflows, heap tracing in HEAP_TRACE_ALL mode tells which callers are allocating which addresses from the heap. See Heap Tracing To Find Heap Corruption for more details. You can try to find the function that allocates memory with an address immediately before the corrupted address, since it is probably the function that overflows the buffer.
- Calling \texttt{heap_caps_dump()} or \texttt{heap_caps_dump_all()} can give an indication of what heap blocks are surrounding the corrupted region and may have overflowed or underflowed, etc.

**Configuration**  
Temporarily increasing the heap corruption detection level can give more detailed information about heap corruption errors.

In the project configuration menu, under Component config, there is a menu Heap memory debugging. The option \texttt{CONFIG_HEAP_CORRUPTION_DETECTION} can be set to one of the following three levels:

**Basic (No Poisoning)**  
This is the default level. By default, no special heap corruption features are enabled, but the provided assertions are enabled. A heap corruption error will be printed if any of the heap’s internal data structures appear overwritten or corrupted. This usually indicates a buffer overrun or out-of-bounds write.

If assertions are enabled, an assertion will also trigger if a double-free occurs (the same memory is freed twice).

Calling \texttt{heap_caps_check_integrity()} in Basic mode checks the integrity of all heap structures, and print errors if any appear to be corrupted.

**Light Impact**  
At this level, heap memory is additionally “poisoned” with head and tail “canary bytes” before and after each block that is allocated. If an application writes outside the bounds of allocated buffers, the canary bytes will be corrupted, and the integrity check will fail.

The head canary word is 0xABBA1234 (3412BAAB in byte order), and the tail canary word is 0xBAAD5678 (7856ADBA in byte order).

With basic heap corruption checks, most out-of-bounds writes can be detected and the number of overrun bytes before a failure is detected depends on the properties of the heap. However, the Light Impact mode is more precise as even a single-byte overrun can be detected.

Enabling light-impact checking increases the memory usage. Each individual allocation uses 9 to 12 additional bytes of memory depending on alignment.

Each time \texttt{heap_caps_free()} is called in Light Impact mode, the head and tail canary bytes of the buffer being freed are checked against the expected values.

When \texttt{heap_caps_check_integrity()} is called, all allocated blocks of heap memory have their canary bytes checked against the expected values.

In both cases, the functions involve checking that the first 4 bytes of an allocated block (before the buffer is returned to the user) should be the word 0xABBA1234, and the last 4 bytes of the allocated block (after the buffer is returned to the user) should be the word 0xBAAD5678.

Different values usually indicate buffer underrun or overrun. Overrun indicates that when writing to memory, the data written exceeds the size of the allocated memory, resulting in writing to an unallocated memory area; underrun indicates that when reading memory, the data read exceeds the allocated memory and reads data from an unallocated memory area.

**Comprehensive**  
This level incorporates the “light impact” detection features plus additional checks for uninitialized-access and use-after-free bugs. In this mode, all freshly allocated memory is filled with the pattern 0xCE, and all freed memory is filled with the pattern 0xFE.

Enabling Comprehensive mode has a substantial impact on runtime performance, as all memory needs to be set to the allocation patterns each time a \texttt{heap_caps_malloc()} or \texttt{heap_caps_free()} completes, and the memory also needs to be checked each time. However, this mode allows easier detection of memory corruption bugs which are much more subtle to find otherwise. It is recommended to only enable this mode when debugging, not in production.
Crashes in Comprehensive Mode If an application crashes when reading or writing an address related to 0xCECECECE in Comprehensive mode, it indicates that it has read uninitialized memory. The application should be changed to either use `heap_caps_calloc()` (which zeroes memory), or initialize the memory before using it. The value 0xCECECECE may also be seen in stack-allocated automatic variables, because, in ESP-IDF, most task stacks are originally allocated from the heap, and in C, stack memory is uninitialized by default.

If an application crashes, and the exception register dump indicates that some addresses or values were 0xFEFEFEFE, this indicates that it is reading heap memory after it has been freed, i.e., a “use-after-free bug”. The application should be changed to not access heap memory after it has been freed.

If a call to `heap_caps_malloc()` or `heap_caps_realloc()` causes a crash because it was expected to find the pattern 0xFEFEFEFE in free memory and a different pattern was found, it indicates that the app has a use-after-free bug where it is writing to memory that has already been freed.

Manual Heap Checks in Comprehensive Mode Calls to `heap_caps_check_integrity()` may print errors relating to 0xFEFEFEFE, 0xABBA1234, or 0xBAAD5678. In each case the checker is expected to find a given pattern, and will error out if not found:

- For free heap blocks, the checker expects to find all bytes set to 0xFE. Any other values indicate a use-after-free bug where free memory has been incorrectly overwritten.
- For allocated heap blocks, the behavior is the same as for the Light Impact mode. The canary bytes 0xABBA1234 and 0xBAAD5678 are checked at the head and tail of each allocated buffer, and any variation indicates a buffer overrun or underrun.

Heap Task Tracking

Heap Task Tracking can be used to get per-task info for heap memory allocation. The application has to specify the heap capabilities for which the heap allocation is to be tracked.

Example code is provided in `system/heap_task_tracking`.

Heap Tracing

Heap Tracing allows the tracing of code which allocates or frees memory. Two tracing modes are supported:

- Standalone. In this mode, traced data are kept on-board, so the size of the gathered information is limited by the buffer assigned for that purpose, and the analysis is done by the on-board code. There are a couple of APIs available for accessing and dumping collected info.
- Host-based. This mode does not have the limitation of the standalone mode, because traced data are sent to the host over JTAG connection using app_trace library. Later on, they can be analyzed using special tools.

Heap tracing can perform two functions:

- Leak checking: find memory that is allocated and never freed.
- Heap use analysis: show all functions that are allocating or freeing memory while the trace is running.

How to Diagnose Memory Leaks If you suspect a memory leak, the first step is to figure out which part of the program is leaking memory. Use the `heap_caps_get_free_size()` or related functions in `heap_information` to track memory use over the life of the application. Try to narrow the leak down to a single function or sequence of functions where free memory always decreases and never recovers.

Standalone Mode Once you have identified the code which you think is leaking:

- Enable the `CONFIG_HEAP_TRACING_DEST` option.
- Call the function `heap_trace_init_standalone()` early in the program, to register a buffer that can be used to record the memory trace.
- Call the function `heap_trace_start()` to begin recording all mallocs or frees in the system. Call this immediately before the piece of code which you suspect is leaking memory.
• Call the function `heap_trace_stop()` to stop the trace once the suspect piece of code has finished executing.
• Call the function `heap_trace_dump()` to dump the results of the heap trace.

The following code snippet demonstrates how application code would typically initialize, start, and stop heap tracing:

```c
#include "esp_heap_trace.h"
#define NUM_RECORDS 100
static heap_trace_record_t trace_record[NUM_RECORDS]; // This buffer must be in internal RAM
...
void app_main()
{
    ...
    ESP_ERROR_CHECK( heap_trace_init_standalone(trace_record, NUM_RECORDS) );
    ...
}
void some_function()
{
    ESP_ERROR_CHECK( heap_trace_start(HEAP_TRACE_LEAKS) );
    do_something_you_suspect_is_leaking();
    ESP_ERROR_CHECK( heap_trace_stop() );
    heap_trace_dump();
    ...
}
```

The output from the heap trace has a similar format to the following example:

```
2 allocations trace (100 entry buffer)
32 bytes (@ 0x3ffaf214) allocated CPU 0 ccount 0x2e9b7384 caller
    0x400d276d:0x400d27c1 0x400d276d: leak_some_memory at /path/to/idf/examples/get-started/blink/main/../blink.c:27
    0x400d27c1: blink_task at /path/to/idf/examples/get-started/blink/main/../blink.c:52
8 bytes (@ 0x3ffaf804) allocated CPU 0 ccount 0x2e9b79c0 caller
    0x400d2776:0x400d27c1 0x400d2776: leak_some_memory at /path/to/idf/examples/get-started/blink/main/../blink.c:29
    0x400d27c1: blink_task at /path/to/idf/examples/get-started/blink/main/../blink.c:52
40 bytes 'leaked' in trace (2 allocations)
total allocations 2 total frees 0
```

**Note:** The above example output uses **IDF Monitor** to automatically decode PC addresses to their source files and line numbers.

The first line indicates how many allocation entries are in the buffer, compared to its total size.

In **HEAP_TRACE_LEAKS** mode, for each traced memory allocation that has not already been freed, a line is printed with:

- • **XX bytes** is the number of bytes allocated.
Chapter 2. API Reference

- @ 0x... is the heap address returned from `heap_caps_malloc()` or `heap_caps_calloc()`.
- Internal or PSRAM is the general location of the allocated memory.
- CPU x is the CPU (0 or 1) running when the allocation was made.
- ccount 0x... is the CCOUNT (CPU cycle count) register value the allocation was made. The value is different for CPU 0 vs CPU 1.
- caller 0x... gives the call stack of the call to `heap_caps_malloc()` or `heap_caps_free()`, as a list of PC addresses. These can be decoded to source files and line numbers, as shown above.

The depth of the call stack recorded for each trace entry can be configured in the project configuration menu, under Heap Memory Debugging > Enable heap tracing > `CONFIG_HEAP_TRACING_STACK_DEPTH`. Up to 32 stack frames can be recorded for each allocation (the default is 2). Each additional stack frame increases the memory usage of each `heap_trace_record_t` record by eight bytes.

Finally, the total number of the ‘leaked’ bytes (bytes allocated but not freed while the trace is running) is printed together with the total number of allocations it represents.

A warning will be printed if the trace buffer was not large enough to hold all the allocations happened. If you see this warning, consider either shortening the tracing period or increasing the number of records in the trace buffer.

**Host-Based Mode** Once you have identified the code which you think is leaking:

- In the project configuration menu, navigate to Component settings > Heap Memory Debugging > `CONFIG_HEAP_TRACING_DEST` and select Host-Based.
- In the project configuration menu, navigate to Component settings > Application Level Tracing > `CONFIG_APPTRACE_DESTINATION1` and select Trace memory.
- In the project configuration menu, navigate to Component settings > Application Level Tracing > FreeRTOS SystemView Tracing and enable `CONFIG_APPTRACE_SV_ENABLE`.
- Call the function `heap_trace_init_tohost()` early in the program, to initialize the JTAG heap tracing module.
- Call the function `heap_trace_start()` to begin recording all memory allocation and free calls in the system. Call this immediately before the piece of code which you suspect is leaking memory. In host-based mode, the argument to this function is ignored, and the heap tracing module behaves like `HEAP_TRACE_ALL` is passed, i.e., all allocations and deallocations are sent to the host.
- Call the function `heap_trace_stop()` to stop the trace once the suspect piece of code has finished executing.

The following code snippet demonstrates how application code would typically initialize, start, and stop host-based mode heap tracing:

```c
#include "esp_heap_trace.h"
...
void app_main()
{
   ...
   ESP_ERROR_CHECK( heap_trace_init_tohost() );
   ...
}

void some_function()
{
   ESP_ERROR_CHECK( heap_trace_start(HEAP_TRACE_LEAKS) );
   do_something_you_suspect_is_leaking();
   ESP_ERROR_CHECK( heap_trace_stop() );
   ...
}
```

To gather and analyze heap trace, do the following on the host:
1. Build the program and download it to the target as described in Step 5. First Steps on ESP-IDF.
2. Run OpenOCD (see JTAG Debugging).

**Note:** In order to use this feature, you need OpenOCD version v0.10.0-esp32-20181105 or later.

3. You can use GDB to start and/or stop tracing automatically. To do this you need to prepare a special `gdbinit` file:

```plaintext
target remote :3333
mon reset halt
maintenance flush register-cache
  tb heap_trace_start
commands
mon esp sysview start file:///tmp/heap.svdat
end

tb heap_trace_stop
commands
mon esp sysview stop
end

```

Using this file GDB can connect to the target, reset it, and start tracing when the program hits breakpoint at `heap_trace_start()`. Tracing will be stopped when the program hits breakpoint at `heap_trace_stop()`. Traced data will be saved to `/tmp/heap_log.svdat`.

4. Run GDB using `xtensa-esp32-elf-gdb -x gdbinit </path/to/program/elf>`.
5. Quit GDB when the program stops at `heap_trace_stop()`. Traced data are saved in `/tmp/heap_log.svdat`.
6. Run processing script `$IDF_PATH/tools/esp_app_trace/sysviewtrace_proc.py -p -b </path/to/program/elf> /tmp/heap_log.svdat`.

The output from the heap trace has a similar format to the following example:

```plaintext
Parse trace from '/tmp/heap.svdat'...
Stop parsing trace. (Timeout 0.000000 sec while reading 1 bytes!)
Process events from '('/tmp/heap.svdat')'...

Heap Tracing To Find Heap Corruption

Heap tracing can also be used to help track down heap corruption. When a region in the heap is corrupted, it may be from some other part of the program that allocated memory at a nearby address.

If you have an approximate idea of when the corruption occurred, enabling heap tracing in \texttt{HEAP\_TRACE\_ALL} mode allows you to record all the memory allocation functions used and the corresponding allocation addresses.

Using heap tracing in this way is very similar to memory leak detection as described above. For memories that are allocated and not freed, the output is the same. However, records will also be shown for memory that has been freed.

Performance Impact

Enabling heap tracing in menuconfig increases the code size of your program, and has a very small negative impact on the performance of heap allocation or free operations even when heap tracing is not running.

When heap tracing is running, heap allocation or free operations are substantially slower than when heap tracing is stopped. Increasing the depth of stack frames recorded for each allocation (see above) also increases this performance impact.

To mitigate the performance loss when the heap tracing is enabled and active, enable \texttt{CONFIG\_HEAP\_TRACE\_HASH\_MAP}. With this configuration enabled, a hash map mechanism will be used to handle the heap trace records, thus considerably decreasing the heap allocation or free execution time. The size of the hash map can be modified by setting the value of \texttt{CONFIG\_HEAP\_TRACE\_HASH\_MAP\_SIZE}.

By default, the hash map is placed into internal RAM. It can also be placed into external RAM if \texttt{CONFIG\_HEAP\_TRACE\_HASH\_MAP\_IN\_EXT\_RAM} is enabled. In order to enable this configuration, make sure to enable \texttt{CONFIG\_SPIRAM} and \texttt{CONFIG\_SPIRAM\_ALLOW\_BSS\_SEG\_EXTERNAL\_MEMORY}.

False-Positive Memory Leaks

Not everything printed by \texttt{heap\_trace\_dump()} is necessarily a memory leak. The following cases may also be printed:

- Any memory that is allocated after \texttt{heap\_trace\_start()} but freed after \texttt{heap\_trace\_stop()} appears in the leaked dump.
- Allocations may be made by other tasks in the system. Depending on the timing of these tasks, it is quite possible that this memory is freed after \texttt{heap\_trace\_stop()} is called.
- The first time a task uses stdio - e.g., when it calls \texttt{heap\_caps\_printf()} - a lock, i.e., RTOS mutex semaphore, is allocated by the libc. This allocation lasts until the task is deleted.
- Certain uses of \texttt{heap\_caps\_printf()}, such as printing floating point numbers and allocating some memory from the heap on demand. These allocations last until the task is deleted.
- The Bluetooth, Wi-Fi, and TCP/IP libraries allocate heap memory buffers to handle incoming or outgoing data. These memory buffers are usually short-lived, but some may be shown in the heap leak trace if the data has been received or transmitted by the lower levels of the network during the heap tracing.
- TCP connections retain some memory even after they are closed due to the \texttt{TIME\_WAIT} state. Once the \texttt{TIME\_WAIT} period is completed, this memory will be freed.
One way to differentiate between “real” and “false positive” memory leaks is to call the suspect code multiple times while tracing is running, and look for patterns (multiple matching allocations) in the heap trace output.

**API Reference - Heap Tracing**

**Header File**
- `components/heap/include/esp_heap_trace.h`
- This header file can be included with:

```c
#include "esp_heap_trace.h"
```

**Functions**

- `esp_err_t heap_trace_init_standalone(heap_trace_record_t *record_buffer, size_t num_records)`
  - Initialise heap tracing in standalone mode.
  - This function must be called before any other heap tracing functions.
  - To disable heap tracing and allow the buffer to be freed, stop tracing and then call `heap_trace_init_standalone(NULL, 0);`

  **Parameters**
  - `record_buffer` – Provide a buffer to use for heap trace data. Note: External RAM is allowed, but it prevents recording allocations made from ISR’s.
  - `num_records` – Size of the heap trace buffer, as number of record structures.

  **Returns**
  - ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
  - ESP_ERR_INVALID_STATE Heap tracing is currently in progress.
  - ESP_OK Heap tracing initialised successfully.

- `esp_err_t heap_trace_init_tohost(void)`
  - Initialise heap tracing in host-based mode.
  - This function must be called before any other heap tracing functions.

  **Returns**
  - ESP_ERR_INVALID_STATE A non-zero-length buffer has not been set via `heap_trace_init_standalone()`.
  - ESP_OK Heap tracing initialised successfully.

- `esp_err_t heap_trace_start(heap_trace_mode_t mode)`
  - Start heap tracing. All heap allocations & frees will be traced, until `heap_trace_stop()` is called.

  **Parameters**
  - `mode` – Mode for tracing.
    - HEAP_TRACE_ALL means all heap allocations and frees are traced.
    - HEAP_TRACE_LEAKS means only suspected memory leaks are traced. (When memory is freed, the record is removed from the trace buffer.)

  **Returns**
  - ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
  - ESP_ERR_INVALID_STATE A non-zero-length buffer has not been set via `heap_trace_init_standalone()`.
  - ESP_OK Tracing is started.
esp_err_t heap_trace_stop (void)
Stop heap tracing.

Returns
• ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
• ESP_ERR_INVALID_STATE Heap tracing was not in progress.
• ESP_OK Heap tracing stopped.

esp_err_t heap_trace_resume (void)
Resume heap tracing which was previously stopped.

Unlike heap_trace_start(), this function does not clear the buffer of any pre-existing trace records.
The heap trace mode is the same as when heap_trace_start() was last called (or HEAP_TRACE_ALL if heap_trace_start() was never called).

Returns
• ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
• ESP_ERR_INVALID_STATE Heap tracing was already started.
• ESP_OK Heap tracing resumed.

size_t heap_trace_get_count (void)
Return number of records in the heap trace buffer.
It is safe to call this function while heap tracing is running.

esp_err_t heap_trace_get (size_t index, heap_trace_record_t *record)
Return a raw record from the heap trace buffer.

Note: It is safe to call this function while heap tracing is running, however in HEAP_TRACE_LEAK mode record indexing may skip entries unless heap tracing is stopped first.

Parameters
• index – Index (zero-based) of the record to return.
• record – [out] Record where the heap trace record will be copied.

Returns
• ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
• ESP_ERR_INVALID_STATE Heap tracing was not initialised.
• ESP_ERR_INVALID_ARG Index is out of bounds for current heap trace record count.
• ESP_OK Record returned successfully.

void heap_trace_dump (void)
Dump heap trace record data to stdout.

Note: It is safe to call this function while heap tracing is running, however in HEAP_TRACE_LEAK mode the dump may skip entries unless heap tracing is stopped first.

void heap_trace_dump_caps (const uint32_t caps)
Dump heap trace from the memory of the capabilities passed as parameter.

Parameters caps – Capability(ies) of the memory from which to dump the trace. Set MAL-LOC_CAP_INTERNAL to dump heap trace data from internal memory. Set MAL-LOC_CAP_SPIRAM to dump heap trace data from PSRAM. Set both to dump both heap trace data.
Esperrif Systems 2324 Release v5.3-dev-277-gc8243465e4

Chapter 2. API Reference

**esp_err_t heap_trace_summary (heap_trace_summary_t *summary)**

Get summary information about the result of a heap trace.

**Note:** It is safe to call this function while heap tracing is running.

**Structures**

**struct heap_trace_record_t**

Trace record data type. Stores information about an allocated region of memory.

**Public Members**

- **uint32_t ccoun**
  
  CCOUNT of the CPU when the allocation was made. LSB (bit value 1) is the CPU number (0 or 1).

- **void *address**
  
  Address which was allocated. If NULL, then this record is empty.

- **size_t size**
  
  Size of the allocation.

- **void *allocated_by[CONFIG_HEAP_TRACING_STACK_DEPTH]**
  
  Call stack of the caller which allocated the memory.

- **void *freed_by[CONFIG_HEAP_TRACING_STACK_DEPTH]**
  
  Call stack of the caller which freed the memory (all zero if not freed.)

**struct heap_trace_summary_t**

Stores information about the result of a heap trace.

**Public Members**

- **heap_trace_mode_t mode**
  
  The heap trace mode we just completed / are running.

- **size_t total_allocations**
  
  The total number of allocations made during tracing.

- **size_t total_frees**
  
  The total number of frees made during tracing.

- **size_t count**
  
  The number of records in the internal buffer.

- **size_t capacity**
  
  The capacity of the internal buffer.
size_t high_water_mark

The maximum value that ‘count’ got to.

size_t has_overflowed

True if the internal buffer overflowed at some point.

Macros

CONFIG_HEAP_TRACING_STACK_DEPTH

Type Definitions

typedef struct heap_trace_record_t

Trace record data type. Stores information about an allocated region of memory.

Enumerations

enum heap_trace_mode_t

Values:

enumerator HEAP_TRACE_ALL

enumerator HEAP_TRACE_LEAKS

2.10.17 High Resolution Timer (ESP Timer)

Overview

Although FreeRTOS provides software timers, FreeRTOS software timers have a few limitations:

• Maximum resolution is equal to the RTOS tick period
• Timer callbacks are dispatched from a low-priority timer service (i.e., daemon) task. This task can be pre-empted by other tasks, leading to decreased precision and accuracy.

Although hardware timers are not subject to the limitations mentioned, they may not be as user-friendly. For instance, application components may require timer events to be triggered at specific future times, but hardware timers typically have only one “compare” value for interrupt generation. This necessitates the creation of an additional system on top of the hardware timer to keep track of pending events and ensure that callbacks are executed when the corresponding hardware interrupts occur.

The hardware timer interrupt’s priority is configured via the CONFIG_ESP_TIMER_INTERRUPT_LEVEL option (possible priorities being 1, 2, or 3). Raising the timer interrupt’s priority can reduce the timer processing delay caused by interrupt latency.

esp_timer set of APIs provides one-shot and periodic timers, microsecond time resolution, and 64-bit range.

Internally, esp_timer uses a 64-bit hardware timer. The exact hardware timer implementation used depends on the target, where LAC timer is used for ESP32.

Timer callbacks can be dispatched by two methods:

• ESP TIMER TASK.
Chapter 2. API Reference

- **ESP_TIMER_ISR**. Available only if `CONFIG_ESP_TIMER_SUPPORTS_ISR_DISPATCH_METHOD` is enabled (by default disabled).

**ESP_TIMER_TASK**. Timer callbacks are dispatched from a high-priority `esp_timer` task. Because all the callbacks are dispatched from the same task, it is recommended to only do the minimal possible amount of work from the callback itself, posting an event to a lower-priority task using a queue instead.

If other tasks with a priority higher than `esp_timer` are running, callback dispatching will be delayed until the `esp_timer` task has a chance to run. For example, this will happen if an SPI Flash operation is in progress.

**ESP_TIMER_ISR**. Timer callbacks are dispatched directly from the timer interrupt handler. This method is useful for some simple callbacks which aim for lower latency.

Creating and starting a timer, and dispatching the callback takes some time. Therefore, there is a lower limit to the timeout value of one-shot `esp_timer`. If `esp_timer_start_once()` is called with a timeout value of less than 20 us, the callback will be dispatched only after approximately 20 us.

Periodic `esp_timer` also imposes a 50 us restriction on the minimal timer period. Periodic software timers with a period of less than 50 us are not practical since they would consume most of the CPU time. Consider using dedicated hardware peripherals or DMA features if you find that a timer with a small period is required.

**Using esp_timer APIs**

A single timer is represented by `esp_timer_handle_t` type. Each timer has a callback function associated with it. This callback function is called from the `esp_timer` task each time the timer elapses.

- To create a timer, call `esp_timer_create()`.  
- To delete the timer when it is no longer needed, call `esp_timer_delete()`.

The timer can be started in one-shot mode or in periodic mode.

- To start the timer in one-shot mode, call `esp_timer_start_once()`, passing the time interval after which the callback should be called. When the callback gets called, the timer is considered to be stopped.  
- To start the timer in periodic mode, call `esp_timer_start_periodic()`, passing the period with which the callback should be called. The timer keeps running until `esp_timer_stop()` is called.

Note that the timer must not be running when `esp_timer_start_once()` or `esp_timer_start_periodic()` is called. To restart a running timer, call `esp_timer_stop()` first, then call one of the start functions.

**Callback Functions**

**Note**: Keep the callback functions as short as possible. Otherwise, it will affect all timers.

Timer callbacks that are processed by the `ESP_TIMER_ISR` method should not call the context switch call `portYIELD_FROM_ISR()`. Instead, use the `esp_timer_isr_dispatch_need_yield()` function. The context switch will be done after all ISR dispatch timers have been processed if required by the system.

**esp_timer** During Light-sleep

During Light-sleep, the `esp_timer` counter stops and no callback functions are called. Instead, the time is counted by the RTC counter. Upon waking up, the system gets the difference between the counters and calls a function that advances the `esp_timer` counter. Since the counter has been advanced, the system starts calling callbacks that were not called during sleep. The number of callbacks depends on the duration of the sleep and the period of the timers. It can lead to the overflow of some queues. This only applies to periodic timers, since one-shot timers are only called once.

This behavior can be changed by calling `esp_timer_stop()` before sleeping. In some cases, this can be inconvenient, and instead of the stop function, you can use the `skip_unhandled_events` option during
**esp_timer_create().** When the `skip_unhandled_events` is true, if a periodic timer expires one or more times during Light-sleep, then only one callback is called on wake.

Using the `skip_unhandled_events` option with automatic Light-sleep (see Power Management APIs) helps to reduce the power consumption of the system when it is in Light-sleep. The duration of Light-sleep is also in part determined by the next event occurs. Timers with `skip_unhandled_events` option does not wake up the system.

### Handling Callbacks

`esp_timer` is designed to achieve a high-resolution and low-latency timer with the ability to handle delayed events. If the timer is late, then the callback will be called as soon as possible, and it will not be lost. In the worst case, when the timer has not been processed for more than one period (for periodic timers), the callbacks will be called one after the other without waiting for the set period. This can be bad for some applications, and the `skip_unhandled_events` option is introduced to eliminate this behavior. If `skip_unhandled_events` is set, then a periodic timer that has expired multiple times without being able to call the callback will still result in only one callback event once processing is possible.

### Obtaining Current Time

`esp_timer` also provides a convenience function to obtain the time passed since start-up, with microsecond precision: `esp_timer_get_time()`. This function returns the number of microseconds since `esp_timer` was initialized, which usually happens shortly before `app_main` function is called.

Unlike `gettimeofday` function, values returned by `esp_timer_get_time()`:

- Start from zero after the chip wakes up from Deep-sleep
- Do not have timezone or DST adjustments applied

### Application Example

The following example illustrates the usage of `esp_timer` APIs: `system/esp_timer`.

### API Reference

#### Header File

- `components/esp_timer/include/esp_timer.h`
- This header file can be included with:

  ```c
  #include "esp_timer.h"
  ```

- This header file is a part of the API provided by the `esp_timer` component. To declare that your component depends on `esp_timer`, add the following to your `CMakeLists.txt`:

  ```cmake
  REQUIREES esp_timer
  ```
  or
  ```cmake
  PRIV_REQUIRES esp_timer
  ```

#### Functions

- `esp_err_t esp_timer_early_init(void)`
  - Minimal initialization of `esp_timer`.

  This function can be called very early in startup process, after this call only `esp_timer_get_time` function can be used.
**Note:** This function is called from startup code. Applications do not need to call this function before using other esp_timer APIs.

**Returns**
- ESP_OK on success

`esp_err_t esp_timer_init (void)`

Initialize esp_timer library.

This function will be called from startup code on every core if CONFIG_ESP_TIMER_ISR_AFFINITY_NO_AFFINITY is enabled. It allocates the timer ISR on MULTIPLE cores and creates the timer task which can be run on any core.

**Note:** This function is called from startup code. Applications do not need to call this function before using other esp_timer APIs. Before calling this function, esp_timer_early_init must be called by the startup code.

**Returns**
- ESP_OK on success
- ESP_ERR_NO_MEM if allocation has failed
- ESP_ERR_INVALID_STATE if already initialized
- other errors from interrupt allocator

`esp_err_t esp_timer_deinit (void)`

De-initialize esp_timer library.

**Note:** Normally this function should not be called from applications

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_STATE if not yet initialized

`esp_err_t esp_timer_create (const esp_timer_create_args_t *create_args, esp_timer_handle_t *out_handle)`

Create an esp_timer instance.

**Note:** When done using the timer, delete it with esp_timer_delete function.

**Parameters**
- `create_args` - Pointer to a structure with timer creation arguments. Not saved by the library, can be allocated on the stack.
- `out_handle` - [out] Output, pointer to esp_timer_handle_t variable which will hold the created timer handle.

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if some of the create_args are not valid
- ESP_ERR_INVALID_STATE if esp_timer library is not initialized yet
- ESP_ERR_NO_MEM if memory allocation fails

`esp_err_t esp_timer_start_once (esp_timer_handle_t timer, uint64_t timeout_us)`

Start one-shot timer.

Timer should not be running when this function is called.
**Parameters**
- `timer` - timer handle created using `esp_timer_create`
- `timeout_us` - timer timeout, in microseconds relative to the current moment

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is already running

*esp_err_t* `esp_timer_start_periodic (esp_timer_handle_t timer, uint64_t period)`

Start a periodic timer.

Timer should not be running when this function is called. This function will start the timer which will trigger every `period` microseconds.

**Parameters**
- `timer` - timer handle created using `esp_timer_create`
- `period` - timer period, in microseconds

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is already running

*esp_err_t* `esp_timer_restart (esp_timer_handle_t timer, uint64_t timeout_us)`

Restart a currently running timer.

If the given timer is a one-shot timer, the timer is restarted immediately and will timeout once in `timeout_us` microseconds. If the given timer is a periodic timer, the timer is restarted immediately with a new period of `timeout_us` microseconds.

**Parameters**
- `timer` - timer handle created using `esp_timer_create`
- `timeout_us` - Timeout, in microseconds relative to the current time. In case of a periodic timer, also represents the new period.

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is not running

*esp_err_t* `esp_timer_stop (esp_timer_handle_t timer)`

Stop the timer.

This function stops the timer previously started using `esp_timer_start_once` or `esp_timer_start_periodic`.

**Parameters**
- `timer` - timer handle created using `esp_timer_create`

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_STATE if the timer is not running

*esp_err_t* `esp_timer_delete (esp_timer_handle_t timer)`

Delete an esp_timer instance.

The timer must be stopped before deleting. A one-shot timer which has expired does not need to be stopped.

**Parameters**
- `timer` - timer handle allocated using `esp_timer_create`

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_STATE if the timer is running

*int64_t* `esp_timer_get_time (void)`

Get time in microseconds since boot.

**Returns** number of microseconds since underlying timer has been started
int64_t esp_timer_get_next_alarm (void)
Get the timestamp when the next timeout is expected to occur.

Returns: Timestamp of the nearest timer event, in microseconds. The timebase is the same as for the values returned by esp_timer_get_time.

int64_t esp_timer_get_next_alarm_for_wake_up (void)
Get the timestamp when the next timeout is expected to occur skipping those which have skip_unhandled_events flag.

Returns: Timestamp of the nearest timer event, in microseconds. The timebase is the same as for the values returned by esp_timer_get_time.

esp_err_t esp_timer_get_period (esp_timer_handle_t timer, uint64_t *period)
Get the period of a timer.

This function fetches the timeout period of a timer.

Note: The timeout period is the time interval with which a timer restarts after expiry. For one-shot timers, the period is 0 as there is no periodicity associated with such timers.

Parameters:
- **timer** — timer handle allocated using esp_timer_create
- **period** — memory to store the timer period value in microseconds

Returns:
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the arguments are invalid

esp_err_t esp_timer_get_expiry_time (esp_timer_handle_t timer, uint64_t *expiry)
Get the expiry time of a one-shot timer.

This function fetches the expiry time of a one-shot timer.

Note: This API returns a valid expiry time only for a one-shot timer. It returns an error if the timer handle passed to the function is for a periodic timer.

Parameters:
- **timer** — timer handle allocated using esp_timer_create
- **expiry** — memory to store the timeout value in microseconds

Returns:
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the arguments are invalid
- ESP_ERR_NOT_SUPPORTED if the timer type is periodic

esp_err_t esp_timer_dump (FILE *stream)
Dump the list of timers to a stream.

If CONFIG_ESP_TIMER_PROFILING option is enabled, this prints the list of all the existing timers. Otherwise, only the list active timers is printed.

The format is:

name period alarm times armed times triggered total_callback_run_time

where:

name — timer name (if CONFIG_ESP_TIMER_PROFILING is defined), or timer pointer period — period of timer, in microseconds, or 0 for one-shot timer alarm - time of the next alarm, in microseconds since boot, or 0 if the timer is not started
The following fields are printed if CONFIG_ESP_TIMER_PROFILING is defined:

- times_armed — number of times the timer was armed via esp_timer_start_X
- times_triggered — number of times the callback was called
- total_callback_run_time — total time taken by callback to execute, across all calls

**Parameters**
- stream — stream (such as stdout) to dump the information to

**Returns**
- ESP_OK on success
- ESP_ERR_NO_MEM if can not allocate temporary buffer for the output

```c
void esp_timer_isr_dispatch_need_yield (void)
```
Requests a context switch from a timer callback function.

This only works for a timer that has an ISR dispatch method. The context switch will be called after all ISR dispatch timers have been processed.

**bool esp_timer_is_active (esp_timer_handle_t timer)**

Returns status of a timer, active or not.

This function is used to identify if the timer is still active or not.

**Parameters**
- timer — timer handle created using esp_timer_create

**Returns**
- 1 if timer is still active
- 0 if timer is not active.

```c
esp_err_t esp_timer_new_etm_alarm_event (esp_etm_event_handle_t *out_event)
```
Get the ETM event handle of esp_timer underlying alarm event.

---

**Note:** The created ETM event object can be deleted later by calling esp_etm_del_event

**Note:** The ETM event is generated by the underlying hardware & systimer, therefore, if the esp_timer is not clocked by systimer, then no ETM event will be generated.

```c
Parameters out_event — [out] Returned ETM event handle
Returns
- ESP_OK Success
- ESP_ERR_INVALID_ARG Parameter error
```

**Structures**

```c
struct esp_timer_create_args_t
```
Timer configuration passed to esp_timer_create.

**Public Members**

```c
esp_timer_cb_t callback
```
Function to call when timer expires.

```c
void *arg
```
Argument to pass to the callback.

```c
esp_timer_dispatch_t dispatch_method
```
Call the callback from task or from ISR.
const char *name
    Timer name, used in esp_timer_dump function.

bool skip_unhandled_events
    Skip unhandled events for periodic timers.

Type Definitions
typedef struct esp_timer *esp_timer_handle_t
    Opaque type representing a single esp_timer.
typedef void (*esp_timer_cb_t)(void *arg)
    Timer callback function type.

Param arg  pointer to opaque user-specific data

Enumerations
enum esp_timer_dispatch_t
    Method for dispatching timer callback.
Values:
enumerator ESP_TIMER_TASK
    Callback is called from timer task.
enumerator ESP_TIMER_MAX
    Count of the methods for dispatching timer callback.

2.10.18 Internal and Unstable APIs

This section is listing some APIs that are internal or likely to be changed or removed in the next releases of ESP-IDF.

API Reference

Header File

- components/esp_rom/include/esp_rom_sys.h
- This header file can be included with:

```
#include "esp_rom_sys.h"
```

Functions

void esp_rom_software_reset_system (void)
    Software Reset digital core include RTC.
    It is not recommended to use this function in esp-idf, use esp_restart() instead.

void esp_rom_software_reset_cpu (int cpu_no)
    Software Reset cpu core.
    It is not recommended to use this function in esp-idf, use esp_restart() instead.

    Parameters cpu_no →: The CPU to reset, 0 for PRO CPU, 1 for APP CPU.
int esp_rom_printf (const char *fmt, ...)  
Print formated string to console device.

**Note:** float and long long data are not supported!

**Parameters**
- **fmt**  Format string
- **...** Additional arguments, depending on the format string

**Returns**  int: Total number of characters written on success; A negative number on failure.

void esp_rom_delay_us (uint32_t us)  
Pauses execution for us microseconds.

**Parameters**
- **us**  Number of microseconds to pause

void esp_rom_install_channel_putchar (int channel, void (*putc)(char c))  
esp_rom_printf can print message to different channels simultaneously. This function can help install the low level putc function for esp_rom_printf.

**Parameters**
- **channel**  Channel number (starting from 1)
- **putc**  Function pointer to the putc implementation. Set NULL can disconnect esp_rom_printf with putc.

void esp_rom_install_uart_putchar (void)  
Install UART1 as the default console channel, equivalent to esp_rom_install_channel_putchar(1, esp_rom_uart_putchar)

soc_reset_reason_t esp_rom_get_reset_reason (int cpu_no)  
Get reset reason of CPU.

**Parameters**
- **cpu_no**  CPU number

**Returns**  Reset reason code (see in soc/reset_reasons.h)

void esp_rom_route_intr_matrix (int cpu_core, uint32_t periph_intr_id, uint32_t cpu_intr_num)  
Route peripheral interrupt sources to CPU’s interrupt port by matrix.

Usually there’re 4 steps to use an interrupt:
- a. Route peripheral interrupt source to CPU. e.g. esp_rom_route_intr_matrix(0, ETS_WIFI_MAC_INTR_SOURCE, ETS_WMALLOC_INTR_NUM)
- b. Set interrupt handler for CPU
- c. Enable CPU interrupt
- d. Enable peripheral interrupt

**Parameters**
- **cpu_core**  The CPU number, which the peripheral interrupt will inform to
- **periph_intr_id**  The peripheral interrupt source number
- **cpu_intr_num**  The CPU (external) interrupt number. On targets that use CLIC as their interrupt controller, this number represents the external interrupt number. For example, passing cpu_intr_num = i to this function would in fact bind peripheral source to CPU interrupt CLIC_EXT_INTR_NUM_OFFSET + i.

uint32_t esp_rom_get_cpu_ticks_per_us (void)  
Get the real CPU ticks per us.

**Returns**  CPU ticks per us
void esp_rom_set_cpu_ticks_per_us(uint32_t ticks_per_us)
Set the real CPU tick rate.

**Note:** Call this function when CPU frequency is changed, otherwise the esp_rom_delay_us can be inaccurate.

**Parameters**
- **ticks_per_us** – CPU ticks per us

### 2.10.19 Inter-Processor Call (IPC)

**Note:** IPC stands for an “Inter-Processor Call” and NOT “Inter-Process Communication” as found on other operating systems.

#### Overview

Due to the dual core nature of the ESP32, there are some scenarios where a certain callback must be executed from a particular core such as:

- When allocating an ISR to an interrupt source of a particular core (applies to freeing a particular core’s interrupt source as well)
- On particular chips (such as the ESP32), accessing memory that is exclusive to a particular core (such as RTC Fast Memory)
- Reading the registers/state of another core

The IPC (Inter-Processor Call) feature allows a particular core (the calling core) to trigger the execution of a callback function on another core (the target core). The IPC feature allows execution of a callback function on the target core in either a task context, or an interrupt context. Depending on the context that the callback function is executed in, different restrictions apply to the implementation of the callback function.

#### IPC in Task Context

The IPC feature implements callback execution in a task context by creating an IPC task for each core during application startup. When the calling core needs to execute a callback on the target core, the callback will execute in the context of the target core’s IPC task.

When using IPCs in a task context, users need to consider the following:

- IPC callbacks should ideally be simple and short. An IPC callback **must never block or yield**.
- The IPC tasks are created at the highest possible priority (i.e., `configMAX_PRIORITIES - 1`).
  - If `CONFIG_ESP_IPC_USES_CALLERS_PRIORITY` is enabled, the target core’s IPC task will be lowered to the current priority of the target core before executing the callback.
  - If `CONFIG_ESP_IPC_USES_CALLERS_PRIORITY` is disabled, the target core will always execute the callback at the highest possible priority.
- Depending on the complexity of the callback, users may need to configure the stack size of the IPC task via `CONFIG_ESP_IPC_TASK_STACK_SIZE`.
- The IPC feature is internally protected by a mutex. Therefore, simultaneous IPC calls from two or more calling cores are serialized on a first come first serve basis.

#### API Usage

Task Context IPC callbacks have the following restrictions:

- The callback must be of the `esp_ipc_func_t` type.
- The callback **must never block or yield** as this will result in the target core’s IPC task blocking or yielding.
The callback must avoid changing any aspect of the IPC task’s state, e.g., by calling \texttt{vTaskPrioritySet(NULL, x)}.

The IPC feature offers the API listed below to execute a callback in a task context on a target core. The API allows the calling core to block until the callback’s execution has completed, or return immediately once the callback’s execution has started.

- \texttt{esp_ipc_call()} triggers an IPC call on the target core. This function will block until the target core’s IPC task begins execution of the callback.
- \texttt{esp_ipc_call_blocking()} triggers an IPC on the target core. This function will block until the target core’s IPC task completes execution of the callback.

### IPC in Interrupt Context

In some cases, we need to quickly obtain the state of another core such as in a core dump, GDB stub, various unit tests, and hardware errata workarounds. The IPC ISR feature implements callback execution from a High Priority Interrupt context by reserving a High Priority Interrupt on each core for IPC usage. When a calling core needs to execute a callback on the target core, the callback will execute in the context of the High Priority Interrupt of the target core.

For such scenarios, the IPC ISR feature supports execution of callbacks in a \textit{High Priority Interrupt} context.

When using IPCs in High Priority Interrupt context, users need to consider the following:

- Since the callback is executed in a High Priority Interrupt context, the callback must be written entirely in assembly. See the API Usage below for more details regarding writing assembly callbacks.
- The priority of the reserved High Priority Interrupt is dependent on the \texttt{CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL} option.

When the callback executes, users need to consider the following:

- The calling core will disable interrupts of priority level 3 and lower.
- Although the priority of the reserved interrupt depends on \texttt{CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL}, during the execution of IPC ISR callback, the target core will disable interrupts of priority level 5 and lower regardless of what \texttt{CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL} is set to.

### API Usage

High Priority Interrupt IPC callbacks have the following restrictions:

- The callback must be of type \texttt{esp_ipc_isr_func_t} but implemented entirely in assembly.
- The callback is invoked via the \texttt{CALLX0} instruction with register windowing disabled, thus the callback:
  - must not call any register window related instructions, e.g., \texttt{entry} and \texttt{retw}.
  - must not call other C functions as register windowing is disabled.
- The callback should be placed in IRAM at a 4-byte aligned address.
- On invocation of, or after returning from the callback, the registers \texttt{a2}, \texttt{a3}, \texttt{a4} are saved/restored automatically, thus:
  - \texttt{a2} contains the \texttt{void *arg} of the callback.
  - \texttt{a3/a4} are free to use as scratch registers.

The IPC feature offers the API listed below to execute a callback in a High Priority Interrupt context:

- \texttt{esp_ipc_isr_call()} triggers an IPC call on the target core. This function will busy-wait until the target core begins execution of the callback.
- \texttt{esp_ipc_isr_call_blocking()} triggers an IPC call on the target core. This function will busy-wait until the target core completes execution of the callback.

The following code-blocks demonstrates a High Priority Interrupt IPC callback written in assembly that simply reads the target core’s cycle count:
Chapter 2. API Reference

/* esp_test_ipc_isr_get_cycle_count_other_cpu(void *arg) */
// this function reads C_COUNT of the target core and stores it in arg.
// use only a2, a3 and a4 regs here.
.section .iram1, "ax"
.align 4
.global esp_test_ipc_isr_get_cycle_count_other_cpu
.type esp_test_ipc_isr_get_cycle_count_other_cpu, @function
// Args:
// a2 - void* arg
esp_test_ipc_isr_get_cycle_count_other_cpu:
rsr.ccount a3
s32i a3, a2, 0
ret

Note: The number of scratch registers available for use is sufficient for most simple use cases. But if your callback requires more scratch registers, void *arg can point to a buffer that is used as a register save area. The callback can then save and restore more registers. See the system/ipc/ipc_isr.

Note: For more examples of High Priority Interrupt IPC callbacks, you can refer to components/esp_system/port/arch/xtensa/esp_ipc_isr_routines.S and components/esp_system/test_apps/esp_system Unity_tests/main/port/arch/xtensa/test_ipc_isr.S.

See examples/system/ipc/ipc_isr/xtensa/main/main.c for an example of its use.

The High Priority Interrupt IPC API also provides the following convenience functions that can stall/resume the target core. These APIs utilize the High Priority Interrupt IPC, but supply their own internal callbacks:

- esp_ipc_isr_stall_other_cpu() stalls the target core. The calling core disables interrupts of level 3 and lower while the target core will busy-wait with interrupts of level 5 and lower disabled. The target core will busy-wait until esp_ipc_isr_release_other_cpu() is called.
- esp_ipc_isr_release_other_cpu() resumes the target core.

API Reference

Header File

- components/esp_system/include/esp_ipc.h
- This header file can be included with:

```c
#include "esp_ipc.h"
```

Functions

- esp_err_t esp_ipc_call(uint32_t cpu_id, esp_ipc_func_t func, void *arg)

  Execute a callback on a given CPU.

  Execute a given callback on a particular CPU. The callback must be of type “esp_ipc_func_t” and will be invoked in the context of the target CPU’s IPC task.

  - This function will block the target CPU’s IPC task has begun execution of the callback
• If another IPC call is ongoing, this function will block until the ongoing IPC call completes
• The stack size of the IPC task can be configured via the CONFIG_ESP_IPC_TASK_STACK_SIZE option

Note: In single-core mode, returns ESP_ERR_INVALID_ARG for cpu_id 1.

Parameters
• cpu_id [in] CPU where the given function should be executed (0 or 1)
• func [in] Pointer to a function of type void func(void* arg) to be executed
• arg [in] Arbitrary argument of type void* to be passed into the function

Returns
• ESP_ERR_INVALID_ARG if cpu_id is invalid
• ESP_ERR_INVALID_STATE if the FreeRTOS scheduler is not running
• ESP_OK otherwise

```c
esp_err_t esp_ipc_call_blocking(uint32_t cpu_id, esp_ipc_func_t func, void *arg)
```

Execute a callback on a given CPU until and block until it completes.

This function is identical to esp_ipc_call() except that this function will block until the execution of the callback completes.

Note: In single-core mode, returns ESP_ERR_INVALID_ARG for cpu_id 1.

Parameters
• cpu_id [in] CPU where the given function should be executed (0 or 1)
• func [in] Pointer to a function of type void func(void* arg) to be executed
• arg [in] Arbitrary argument of type void* to be passed into the function

Returns
• ESP_ERR_INVALID_ARG if cpu_id is invalid
• ESP_ERR_INVALID_STATE if the FreeRTOS scheduler is not running
• ESP_OK otherwise

Type Definitions
typedef void (*esp_ipc_func_t)(void *arg)

IPC Callback.
A callback of this type should be provided as an argument when calling esp_ipc_call() or esp_ipc_call_blocking().

Header File
• components/esp_system/include/esp_ipc_isr.h
• This header file can be included with:

```
#include "esp_ipc_isr.h"
```

Functions
void esp_ipc_isr_call (esp_ipc_isr_func_t func, void *arg)

Execute an ISR callback on the other CPU.

Execute a given callback on the other CPU in the context of a High Priority Interrupt.

• This function will busy-wait in a critical section until the other CPU has started execution of the callback
• The callback must be written:
  – in assembly for XTENSA chips (such as ESP32, ESP32S3). The function is invoked using a
    CALLX0 instruction and can use only a2, a3, a4 registers. See doc:IPC in Interrupt Con-
    text </api-reference/system/ipc> doc for more details.
  – in C or assembly for RISCV chips (such as ESP32P4).

Note: This function is not available in single-core mode.

**Parameters**

- `func` - [in] Pointer to a function of type `void func(void* arg)` to be executed
- `arg` - [in] Arbitrary argument of type `void*` to be passed into the function

```c
void esp_ipc_isr_call_blocking(esp_ipc_isr_func_t func, void *arg)
```

Execute an ISR callback on the other CPU and busy-wait until it completes.

This function is identical to `esp_ipc_isr_call()` except that this function will busy-wait until the execution of the
callback completes.

Note: This function is not available in single-core mode.

**Parameters**

- `func` - [in] Pointer to a function of type `void func(void* arg)` to be executed
- `arg` - [in] Arbitrary argument of type `void*` to be passed into the function

```c
void esp_ipc_isr_stall_other_cpu(void)
```

Stall the other CPU.

This function will stall the other CPU. The other CPU is stalled by busy-waiting in the context of a High
Priority Interrupt. The other CPU will not be resumed until `esp_ipc_isr_release_other_cpu()` is called.

- This function is internally implemented using IPC ISR
- This function is used for DPORT workaround.
- If the stall feature is paused using `esp_ipc_isr_stall_pause()`, this function will have no effect

Note: This function is not available in single-core mode.

Note: It is the caller’s responsibility to avoid deadlocking on spinlocks

```c
void esp_ipc_isr_release_other_cpu(void)
```

Release the other CPU.

This function will release the other CPU that was previously stalled from calling `esp_ipc_isr_stall_other_cpu()`

- This function is used for DPORT workaround.
- If the stall feature is paused using `esp_ipc_isr_stall_pause()`, this function will have no effect

Note: This function is not available in single-core mode.
void **esp_ipc_isr_stall_pause**(void)

Pause the CPU stall feature.

This function will pause the CPU stall feature. Once paused, calls to esp_ipc_isr_stall_other_cpu() and esp_ipc_isr_release_other_cpu() will have no effect. If a IPC ISR call is already in progress, this function will busy-wait until the call completes before pausing the CPU stall feature.

void **esp_ipc_isr_stall_abort**(void)

Abort a CPU stall.

This function will abort any stalling routine of the other CPU due to a previous call to esp_ipc_isr_stall_other_cpu(). This function aborts the stall in a non-recoverable manner, thus should only be called in case of a panic().

- This function is used in panic handling code

void **esp_ipc_isr_stall_resume**(void)

Resume the CPU stall feature.

This function will resume the CPU stall feature that was previously paused by calling esp_ipc_isr_stall_pause(). Once resumed, calls to esp_ipc_isr_stall_other_cpu() and esp_ipc_isr_release_other_cpu() will have effect again.

**Macros**

**esp_ipc_isr_asm_call**(func, arg)

Execute an ISR callback on the other CPU See esp_ipc_isr_call().

**esp_ipc_isr_asm_call_blocking**(func, arg)

Execute an ISR callback on the other CPU and busy-wait until it completes See esp_ipc_isr_call_blocking().

**Type Definitions**

typedef void *(^**esp_ipc_isr_func_t**)(void *arg)

IPC ISR Callback.

The callback must be written:

- in assembly for XTENSA chips (such as ESP32, ESP32S3).
- in C or assembly for RISCV chips (such as ESP32P4).

A callback of this type should be provided as an argument when calling esp_ipc_isr_call() or esp_ipc_isr_call_blocking().

### 2.10.20 Interrupt Allocation

**Overview**

The ESP32 has two cores, with 32 interrupts each. Each interrupt has a fixed priority, most (but not all) interrupts are connected to the interrupt matrix.

Because there are more interrupt sources than interrupts, sometimes it makes sense to share an interrupt in multiple drivers. The esp_intr_alloc() abstraction exists to hide all these implementation details.

A driver can allocate an interrupt for a certain peripheral by calling esp_intr_alloc() (or esp_intr_alloc_intrstatus()). It can use the flags passed to this function to specify the type, priority, and trigger method of the interrupt to allocate. The interrupt allocation code will then find an applicable interrupt, use the interrupt matrix to hook it up to the peripheral, and install the given interrupt handler and ISR to it.
Chapter 2. API Reference

The interrupt allocator presents two different types of interrupts, namely shared interrupts and non-shared interrupts, both of which require different handling. Non-shared interrupts will allocate a separate interrupt for every `esp_intr_alloc()` call, and this interrupt is use solely for the peripheral attached to it, with only one ISR that will get called. Shared interrupts can have multiple peripherals triggering them, with multiple ISRs being called when one of the peripherals attached signals an interrupt. Thus, ISRs that are intended for shared interrupts should check the interrupt status of the peripheral they service in order to check if any action is required.

Non-shared interrupts can be either level- or edge-triggered. Shared interrupts can only be level interrupts due to the chance of missed interrupts when edge interrupts are used.

To illustrate why shared interrupts can only be level-triggered, take the scenario where peripheral A and peripheral B share the same edge-triggered interrupt. Peripheral B triggers an interrupt and sets its interrupt signal high, causing a low-to-high edge, which in turn latches the CPU’s interrupt bit and triggers the ISR. The ISR executes, checks that peripheral A did not trigger an interrupt, and proceeds to handle and clear peripheral B’s interrupt signal. Before the ISR returns, the CPU clears its interrupt bit latch. Thus, during the entire interrupt handling process, if peripheral A triggers an interrupt, it will be missed due the CPU clearing the interrupt bit latch.

Multicore Issues

Peripherals that can generate interrupts can be divided in two types:

- External peripherals, within the ESP32 but outside the Xtensa cores themselves. Most ESP32 peripherals are of this type.
- Internal peripherals, part of the Xtensa CPU cores themselves.

Interrupt handling differs slightly between these two types of peripherals.

Internal Peripheral Interrupts Each Xtensa CPU core has its own set of six internal peripherals:

- Three timer comparators
- A performance monitor
- Two software interrupts

Internal interrupt sources are defined in `esp_intr_alloc.h` as `ETS_INTERNAL_*_INTR_SOURCE`.

These peripherals can only be configured from the core they are associated with. When generating an interrupt, the interrupt they generate is hard-wired to their associated core; it is not possible to have, for example, an internal timer comparator of one core generate an interrupt on another core. That is why these sources can only be managed using a task running on that specific core. Internal interrupt sources are still allocatable using `esp_intr_alloc()` as normal, but they cannot be shared and will always have a fixed interrupt level (namely, the one associated in hardware with the peripheral).

External Peripheral Interrupts The remaining interrupt sources are from external peripherals. These are defined in `soc/soc.h` as `ETS_*_INTR_SOURCE`.

Non-internal interrupt slots in both CPU cores are wired to an interrupt matrix, which can be used to route any external interrupt source to any of these interrupt slots.

- Allocating an external interrupt will always allocate it on the core that does the allocation.
- Freeing an external interrupt must always happen on the same core it was allocated on.
- Disabling and enabling external interrupts from another core is allowed.
- Multiple external interrupt sources can share an interrupt slot by passing `ESP_INTR_FLAG_SHARED` as a flag to `esp_intr_alloc()`.

Care should be taken when calling `esp_intr_alloc()` from a task which is not pinned to a core. During task switching, these tasks can migrate between cores. Therefore it is impossible to tell which CPU the interrupt is allocated on, which makes it difficult to free the interrupt handle and may also cause debugging difficulties. It is advised to use `xTaskCreatePinnedToCore()` with a specific CoreID argument to create tasks that allocate interrupts. In the case of internal interrupt sources, this is required.
IRAM-Safe Interrupt Handlers

The ESP_INTR_FLAG_IRAM flag registers an interrupt handler that always runs from IRAM (and reads all its data from DRAM), and therefore does not need to be disabled during flash erase and write operations.

This is useful for interrupts which need a guaranteed minimum execution latency, as flash write and erase operations can be slow (erasers can take tens or hundreds of milliseconds to complete).

It can also be useful to keep an interrupt handler in IRAM if it is called very frequently, to avoid flash cache misses.

Refer to the SPI flash API documentation for more details.

Multiple Handlers Sharing A Source

Several handlers can be assigned to a same source, given that all handlers are allocated using the ESP_INTR_FLAG_SHARED flag. They will all be allocated to the interrupt, which the source is attached to, and called sequentially when the source is active. The handlers can be disabled and freed individually. The source is attached to the interrupt (enabled), if one or more handlers are enabled, otherwise detached. A handler will never be called when disabled, while its source may still be triggered if any one of its handler enabled.

Sources attached to non-shared interrupt do not support this feature.

By default, when ESP_INTR_FLAG_SHARED flag is specified, the interrupt allocator will allocate only priority level 1 interrupts. Use ESP_INTR_FLAG_SHARED | ESP_INTR_FLAG_LOWMED to also allow allocating shared interrupts at priority levels 2 and 3.

Though the framework supports this feature, you have to use it very carefully. There usually exist two ways to stop an interrupt from being triggered: disable the source or mask peripheral interrupt status. ESP-IDF only handles enabling and disabling of the source itself, leaving status and mask bits to be handled by users.

Status bits shall either be masked before the handler responsible for it is disabled, or be masked and then properly handled in another enabled interrupt.

Note: Leaving some status bits unhandled without masking them, while disabling the handlers for them, will cause the interrupt(s) to be triggered indefinitely, resulting therefore in a system crash.

Troubleshooting Interrupt Allocation

On most Espressif SoCs, CPU interrupts are a limited resource. Therefore it is possible for a program to run out of CPU interrupts, for example by initializing several peripheral drivers. Typically, this will result in the driver initialization function returning ESP_ERR_NOT_FOUND error code.

If this happens, you can use esp_intr_dump() function to print the list of interrupts along with their status. The output of this function typically looks like this:

```
CPU 0 interrupt status:
Int Level Type Status
0 1 Level Reserved
1 1 Level Reserved
2 1 Level Used: RTC_CORE
3 1 Level Used: TG0_LACT_LEVEL
...
```

The columns of the output have the following meaning:

- **Int**: CPU interrupt input number. This is typically not used in software directly, and is provided for reference only.
- **Level**: Interrupt priority (1-7) of the CPU interrupt. This priority is fixed in hardware, and cannot be changed.
• **Type**: Interrupt type (Level or Edge) of the CPU interrupt. This type is fixed in hardware, and cannot be changed.

• **Status**: One of the possible statuses of the interrupt:
  - **Reserved**: The interrupt is reserved either at hardware level, or by one of the parts of ESP-IDF. It cannot be allocated using `esp_intr_alloc()`.
  - **Used**: `<source>`: The interrupt is allocated and connected to a single peripheral.
  - **Shared**: `<source1> <source2> ...`: The interrupt is allocated and connected to multiple peripherals. See **Multiple Handlers Sharing A Source** above.
  - **Free**: The interrupt is not allocated and can be used by `esp_intr_alloc()`.

• **Free (not general-use)**: The interrupt is not allocated, but is either a high-priority interrupt (priority 4-7) or an edge-triggered interrupt. High-priority interrupts can be allocated using `esp_intr_alloc()` but requires the handlers to be written in Assembly, see **High Priority Interrupts**. Edge-triggered low- and medium-priority interrupts can also be allocated using `esp_intr_alloc()`, but are not used often since most peripheral interrupts are level-triggered.

If you have confirmed that the application is indeed running out of interrupts, a combination of the following suggestions can help resolve the issue:

• On multi-core SoCs, try initializing some of the peripheral drivers from a task pinned to the second core. Interrupts are typically allocated on the same core where the peripheral driver initialization function runs. Therefore by running the initialization function on the second core, more interrupt inputs can be used.

• Determine the interrupts which can tolerate higher latency, and allocate them using `ESP_INTR_FLAG_SHARED` flag (optionally ORed with `ESP_INTR_FLAG_LOWMED`). Using this flag for two or more peripherals will let them use a single interrupt input, and therefore save interrupt inputs for other peripherals. See **Multiple Handlers Sharing A Source** above.

• Some peripheral driver may default to allocating interrupts with `ESP_INTR_FLAG_LEVEL1` flag, so priority 2 and 3 interrupts do not get used by default. If `esp_intr_dump()` shows that some priority 2 or 3 interrupts are available, try changing the interrupt allocation flags when initializing the driver to `ESP_INTR_FLAG_LEVEL2` or `ESP_INTR_FLAG_LEVEL3`.

• Check if some of the peripheral drivers do not need to be used all the time, and initialize or deinitialize them on demand. This can reduce the number of simultaneously allocated interrupts.

### API Reference

#### Header File

- `components/esp_hw_support/include/esp_intr_types.h`
- This header file can be included with:

  ```
  #include "esp_intr_types.h"
  ```

#### Macros

**ESP_INTR_CPU_AFFINITY_TO_CORE_ID** (cpu_affinity)

Convert esp_intr_cpu_affinity_t to CPU core ID.

#### Type Definitions

typedef void (*`intr_handler_t`)(void *arg)

Function prototype for interrupt handler function

typedef struct intr_handle_data_t *`intr_handle_t`

Handle to an interrupt handler
Chapter 2. API Reference

Enumerations

enum esp_intr_cpu_affinity_t
  Interrupt CPU core affinity.
  
  This type specify the CPU core that the peripheral interrupt is connected to.
  
  Values:

  enumerator ESP_INTR_CPU_AFFINITY_AUTO
    Install the peripheral interrupt to ANY CPU core, decided by on which CPU the interrupt allocator is running.

  enumerator ESP_INTR_CPU_AFFINITY_0
    Install the peripheral interrupt to CPU core 0.

  enumerator ESP_INTR_CPU_AFFINITY_1
    Install the peripheral interrupt to CPU core 1.

Header File

- components/esp_hw_support/include/esp_intr_alloc.h
  This header file can be included with:
  
  #include "esp_intr_alloc.h"

Functions

esp_err_t esp_intr_mark_shared (int intno, int cpu, bool is_in_iram)
  Mark an interrupt as a shared interrupt.
  
  This will mark a certain interrupt on the specified CPU as an interrupt that can be used to hook shared interrupt handlers to.

  Parameters

  • intno – The number of the interrupt (0-31)
  • cpu – CPU on which the interrupt should be marked as shared (0 or 1)
  • is_in_iram – Shared interrupt is for handlers that reside in IRAM and the int can be left enabled while the flash cache is disabled.

  Returns
    ESP_ERR_INVALID_ARG if cpu or intno is invalid
    ESP_OK otherwise

esp_err_t esp_intr_reserve (int intno, int cpu)
  Reserve an interrupt to be used outside of this framework.
  
  This will mark a certain interrupt on the specified CPU as reserved, not to be allocated for any reason.

  Parameters

  • intno – The number of the interrupt (0-31)
  • cpu – CPU on which the interrupt should be marked as shared (0 or 1)

  Returns
    ESP_ERR_INVALID_ARG if cpu or intno is invalid
    ESP_OK otherwise

esp_err_t esp_intr_alloc (int source, int flags, intr_handler_t handler, void *arg, intr_handle_t *ret_handle)
  Allocate an interrupt with the given parameters.
  
  This finds an interrupt that matches the restrictions as given in the flags parameter, maps the given interrupt source to it and hooks up the given interrupt handler (with optional argument) as well. If needed, it can return a handle for the interrupt as well.
  
  The interrupt will always be allocated on the core that runs this function.
  
  If ESP_INTR_FLAG_IRAM flag is used, and handler address is not in IRAM or RTC_FAST_MEM, then ESP_ERR_INVALID_ARG is returned.
Parameters

- **source** – The interrupt source. One of the ETS_*_INTR_SOURCE interrupt mux sources, as defined in soc/soc.h, or one of the internal ETS_INTERNAL_*_INTR_SOURCE sources as defined in this header.

- **flags** – An ORed mask of the ESP_INTR_FLAG_* defines. These restrict the choice of interrupts that this routine can choose from. If this value is 0, it will default to allocating a non-shared interrupt of level 1, 2 or 3. If this is ESP_INTR_FLAG_SHARED, it will allocate a shared interrupt of level 1. Setting ESP_INTR_FLAG_INTRDISABLED will return from this function with the interrupt disabled.

- **handler** – The interrupt handler. Must be NULL when an interrupt of level >3 is requested, because these types of interrupts aren’t C-callable.

- **arg** – Optional argument for passed to the interrupt handler

- **ret_handle** – Pointer to an intr_handle_t to store a handle that can later be used to request details or free the interrupt. Can be NULL if no handle is required.

Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
ESP_ERR_NOT_FOUND No free interrupt found with the specified flags ESP_OK otherwise

```c
esp_err_t esp_intr_alloc_intrstatus(int source, int flags, uint32_t intrstatusreg, uint32_t intrstatusmask, intr_handler_t handler, void *arg, intr_handle_t *ret_handle)
```

Allocate an interrupt with the given parameters.

This essentially does the same as esp_intr_alloc, but allows specifying a register and mask combo. For shared interrupts, the handler is only called if a read from the specified register, ANDed with the mask, returns non-zero. By passing an interrupt status register address and a fitting mask, this can be used to accelerate interrupt handling in the case a shared interrupt is triggered; by checking the interrupt statuses first, the code can decide which ISRs can be skipped.

Parameters

- **source** – The interrupt source. One of the ETS_*_INTR_SOURCE interrupt mux sources, as defined in soc/soc.h, or one of the internal ETS_INTERNAL_*_INTR_SOURCE sources as defined in this header.

- **flags** – An ORed mask of the ESP_INTR_FLAG_* defines. These restrict the choice of interrupts that this routine can choose from. If this value is 0, it will default to allocating a non-shared interrupt of level 1, 2 or 3. If this is ESP_INTR_FLAG_SHARED, it will allocate a shared interrupt of level 1. Setting ESP_INTR_FLAG_INTRDISABLED will return from this function with the interrupt disabled.

- **intrstatusreg** – The address of an interrupt status register

- **intrstatusmask** – A mask. If a read of address intrstatusreg has any of the bits that are 1 in the mask set, the ISR will be called. If not, it will be skipped.

- **handler** – The interrupt handler. Must be NULL when an interrupt of level >3 is requested, because these types of interrupts aren’t C-callable.

- **arg** – Optional argument for passed to the interrupt handler

- **ret_handle** – Pointer to an intr_handle_t to store a handle that can later be used to request details or free the interrupt. Can be NULL if no handle is required.

Returns ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
ESP_ERR_NOT_FOUND No free interrupt found with the specified flags ESP_OK otherwise

```c
esp_err_t esp_intr_free(intr_handle_t handle)
```

Disable and free an interrupt.

Use an interrupt handle to disable the interrupt and release the resources associated with it. If the current core is not the core that registered this interrupt, this routine will be assigned to the core that allocated this interrupt, blocking and waiting until the resource is successfully released.

Note: When the handler shares its source with other handlers, the interrupt status bits it’s responsible for should be managed properly before freeing it. see esp_intr_disable for more details. Please do not call
this function in `esp_ipc_call_blocking`.

```c
int esp_intr_get_cpu(intr_handle_t handle)
```

Get CPU number an interrupt is tied to.

---

### Parameters
- **handle** - The handle, as obtained by `esp_intr_alloc` or `esp_intr_alloc_intrstatus`

---

### Returns
- `ESP_OK` otherwise
- `ESP_ERR_INVALID_ARG` if the combination of arguments is invalid.

---

```c
int esp_intr_get_intno(intr_handle_t handle)
```

Get the allocated interrupt for a certain handle.

---

### Parameters
- **handle** - The handle, as obtained by `esp_intr_alloc` or `esp_intr_alloc_intrstatus`

---

### Returns
- The interrupt number
- `ESP_ERR_INVALID_ARG` if the combination of arguments is invalid.

---

```c
esp_err_t esp_intr_disable(intr_handle_t handle)
```

Disable the interrupt associated with the handle.

---

### Parameters
- **handle** - The handle, as obtained by `esp_intr_alloc` or `esp_intr_alloc_intrstatus`

---

### Returns
- `ESP_OK` otherwise
- `ESP_ERR_INVALID_ARG` if the combination of arguments is invalid.

---

```c
esp_err_t esp_intr_enable(intr_handle_t handle)
```

Enable the interrupt associated with the handle.

---

### Parameters
- **handle** - The handle, as obtained by `esp_intr_alloc` or `esp_intr_alloc_intrstatus`

---

### Returns
- `ESP_OK` otherwise
- `ESP_ERR_INVALID_ARG` if the combination of arguments is invalid.

---

```c
esp_err_t esp_intr_set_in_iram(intr_handle_t handle, bool is_in_iram)
```

Set the “in IRAM” status of the handler.

---

### Parameters
- **handle** - The handle, as obtained by `esp_intr_alloc` or `esp_intr_alloc_intrstatus`
- **is_in_iram** - Whether the handler associated with this handle resides in IRAM. Handlers residing in IRAM can be called when cache is disabled.

---

### Returns
- `ESP_OK` otherwise
- `ESP_ERR_INVALID_ARG` if the combination of arguments is invalid.
void esp_intr_noniram_disable (void)
    Disable interrupts that aren’t specifically marked as running from IRAM.

void esp_intr_noniram_enable (void)
    Re-enable interrupts disabled by esp_intr_noniram_disable.

void esp_intr_enable_source (int inum)
    enable the interrupt source based on its number

    Parameters inum – interrupt number from 0 to 31

void esp_intr_disable_source (int inum)
    disable the interrupt source based on its number

    Parameters inum – interrupt number from 0 to 31

static inline int esp_intr_flags_to_level (int flags)
    Get the lowest interrupt level from the flags.

    Parameters flags – The same flags that pass to esp_intr_alloc_intrstatus API

static inline int esp_intr_level_to_flags (int level)
    Get the interrupt flags from the supplied level (priority)

    Parameters level – The interrupt priority level

esp_err_t esp_intr_dump (FILE *stream)
    Dump the status of allocated interrupts.

    Parameters stream – The stream to dump to, if NULL then stdout is used
    Returns ESP_OK on success

Macros

ESP_INTR_FLAG_LEVEL1
    Interrupt allocation flags.
    These flags can be used to specify which interrupt qualities the code calling esp_intr_alloc* needs. Accept a Level 1 interrupt vector (lowest priority)

ESP_INTR_FLAG_LEVEL2
    Accept a Level 2 interrupt vector.

ESP_INTR_FLAG_LEVEL3
    Accept a Level 3 interrupt vector.

ESP_INTR_FLAG_LEVEL4
    Accept a Level 4 interrupt vector.

ESP_INTR_FLAG_LEVEL5
    Accept a Level 5 interrupt vector.

ESP_INTR_FLAG_LEVEL6
    Accept a Level 6 interrupt vector.

ESP_INTR_FLAG_NMI
    Accept a Level 7 interrupt vector (highest priority)
ESP_INTR_FLAG_SHARED
Interrupt can be shared between ISRs.

ESP_INTR_FLAG_EDGE
Edge-triggered interrupt.

ESP_INTR_FLAG_IRAM
ISR can be called if cache is disabled.

ESP_INTR_FLAG_INTRDISABLED
Return with this interrupt disabled.

ESP_INTR_FLAG_LOWMED
Low and medium prio interrupts. These can be handled in C.

ESP_INTR_FLAG_HIGH
High level interrupts. Need to be handled in assembly.

ESP_INTR_FLAG_LEVELMASK
Mask for all level flags.

ETS_INTERNAL_TIMER0_INTR_SOURCE
Platform timer 0 interrupt source.
The esp_intr_alloc* functions can allocate an int for all ETS_*_INTR_SOURCE interrupt sources that are routed through the interrupt mux. Apart from these sources, each core also has some internal sources that do not pass through the interrupt mux. To allocate an interrupt for these sources, pass these pseudo-sources to the functions.

ETS_INTERNAL_TIMER1_INTR_SOURCE
Platform timer 1 interrupt source.

ETS_INTERNAL_TIMER2_INTR_SOURCE
Platform timer 2 interrupt source.

ETS_INTERNAL_SW0_INTR_SOURCE
Software int source 1.

ETS_INTERNAL_SW1_INTR_SOURCE
Software int source 2.

ETS_INTERNAL_PROFILING_INTR_SOURCE
Int source for profiling.

ETS_INTERNAL_UNUSED_INTR_SOURCE
Interrupt is not assigned to any source.

ETS_INTERNAL_INTR_SOURCE_OFF
Provides SystemView with positive IRQ IDs, otherwise scheduler events are not shown properly.
ESP_INTR_ENABLE (inum)
Enable interrupt by interrupt number

ESP_INTR_DISABLE (inum)
Disable interrupt by interrupt number

2.10.21 Logging library

Overview

The logging library provides three ways for setting log verbosity:

- **At compile time**: in menuconfig, set the verbosity level using the option `CONFIG_LOG_DEFAULT_LEVEL`. Optionally, also in menuconfig, set the maximum verbosity level using the option `CONFIG_LOG_MAXIMUM_LEVEL`. By default, this is the same as the default level, but it can be set higher in order to compile more optional logs into the firmware.
- **At runtime**: all logs for verbosity levels lower than `CONFIG_LOG_DEFAULT_LEVEL` are enabled by default. The function `esp_log_level_set()` can be used to set a logging level on a per-module basis. Modules are identified by their tags, which are human-readable ASCII zero-terminated strings.
- **At runtime**: if `CONFIG_LOG_MASTER_LEVEL` is enabled then a Master logging level can be set using `esp_log_set_level_master()`. This option adds an additional logging level check for all compiled logs. Note that this will increase application size. This feature is useful if you want to compile in a lot of logs that are selectable at runtime, but also want to avoid the performance hit from looking up the tags and their log level when you don’t want log output.

There are the following verbosity levels:

- Error (lowest)
- Warning
- Info
- Debug
- Verbose (highest)

**Note**: The function `esp_log_level_set()` cannot set logging levels higher than specified by `CONFIG_LOG_MAXIMUM_LEVEL`. To increase log level for a specific file above this maximum at compile time, use the macro `LOG_LOCAL_LEVEL` (see the details below).

How to use this library

In each C file that uses logging functionality, define the TAG variable as shown below:

```c
cstatic const char* TAG = "MyModule";
```

Then use one of the logging macros to produce output, e.g:

```c
ESP_LOGW(TAG, "Baud rate error %.1f%. Requested: %d baud, actual: %d baud", error_100, baud_req, baud_real);
```

Several macros are available for different verbosity levels:

- ESP_LOGE - error (lowest)
- ESP_LOGW - warning
- ESP_LOGI - info
- ESP_LOGD - debug
- ESP_LOGV - verbose (highest)
Additionally, there are ESP_EARLY_LOGx versions for each of these macros, e.g. ESP_EARLY_LOGE. These versions have to be used explicitly in the early startup code only, before heap allocator and syscalls have been initialized. Normal ESP_LOGx macros can also be used while compiling the bootloader, but they will fall back to the same implementation as ESP_EARLY_LOGx macros.

There are also ESP_DRAM_LOGx versions for each of these macros, e.g. ESP_DRAM_LOGE. These versions are used in some places where logging may occur with interrupts disabled or with flash cache inaccessible. Use of this macros should be as sparing as possible, as logging in these types of code should be avoided for performance reasons.

**Note:** Inside critical sections interrupts are disabled so it’s only possible to use ESP_DRAM_LOGx (preferred) or ESP_EARLY_LOGx. Even though it’s possible to log in these situations, it’s better if your program can be structured not to require it.

To override default verbosity level at file or component scope, define the LOG_LOCAL_LEVEL macro.

At file scope, define it before including esp_log.h, e.g.:

```c
#define LOG_LOCAL_LEVEL ESP_LOG_VERBOSE
#include "esp_log.h"
```

At component scope, define it in the component CMakeLists:

```cmake
target_compile_definitions(${COMPONENT_LIB} PUBLIC "-DLOG_LOCAL_LEVEL=ESP_LOG_VERBOSE")
```

To configure logging output per module at runtime, add calls to the function esp_log_level_set() as follows:

```c
esp_log_level_set("*", ESP_LOG_ERROR); // set all components to ERROR level
esp_log_level_set("wifi", ESP_LOG_WARN); // enable WARN logs from WiFi stack
esp_log_level_set("dhcpc", ESP_LOG_INFO); // enable INFO logs from DHCP client
```

**Note:** The “DRAM” and “EARLY” log macro variants documented above do not support per module setting of log verbosity. These macros will always log at the “default” verbosity level, which can only be changed at runtime by calling esp_log_level("*", level).

Even when logs are disabled by using a tag name they will still require a processing time of around 10.9 microseconds per entry.

**Master Logging Level** To enable the Master logging level feature, the CONFIG_LOG_MASTER_LEVEL option must be enabled. It adds an additional level check for ESP_LOGx macros before calling esp_log_write(). This allows to set a higher CONFIG_LOG_MAXIMUM_LEVEL, but not inflict a performance hit during normal operation (only when directed). An application may set the master logging level (esp_log_set_level_master()) globally to enforce a maximum log level. ESP_LOGx macros above this level will be skipped immediately, rather than calling esp_log_write() and doing a tag lookup. It is recommended to only use this in an top-level application and not in shared components as this would override the global log level for any user using the component. By default, at startup, the Master logging level is CONFIG_LOG_DEFAULT_LEVEL.

Note that this feature increases application size because the additional check is added into all ESP_LOGx macros.

The snippet below shows how it works. Setting the Master logging level to ESP_LOG_NONE disables all logging globally. esp_log_level_set() does not currently affect logging. But after the Master logging level is released, the logs will be printed as set by esp_log_level_set().

```c
// Master logging level is CONFIG_LOG_DEFAULT_LEVEL at start up and = ESP_LOG_INFO
ESP_LOGI("lib_name", "Message for print"); // prints a INFO message
esp_log_level_set("lib_name", ESP_LOG_WARN); // enables WARN logs from lib_name
```

(continues on next page)
esp_log_set_level_master(ESP_LOG_NONE);  // disables all logs globally.
 Esp_log_level_set has no effect at the moment.

ESP_LOGW("lib_name", "Message for print");  // no print, Master logging.
 Esp_log_level_set("lib_name", ESP_LOG_INFO);  // enable INFO logs from lib_name

ESP_LOGI("lib_name", "Message for print");  // no print, Master logging.

ESP_LOGI("lib_name", "Message for print");  // prints a INFO message

Logging to Host via JTAG  By default, the logging library uses the vprintf-like function to write formatted output to the dedicated UART. By calling a simple API, all log output may be routed to JTAG instead, making logging several times faster. For details, please refer to Section Logging to Host.

Thread Safety  The log string is first written into a memory buffer and then sent to the UART for printing. Log calls are thread-safe, i.e., logs of different threads do not conflict with each other.

Application Example  The logging library is commonly used by most ESP-IDF components and examples. For demonstration of log functionality, check ESP-IDF’s examples directory. The most relevant examples that deal with logging are the following:

- system/ota
- storage/sd_card
- protocols/https_request

API Reference

Header File

- components/log/include/esp_log.h
- This header file can be included with:

```
#include "esp_log.h"
```

Functions

void esp_log_set_level_master(esp_log_level_t level)

Master log level.

Optional master log level to check against for ESP_LOGx macros before calling esp_log_write. Allows one to set a higher CONFIG_LOG_MAXIMUM_LEVEL but not impose a performance hit during normal operation (only when instructed). An application may set esp_log_set_level_master(level) to globally enforce a maximum log level. ESP_LOGx macros above this level will be skipped immediately, rather than calling esp_log_write and doing a cache hit.

The tradeoff is increased application size.

Parameters level  --Master log level

**esp_log_level_t esp_log_get_level_master**(void)

Returns master log level.

**Parameters**

- `tag` -- Tag of the log entries to enable. Must be a non-NULL zero terminated string. Value "*" resets log level for all tags to the given value.
- `level` -- Selects log level to enable. Only logs at this and lower verbosity levels will be shown.

**esp_log_level_t esp_log_level_set**(const char *tag, esp_log_level_t level)

Set log level for given tag.

If logging for given component has already been enabled, changes previous setting.

**Note:** Note that this function can not raise log level above the level set using CONFIG_LOG_MAXIMUM_LEVEL setting in menuconfig. To raise log level above the default one for a given file, define LOG_LOCAL_LEVEL to one of the ESP_LOG_* values, before including esp_log.h in this file.

**Parameters**

- `tag` -- Tag of the log to query current level. Must be a non-NULL zero terminated string.

**Returns**

The current log level for the given tag

**vprintf_like_t esp_log_set_vprintf**(vprintf_like_t func)

Set function used to output log entries.

By default, log output goes to UART0. This function can be used to redirect log output to some other destination, such as file or network. Returns the original log handler, which may be necessary to return output to the previous destination.

**Note:** Please note that function callback here must be re-entrant as it can be invoked in parallel from multiple thread context.

**Parameters**

- `func` -- new Function used for output. Must have same signature as vprintf.

**Returns**

func old Function used for output.

**uint32_t esp_log_timestamp**(void)

Function which returns timestamp to be used in log output.

This function is used in expansion of ESP_LOGx macros. In the 2nd stage bootloader, and at early application startup stage this function uses CPU cycle counter as time source. Later when FreeRTOS scheduler start running, it switches to FreeRTOS tick count.

For now, we ignore millisecond counter overflow.

**Returns**

timestamp, in milliseconds

**char *esp_log_system_timestamp**(void)

Function which returns system timestamp to be used in log output.

This function is used in expansion of ESP_LOGx macros to print the system time as “HH:MM:SS.sss”. The system time is initialized to 0 on startup, this can be set to the correct time with an SNTP sync, or manually with standard POSIX time functions.
Currently, this will not get used in logging from binary blobs (i.e. Wi-Fi & Bluetooth libraries), these will still print the RTOS tick time.

**Returns** timestamp, in “HH:MM:SS.sss”

uint32_t esp_log_early_timestamp (void)

Function which returns timestamp to be used in log output.

This function uses HW cycle counter and does not depend on OS, so it can be safely used after application crash.

**Returns** timestamp, in milliseconds

void esp_log_write (esp_log_level_t level, const char*tag, const char*format,...)

Write message into the log.

This function is not intended to be used directly. Instead, use one of ESP_LOGE, ESP_LOGW, ESP_LOGI, ESP_LOGD, ESP_LOGV macros.

This function or these macros should not be used from an interrupt.

void esp_log_writev (esp_log_level_t level, const char*tag, const char*format, va_list args)

Write message into the log, va_list variant.

This function is provided to ease integration toward other logging framework, so that esp_log can be used as a log sink.

**See also:**

esp_log_write()

**Macros**

ESP_LOG_BUFFER_HEX_LEVEL (tag, buffer, buff_len, level)

Log a buffer of hex bytes at specified level, separated into 16 bytes each line.

**Parameters**

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes
- **level** – level of the log

ESP_LOG_BUFFER_CHAR_LEVEL (tag, buffer, buff_len, level)

Log a buffer of characters at specified level, separated into 16 bytes each line. Buffer should contain only printable characters.

**Parameters**

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes
- **level** – level of the log

ESP_LOG_BUFFER_HEXDUMP (tag, buffer, buff_len, level)

Dump a buffer to the log at specified level.

The dump log shows just like the one below:

<table>
<thead>
<tr>
<th>W (195)</th>
<th>log_example: 0x3ff84280</th>
</tr>
</thead>
<tbody>
<tr>
<td>45 53 50 33 32 20 69 73</td>
<td>20 67 72 65 61 74…</td>
</tr>
<tr>
<td>→2c 20</td>
<td>ESP32 is great,</td>
</tr>
<tr>
<td>W (195)</td>
<td>log_example: 0x3ff84290</td>
</tr>
<tr>
<td>77 6f 72 6b 69 6e 67 20</td>
<td>61 6c 6f 6e 67 20…</td>
</tr>
<tr>
<td>→77 69</td>
<td>working along wi</td>
</tr>
<tr>
<td>W (205)</td>
<td>log_example: 0x3ff842a0</td>
</tr>
<tr>
<td>74 68 20 74 68 65 20 49</td>
<td>44 46 2e 00…</td>
</tr>
<tr>
<td>→</td>
<td>th the IDF..</td>
</tr>
</tbody>
</table>

It is highly recommended to use terminals with over 102 text width.
Parameters

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes
- **level** – level of the log

**ESP_LOG_BUFFER_HEX** (tag, buffer, buff_len)

Log a buffer of hex bytes at Info level.

**See also:**

esp_log_buffer_hex_level

Parameters

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes

**ESP_LOG_BUFFER_CHAR** (tag, buffer, buff_len)

Log a buffer of characters at Info level. Buffer should contain only printable characters.

**See also:**

esp_log_buffer_char_level

Parameters

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes

**ESP_EARLY_LOGE** (tag, format, ...)

Macro to output logs in startup code, before heap allocator and syscalls have been initialized. Log at ESP_LOG_ERROR level.

**See also:**

printf, ESP_LOGE, ESP_DRAM_LOGE In the future, we want to become compatible with clang. Hence, we provide two versions of the following macros which are using variadic arguments. The first one is using the GNU extension ##__VA_ARGS__. The second one is using the C++20 feature VA_OPT(...). This allows users to compile their code with standard C++20 enabled instead of the GNU extension. Below C++20, we haven’t found any good alternative to using ##__VA_ARGS__.

ESP_EARLY_LOGW (tag, format, ...)

Macro to output logs in startup code at ESP_LOG_WARN level.

**See also:**

ESP_EARLY_LOGE, ESP_LOGE, printf

ESP_EARLY_LOGI (tag, format, ...)

Macro to output logs in startup code at ESP_LOG_INFO level.

**See also:**

ESP_EARLY_LOGE, ESP_LOGE, printf
**ESP_EARLY_LOGD** (tag, format, ...)

Macro to output logs in startup code at ESP_LOG_DEBUG level.

See also:
ESP_EARLY_LOGE, ESP_LOGE, printf

**ESP_EARLY_LOGV** (tag, format, ...)

Macro to output logs in startup code at ESP_LOG_VERBOSE level.

See also:
ESP_EARLY_LOGE, ESP_LOGE, printf

**_ESP_LOG_EARLY_ENABLED** (log_level)

**ESP_LOG_EARLY_IMPL** (tag, format, log_level, log_tag_letter, ...)

**ESP_LOGE** (tag, format, ...)

**ESP_LOGW** (tag, format, ...)

**ESP_LOGI** (tag, format, ...)

**ESP_LOGD** (tag, format, ...)

**ESP_LOGV** (tag, format, ...)

**ESP_LOG_LEVEL** (level, tag, format, ...)

Runtime macro to output logs at a specified level.

See also:
printf

Parameters

• **tag** – tag of the log, which can be used to change the log level by esp_log_level_set at runtime.

• **level** – level of the output log.

• **format** – format of the output log. See printf

• ... – variables to be replaced into the log. See printf

**ESP_LOG_LEVEL_LOCAL** (level, tag, format, ...)

Runtime macro to output logs at a specified level. Also check the level with LOG_LOCAL_LEVEL. If CONFIG_LOG_MASTER_LEVEL set, also check first against esp_log_get_level_master().

See also:
printf, ESP_LOG_LEVEL

**ESP_DRAM_LOGE** (tag, format, ...)

Macro to output logs when the cache is disabled. Log at ESP_LOG_ERROR level.

Similar to

Usage: ESP_DRAM_LOGE(DRAM_STR("my_tag"), "format", orESP_DRAM_LOGE(TAG, "format", "", ...), where TAG is a char* that points to a str in the DRAM.
See also:
ESP_EARLY_LOGE, the log level cannot be changed per-tag, however esp_log_level_set("*", level) will set the default level which controls these log lines also.

See also:
esp_rom_printf, ESP_LOGE

Note: Unlike normal logging macros, it’s possible to use this macro when interrupts are disabled or inside an ISR.

Note: Placing log strings in DRAM reduces available DRAM, so only use when absolutely essential.

ESP_DRAM_LOGW (tag, format, ...)
macro to output logs when the cache is disabled at ESP_LOG_WARN level.

See also:
ESP_DRAM_LOGW, ESP_LOGW, esp_rom_printf

ESP_DRAM_LOGI (tag, format, ...)
macro to output logs when the cache is disabled at ESP_LOG_INFO level.

See also:
ESP_DRAM_LOGI, ESP_LOGI, esp_rom_printf

ESP_DRAM_LOGD (tag, format, ...)
macro to output logs when the cache is disabled at ESP_LOG_DEBUG level.

See also:
ESP_DRAM_LOGD, ESP_LOGD, esp_rom_printf

ESP_DRAM_LOGV (tag, format, ...)
macro to output logs when the cache is disabled at ESP_LOG_VERBOSE level.

See also:
ESP_DRAM_LOGV, ESP_LOGV, esp_rom_printf

Type Definitions
typedef int (*vprintf_like_t)(const char*, va_list)

Enumerations
enum esp_log_level_t
    Log level.
    Values:
enumerator **ESP_LOG_NONE**
   No log output

enumerator **ESP_LOG_ERROR**
   Critical errors, software module can not recover on its own

enumerator **ESP_LOG_WARN**
   Error conditions from which recovery measures have been taken

enumerator **ESP_LOG_INFO**
   Information messages which describe normal flow of events

enumerator **ESP_LOG_DEBUG**
   Extra information which is not necessary for normal use (values, pointers, sizes, etc).

enumerator **ESP_LOG_VERBOSE**
   Bigger chunks of debugging information, or frequent messages which can potentially flood the output.

### 2.10.22 Miscellaneous System APIs

**Software Reset**

To perform software reset of the chip, the `esp_restart()` function is provided. When the function is called, execution of the program stops, both CPUs are reset, the application is loaded by the bootloader and starts execution again.

Additionally, the `esp_register_shutdown_handler()` function can register a routine that will be automatically called before a restart (that is triggered by `esp_restart()`) occurs. This is similar to the functionality of `atexit` POSIX function.

**Reset Reason**

ESP-IDF applications can be started or restarted due to a variety of reasons. To get the last reset reason, call `esp_reset_reason()` function. See description of `esp_reset_reason_t` for the list of possible reset reasons.

**Heap Memory**

Two heap-memory-related functions are provided:

- `esp_get_free_heap_size()` returns the current size of free heap memory.
- `esp_get_minimum_free_heap_size()` returns the minimum size of free heap memory that has ever been available (i.e., the smallest size of free heap memory in the application’s lifetime).

Note that ESP-IDF supports multiple heaps with different capabilities. The functions mentioned in this section return the size of heap memory that can be allocated using the `malloc` family of functions. For further information about heap memory, see *Heap Memory Allocation.*
MAC Address

These APIs allow querying and customizing MAC addresses for different supported network interfaces (e.g., Wi-Fi, Bluetooth, Ethernet).

To fetch the MAC address for a specific network interface (e.g., Wi-Fi, Bluetooth, Ethernet), call the function `esp_read_mac()`.

In ESP-IDF, the MAC addresses for the various network interfaces are calculated from a single base MAC address. By default, the Espressif base MAC address is used. This base MAC address is pre-programmed into the ESP32 eFuse in the factory during production.

<table>
<thead>
<tr>
<th>Interface</th>
<th>MAC Address (4 universally administered, default)</th>
<th>MAC Address (2 universally administered)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wi-Fi Station</td>
<td>base_mac</td>
<td>base_mac</td>
</tr>
<tr>
<td>Wi-Fi SoftAP</td>
<td>base_mac, +1 to the last octet</td>
<td>Local MAC (derived from Wi-Fi Station MAC)</td>
</tr>
<tr>
<td>Bluetooth</td>
<td>base_mac, +2 to the last octet</td>
<td>base_mac, +1 to the last octet</td>
</tr>
<tr>
<td>Ethernet</td>
<td>base_mac, +3 to the last octet</td>
<td>Local MAC (derived from Bluetooth MAC)</td>
</tr>
</tbody>
</table>

Note: The configuration configures the number of universally administered MAC addresses that are provided by Espressif.

Custom Interface MAC Sometimes you may need to define custom MAC addresses that are not generated from the base MAC address. To set a custom interface MAC address, use the `esp_iface_mac_addr_set()` function. This function allows you to overwrite the MAC addresses of interfaces set (or not yet set) by the base MAC address. Once a MAC address has been set for a particular interface, it will not be affected when the base MAC address is changed.

Custom Base MAC The default base MAC is pre-programmed by Espressif in eFuse BLK0. To set a custom base MAC instead, call the function `esp_iface_mac_addr_set()` with the ESP_MAC_BASE argument (or `esp_base_mac_addr_set()`) before initializing any network interfaces or calling the `esp_read_mac()` function. The custom MAC address can be stored in any supported storage device (e.g., flash, NVS).

The custom base MAC addresses should be allocated such that derived MAC addresses will not overlap. Based on the table above, users can configure the option CONFIG_ESP32_UNIVERSAL_MAC_ADDRESSES to set the number of valid universal MAC addresses that can be derived from the custom base MAC.

Note: It is also possible to call the function `esp_netif_set_mac()` to set the specific MAC used by a network interface after network initialization. But it is recommended to use the base MAC approach documented here to avoid the possibility of the original MAC address briefly appearing on the network before being changed.

Custom MAC Address in eFuse When reading custom MAC addresses from eFuse, ESP-IDF provides a helper function `esp_efuse_mac_get_custom()`. Users can also use `esp_read_mac()` with the ESP_MAC_EFUSE_CUSTOM argument. This loads the MAC address from eFuse BLK3. The `esp_efuse_mac_get_custom()` function assumes that the custom base MAC address is stored in the following format:

<table>
<thead>
<tr>
<th>Field</th>
<th># of bits</th>
<th>Range of bits</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>8</td>
<td>191:184</td>
<td>0: invalid, others — valid</td>
</tr>
<tr>
<td>Reserved</td>
<td>128</td>
<td>183:56</td>
<td></td>
</tr>
<tr>
<td>MAC address</td>
<td>48</td>
<td>55:8</td>
<td></td>
</tr>
<tr>
<td>MAC address CRC</td>
<td>8</td>
<td>7.0</td>
<td>CRC-8-CCITT, polynomial 0x07</td>
</tr>
</tbody>
</table>
Note: If the 3/4 coding scheme is enabled, all eFuse fields in this block must be burnt at the same time.

Once custom eFuse MAC address has been obtained (using `esp_efuse_mac_get_custom()` or `esp_read_mac()`), you need to set it as the base MAC address. There are two ways to do it:

1. Use an old API: call `esp_base_mac_addr_set()`.
2. Use a new API: call `esp_iface_mac_addr_set()` with the `ESP_MAC_BASE` argument.

Local Versus Universal MAC Addresses ESP32 comes pre-programmed with enough valid Espressif universally administered MAC addresses for all internal interfaces. The table above shows how to calculate and derive the MAC address for a specific interface according to the base MAC address.

When using a custom MAC address scheme, it is possible that not all interfaces can be assigned with a universally administered MAC address. In these cases, a locally administered MAC address is assigned. Note that these addresses are intended for use on a single local network only.

See this article for the definition of locally and universally administered MAC addresses.

Function `esp_derive_local_mac()` is called internally to derive a local MAC address from a universal MAC address. The process is as follows:

1. The U/L bit (bit value 0x2) is set in the first octet of the universal MAC address, creating a local MAC address.
2. If this bit is already set in the supplied universal MAC address (i.e., the supplied “universal” MAC address was in fact already a local MAC address), then the first octet of the local MAC address is XORed with 0x4.

Chip Version

`esp_chip_info()` function fills `esp_chip_info_t` structure with information about the chip. This includes the chip revision, number of CPU cores, and a bit mask of features enabled in the chip.

SDK Version

`esp_get_idf_version()` returns a string describing the ESP-IDF version which is used to compile the application. This is the same value as the one available through `IDF_VER` variable of the build system. The version string generally has the format of `git describe` output.

To get the version at build time, additional version macros are provided. They can be used to enable or disable parts of the program depending on the ESP-IDF version.

- `ESP_IDF_VERSION_MAJOR`, `ESP_IDF_VERSION_MINOR`, `ESP_IDF_VERSION_PATCH` are defined to integers representing major, minor, and patch version.
- `ESP_IDF_VERSION_VAL` and `ESP_IDF_VERSION` can be used when implementing version checks:

```c
#include "esp_idf_version.h"

#if ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)
   // enable functionality present in ESP-IDF v4.0
#endif
```

App Version

The application version is stored in `esp_app_desc_t` structure. It is located in DROM sector and has a fixed offset from the beginning of the binary file. The structure is located after `esp_image_header_t` and `esp_image_segment_header_t` structures. The type of the field version is string and it has a maximum length of 32 chars.
To set the version in your project manually, you need to set the `PROJECT_VER` variable in the `CMakeLists.txt` of your project. In application `CMakeLists.txt`, put `set(PROJECT_VER "0.1.0.1")` before including project.cmake.

If the `CONFIG_APP_PROJECT_VER_FROM_CONFIG` option is set, the value of `CONFIG_APP_PROJECT_VER` will be used. Otherwise, if the `PROJECT_VER` variable is not set in the project, it will be retrieved either from the `$(PROJECT_PATH)/version.txt` file (if present) or using `git describe`. If neither is available, `PROJECT_VER` will be set to “1”. Application can make use of this by calling `esp_app_get_description()` or `esp_ota_get_partition_description()` functions.

### API Reference

#### Header File

- components/esp_system/include/esp_system.h
- This header file can be included with:

  ```
  #include "esp_system.h"
  ```

#### Functions

**esp_err_t esp_register_shutdown_handler (shutdown_handler_t handle)**

Registers shutdown handler.

This function allows you to register a handler that gets invoked before the application is restarted using `esp_restart` function.

- **Parameters**
  - `handle` – function to execute on restart

- **Returns**
  - ESP_OK on success
  - ESP_ERR_INVALID_STATE if the handler has already been registered
  - ESP_ERR_NO_MEM if no more shutdown handler slots are available

**esp_err_t esp_unregister_shutdown_handler (shutdown_handler_t handle)**

Unregisters shutdown handler.

This function allows you to unregister a handler which was previously registered using `esp_register_shutdown_handler` function.

- **Parameters**
  - `handle` – function to execute on restart

- **Returns**
  - ESP_OK on success
  - ESP_ERR_INVALID_STATE if the given handler hasn’t been registered before

**void esp_restart (void)**

Restarts PRO and APP CPUs.

This function can be called both from PRO and APP CPUs. After successful restart, CPU reset reason will be SW_CPU_RESET. Peripherals (except for Wi-Fi, BT, UART0, SPI1, and legacy timers) are not reset. This function does not return.

**esp_reset_reason_t esp_reset_reason (void)**

Get reason of last reset.

- **Returns**
  See description of `esp_reset_reason_t` for explanation of each value.

**uint32_t esp_get_free_heap_size (void)**

Get the size of available heap.

---

**Note:** Note that the returned value may be larger than the maximum contiguous block which can be allocated.

**Returns**

Available heap size, in bytes.
Chapter 2. API Reference

```c
uint32_t esp_get_free_internal_heap_size(void)
Get the size of available internal heap.

Note: Note that the returned value may be larger than the maximum contiguous block which can be allocated.

Returns Available internal heap size, in bytes.
```

```c
uint32_t esp_get_minimum_free_heap_size(void)
Get the minimum heap that has ever been available.

Returns Minimum free heap ever available
```

```c
void esp_system_abort (const char *details)
Trigger a software abort.

Parameters details - Details that will be displayed during panic handling.
```

Type Definitions

typedef void (*shutdown_handler_t)(void)
Shutdown handler type

Enumerations

enum esp_reset_reason_t
Reset reasons.

Values:

enumerator ESP_RST_UNKNOWN
Reset reason can not be determined.

enumerator ESP_RST_POWERON
Reset due to power-on event.

enumerator ESP_RST_EXT
Reset by external pin (not applicable for ESP32)

enumerator ESP_RST_SW
Software reset via esp_restart.

enumerator ESP_RST_PANIC
Software reset due to exception/panic.

enumerator ESP_RST_INT_WDT
Reset (software or hardware) due to interrupt watchdog.

enumerator ESP_RST_TASK_WDT
Reset due to task watchdog.

enumerator ESP_RST_WDT
Reset due to other watchdogs.
enumerator **ESP_RST_DEEPSLEEP**
   Reset after exiting deep sleep mode.

enumerator **ESP_RST_BROWNOUT**
   Brownout reset (software or hardware)

enumerator **ESP_RST_SDIO**
   Reset over SDIO.

enumerator **ESP_RST_USB**
   Reset by USB peripheral.

enumerator **ESP_RST_JTAG**
   Reset by JTAG.

**Header File**

- components/esp_common/include/esp_idf_version.h
- This header file can be included with:

```c
#include "esp_idf_version.h"
```

**Functions**

const char* **`esp_get_idf_version`** (void)

Return full IDF version string, same as ‘git describe’ output.

**Note:** If you are printing the ESP-IDF version in a log file or other information, this function provides more information than using the numerical version macros. For example, numerical version macros don’t differentiate between development, pre-release and release versions, but the output of this function does.

**Returns** constant string from IDF_VER

**Macros**

**ESP_IDF_VERSION_MAJOR**

   Major version number (X.x.x)

**ESP_IDF_VERSION_MINOR**

   Minor version number (x.X.x)

**ESP_IDF_VERSION_PATCH**

   Patch version number (x.x.X)

**ESP_IDF_VERSION_VAL** (major, minor, patch)

   Macro to convert IDF version number into an integer

   To be used in comparisons, such as ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)

**ESP_IDF_VERSION**

   Current IDF version, as an integer

   To be used in comparisons, such as ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)
Chapter 2. API Reference

Header File

- components/esp_hw_support/include/esp_mac.h
- This header file can be included with:

```
#include "esp_mac.h"
```

Functions

**esp_err_t esp_base_mac_addr_set (const uint8_t *mac)**

Set base MAC address with the MAC address which is stored in BLK3 of EFUSE or external storage e.g. flash and EEPROM.

Base MAC address is used to generate the MAC addresses used by network interfaces.

If using a custom base MAC address, call this API before initializing any network interfaces. Refer to the ESP-IDF Programming Guide for details about how the Base MAC is used.

**Note:** Base MAC must be a unicast MAC (least significant bit of first byte must be zero).

**Note:** If not using a valid OUI, set the “locally administered” bit (bit value 0x02 in the first byte) to avoid collisions.

**Parameters**
- mac: base MAC address, length: 6 bytes.

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG If mac is NULL or is not a unicast MAC

**esp_err_t esp_base_mac_addr_get (uint8_t *mac)**

Return base MAC address which is set using esp_base_mac_addr_set.

**Note:** If no custom Base MAC has been set, this returns the pre-programmed Espressif base MAC address.

**Parameters**
- mac: base MAC address, length: 6 bytes.

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG If mac is NULL
- ESP_ERR_INVALID_MAC Base MAC address has not been set

**esp_err_t esp_efuse_mac_get_custom (uint8_t *mac)**

Return base MAC address which was previously written to BLK3 of EFUSE.

Base MAC address is used to generate the MAC addresses used by the networking interfaces. This API returns the custom base MAC address which was previously written to EFUSE BLK3 in a specified format.

Writing this EFUSE allows setting of a different (non-Espressif) base MAC address. It is also possible to store a custom base MAC address elsewhere, see esp_base_mac_addr_set() for details.

**Note:** This function is currently only supported on ESP32.

**Parameters**
- mac: base MAC address, length: 6 bytes/8 bytes.

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG If mac is NULL
- ESP_ERR_INVALID_MAC CUSTOM_MAC address has not been set
- ESP_ERR_INVALID_VERSION An invalid MAC version field was read from BLK3 of EFUSE (for esp32)
- ESP_ERR_INVALID_CRC An invalid MAC CRC was read from BLK3 of EFUSE (for esp32)
### Chapter 2. API Reference

```c
esp_err_t esp_efuse_mac_get_default (uint8_t* mac)

Return base MAC address which is factory-programmed by Espressif in EFUSE.

**Parameters**
- `mac` — base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64 (used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if mac is NULL
```

```c
esp_err_t esp_read_mac (uint8_t* mac, esp_mac_type_t type)

Read base MAC address and set MAC address of the interface.

This function first get base MAC address using esp_base_mac_addr_get(). Then calculates the MAC address of the specific interface requested, refer to ESP-IDF Programming Guide for the algorithm.

The MAC address set by the esp_iface_mac_addr_set() function will not depend on the base MAC address.

**Parameters**
- `mac` — base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64 (used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)
- `type` — Type of MAC address to return

**Returns**
- ESP_OK on success
```

```c
esp_err_t esp_derive_local_mac (uint8_t* local_mac, const uint8_t* universal_mac)

Derive local MAC address from universal MAC address.

This function copies a universal MAC address and then sets the “locally administered” bit (bit 0x2) in the first octet, creating a locally administered MAC address.

If the universal MAC address argument is already a locally administered MAC address, then the first octet is XORed with 0x4 in order to create a different locally administered MAC address.

**Parameters**
- `local_mac` — base MAC address, length: 6 bytes. length: 6 bytes for MAC-48
- `universal_mac` — Source universal MAC address, length: 6 bytes.

**Returns**
- ESP_OK on success
```

```c
esp_err_t esp_iface_mac_addr_set (const uint8_t* mac, esp_mac_type_t type)

Set custom MAC address of the interface. This function allows you to overwrite the MAC addresses of the interfaces set by the base MAC address.

**Parameters**
- `mac` — MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64 (used for ESP_MAC_IEEE802154 type, if CONFIG_SOC_IEEE802154_SUPPORTED=y)
- `type` — Type of MAC address

**Returns**
- ESP_OK on success
```

```c
size_t esp_mac_addr_len_get (esp_mac_type_t type)

Return the size of the MAC type in bytes.

If CONFIG_SOC_IEEE802154_SUPPORTED is set then for these types:

- ESP_MAC_IEEE802154 is 8 bytes.
- ESP_MAC_BASE, ESP_MAC_EFUSE_FACTORY and ESP_MAC_EFUSE_CUSTOM the MAC size is 6 bytes.
- ESP_MAC_EFUSE_EXT is 2 bytes. If CONFIG_SOC_IEEE802154_SUPPORTED is not set then for all types it returns 6 bytes.

**Parameters**
- `type` — Type of MAC address

**Returns**
- 0 MAC type not found (not supported) 6 bytes for MAC-48. 8 bytes for EUI-64.
Chapter 2. API Reference

Macros

MAC2STR (a)

MACSTR

Enumerations

def

type esp_mac_type_t

Values:

enumerator ESP_MAC_WIFI_STA
    MAC for WiFi Station (6 bytes)

enumerator ESP_MAC_WIFI_SOFTAP
    MAC for WiFi Soft-AP (6 bytes)

enumerator ESP_MAC_BT
    MAC for Bluetooth (6 bytes)

enumerator ESP_MAC_ETH
    MAC for Ethernet (6 bytes)

enumerator ESP_MAC_IEEE802154
    if CONFIG_SOC_IEEE802154_SUPPORTED=y, MAC for IEEE802154 (8 bytes)

enumerator ESP_MAC_BASE
    Base MAC for that used for other MAC types (6 bytes)

enumerator ESP_MAC_EFUSE_FACTORY
    MAC_FACTORY eFuse which was burned by Espressif in production (6 bytes)

enumerator ESP_MAC_EFUSE_CUSTOM
    MAC_CUSTOM eFuse which was can be burned by customer (6 bytes)

enumerator ESP_MAC_EFUSE_EXT
    if CONFIG_SOC_IEEE802154_SUPPORTED=y, MAC_EXT eFuse which is used as an extender for
    IEEE802154 MAC (2 bytes)

Header File

- components/esp_hw_support/include/esp_chip_info.h
- This header file can be included with:

```c
#include "esp_chip_info.h"
```

Functions

void esp_chip_info (esp_chip_info_t *out_info)

Fill an esp_chip_info_t structure with information about the chip.

Parameters

out_info - [out] structure to be filled
Structures

struct esp_chip_info_t
The structure represents information about the chip.

Public Members

    esp_chip_model_t model
        chip model, one of esp_chip_model_t

    uint32_t features
        bit mask of CHIP_FEATURE_\* feature flags

    uint16_t revision
        chip revision number (in format MXX; where M - wafer major version, XX - wafer minor version)

    uint8_t cores
        number of CPU cores

Macros

CHIP_FEATURE_EMB_FLASH
    Chip has embedded flash memory.

CHIP_FEATURE_WIFI_BGN
    Chip has 2.4GHz WiFi.

CHIP_FEATURE_BLE
    Chip has Bluetooth LE.

CHIP_FEATURE_BT
    Chip has Bluetooth Classic.

CHIP_FEATURE_IEEE802154
    Chip has IEEE 802.15.4.

CHIP_FEATURE_EMB_PSRAM
    Chip has embedded pslam.

Enumerations

enum esp_chip_model_t
    Chip models.

    Values:

        enumerator CHIP_ESP32
            ESP32.

        enumerator CHIP_ESP32S2
            ESP32-S2.
enumerator CHIP_ESP32S3
    ESP32-S3.

enumerator CHIP_ESP32C3
    ESP32-C3.

enumerator CHIP_ESP32C2
    ESP32-C2.

enumerator CHIP_ESP32C6
    ESP32-C6.

enumerator CHIP_ESP32H2
    ESP32-H2.

enumerator CHIP_ESP32P4
    ESP32-P4.

enumerator CHIP_POSIX_LINUX
    The code is running on POSIX/Linux simulator.

Header File

- components/esp_hw_support/include/esp_cpu.h
- This header file can be included with:

```c
#include "esp_cpu.h"
```

Functions

void esp_cpu_stall (int core_id)
    Stall a CPU core.

    Parameters
    core_id - The core’s ID

void esp_cpu_unstall (int core_id)
    Resume a previously stalled CPU core.

    Parameters
    core_id - The core’s ID

void esp_cpu_reset (int core_id)
    Reset a CPU core.

    Parameters
    core_id - The core’s ID

void esp_cpu_wait_for_intr (void)
    Wait for Interrupt.

    This function causes the current CPU core to execute its Wait For Interrupt (WFI or equivalent) instruction. After executing this function, the CPU core will stop execution until an interrupt occurs.

int esp_cpu_get_core_id (void)
    Get the current core’s ID.

    This function will return the ID of the current CPU (i.e., the CPU that calls this function).

    Returns
    The current core’s ID [0..SOC_CPU_CORES_NUM - 1]
void *\texttt{esp\_cpu\_get\_sp} (void)
Read the current stack pointer address.

\textbf{Returns} Stack pointer address

\texttt{esp\_cpu\_cycle\_count\_t esp\_cpu\_get\_cycle\_count} (void)
Get the current CPU core’s cycle count.

Each CPU core maintains an internal counter (i.e., cycle count) that increments every CPU clock cycle.

\textbf{Returns} Current CPU core’s cycle count, 0 if not supported.

void \texttt{esp\_cpu\_set\_cycle\_count} (\texttt{esp\_cpu\_cycle\_count\_t cycle\_count})
Set the current CPU core’s cycle count.

Set the given value into the internal counter that increments every CPU clock cycle.

\textbf{Parameters} \texttt{cycle\_count} – CPU cycle count

void \texttt{esp\_cpu\_pc\_to\_addr} (uint32\_t pc)
Convert a program counter (PC) value to address.

If the architecture does not store the true virtual address in the CPU’s PC or return addresses, this function will convert the PC value to a virtual address. Otherwise, the PC is just returned

\textbf{Parameters} \texttt{pc} – PC value
\textbf{Returns} Virtual address

void \texttt{esp\_cpu\_intr\_get\_desc} (int core\_id, int intr\_num, \texttt{esp\_cpu\_intr\_desc\_t *intr\_desc\_ret})
Get a CPU interrupt’s descriptor.

Each CPU interrupt has a descriptor describing the interrupt’s capabilities and restrictions. This function gets the descriptor of a particular interrupt on a particular CPU.

\textbf{Parameters}
- \texttt{core\_id} –[in] The core’s ID
- \texttt{intr\_num} –[in] Interrupt number
- \texttt{intr\_desc\_ret} –[out] The interrupt’s descriptor

void \texttt{esp\_cpu\_intr\_set\_ivt\_addr} (const void *ivt\_addr)
Set the base address of the current CPU’s Interrupt Vector Table (IVT)

\textbf{Parameters} \texttt{ivt\_addr} –Interrupt Vector Table’s base address

bool \texttt{esp\_cpu\_intr\_has\_handler} (int intr\_num)
Check if a particular interrupt already has a handler function.

Check if a particular interrupt on the current CPU already has a handler function assigned.

\textbf{Note:} This function simply checks if the IVT of the current CPU already has a handler assigned.

\textbf{Parameters} \texttt{intr\_num} – Interrupt number (from 0 to 31)
\textbf{Returns} True if the interrupt has a handler function, false otherwise.

void \texttt{esp\_cpu\_intr\_set\_handler} (int intr\_num, \texttt{esp\_cpu\_intr\_handler\_t handler}, void *handler\_arg)
Set the handler function of a particular interrupt.

Assign a handler function (i.e., ISR) to a particular interrupt on the current CPU.

\textbf{Note:} This function simply sets the handler function (in the IVT) and does not actually enable the interrupt.

\textbf{Parameters}

• **intr_num** – Interrupt number (from 0 to 31)
• **handler** – Handler function
• **handler_arg** – Argument passed to the handler function

```c
void *esp_cpu_intr_get_handler_arg (int intr_num)
```
Get a handler function’s argument of.

Get the argument of a previously assigned handler function on the current CPU.

**Parameters**
- **intr_num** – Interrupt number (from 0 to 31)

**Returns**
The the argument passed to the handler function

```c
void esp_cpu_intr_enable (uint32_t intr_mask)
```
Enable particular interrupts on the current CPU.

**Parameters**
- **intr_mask** – Bit mask of the interrupts to enable

```c
void esp_cpu_intr_disable (uint32_t intr_mask)
```
Disable particular interrupts on the current CPU.

**Parameters**
- **intr_mask** – Bit mask of the interrupts to disable

```c
uint32_t esp_cpu_intr_get_enabled_mask (void)
```
Get the enabled interrupts on the current CPU.

**Returns**
Bit mask of the enabled interrupts

```c
void esp_cpu_intr_edge_ack (int intr_num)
```
Acknowledge an edge interrupt.

**Parameters**
- **intr_num** – Interrupt number (from 0 to 31)

```c
void esp_cpu_configure_region_protection (void)
```
Configure the CPU to disable access to invalid memory regions.

```c
esp_err_t esp_cpu_set_breakpoint (int bp_num, const void *bp_addr)
```
Set and enable a hardware breakpoint on the current CPU.

**Note:** This function is meant to be called by the panic handler to set a breakpoint for an attached debugger during a panic.

**Note:** Overwrites previously set breakpoint with same breakpoint number.

**Parameters**
- **bp_num** – Hardware breakpoint number [0..SOC_CPU_BREAKPOINTS_NUM - 1]
- **bp_addr** – Address to set a breakpoint on

**Returns**
ESP_OK if breakpoint is set. Failure otherwise

```c
esp_err_t esp_cpu_clear_breakpoint (int bp_num)
```
Clear a hardware breakpoint on the current CPU.

**Note:** Clears a breakpoint regardless of whether it was previously set

**Parameters**
- **bp_num** – Hardware breakpoint number [0..SOC_CPU_BREAKPOINTS_NUM - 1]

**Returns**
ESP_OK if breakpoint is cleared. Failure otherwise
**esp_err_t esp_cpu_set_watchpoint** (int wp_num, const void *wp_addr, size_t size, esp_cpu_watchpoint_trigger_t trigger)

Set and enable a hardware watchpoint on the current CPU.

Set and enable a hardware watchpoint on the current CPU, specifying the memory range and trigger operation. Watchpoints will break/panic the CPU when the CPU accesses (according to the trigger type) on a certain memory range.

**Note:** Overwrites previously set watchpoint with same watchpoint number.

**Parameters**
- **wp_num** – Hardware watchpoint number [0..SOC_CPU_WATCHPOINTS_NUM - 1]
- **wp_addr** – Watchpoint’s base address
- **size** – Size of the region to watch. Must be one of 2^n, with n in [0..6].
- **trigger** – Trigger type

**Returns** ESP_ERR_INVALID_ARG on invalid arg, ESP_OK otherwise

**esp_err_t esp_cpu_clear_watchpoint** (int wp_num)

Clear a hardware watchpoint on the current CPU.

**Note:** Clears a watchpoint regardless of whether it was previously set

**Parameters** **wp_num** – Hardware watchpoint number [0..SOC_CPU_WATCHPOINTS_NUM - 1]

**Returns** ESP_OK if watchpoint was cleared. Failure otherwise.

**bool esp_cpu_dbgr_is_attached** (void)

Check if the current CPU has a debugger attached.

**Returns** True if debugger is attached, false otherwise

**void esp_cpu_dbgr_break** (void)

Trigger a call to the current CPU’s attached debugger.

**intptr_t esp_cpu_get_call_addr** (intptr_t return_address)

Given the return address, calculate the address of the preceding call instruction. This is typically used to answer the question “where was the function called from?”.

**Parameters** **return_address** – The value of the return address register. Typically set to the value of __builtin_return_address(0).

**Returns** Address of the call instruction preceding the return address.

**bool esp_cpu_compare_and_set** (volatile uint32_t *addr, uint32_t compare_value, uint32_t new_value)

Atomic compare-and-set operation.

**Parameters**
- **addr** – Address of atomic variable
- **compare_value** – Value to compare the atomic variable to
- **new_value** – New value to set the atomic variable to

**Returns** Whether the atomic variable was set or not

**Structures**

**struct esp_cpu_intr_desc_t**

CPU interrupt descriptor.
Each particular CPU interrupt has an associated descriptor describing that particular interrupt’s characteristics. Call esp_cpu_intr_get_desc() to get the descriptors of a particular interrupt.

**Public Members**

`int priority`
- Priority of the interrupt if it has a fixed priority, (-1) if the priority is configurable.

`esp_cpu_intr_type_t type`
- Whether the interrupt is an edge or level type interrupt, ESP_CPU_INTR_TYPE_NA if the type is configurable.

`uint32_t flags`
- Flags indicating extra details.

**Macros**

`ESP_CPU_INTR_DESC_FLAG_SPECIAL`
- Interrupt descriptor flags of `esp_cpu_intr_desc_t`.
  - The interrupt is a special interrupt (e.g., a CPU timer interrupt)

`ESP_CPU_INTR_DESC_FLAG_RESVD`
- The interrupt is reserved for internal use

**Type Definitions**

`typedef uint32_t esp_cpu_cycle_count_t`
- CPU cycle count type.
  - This data type represents the CPU’s clock cycle count

`typedef void (*esp_cpu_intr_handler_t)(void *arg)`
- CPU interrupt handler type.

**Enumerations**

`enum esp_cpu_intr_type_t`
- CPU interrupt type.
  - `Values`:
    - `enumerator ESP_CPU_INTR_TYPE_LEVEL`
    - `enumerator ESP_CPU_INTR_TYPE_EDGE`
    - `enumerator ESP_CPU_INTR_TYPE_NA`

`enum esp_cpu_watchpoint_trigger_t`
- CPU watchpoint trigger type.
  - `Values`:
Chapter 2. API Reference

enumerator ESP_CPU_WATCHPOINT_LOAD

enumerator ESP_CPU_WATCHPOINT_STORE

enumerator ESP_CPU_WATCHPOINT_ACCESS

Header File

- components/esp_app_format/include/esp_app_desc.h
- This header file can be included with:

  ```
  #include "esp_app_desc.h"
  ```

- This header file is a part of the API provided by the esp_app_format component. To declare that your component depends on esp_app_format, add the following to your CMakeLists.txt:

  ```
  REQUIRES esp_app_format
  ```

  or

  ```
  PRIV_REQUIRES esp_app_format
  ```

Functions

const esp_app_desc_t *esp_app_get_description (void)

Return esp_app_desc structure. This structure includes app version.

Return description for running app.

Returns Pointer to esp_app_desc structure.

int esp_app_get_elf_sha256 (char *dst, size_t size)

Fill the provided buffer with SHA256 of the ELF file, formatted as hexadecimal, null-terminated. If the buffer size is not sufficient to fit the entire SHA256 in hex plus a null terminator, the largest possible number of bytes will be written followed by a null.

Parameters

- `dst` – Destination buffer
- `size` – Size of the buffer

Returns Number of bytes written to dst (including null terminator)

char *esp_app_get_elf_sha256_str (void)

Return SHA256 of the ELF file which is already formatted as hexadecimal, null-terminated included. Can be used in panic handler or core dump during when cache is disabled. The length is defined by CONFIG_APP_RETRIEVE_LEN_ELF_SHA option.

Returns Hexadecimal SHA256 string

Structures

struct esp_app_desc_t

Description about application.

Public Members

uint32_t magic_word

Magic word ESP_APP_DESC_MAGIC_WORD
Chapter 2. API Reference

```c
uint32_t secure_version
    Secure version

uint32_t reserv1[2]
    reserv1

char version[32]
    Application version

char project_name[32]
    Project name

char time[16]
    Compile time

char date[16]
    Compile date

char idf_ver[32]
    Version IDF

uint8_t app_elf_sha256[32]
    sha256 of elf file

uint32_t reserv2[20]
    reserv2
```

**Macros**

**ESP_APP_DESC_MAGIC_WORD**

The magic word for the esp_app_desc structure that is in DROM.

### 2.10.23 Over The Air Updates (OTA)

**OTA Process Overview**

The OTA update mechanism allows a device to update itself based on data received while the normal firmware is running (for example, over Wi-Fi or Bluetooth.)

OTA requires configuring the **Partition Tables** of the device with at least two OTA app slot partitions (i.e., `ota_0` and `ota_1`) and an OTA Data Partition.

The OTA operation functions write a new app firmware image to whichever OTA app slot that is currently not selected for booting. Once the image is verified, the OTA Data partition is updated to specify that this image should be used for the next boot.
OTA Data Partition

An OTA data partition (type data, subtype ota) must be included in the Partition Tables of any project which uses the OTA functions.

For factory boot settings, the OTA data partition should contain no data (all bytes erased to 0xFF). In this case, the ESP-IDF software bootloader will boot the factory app if it is present in the partition table. If no factory app is included in the partition table, the first available OTA slot (usually ota_0) is booted.

After the first OTA update, the OTA data partition is updated to specify which OTA app slot partition should be booted next.

The OTA data partition is two flash sectors (0x2000 bytes) in size, to prevent problems if there is a power failure while it is being written. Sectors are independently erased and written with matching data, and if they disagree a counter field is used to determine which sector was written more recently.

App Rollback

The main purpose of the application rollback is to keep the device working after the update. This feature allows you to roll back to the previous working application in case a new application has critical errors. When the rollback process is enabled and an OTA update provides a new version of the app, one of three things can happen:

- The application works fine, esp_ota_mark_app_valid_cancel_rollback() marks the running application with the state ESP_OTA_IMG_VALID. There are no restrictions on booting this application.
- The application has critical errors and further work is not possible, a rollback to the previous application is required, esp_ota_mark_app_invalid_rollback_and_reboot() marks the running application with the state ESP_OTA_IMG_INVALID and reset. This application will not be selected by the bootloader for boot and will boot the previously working application.
- If the CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is set, and a reset occurs without calling either function then the application is rolled back.

Note: The state is not written to the binary image of the application but rather to the ota data partition. The partition contains a ota_seq counter, which is a pointer to the slot (ota_0, ota_1, …) from which the application will be selected for boot.

App OTA State

States control the process of selecting a boot app:

<table>
<thead>
<tr>
<th>States</th>
<th>Restriction of selecting a boot app in bootloader</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP_OTA_IMG_VALID</td>
<td>The restriction. Will be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG_UNDEFINED</td>
<td>The restriction. Will be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG_INVALID</td>
<td>Will not be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG_ABORTED</td>
<td>be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG_NEW</td>
<td>CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is set it will be selected only once. In bootloader the state immediately changes to ESP_OTA_IMG_PENDING_VERIFY.</td>
</tr>
<tr>
<td>ESP_OTA_IMG_PENDING_VER</td>
<td>CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is set it will not be selected, and the state will change to ESP_OTA_IMG_ABORTED.</td>
</tr>
</tbody>
</table>

If CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is not enabled (by default), then the use of the following functions esp_ota_mark_app_valid_cancel_rollback() and esp_ota_mark_app_invalid_rollback_and_reboot() are optional, and ESP_OTA_IMG_NEW and ESP_OTA_IMG_PENDING_VERIFY states are not used.

An option in Kconfig CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE allows you to track the first boot of a new application. In this case, the application must confirm its operability by calling esp_ota_mark_app_valid_cancel_rollback() function, otherwise the application will be rolled back.
upon reboot. It allows you to control the operability of the application during the boot phase. Thus, a new application has only one attempt to boot successfully.

**Rollback Process** The description of the rollback process when `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` option is enabled:

- The new application is successfully downloaded and `esp_ota_set_boot_partition()` function makes this partition bootable and sets the state `ESP_OTA_IMG_NEW`. This state means that the application is new and should be monitored for its first boot.
- Reboot `esp_restart()`.
- The bootloader checks for the `ESP_OTA_IMG_PENDING_VERIFY` state if it is set, then it will be written to `ESP_OTA_IMG_ABORTED`.
- The bootloader selects a new application to boot so that the state is not set as `ESP_OTA_IMG_INVALID` or `ESP_OTA_IMG_ABORTED`.
- The bootloader checks the selected application for `ESP_OTA_IMG_NEW` state if it is set, then it will be written to `ESP_OTA_IMG_PENDING_VERIFY`. This state means that the application requires confirmation of its operability, if this does not happen and a reboot occurs, this state will be overwritten to `ESP_OTA_IMG_ABORTED` (see above) and this application will no longer be able to start, i.e., there will be a rollback to the previous working application.
- A new application has started and should make a self-test.
- If the self-test has completed successfully, then you must call the function `esp_ota_mark_app_valid_cancel_rollback()` because the application is awaiting confirmation of operability (`ESP_OTA_IMG_PENDING_VERIFY` state).
- If the self-test fails, then call `esp_ota_mark_app_invalid_rollback_and_reboot()` function to rollback to the previous working application, while the invalid application is set `ESP_OTA_IMG_INVALID` state.
- If the application has not been confirmed, the state remains `ESP_OTA_IMG_PENDING_VERIFY`, and the next boot it will be changed to `ESP_OTA_IMG_ABORTED`, which prevents re-boot of this application. There will be a rollback to the previous working application.

**Unexpected Reset** If a power loss or an unexpected crash occurs at the time of the first boot of a new application, it will roll back the application.

Recommendation: Perform the self-test procedure as quickly as possible, to prevent rollback due to power loss.

Only OTA partitions can be rolled back. Factory partition is not rolled back.

**Booting Invalid/aborted Apps** Booting an application which was previously set to `ESP_OTA_IMG_INVALID` or `ESP_OTA_IMG_ABORTED` is possible:

- Get the last invalid application partition `esp_ota_get_last_invalid_partition()`.
- Pass the received partition to `esp_ota_set_boot_partition()`, this will update the odata.
- Restart `esp_restart()`. The bootloader will boot the specified application.

To determine if self-tests should be run during startup of an application, call the `esp_ota_get_state_partition()` function. If result is `ESP_OTA_IMG_PENDING_VERIFY` then self-testing and subsequent confirmation of operability is required.

**Where the States Are Set** A brief description of where the states are set:

- `ESP_OTA_IMG_VALID` state is set by `esp_ota_mark_app_valid_cancel_rollback()` function.
- `ESP_OTA_IMG_UNDEFINED` state is set by `esp_ota_set_boot_partition()` function if `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` option is not enabled.
- `ESP_OTA_IMG_NEW` state is set by `esp_ota_set_boot_partition()` function if `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` option is enabled.
- `ESP_OTA_IMG_INVALID` state is set by `esp_ota_mark_app_invalid_rollback_and_reboot()` function.
• ESP_OTA_IMG_ABORTED state is set if there was no confirmation of the application operability and occurs reboots (if CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is enabled).
• ESP_OTA_IMG_PENDING_VERIFY state is set in a bootloader if CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is enabled and selected app has ESP_OTA_IMG_NEW state.

Anti-rollback

Anti-rollback prevents rollback to application with security version lower than one programmed in eFuse of chip. This function works if set CONFIG_BOOTLOADER_APP_ANTI_ROLLBACK option. In the bootloader, when selecting a bootable application, an additional security version check is added which is on the chip and in the application image. The version in the bootable firmware must be greater than or equal to the version in the chip. CONFIG_BOOTLOADER_APP_ANTI_ROLLBACK and CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE options are used together. In this case, rollback is possible only on the security version which is equal or higher than the version in the chip.

A Typical Anti-rollback Scheme Is

• New firmware released with the elimination of vulnerabilities with the previous version of security.
• After the developer makes sure that this firmware is working. He can increase the security version and release a new firmware.
• Download new application.
• To make it bootable, run the function esp_ota_set_boot_partition(). If the security version of the new application is smaller than the version in the chip, the new application will be erased. Update to new firmware is not possible.
• Reboot.
• In the bootloader, an application with a security version greater than or equal to the version in the chip will be selected. If otadata is in the initial state, and one firmware was loaded via a serial channel, whose secure version is higher than the chip, then the secure version of efuse will be immediately updated in the bootloader.
• New application booted. Then the application should perform diagnostics of the operation and if it is completed successfully, you should call esp_ota_mark_app_valid_cancel_rollback() function to mark the running application with the ESP_OTA_IMG_VALID state and update the secure version on chip. Note that if was called esp_ota_mark_app_invalid_rollbback_and_reboot() function a rollback may not happen as the device may not have any bootable apps. It will then return ESP_ERR_OTA_ROLLBACK_FAILED error and stay in the ESP_OTA_IMG_PENDING_VERIFY state.
• The next update of app is possible if a running app is in the ESP_OTA_IMG_VALID state.

Recommendation:

If you want to avoid the download/erase overhead in case of the app from the server has security version lower than the running app, you have to get new_app_info.secure_version from the first package of an image and compare it with the secure version of efuse. Use esp_efuse_check_secure_version(new_app_info.secure_version) function if it is true then continue downloading otherwise abort.

```c
bool image_header_was_checked = false;
while (1) {
    int data_read = esp_http_client_read(client, ota_write_data, BUFFSIZE);
    ...
    if (data_read > 0) {
        if (image_header_was_checked == false) {
            esp_app_desc_t new_app_info;
            if (data_read > sizeof(esp_image_header_t) + sizeof(esp_image_segment_header_t) + sizeof(esp_app_desc_t)) {
                // check current version with downloading
                if (esp_efuse_check_secure_version(new_app_info.secure_version) == false)
                    ESP_LOGE(TAG, "This a new app can not be downloaded due to a secure version is lower than stored in efuse.");
            }
        }
    }
}(continues on next page)
```
http_cleanup(client);
    task_fatal_error();
}

image_header_was_checked = true;
esp_ota_begin(update_partition, OTA_SIZE_UNKNOWN, &update_handle);
}

esp_ota_write(update_handle, (const void *)ota_write_data, data_read);
}

Restrictions:

- The number of bits in the secure_version field is limited to 32 bits. This means that only 32 times you can do an anti-rollback. You can reduce the length of this efuse field using CONFIG_BOOTLOADER_APP_SEC_VER_SIZE_EFUSE_FIELD option.
- Anti-rollback works only if the encoding scheme for efuse is set to NONE.
- Factory and Test partitions are not supported in anti rollback scheme and hence partition table should not have partition with SubType set to factory or test.

security_version:

- In application image it is stored in esp_app_desc structure. The number is set CONFIG_BOOTLOADER_APP_SECURE_VERSION.
- In ESP32 it is stored in efuse EFUSE_BLK3_RDATA4_REG. (when a eFuse bit is programmed to 1, it can never be reverted to 0). The number of bits set in this register is the security_version from app.

Secure OTA Updates Without Secure Boot

The verification of signed OTA updates can be performed even without enabling hardware secure boot. This can be achieved by setting CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT and CONFIG_SECURE_SIGNED_ON_UPDATE_NO_SECURE_BOOT

For more information refer to Signed App Verification Without Hardware Secure Boot

OTA Tool otatool.py

The component app_update provides a tool app_update/otatool.py for performing OTA partition-related operations on a target device. The following operations can be performed using the tool:

- read contents of otadata partition (read_otadata)
- erase otadata partition, effectively resetting device to factory app (erase_otadata)
- switch OTA partitions (switch_ota_partition)
- erasing OTA partition (erase_ota_partition)
- write to OTA partition (write_ota_partition)
- read contents of OTA partition (read_ota_partition)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool’s Python API and command-line interface, respectively.

Python API Before anything else, make sure that the otatool module is imported.
import sys
import os

idf_path = os.environ['IDF_PATH']  # get value of IDF_PATH from environment
otatool_dir = os.path.join(idf_path, "components", "app_update")  # otatool.py lives in $IDF_PATH/components/app_update

sys.path.append(notatool_dir)  # this enables Python to find otatool module

from otatool import *  # import all names inside otatool module

The starting point for using the tool’s Python API to do is create a OtatoolTarget object:

```python
# Create a partool.py target device connected on serial port /dev/ttyUSB1
target = OtatoolTarget("/dev/ttyUSB1")
```

The created object can now be used to perform operations on the target device:

```python
# Erase otadata, resetting the device to factory app
target.erase_otadata()

# Erase contents of OTA app slot 0
target.erase_ota_partition(0)

# Switch boot partition to that of app slot 1
target.switch_ota_partition(1)

# Read OTA partition 'ota_3' and save contents to a file named 'ota_3.bin'
target.read_ota_partition("ota_3", "ota_3.bin")
```

The OTA partition to operate on is specified using either the app slot number or the partition name.

More information on the Python API is available in the docstrings for the tool.

### Command-line Interface

The command-line interface of otatool.py has the following structure:

```
otatool.py [command-args] [subcommand] [subcommand-args]
```

- command-args - these are arguments that are needed for executing the main_command (parttool.py), mostly pertaining to the target device
- subcommand - this is the operation to be performed
- subcommand-args - these are arguments that are specific to the chosen operation

```
# Erase otadata, resetting the device to factory app
otatool.py --port "/dev/ttyUSB1" erase_otadata

# Erase contents of OTA app slot 0
otatool.py --port "/dev/ttyUSB1" erase_ota_partition --slot 0

# Switch boot partition to that of app slot 1
otatool.py --port "/dev/ttyUSB1" switch_ota_partition --slot 1

# Read OTA partition 'ota_3' and save contents to a file named 'ota_3.bin'
otatool.py --port "/dev/ttyUSB1" read_ota_partition --name=ota_3 --output=ota_3.bin
```

More information can be obtained by specifying --help as argument:

```
# Display possible subcommands and show main command argument descriptions
otatool.py --help

# Show descriptions for specific subcommand arguments
otatool.py [subcommand] --help
```

Application Example

End-to-end example of OTA firmware update workflow: system/ota.

API Reference

Header File

• components/app_update/include/esp_ota_ops.h
• This header file can be included with:

```c
#include "esp_ota_ops.h"
```

• This header file is a part of the API provided by the app_update component. To declare that your component depends on app_update, add the following to your CMakeLists.txt:

```c
REQUIRES app_update
```
or

```c
PRIV_REQUIRES app_update
```

Functions

```c
const esp_app_desc_t *esp_ota_get_app_description (void)
```

Return esp_app_desc structure. This structure includes app version.

Note: This API is present for backward compatibility reasons. Alternative function with the same functionality is esp_app_get_description.

**Returns** Pointer to esp_app_desc structure.

```c
int esp_ota_get_app_elf_sha256 (char *dst, size_t size)
```

Fill the provided buffer with SHA256 of the ELF file, formatted as hexadecimal, null-terminated. If the buffer size is not sufficient to fit the entire SHA256 in hex plus a null terminator, the largest possible number of bytes will be written followed by a null.

Note: This API is present for backward compatibility reasons. Alternative function with the same functionality is esp_app_get_elf_sha256.

**Parameters**

- **dst** – Destination buffer
- **size** – Size of the buffer

**Returns** Number of bytes written to dst (including null terminator)
### esp_err_t esp_ota_begin(const esp_partition_t *partition, size_t image_size, esp_ota_handle_t *out_handle)

Commence an OTA update writing to the specified partition.

The specified partition is erased to the specified image size.

If image size is not yet known, pass OTA_SIZE_UNKNOWN which will cause the entire partition to be erased.

On success, this function allocates memory that remains in use until esp_ota_end() is called with the returned handle.

Note: If the rollback option is enabled and the running application has the ESP_OTA_IMG_PENDING_VERIFY state then it will lead to the ESP_ERR_OTA_ROLLBACK_INVALID_STATE error. Confirm the running app before to run download a new app, use esp_ota_mark_app_valid_cancel_rollback() function for it (this should be done as early as possible when you first download a new application).

**Parameters**

- **partition** – Pointer to info for partition which will receive the OTA update. Required.
- **image_size** – Size of new OTA app image. Partition will be erased in order to receive this size of image. If 0 or OTA_SIZE_UNKNOWN, the entire partition is erased.
- **out_handle** – On success, returns a handle which should be used for subsequent esp_ota_write() and esp_ota_end() calls.

**Returns**

- ESP_OK: OTA operation commenced successfully.
- ESP_ERR_INVALID_ARG: partition or out_handle arguments were NULL, or partition doesn’t point to an OTA app partition.
- ESP_ERR_NO_MEM: Cannot allocate memory for OTA operation.
- ESP_ERR_OTA_PARTITION_CONFLICT: Partition holds the currently running firmware, cannot update in place.
- ESP_ERR_NOT_FOUND: Partition argument not found in partition table.
- ESP_ERR_OTA_SELECT_INFO_INVALID: The OTA data partition contains invalid data.
- ESP_ERR_OTA_INVALID_SIZE: Partition doesn’t fit in configured flash size.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_ROLLBACK_INVALID_STATE: If the running app has not confirmed state. Before performing an update, the application must be valid.

### esp_err_t esp_ota_write(const void *data, size_t size)

Write OTA update data to partition.

This function can be called multiple times as data is received during the OTA operation. Data is written sequentially to the partition.

**Parameters**

- **handle** – Handle obtained from esp_ota_begin
- **data** – Data buffer to write
- **size** – Size of data buffer in bytes.

**Returns**

- ESP_OK: Data was written to flash successfully.
- ESP_ERR_OTA_VALIDATE_FAILED: First byte of image contains invalid app image magic byte.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_SELECT_INFO_INVALID: OTA data partition has invalid contents

### esp_err_t esp_ota_write_with_offset(const void *data, size_t size, uint32_t offset)

Write OTA update data to partition at an offset.
This function can write data in non-contiguous manner. If flash encryption is enabled, data should be 16 bytes aligned.

**Note:** While performing OTA, if the packets arrive out of order, `esp_ota_write_with_offset()` can be used to write data in non-contiguous manner. Use of `esp_ota_write_with_offset()` in combination with `esp_ota_write()` is not recommended.

**Parameters**
- `handle` - Handle obtained from `esp_ota_begin`
- `data` - Data buffer to write
- `size` - Size of data buffer in bytes
- `offset` - Offset in flash partition

**Returns**
- ESP_OK: Data was written to flash successfully.
- ESP_ERR_INVALID_ARG: Handle is invalid.
- ESP_ERR_OTA_VALIDATE_FAILED: First byte of image contains invalid app image magic byte.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_SELECT_INFO_INVALID: OTA data partition has invalid contents

```c
esp_err_t esp_ota_end(esp_ota_handle_t handle)
```
Finish OTA update and validate newly written app image.

**Note:** After calling `esp_ota_end()`, the handle is no longer valid and any memory associated with it is freed (regardless of result).

**Parameters** `handle` - Handle obtained from `esp_ota_begin()`.

**Returns**
- ESP_OK: Newly written OTA app image is valid.
- ESP_ERR_NOT_FOUND: OTA handle was not found.
- ESP_ERR_INVALID_ARG: Handle was never written to.
- ESP_ERR_OTA_VALIDATE_FAILED: OTA image is invalid (either not a valid app image, or if secure boot is enabled - signature failed to verify.)
- ESP_ERR_INVALID_STATE: If flash encryption is enabled, this result indicates an internal error writing the final encrypted bytes to flash.

```c
esp_err_t esp_ota_abort(esp_ota_handle_t handle)
```
Abort OTA update, free the handle and memory associated with it.

**Parameters** `handle` - obtained from `esp_ota_begin()`.

**Returns**
- ESP_OK: Handle and its associated memory is freed successfully.
- ESP_ERR_NOT_FOUND: OTA handle was not found.

```c
esp_err_t esp_ota_set_boot_partition(const esp_partition_t *partition)
```
Configure OTA data for a new boot partition.

**Note:** If this function returns ESP_OK, calling `esp_restart()` will boot the newly configured app partition.

**Parameters** `partition` - Pointer to info for partition containing app image to boot.

**Returns**
- ESP_OK: OTA data updated, next reboot will use specified partition.
• ESP_ERR_INVALID_ARG: partition argument was NULL or didn’t point to a valid OTA partition of type “app”.
• ESP_ERR_OTA_VALIDATE_FAILED: Partition contained invalid app image. Also returned if secure boot is enabled and signature validation failed.
• ESP_ERR_NOT_FOUND: OTA data partition not found.
• ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash erase or write failed.

const esp_partition_t *esp_ota_get_boot_partition (void)
Get partition info of currently configured boot app.

If esp_ota_set_boot_partition() has been called, the partition which was set by that function will be returned.
If esp_ota_set_boot_partition() has not been called, the result is usually the same as esp_ota_get_running_partition(). The two results are not equal if the configured boot partition does not contain a valid app (meaning that the running partition will be an app that the bootloader chose via fallback).

If the OTA data partition is not present or not valid then the result is the first app partition found in the partition table. In priority order, this means: the factory app, the first OTA app slot, or the test app partition.

Note that there is no guarantee the returned partition is a valid app. Use esp_image_verify(ESP_IMAGE_VERIFY, ⋯) to verify if the returned partition contains a bootable image.

Returns Pointer to info for partition structure, or NULL if partition table is invalid or a flash read operation failed. Any returned pointer is valid for the lifetime of the application.

const esp_partition_t *esp_ota_get_running_partition (void)
Get partition info of currently running app.

This function is different to esp_ota_get_boot_partition() in that it ignores any change of selected boot partition caused by esp_ota_set_boot_partition(). Only the app whose code is currently running will have its partition information returned.

The partition returned by this function may also differ from esp_ota_get_boot_partition() if the configured boot partition is somehow invalid, and the bootloader fell back to a different app partition at boot.

Returns Pointer to info for partition structure, or NULL if no partition is found or flash read operation failed. Returned pointer is valid for the lifetime of the application.

const esp_partition_t *esp_ota_get_next_update_partition (const esp_partition_t *start_from)
Return the next OTA app partition which should be written with a new firmware.

Call this function to find an OTA app partition which can be passed to esp_ota_begin().

Finds next partition round-robin, starting from the current running partition.

Parameters start_from – If set, treat this partition info as describing the current running partition. Can be NULL, in which case esp_ota_get_running_partition() is used to find the currently running partition. The result of this function is never the same as this argument.

Returns Pointer to info for partition which should be updated next. NULL result indicates invalid OTA data partition, or that no eligible OTA app slot partition was found.

esp_err_t esp_ota_get_partition_description (const esp_partition_t *partition, esp_app_desc_t *app_desc)
Returns esp_app_desc structure for app partition. This structure includes app version.

Returns a description for the requested app partition.

Parameters
  • partition – [in] Pointer to app partition. (only app partition)
  • app_desc – [out] Structure of info about app.

Returns
  • ESP_OK Successful.
• ESP_ERR_NOT_FOUND app_desc structure is not found. Magic word is incorrect.
• ESP_ERR_NOT_SUPPORTED Partition is not application.
• ESP_ERR_INVALID_ARG Arguments is NULL or if partition’s offset exceeds partition size.
• ESP_ERR_INVALID_SIZE Read would go out of bounds of the partition.
• or one of error codes from lower-level flash driver.

`esp_err_t esp_ota_get_bootloader_description(const esp_partition_t *bootloader_partition,
                                            esp_bootloader_desc_t *desc)`

Returns the description structure of the bootloader.

Parameters

• bootloader_partition - [in] Pointer to bootloader partition. If NULL, then the current bootloader is used (the default location).
  offset = CONFIG_BOOTLOADER_OFFSET_IN_FLASH,
  size = CONFIG_PARTITION_TABLE_OFFSET - CONFIG_BOOTLOADER_OFFSET_IN_FLASH,
• desc - [out] Structure of info about bootloader.

Returns

• ESP_OK Successful.
• ESP_ERR_NOT_FOUND Description structure is not found in the bootloader image. Magic byte is incorrect.
• ESP_ERR_INVALID_ARG Arguments is NULL.
• ESP_ERR_INVALID_SIZE Read would go out of bounds of the partition.
• or one of error codes from lower-level flash driver.

`uint8_t esp_ota_get_app_partition_count(void)`

Returns number of OTA partitions provided in partition table.

Returns

• Number of OTA partitions

`esp_err_t esp_ota_mark_app_valid_cancel_rollback(void)`

This function is called to indicate that the running app is working well.

Returns

• ESP_OK: if successful.

`esp_err_t esp_ota_mark_app_invalid_rollback_and_reboot(void)`

This function is called to rollback to the previously workable app with reboot.

If rollback is successful then device will reset else API will return with error code. Checks applications on a flash drive that can be booted in case of rollback. If the flash does not have at least one app (except the running app) then rollback is not possible.

Returns

• ESP_FAIL: if not successful.
• ESP_ERR_OTA.Rollback.FAILED: The rollback is not possible due to flash does not have any apps.

`const esp_partition_t *esp_ota_get_last_invalid_partition(void)`

Returns last partition with invalid state (ESP.OTA_IMG_INVALID or ESP.OTA_IMG_ABORTED).

Returns partition.

`esp_err_t esp_ota_get_state_partition(const esp_partition_t *partition, esp_ota_img_states_t *ota_state)`

Returns state for given partition.

Parameters

• partition - [in] Pointer to partition.
• ota_state - [out] state of partition (if this partition has a record in otadata).
• ESP_OK: Successful.
• ESP_ERR_INVALID_ARG: partition or ota_state arguments were NULL.
• ESP_ERR_NOT_SUPPORTED: partition is not ota.
• ESP_ERR_NOT_FOUND: Partition table does not have otadata or state was not found for given partition.

```c
esp_err_t esp_ota_erase_last_boot_app_partition (void)
```

Erase previous boot app partition and corresponding otadata select for this partition.

When current app is marked to as valid then you can erase previous app partition.

Returns
• ESP_OK: Successful, otherwise ESP_ERR.

```c
bool esp_ota_check_rollback_is_possible (void)
```

Checks applications on the slots which can be booted in case of rollback.

These applications should be valid (marked in otadata as not UNDEFINED, INVALID or ABORTED and crc is good) and be able booted, and secure_version of app >= secure_version of efuse (if anti-rollback is enabled).

Returns
• True: Returns true if the slots have at least one app (except the running app).
• False: The rollback is not possible.

Macros

```
OTA_SIZE_UNKNOWN
```
Used for esp_ota_begin() if new image size is unknown

```
OTA_WITH_SEQUENTIAL_WRITES
```
Used for esp_ota_begin() if new image size is unknown and erase can be done in incremental manner (assuming write operation is in continuous sequence)

```
ESP_ERR_OTA_BASE
```
Base error code for ota_ops api

```
ESP_ERR_OTA_PARTITION_CONFLICT
```
Error if request was to write or erase the current running partition

```
ESP_ERR_OTA_SELECT_INFO_INVALID
```
Error if OTA data partition contains invalid content

```
ESP_ERR_OTA_VALIDATE_FAILED
```
Error if OTA app image is invalid

```
ESP_ERR_OTA_SMALL_SEC_VER
```
Error if the firmware has a secure version less than the running firmware.

```
ESP_ERR_OTA_ROLLBACK_FAILED
```
Error if flash does not have valid firmware in passive partition and hence rollback is not possible

```
ESP_ERR_OTA_ROLLBACK_INVALID_STATE
```
Error if current active firmware is still marked in pending validation state (ESP_OTA_IMG_PENDING_VERIFY), essentially first boot of firmware image post upgrade and hence firmware upgrade is not possible
Type Definitions

typedef uint32_t esp_ota_handle_t

Opaque handle for an application OTA update.

esp_ota_begin() returns a handle which is then used for subsequent calls to esp_ota_write() and esp_ota_end().

Debugging OTA Failure

![Diagram of how to debug when OTA fails](image)

**Fig. 45: How to Debug When OTA Fails (click to enlarge)**

2.10.24 Performance Monitor

The Performance Monitor component provides APIs to use ESP32 internal performance counters to profile functions and applications.

Application Example

An example which combines performance monitor is provided in `examples/system/perfmon` directory. This example initializes the performance monitor structure and execute them with printing the statistics.
High-Level API Reference

Header Files
- perfmon/include/perfmon.h

API Reference

Header File
- components/perfmon/include/xtensa_perfmon_access.h
  - This header file can be included with:
    ```
    #include "xtensa_perfmon_access.h"
    ```
  - This header file is a part of the API provided by the perfmon component. To declare that your component depends on perfmon, add the following to your CMakeLists.txt:
    ```
    REQUIRES perfmon
    or
    PRIV_REQUIRES perfmon
    ```

Functions

```c
esp_err_t xtensa_perfmon_init (int id, uint16_t select, uint16_t mask, int kernelcnt, int tracelevel)
```
- Init Performance Monitor.
- Parameters
  - id – [in] performance counter number
  - select – [in] select value from PMCTRLx register
  - mask – [in] mask value from PMCTRLx register
  - kernelcnt – [in] kernelcnt value from PMCTRLx register
  - tracelevel – [in] tracelevel value from PMCTRLx register
- Returns
  - ESP_OK on success
  - ESP_ERR_INVALID_ARG if one of the arguments is not correct

```c
esp_err_t xtensa_perfmon_reset (int id)
```
- Reset PM counter.
- Parameters id – [in] performance counter number
- Returns
  - ESP_OK on success
  - ESP_ERR_INVALID_ARG if id out of range

```c
void xtensa_perfmon_start (void)
```
- Start PM counters.
- Parameters
  - id – [in] performance counter number
- Returns
  - ESP_OK on success
  - ESP_ERR_INVALID_ARG if id out of range

```c
void xtensa_perfmon_stop (void)
```
- Stop PM counters.
- Parameters
  - id – [in] performance counter number
- Returns
  - ESP_OK on success
  - ESP_ERR_INVALID_ARG if id out of range

```c
uint32_t xtensa_perfmon_value (int id)
```
- Read PM counter.
- Parameters
  - id – [in] performance counter number
- Returns
  - Read value of defined PM counter.
**Parameters**  
*id* - [in] performance counter number

**Returns**
- Performance counter value

```c
esp_err_t xtensa_perfmon_overflow(int id)
```
Read PM overflow state.

Read overflow value of defined PM counter.

**Parameters**  
*id* - [in] performance counter number

**Returns**
- ESP_OK if there is no overflow (overflow = 0)
- ESP_FAIL if overflow occure (overflow = 1)

```c
void xtensa_perfmon_dump (void)
```
Dump PM values.

Dump all PM register to the console.

**Header File**
- components/perfmon/include/xtensa_perfmon_apis.h

This header file can be included with:

```c
#include "xtensa_perfmon_apis.h"
```

This header file is a part of the API provided by the perfmon component. To declare that your component depends on perfmon, add the following to your CMakeLists.txt:

```cmake
REQUIRES perfmon
```

or

```cmake
PRIV_REQUIRES perfmon
```

**Functions**

```c
esp_err_t xtensa_perfmon_exec(const xtensa_perfmon_config_t *config)
```
Execute PM.

Execute performance counter for dedicated function with defined parameters

**Parameters**  
*config* - [in] pointer to the configuration structure

**Returns**
- ESP_OK if no errors
- ESP_ERR_INVALID_ARG if one of the required parameters not defined
- ESP_FAIL - counter overflow

```c
void xtensa_perfmon_view_cb (void *params, uint32_t select, uint32_t mask, uint32_t value)
```
Dump PM results.

Callback to dump perfmon result to a FILE* stream specified in perfmon_config_t:callback_params. If callback_params is set to NULL, will print to stdout

**Parameters**
- *params* - [in] used parameters passed from configuration (callback_params). This parameter expected as FILE* hanle, where data will be stored. If this parameter NULL, then data will be stored to the stdout.
- *select* - [in] select value for current counter
- *mask* - [in] mask value for current counter
- *value* - [in] counter value for current counter
Structures

struct xtensa_perfmon_config

Performance monitor configuration structure.
Structure to configure performance counter to measure dedicated function

Public Members

int repeat_count
how much times function will be called before the callback will be repeated

float max_deviation
Difference between min and max counter number 0..1, 0 - no difference, 1 - not used

void *call_params
This pointer will be passed to the call_function as a parameter

void (*call_function)(void *params)
pointer to the function that have to be called

void (*callback)(void *params, uint32_t select, uint32_t mask, uint32_t value)
pointer to the function that will be called with result parameters

void *callback_params
parameter that will be passed to the callback

int tracelevel
trace level for all counters. In case of negative value, the filter will be ignored. If it’s >=0, then the perfmon will count only when interrupt level > tracelevel. It’s useful to monitor interrupts.

uint32_t counters_size
amount of counter in the list

const uint32_t *select_mask
list of the select/mask parameters

Type Definitions

typedef struct xtensa_perfmon_config xtensa_perfmon_config_t

Performance monitor configuration structure.
Structure to configure performance counter to measure dedicated function

2.10.25 Power Management
Overview

Power management algorithm included in ESP-IDF can adjust the advanced peripheral bus (APB) frequency, CPU frequency, and put the chip into Light-sleep mode to run an application at smallest possible power consumption, given the requirements of application components.

Application components can express their requirements by creating and acquiring power management locks.

For example:

- Driver for a peripheral clocked from APB can request the APB frequency to be set to 80 MHz while the peripheral is used.
- RTOS can request the CPU to run at the highest configured frequency while there are tasks ready to run.
- A peripheral driver may need interrupts to be enabled, which means it has to request disabling Light-sleep.

Since requesting higher APB or CPU frequencies or disabling Light-sleep causes higher current consumption, please keep the usage of power management locks by components to a minimum.

Configuration

Power management can be enabled at compile time, using the option `CONFIG_PM_ENABLE`.

Enabling power management features comes at the cost of increased interrupt latency. Extra latency depends on a number of factors, such as the CPU frequency, single/dual core mode, whether or not frequency switch needs to be done. Minimum extra latency is 0.2 us (when the CPU frequency is 240 MHz and frequency scaling is not enabled). Maximum extra latency is 40 us (when frequency scaling is enabled, and a switch from 40 MHz to 80 MHz is performed on interrupt entry).

Dynamic frequency scaling (DFS) and automatic Light-sleep can be enabled in an application by calling the function `esp_pm_configure()`. Its argument is a structure defining the frequency scaling settings, `esp_pm_config_t`. In this structure, three fields need to be initialized:

- `max_freq_mhz`: Maximum CPU frequency in MHz, i.e., the frequency used when the `ESP_PM_CPU_FREQ_MAX` lock is acquired. This field is usually set to the default CPU frequency.
- `min_freq_mhz`: Minimum CPU frequency in MHz, i.e., the frequency used when only the `ESP_PM_APB_FREQ_MAX` lock is acquired. This field can be set to the XTAL frequency value, or the XTAL frequency divided by an integer. Note that 10 MHz is the lowest frequency at which the default REF_TICK clock of 1 MHz can be generated.
- `light_sleep_enable`: Whether the system should automatically enter Light-sleep when no locks are acquired (`true`/`false`).

Alternatively, if you enable the option `CONFIG_PM_DFS_INIT_AUTO` in menuconfig, the maximum CPU frequency will be determined by the `CONFIG_ESP_DEFAULT_CPU_FREQ_MHZ` setting, and the minimum CPU frequency will be locked to the XTAL frequency.

Note: Automatic Light-sleep is based on FreeRTOS Tickless Idle functionality. If automatic Light-sleep is requested while the option `CONFIG_FREERTOS_USE_TICKLESS_IDLE` is not enabled in menuconfig, `esp_pm_configure()` will return the error `ESP_ERR_NOT_SUPPORTED`.

Note: In Light-sleep, peripherals are clock gated, and interrupts (from GPIOs and internal peripherals) will not be generated. A wakeup source described in the Sleep Modes documentation can be used to trigger wakeup from the Light-sleep state.

For example, the EXT0 and EXT1 wakeup sources can be used to wake up the chip via a GPIO.

Power Management Locks

Applications have the ability to acquire/release locks in order to control the power management algorithm. When an application acquires a lock, the power management algorithm operation is restricted in a way described below. When
the lock is released, such restrictions are removed.

Power management locks have acquire/release counters. If the lock has been acquired a number of times, it needs to be released the same number of times to remove associated restrictions.

ESP32 supports three types of locks described in the table below.

<table>
<thead>
<tr>
<th>Lock</th>
<th>Description</th>
</tr>
</thead>
</table>
| ESP_PM_CPU_FREQ_MAX         | Requests CPU frequency to be at the maximum value set with `esp_pm_configure()`.
|                             | For ESP32, this value can be set to 80 MHz, 160 MHz, or 240 MHz.             |
| ESP_PM_APB_FREQ_MAX         | Requests the APB frequency to be at the maximum supported value. For ESP32, this is 80 MHz. |
| ESP_PM_NO_LIGHT_SLEEP       | Disables automatic switching to Light-sleep.                                |

ESP32 Power Management Algorithm

The table below shows how CPU and APB frequencies will be switched if dynamic frequency scaling is enabled. You can specify the maximum CPU frequency with either `esp_pm_configure()` or `CONFIG_ESP_DEFAULT_CPU_FREQ_MHZ`.

<table>
<thead>
<tr>
<th>Max CPU Frequency Set</th>
<th>Lock Acquisition</th>
<th>CPU and APB Frequencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>240</td>
<td>Any of ESP_PM_CPU_FREQ_MAX or ESP_PM_APB_FREQ_MAX acquired</td>
<td>CPU: 240 MHz</td>
</tr>
<tr>
<td></td>
<td></td>
<td>APB: 80 MHz</td>
</tr>
<tr>
<td></td>
<td>None</td>
<td>Min values for both frequencies set with <code>esp_pm_configure()</code></td>
</tr>
<tr>
<td>160</td>
<td>ESP_PM_CPU_FREQ_MAX acquired</td>
<td>CPU: 160 MHz</td>
</tr>
<tr>
<td></td>
<td></td>
<td>APB: 80 MHz</td>
</tr>
<tr>
<td></td>
<td>ESP_PM_APB_FREQ_MAX acquired, ESP_PM_CPU_FREQ_MAX not acquired</td>
<td>CPU: 80 MHz</td>
</tr>
<tr>
<td></td>

<td>APB: 80 MHz</td>
</tr>
<tr>
<td></td>
<td>None</td>
<td>Min values for both frequencies set with <code>esp_pm_configure()</code></td>
</tr>
<tr>
<td>80</td>
<td>Any of ESP_PM_CPU_FREQ_MAX or ESP_PM_APB_FREQ_MAX acquired</td>
<td>CPU: 80 MHz</td>
</tr>
<tr>
<td></td>
<td></td>
<td>APB: 80 MHz</td>
</tr>
<tr>
<td></td>
<td>None</td>
<td>Min values for both frequencies set with <code>esp_pm_configure()</code></td>
</tr>
</tbody>
</table>

If none of the locks are acquired, and Light-sleep is enabled in a call to `esp_pm_configure()`, the system will go into Light-sleep mode. The duration of Light-sleep will be determined by:

- FreeRTOS tasks blocked with finite timeouts
- Timers registered with High resolution timer APIs
Light-sleep duration is chosen to wake up the chip before the nearest event (task being unblocked, or timer elapses).

To skip unnecessary wake-up, you can consider initializing an `esp_timer` with the `skip_unhandled_events` option as `true`. Timers with this flag will not wake up the system and it helps to reduce consumption.

**Dynamic Frequency Scaling and Peripheral Drivers**

When DFS is enabled, the APB frequency can be changed multiple times within a single RTOS tick. The APB frequency change does not affect the operation of some peripherals, while other peripherals may have issues. For example, Timer Group peripheral timers keeps counting, however, the speed at which they count changes proportionally to the APB frequency.

Peripheral clock sources such as `REF_TICK`, `XTAL`, `RC_FAST` (i.e., `RTC_SM`), their frequencies will not be influenced by APB frequency. And therefore, to ensure the peripheral behaves consistently during DFS, it is recommended to select one of these clocks as the peripheral clock source. For more specific guidelines, please refer to the “Power Management” section of each peripheral’s “API Reference > Peripherals API” page.

Currently, the following peripheral drivers are aware of DFS and use the `ESP_PM_APB_FREQ_MAX` lock for the duration of the transaction:

- SPI master
- I2C
- I2S (If the APLL clock is used, then it will use the `ESP_PM_NO_LIGHT_SLEEP` lock)
- SDMMC

The following drivers hold the `ESP_PM_APB_FREQ_MAX` lock while the driver is enabled:

- SPI slave: between calls to `spi_slave_initialize()` and `spi_slave_free()`.
- GPTimer: between calls to `gptimer_enable()` and `gptimer_disable()`.
- Ethernet: between calls to `esp_eth_driver_install()` and `esp_eth_driver_uninstall()`.
- WiFi: between calls to `esp_wifi_start()` and `esp_wifi_stop()`. If modem sleep is enabled, the lock will be released for the periods of time when radio is disabled.
- TWAI: between calls to `twai_driver_install()` and `twai_driver_uninstall()` (only when the clock source is set to `TWAI_CLK_SRC_APB`).
- Bluetooth: between calls to `esp_bt_controller_enable()` and `esp_bt_controller_disable()`. If Bluetooth Modem-sleep is enabled, the `ESP_PM_APB_FREQ_MAX` lock will be released for the periods of time when radio is disabled. However the `ESP_PM_NO_LIGHT_SLEEP` lock will still be held, unless `CONFIG_BTDMS_CTRL_LOW_POWER_CLOCK` option is set to “External 32kHz crystal”.

The following peripheral drivers are not aware of DFS yet. Applications need to acquire/release locks themselves, when necessary:

- PCNT
- Sigma-delta
- The legacy timer group driver
- MCPWM

**Light-sleep Peripheral Power Down**

**API Reference**

**Header File**

- `components/esp_pm/include/esp_pm.h`
- This header file can be included with:
#include "esp_pm.h"

- This header file is a part of the API provided by the esp_pm component. To declare that your component depends on esp_pm, add the following to your CMakeLists.txt:

```cmake
REQUIRES esp_pm
```

or

```cmake
PRIV_REQUIRES esp_pm
```

## Functions

### esp_err_t esp_pm_configure (const void *config)

Set implementation-specific power management configuration.

**Parameters**
- `config` — pointer to implementation-specific configuration structure (e.g. esp_pm_config.esp32)

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the configuration values are not correct
- ESP_ERR_NOT_SUPPORTED if certain combination of values is not supported, or if CONFIG_PM_ENABLE is not enabled in sdkconfig

### esp_err_t esp_pm_get_configuration (void *config)

Get implementation-specific power management configuration.

**Parameters**
- `config` — pointer to implementation-specific configuration structure (e.g. esp_pm_config.esp32)

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the pointer is null

### esp_err_t esp_pm_lock_create (esp_pm_lock_type_t lock_type, int arg, const char *name, esp_pm_lock_handle_t *out_handle)

Initialize a lock handle for certain power management parameter.

When lock is created, initially it is not taken. Call esp_pm_lock_acquire to take the lock.

This function must not be called from an ISR.

**Parameters**
- `lock_type` — Power management constraint which the lock should control
- `arg` — argument, value depends on lock_type, see esp_pm_lock_type_t
- `name` — arbitrary string identifying the lock (e.g. “wifi” or “spi”). Used by the esp_pm_dump_locks function to list existing locks. May be set to NULL. If not set to NULL, must point to a string which is valid for the lifetime of the lock.
- `out_handle` — [out] handle returned from this function. Use this handle when calling esp_pm_lock_delete, esp_pm_lock_acquire, esp_pm_lock_release. Must not be NULL.

**Returns**
- ESP_OK on success
- ESP_ERR_NO_MEM if the lock structure cannot be allocated
- ESP_ERR_INVALID_ARG if out_handle is NULL or type argument is not valid
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

### esp_err_t esp_pm_lock_acquire (esp_pm_lock_handle_t handle)

Take a power management lock.

Once the lock is taken, power management algorithm will not switch to the mode specified in a call to esp_pm_lock_create, or any of the lower power modes (higher numeric values of ‘mode’).

The lock is recursive, in the sense that if esp_pm_lock_acquire is called a number of times, esp_pm_lock_release has to be called the same number of times in order to release the lock.
This function may be called from an ISR.
This function is not thread-safe w.r.t. calls to other esp_pm_lock_* functions for the same handle.

**Parameters**

- handle – handle obtained from esp_pm_lock_create function

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

```c
esp_err_t esp_pm_lock_release(esp_pm_lock_handle_t handle)
```

Release the lock taken using esp_pm_lock_acquire.

Call to this function removes power management restrictions placed when taking the lock.

Locks are recursive, so if esp_pm_lock_acquire is called a number of times, esp_pm_lock_release has to be called the same number of times in order to actually release the lock.

This function may be called from an ISR.
This function is not thread-safe w.r.t. calls to other esp_pm_lock_* functions for the same handle.

**Parameters**

- handle – handle obtained from esp_pm_lock_create function

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if lock is not acquired
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

```c
esp_err_t esp_pm_lock_delete(esp_pm_lock_handle_t handle)
```

Delete a lock created using esp_pm_lock.

The lock must be released before calling this function.
This function must not be called from an ISR.

**Parameters**

- handle – handle obtained from esp_pm_lock_create function

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle argument is NULL
- ESP_ERR_INVALID_STATE if the lock is still acquired
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

```c
esp_err_t esp_pm_dump_locks(FILE *stream)
```

Dump the list of all locks to stderr

This function dumps debugging information about locks created using esp_pm_lock_create to an output stream.
This function must not be called from an ISR. If esp_pm_lock_acquire/release are called while this function is running, inconsistent results may be reported.

**Parameters**

- stream – stream to print information to; use stdout or stderr to print to the console; use fmemopen/open_memstream to print to a string buffer.

**Returns**

- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

**Structures**

```c
struct esp_pm_config_t
```

Power management config.

Pass a pointer to this structure as an argument to esp_pm_configure function.
Public Members

int \texttt{max\_freq\_mhz}
Maximum CPU frequency, in MHz

int \texttt{min\_freq\_mhz}
Minimum CPU frequency to use when no locks are taken, in MHz

bool \texttt{light\_sleep\_enable}
Enter light sleep when no locks are taken

Type Definitions

typedef \texttt{esp\_pm\_config\_t} \texttt{esp\_pm\_config\_esp32\_t}
backward compatibility newer chips no longer require this typedef

typedef \texttt{esp\_pm\_config\_t} \texttt{esp\_pm\_config\_esp32s2\_t}

typedef \texttt{esp\_pm\_config\_t} \texttt{esp\_pm\_config\_esp32s3\_t}

typedef \texttt{esp\_pm\_config\_t} \texttt{esp\_pm\_config\_esp32c3\_t}

typedef \texttt{esp\_pm\_config\_t} \texttt{esp\_pm\_config\_esp32c2\_t}

typedef \texttt{esp\_pm\_config\_t} \texttt{esp\_pm\_config\_esp32c6\_t}

typedef struct \texttt{esp\_pm\_lock} *\texttt{esp\_pm\_lock\_handle\_t}
Opaque handle to the power management lock.

Enumerations

enum \texttt{esp\_pm\_lock\_type\_t}
Power management constraints.

\begin{verbatim}
"Values:

enumerator \texttt{ESP\_PM\_CPU\_FREQ\_MAX}
Require CPU frequency to be at the maximum value set via \texttt{esp\_pm\_configure}. Argument is unused and should be set to 0.

enumerator \texttt{ESP\_PM\_APB\_FREQ\_MAX}
Require APB frequency to be at the maximum value supported by the chip. Argument is unused and should be set to 0.

enumerator \texttt{ESP\_PM\_NO\_LIGHT\_SLEEP}
Prevent the system from going into light sleep. Argument is unused and should be set to 0.
\end{verbatim}

2.10.26 POSIX Threads Support
Overview

ESP-IDF is based on FreeRTOS but offers a range of POSIX-compatible APIs that allow easy porting of third-party code. This includes support for common parts of the POSIX Threads pthread API.

POSIX Threads are implemented in ESP-IDF as wrappers around equivalent FreeRTOS features. The runtime memory or performance overhead of using the pthreads API is quite low, but not every feature available in either pthreads or FreeRTOS is available via the ESP-IDF pthreads support.

Pthreads can be used in ESP-IDF by including standard `pthread.h` header, which is included in the toolchain libc. An additional ESP-IDF specific header, `esp_pthread.h`, provides additional non-POSIX APIs for using some ESP-IDF features with pthreads.

C++ Standard Library implementations for `std::thread`, `std::mutex`, `std::condition_variable`, etc., are realized using pthreads (via GCC libstdc++). Therefore, restrictions mentioned here also apply to the equivalent C++ standard library functionality.

RTOS Integration

Unlike many operating systems using POSIX Threads, ESP-IDF is a real-time operating system with a real-time scheduler. This means that a thread will only stop running if a higher priority task is ready to run, the thread blocks on an OS synchronization structure like a mutex, or the thread calls any of the functions `sleep`, `vTaskDelay()`, or `usleep`.

Note: When calling a standard libc or C++ sleep function, such as `usleep` defined in `unistd.h`, the task will only block and yield the core if the sleep time is longer than one FreeRTOS tick period. If the time is shorter, the thread will busy-wait instead of yielding to another RTOS task.

By default, all POSIX Threads have the same RTOS priority, but it is possible to change this by calling a custom API.

Standard Features

The following standard APIs are implemented in ESP-IDF.

Refer to standard POSIX Threads documentation, or `pthread.h`, for details about the standard arguments and behaviour of each function. Differences or limitations compared to the standard APIs are noted below.

Thread APIs

- `pthread_create()`
  - The `attr` argument is supported for setting stack size and detach state only. Other attribute fields are ignored.
  - Unlike FreeRTOS task functions, the `start_routine` function is allowed to return. A detached type thread is automatically deleted if the function returns. The default joinable type thread will be suspended until `pthread_join()` is called on it.
- `pthread_join()`
- `pthread_detach()`
- `pthread_exit()`
- `sched_yield()`
- `pthread_self()`
  - An assert will fail if this function is called from a FreeRTOS task which is not a pthread.
- `pthread_equal()`

Thread Attributes

- `pthread_attr_init()`
- `pthread_attr_destroy()`
Chapter 2. API Reference

This function does not need to free any resources and instead resets the attr structure to defaults. The implementation is the same as pthread_attr_init().

- pthread_attr_getstacksize() / pthread_attr_setstacksize()
- pthread_attr_getdetachstate() / pthread_attr_setdetachstate()

Once

- pthread_once()

Static initializer constant PTHREAD_ONCE_INIT is supported.

Note: This function can be called from tasks created using either pthread or FreeRTOS APIs.

Mutexes

POSIX Mutexes are implemented as FreeRTOS Mutex Semaphores (normal type for “fast” or “error check” mutexes, and Recursive type for “recursive” mutexes). This means that they have the same priority inheritance behavior as mutexes created with xSemaphoreCreateMutex().

- pthread_mutex_init()
- pthread_mutex_destroy()
- pthread_mutex_lock()
- pthread_mutex_timedlock()
- pthread_mutex_trylock()
- pthread_mutex_unlock()
- pthread_mutexattr_init()
- pthread_mutexattr_destroy()
- pthread_mutexattr_gettype() / pthread_mutexattr_settype()

Static initializer constant PTHREAD_MUTEX_INITIALIZER is supported, but the non-standard static initializer constants for other mutex types are not supported.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs.

Condition Variables

- pthread_cond_init()
  - The attr argument is not implemented and is ignored.
- pthread_cond_destroy()
- pthread_cond_signal()
- pthread_cond_broadcast()
- pthread_cond_wait()
- pthread_cond_timedwait()

Static initializer constant PTHREAD_COND_INITIALIZER is supported.

- The resolution of pthread_cond_timedwait() timeouts is the RTOS tick period (see CONFIG_FREERTOS_HZ).Timeouts may be delayed up to one tick period after the requested timeout.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs.

Semaphores

In ESP-IDF, POSIX unnamed semaphores are implemented. The accessible API is described below. It implements semaphores as specified in the POSIX standard, unless specified otherwise.

- sem_init()
- sem_destroy()
  - pshared is ignored. Semaphores can always be shared between FreeRTOS tasks.
Chapter 2. API Reference

- **sem_post()**
  - If the semaphore has a value of `SEM_VALUE_MAX` already, -1 is returned and `errno` is set to `EAGAIN`.
- **sem_wait()**
- **sem_trywait()**
- **sem_timedwait()**
  - The time value passed by abstime will be rounded up to the next FreeRTOS tick.
  - The actual timeout happens after the tick that the time was rounded to and before the following tick.
  - It is possible, though unlikely, that the task is preempted directly after the timeout calculation, delaying the timeout of the following blocking operating system call by the duration of the preemption.
- **sem_getvalue()**

**Read/Write Locks** The following API functions of the POSIX reader-writer locks specification are implemented:

- **pthread_rwlock_init()**
  - The `attr` argument is not implemented and is ignored.
- **pthread_rwlock_destroy()**
- **pthread_rwlock_rdlock()**
- **pthread_rwlock_tryrdlock()**
- **pthread_rwlock_wrlock()**
- **pthread_rwlock_trywrlock()**
- **pthread_rwlock_unlock()**

The static initializer constant `PTHREAD_RWLOCK_INITIALIZER` is supported.

**Note:** These functions can be called from tasks created using either pthread or FreeRTOS APIs.

**Thread-Specific Data**

- **pthread_key_create()**
  - The `destr_function` argument is supported and will be called if a thread function exits normally, calls `pthread_exit()`, or if the underlying task is deleted directly using the FreeRTOS function `vTaskDelete()`.
- **pthread_key_delete()**
- **pthread_setspecific() / pthread_getspecific()**

**Note:** These functions can be called from tasks created using either pthread or FreeRTOS APIs. When calling these functions from tasks created using FreeRTOS APIs, `CONFIG_FREERTOS_TLSP_DELETION_CALLBACKS` config option must be enabled to ensure the thread-specific data is cleaned up before the task is deleted.

**Note:** There are other options for thread local storage in ESP-IDF, including options with higher performance. See **Thread Local Storage**.

**Not Implemented**

The `pthread.h` header is a standard header and includes additional APIs and features which are not implemented in ESP-IDF. These include:

- `pthread_cancel()` returns `ENOSYS` if called.
- `pthread_condattr_init()` returns `ENOSYS` if called.

Other POSIX Threads functions (not listed here) are not implemented and will produce either a compiler or a linker error if referenced from an ESP-IDF application. If you identify a useful API that you would like to see implemented in ESP-IDF, please open a feature request on GitHub with the details.
Chapter 2. API Reference

ESP-IDF Extensions

The API `esp_pthread_set_cfg()` defined in the `esp_pthreads.h` header offers custom extensions to control how subsequent calls to `pthread_create()` behaves. Currently, the following configuration can be set:

- Default stack size of new threads, if not specified when calling `pthread_create()` (overrides `CONFIG_PTHREAD_TASK_STACK_SIZE_DEFAULT`).
- RTOS priority of new threads (overrides `CONFIG_PTHREAD_TASK_PRIO_DEFAULT`).
- Core affinity / core pinning of new threads (overrides `CONFIG_PTHREAD_TASK_CORE_DEFAULT`).
- FreeRTOS task name for new threads (overrides `CONFIG_PTHREAD_TASK_NAME_DEFAULT`).

This configuration is scoped to the calling thread (or FreeRTOS task), meaning that `esp_pthread_set_cfg()` can be called independently in different threads or tasks. If the `inherit_cfg` flag is set in the current configuration then any new thread created will inherit the creator’s configuration (if that thread calls `pthread_create()` recursively), otherwise the new thread will have the default configuration.

Examples

- `system/pthread` demonstrates using the pthread API to create threads.
- `cxx/pthread` demonstrates using C++ Standard Library functions with threads.

API Reference

Header File

- `components/pthread/include/esp_pthread.h`
- This header file can be included with:

```c
#include "esp_pthread.h"
```

- This header file is a part of the API provided by the `pthread` component. To declare that your component depends on `pthread`, add the following to your CMakeLists.txt:

```cmake
REQUIRES pthread
```

or

```cmake
PRIV_REQUIRES pthread
```

Functions

`esp_pthreadCfg_t esp_pthread_get_default_config(void)`  
Creates a default pthread configuration based on the values set via menuconfig.

**Returns**  
A default configuration structure.

`esp_err_t esp_pthread_set_cfg(const esp_pthreadCfg_t *cfg)`  
Configures parameters for creating pthread.

This API allows you to configure how the subsequent `pthread_create()` call will behave. This call can be used to setup configuration parameters like stack size, priority, configuration inheritance etc.

If the ‘inherit’ flag in the configuration structure is enabled, then the same configuration is also inherited in the thread subtree.

**Note:** Passing non-NULL attributes to `pthread_create()` will override the `stack_size` parameter set using this API.

**Parameters**  
`cfg` - The pthread config parameters
Returns

- ESP_OK if configuration was successfully set
- ESP_ERR_NO_MEM if out of memory
- ESP_ERR_INVALID_ARG if stack_size is less than PTHREAD_STACK_MIN

```c
esp_err_t esp_pthread_get_cfg(esp_pthread_cfg_t *p)
```

Get current pthread creation configuration.

This will retrieve the current configuration that will be used for creating threads.

**Parameters**
- `p` - Pointer to the pthread config structure that will be updated with the currently configured parameters

**Returns**

- ESP_OK if the configuration was available
- ESP_ERR_NOT_FOUND if a configuration wasn’t previously set

```c
esp_err_t esp_pthread_init (void)
```

Initialize pthread library.

**Structures**

```c
struct esp_pthread_cfg_t
```

pthread configuration structure that influences pthread creation

**Public Members**

```c
size_t stack_size
```

The stack size of the pthread.

```c
size_t prio
```

The thread’s priority.

```c
bool inherit_cfg
```

Inherit this configuration further.

```c
const char *thread_name
```

The thread name.

```c
int pin_to_core
```

The core id to pin the thread to. Has the same value range as xCoreId argument of xTaskCreatePinnedToCore.

**Macros**

```c
PTHREAD_STACK_MIN
```

## 2.10.27 Random Number Generation

ESP32 contains a hardware random number generator, values from it can be obtained using the APIs `esp_random()` and `esp_fill_random()`.

The hardware RNG produces true random numbers under any of the following conditions:

- RF subsystem is enabled (i.e., Wi-Fi or Bluetooth are enabled).
• An internal entropy source has been enabled by calling `bootloader_random_enable()` and not yet disabled by calling `bootloader_random_disable()`.
• While the ESP-IDF Second Stage Bootloader is running. This is because the default ESP-IDF bootloader implementation calls `bootloader_random_enable()` when the bootloader starts, and `bootloader_random_disable()` before executing the app.

When any of these conditions are true, samples of physical noise are continuously mixed into the internal hardware RNG state to provide entropy. Consult the ESP32 Technical Reference Manual > Random Number Generator (RNG) [PDF] chapter for more details.

If none of the above conditions are true, the output of the RNG should be considered pseudo-random only.

**Startup**

During startup, ESP-IDF bootloader temporarily enables a non-RF entropy source (internal reference voltage noise) that provides entropy for any first boot key generation. However, after the app starts executing then normally only pseudo-random numbers are available until Wi-Fi or Bluetooth are initialized.

To re-enable the entropy source temporarily during app startup, or for an application that does not use Wi-Fi or Bluetooth, call the function `bootloader_random_enable()` to re-enable the internal entropy source. The function `bootloader_random_disable()` must be called to disable the entropy source again before using ADC, I2S, Wi-Fi or Bluetooth.

**Note:** The entropy source enabled during the boot process by the ESP-IDF Second Stage Bootloader seeds the internal RNG state with some entropy. However, the internal hardware RNG state is not large enough to provide a continuous stream of true random numbers. This is why a continuous entropy source must be enabled whenever true random numbers are required.

**Note:** If an application requires a source of true random numbers but it is not possible to permanently enable a hardware entropy source, consider using a strong software DRBG implementation such as the mbedTLS CTR-DRBG or HMAC-DRBG, with an initial seed of entropy from hardware RNG true random numbers.

**API Reference**

**Header File**

- components/esp_hw_support/include/esp_random.h
- This header file can be included with:

```
#include "esp_random.h"
```

**Functions**

```c
uint32_t esp_random(void)
```

Get one random 32-bit word from hardware RNG.

If Wi-Fi or Bluetooth are enabled, this function returns true random numbers. In other situations, if true random numbers are required then consult the ESP-IDF Programming Guide “Random Number Generation” section for necessary prerequisites.

This function automatically busy-waits to ensure enough external entropy has been introduced into the hardware RNG state, before returning a new random number. This delay is very short (always less than 100 CPU cycles).

**Returns** Random value between 0 and UINT32_MAX
void `esp_fill_random` (void *buf, size_t len)

Fill a buffer with random bytes from hardware RNG.

**Note:** This function is implemented via calls to `esp_random()`, so the same constraints apply.

**Parameters**
- `buf` – Pointer to buffer to fill with random numbers.
- `len` – Length of buffer in bytes

**Header File**

- `components/bootloader_support/include/bootloader_random.h`

This header file can be included with:

```c
#include "bootloader_random.h"
```

This header file is a part of the API provided by the `bootloader_support` component. To declare that your component depends on `bootloader_support`, add the following to your `CMakeLists.txt`:

```c
REQUIRES bootloader_support
```

or

```c
PRIV_REQUIRES bootloader_support
```

**Functions**

void `bootloader_random_enable` (void)

Enable an entropy source for RNG if RF subsystem is disabled.

The exact internal entropy source mechanism depends on the chip in use but all SoCs use the SAR ADC to continuously mix random bits (an internal noise reading) into the HWRNG. Consult the SoC Technical Reference Manual for more information.

Can also be called from app code, if true random numbers are required without initialized RF subsystem. This might be the case in early startup code of the application when the RF subsystem has not started yet or if the RF subsystem should not be enabled for power saving.

**Warning:** This function is not safe to use if any other subsystem is accessing the RF subsystem or the ADC at the same time!

void `bootloader_random_disable` (void)

Disable entropy source for RNG.

Disables internal entropy source. Must be called after `bootloader_random_enable()` and before RF subsystem features, ADC, or I2S (ESP32 only) are initialized.

Consult the ESP-IDF Programming Guide “Random Number Generation” section for details.

void `bootloader_fill_random` (void *buffer, size_t length)

Fill buffer with ‘length’ random bytes.

**Note:** If this function is being called from app code only, and never from the bootloader, then it’s better to call `esp_fill_random()`.
Chapter 2. API Reference

Parameters
- **buffer** - Pointer to buffer
- **length** - This many bytes of random data will be copied to buffer

**getrandom()**

A compatible version of the Linux `getrandom()` function is also provided for ease of porting:

```c
#include <sys/random.h>

ssize_t getrandom(void *buf, size_t buflen, unsigned int flags);
```

This function is implemented by calling `esp_fill_random()` internally.

The **flags** argument is ignored, this function is always non-blocking but the strength of any random numbers is dependent on the same conditions described above.

Return value is -1 (with **errno** set to **EFAULT**) if the **buf** argument is NULL, and equal to **buflen** otherwise.

**getentropy()**

A compatible version of the Linux `getentropy()` function is also provided for ease of porting:

```c
#include <unistd.h>

int getentropy(void *buffer, size_t length);
```

This function is implemented by calling `getrandom()` internally.

Strength of any random numbers is dependent on the same conditions described above.

**Return value is 0 on success and -1 otherwise with **errno** set to:**
- EFAULT if the **buffer** argument is NULL.
- EIO if the **length** is more then 256.

### 2.10.28 Sleep Modes

**Overview**

ESP32 supports two major power saving modes: Light-sleep and Deep-sleep. According to the features used by an application, there are some sub sleep modes. See *Sleep Modes* for these sleep modes and sub sleep modes. Additionally, there are some power-down options that can be configured to further reduce the power consumption. See *Power-down Options* for more details.

There are several wakeup sources in the sleep modes. These sources can also be combined so that the chip will wake up when any of the sources are triggered. *Wakeup Sources* describes these wakeup sources and configuration APIs in detail.

The configuration of power-down options and wakeup sources are optional. They can be configured at any moment before entering the sleep modes.

Then the application can call sleep start APIs to enter one of the sleep modes. See *Entering Sleep* for more details. When the wakeup condition is met, the application is awoken from sleep. See *Checking Sleep Wakeup Cause* on how to get the wakeup cause, and *Disable Sleep Wakeup Source* on how to handle the wakeup sources after wakeup.
## Sleep Modes

In **Light-sleep mode**, most of the RAM, and CPUs are clock-gated and their supply voltage is reduced. Upon exit from Light-sleep, the digital peripherals, RAM, and CPUs resume operation and their internal states are preserved.

In **Deep-sleep mode**, the CPUs, most of the RAM, and all digital peripherals that are clocked from APB_CLK are powered off. The only parts of the chip that remain powered on are:

- RTC controller
- ULP coprocessor
- RTC FAST memory
- RTC SLOW memory

### Wi-Fi/Bluetooth and Sleep Modes

In Deep-sleep and Light-sleep modes, the wireless peripherals are powered down. Before entering Deep-sleep or Light-sleep modes, the application must disable Wi-Fi and Bluetooth using the appropriate calls (i.e., `esp_bluedroid_disable()`, `esp_bt_controller_disable()`, `esp_wifi_stop()`). Wi-Fi and Bluetooth connections are not maintained in Deep-sleep or Light-sleep mode, even if these functions are not called.

If Wi-Fi/Bluetooth connections need to be maintained, enable Wi-Fi/Bluetooth Modem-sleep mode and automatic Light-sleep feature (see **Power Management APIs**). This allows the system to wake up from sleep automatically when required by the Wi-Fi/Bluetooth driver, thereby maintaining the connection.

### Wakeup Sources

Wakeup sources can be enabled using `esp_sleep_enable_X_wakeup` APIs. Wakeup sources are not disabled after wakeup, you can disable them using `esp_sleep_disable_wakeup_source()` API if you do not need them any more. See **Disable Sleep Wakeup Source**.

Following are the wakeup sources supported on ESP32.

#### Timer

The RTC controller has a built-in timer which can be used to wake up the chip after a predefined amount of time. Time is specified at microsecond precision, but the actual resolution depends on the clock source selected for RTC_SLOW_CLK.

For details on RTC clock options, see **ESP32 Technical Reference Manual > ULP Coprocessor** [PDF].

RTC peripherals or RTC memories do not need to be powered on during sleep in this wakeup mode. `esp_sleep_enable_timer_wakeup()` function can be used to enable sleep wakeup using a timer.

#### Touchpad

The RTC IO module contains the logic to trigger wakeup when a touch sensor interrupt occurs. To wakeup from a touch sensor interrupt, users need to configure the touch pad interrupt before the chip enters Deep-sleep or Light-sleep modes.

Revisions 0 and 1 of ESP32 only support this wakeup mode when RTC peripherals are not forced to be powered on (i.e., ESP_PD_DOMAIN_RTC_PERIPH should be set to ESP_PD_OPTION_AUTO).

`esp_sleep_enable_touchpad_wakeup()` function can be used to enable this wakeup source.

#### External Wakeup (ext0)

The RTC IO module contains the logic to trigger wakeup when one of RTC GPIOs is set to a predefined logic level. RTC IO is part of the RTC peripherals power domain, so RTC peripherals will be kept powered on during Deep-sleep if this wakeup source is requested.

The RTC IO module is enabled in this mode, so internal pullup or pulldown resistors can also be used. They need to be configured by the application using `rtc_gpio_pullup_en()` and `rtc_gpio_pulldown_en()` functions before calling `esp_deep_sleep_start()`.

Espressif Systems Release v5.3-dev-277-gc8243465e4
In revisions 0 and 1 of ESP32, this wakeup source is incompatible with ULP and touch wakeup sources. `esp_sleep_enable_ext0_wakeup()` function can be used to enable this wakeup source.

**Warning:** After waking up from sleep, the IO pad used for wakeup will be configured as RTC IO. Therefore, before using this pad as digital GPIO, users need to reconfigure it using `rtc_gpio_deinit()` function.

### External Wakeup (ext1)

The RTC controller contains the logic to trigger wakeup using multiple RTC GPIOs. One of the following two logic functions can be used to trigger general ext1 wakeup:

- wake up if any of the selected pins is high (`ESP_EXT1_WAKEUP_ANY_HIGH`)
- wake up if all the selected pins are low (`ESP_EXT1_WAKEUP_ALL_LOW`)

This wakeup source is controlled by the RTC controller. Unlike ext0, this wakeup source supports wakeup even when the RTC peripheral is powered down. Although the power domain of the RTC peripheral, where RTC IOs are located, is powered down during sleep modes, ESP-IDF will automatically lock the state of the wakeup pin before the system enters sleep modes and unlock upon exiting sleep modes. Therefore, the internal pull-up or pull-down resistors can still be configured for the wakeup pin:

```c
esp_sleep_pd_config(ESP_PD_DOMAIN_RTC_PERIPH, ESP_PD_OPTION_ON);
rtc_gpio_pullup_dis(gpio_num);
rtc_gpio_pulldown_en(gpio_num);
```

If we turn off the `RTC_PERIPH` domain, we will use the HOLD feature to maintain the pull-up and pull-down on the pins during sleep. HOLD feature will be acted on the pin internally before the system enters sleep modes, and this can further reduce power consumption:

```c
rtc_gpio_pullup_dis(gpio_num);
rtc_gpio_pulldown_en(gpio_num);
```

If certain chips lack the `RTC_PERIPH` domain, we can only use the HOLD feature to maintain the pull-up and pull-down on the pins during sleep modes:

```c
gpio_pullup_dis(gpio_num);
gpio_pulldown_en(gpio_num);
```

`esp_sleep_enable_ext1_wakeup()` function can be used to enable this wakeup source for general ext1 wakeup.

**Warning:**

- To use the EXT1 wakeup, the IO pad(s) are configured as RTC IO. Therefore, before using these pads as digital GPIOs, users need to reconfigure them by calling the `rtc_gpio_deinit()` function.
- If the RTC peripherals are configured to be powered down (which is by default), the wakeup IOs will be set to the holding state before entering sleep. Therefore, after the chip wakes up from Light-sleep, please call `rtc_gpio_hold_dis` to disable the hold function to perform any pin re-configuration. For Deep-sleep wakeup, this is already being handled at the application startup stage.

### ULP Coprocessor Wakeup

ULP coprocessor can run while the chip is in sleep mode, and may be used to poll sensors, monitor ADC or touch sensor values, and wake up the chip when a specific event is detected. ULP coprocessor is part of the RTC peripherals power domain, and it runs the program stored in RTC SLOW memory. RTC SLOW memory will be powered on during sleep if this wakeup mode is requested. RTC peripherals will be automatically powered on before ULP coprocessor starts running the program; once the program stops running, RTC peripherals are automatically powered down again.

Revisions 0 and 1 of ESP32 only support this wakeup mode when RTC peripherals are not forced to be powered on (i.e., `ESP_PD_DOMAIN_RTC_PERIPH` should be set to `ESP_PD_OPTION_AUTO`).
**esp_sleep_enable_ulp_wakeup()** function can be used to enable this wakeup source.

**GPIO Wakeup (Light-sleep Only)**  In addition to EXT0 and EXT1 wakeup sources described above, one more method of wakeup from external inputs is available in Light-sleep mode. With this wakeup source, each pin can be individually configured to trigger wakeup on high or low level using **gpio_wakeup_enable()** function. Unlike EXT0 and EXT1 wakeup sources, which can only be used with RTC IOs, this wakeup source can be used with any IO (RTC or digital).

**esp_sleep_enable_gpio_wakeup()** function can be used to enable this wakeup source.

**Warning:** Before entering Light-sleep mode, check if any GPIO pin to be driven is part of the VDD_SDIO power domain. If so, this power domain must be configured to remain ON during sleep.

For example, on ESP32-WROOM-32 board, GPIO16 and GPIO17 are linked to VDD_SDIO power domain. If they are configured to remain high during Light-sleep, the power domain should be configured to remain powered ON. This can be done with **esp_sleep_pd_config()**:

```c
esp_sleep_pd_config(ESP_PD_DOMAIN_VDDSDIO, ESP_PD_OPTION_ON);
```

**UART Wakeup (Light-sleep Only)**  When ESP32 receives UART input from external devices, it is often necessary to wake up the chip when input data is available. The UART peripheral contains a feature which allows waking up the chip from Light-sleep when a certain number of positive edges on RX pin are seen. This number of positive edges can be set using **uart_set_wakeup_threshold()** function. Note that the character which triggers wakeup (and any characters before it) will not be received by the UART after wakeup. This means that the external device typically needs to send an extra character to the ESP32 to trigger wakeup before sending the data.

**esp_sleep_enable_uart_wakeup()** function can be used to enable this wakeup source.

**Disable Sleep Wakeup Source**  Previously configured wakeup sources can be disabled later using **esp_sleep_disable_wakeup_source()** API. This function deactivates trigger for the given wakeup source. Additionally, it can disable all triggers if the argument is **ESP_SLEEP_WAKEUP_ALL**.

**Power-down Options**

The application can force specific powerdown modes for RTC peripherals and RTC memories. In Deep-sleep mode, we can also isolate some IOs to further reduce current consumption.

**Power-down of RTC Peripherals and Memories**  By default, **esp_deep_sleep_start()** and **esp_light_sleep_start()** functions power down all RTC power domains which are not needed by the enabled wakeup sources. To override this behaviour, **esp_sleep_pd_config()** function is provided.

**Note:** in revision 0 of ESP32, RTC FAST memory is always kept enabled in Deep-sleep, so that the Deep-sleep stub can run after reset. This can be overridden, if the application does not need clean reset behaviour after Deep-sleep. If some variables in the program are placed into RTC SLOW memory (for example, using **RTC_DATA_ATTR** attribute), RTC SLOW memory will be kept powered on by default. This can be overridden using **esp_sleep_pd_config()** function, if desired.

**Power-down of Flash**  By default, to avoid potential issues, **esp_light_sleep_start()** function does **not** power down flash. To be more specific, it takes time to power down the flash and during this period the system may be woken up, which then actually powers up the flash before this flash could be powered down completely. As a result, there is a chance that the flash may not work properly.

So, in theory, it is ok if you only wake up the system after the flash is completely powered down. However, in reality, the flash power-down period can be hard to predict (for example, this period can be much longer when you add filter
capacitors to the flash’s power supply circuit) and uncontrollable (for example, the asynchronous wake-up signals make the actual sleep time uncontrollable).

**Warning:** If a filter capacitor is added to your flash power supply circuit, please do everything possible to avoid powering down flash.

Therefore, it is recommended not to power down flash when using ESP-IDF. For power-sensitive applications, it is recommended to use Kconfig option `CONFIG_ESP_SLEEP_FLASH_LEAKAGE_WORKAROUND` to reduce the power consumption of the flash during Light-sleep, instead of powering down the flash.

It is worth mentioning that PSRAM has a similar Kconfig option `CONFIG_ESP_SLEEP_PSRAM_LEAKAGE_WORKAROUND`.

However, for those who have fully understood the risk and are still willing to power down the flash to further reduce the power consumption, please check the following mechanisms:

- Setting Kconfig option `CONFIG_ESP_SLEEP_POWER_DOWN_FLASH` only powers down the flash when the RTC timer is the only wake-up source and the sleep time is longer than the flash power-down period.
- Calling `esp_sleep_pd_config(ESP_PD_DOMAIN_VDDSDIO, ESP_PD_OPTION_OFF)` powers down flash when the RTC timer is not enabled as a wakeup source or the sleep time is longer than the flash power-down period.

**Note:**
- ESP-IDF does not provide any mechanism that can power down the flash in all conditions when Light-sleep.
- `esp_deep_sleep_start()` function forces power down flash regardless of user configuration.

**Configuring IOs (Deep-sleep Only)** Some ESP32 IOs have internal pullups or pulldowns, which are enabled by default. If an external circuit drives this pin in Deep-sleep mode, current consumption may increase due to current flowing through these pullups and pulldowns.

To isolate a pin to prevent extra current draw, call `rtc_gpio_isolate()` function.

For example, on ESP32-WROVER module, GPIO12 is pulled up externally, and it also has an internal pulldown in the ESP32 chip. This means that in Deep-sleep, some current flows through these external and internal resistors, increasing Deep-sleep current above the minimal possible value.

Add the following code before `esp_deep_sleep_start()` to remove such extra current:

```c
rtc_gpio_isolate(GPIO_NUM_12);
```

**Entering Sleep**

`esp_light_sleep_start()` or `esp_deep_sleep_start()` functions can be used to enter Light-sleep or Deep-sleep modes correspondingly. After that, the system configures the parameters of RTC controller according to the requested wake-up sources and power-down options.

It is also possible to enter sleep modes with no wakeup sources configured. In this case, the chip will be in sleep modes indefinitely until external reset is applied.

**UART Output Handling** Before entering sleep mode, `esp_deep_sleep_start()` will flush the contents of UART FIFOs.
When entering Light-sleep mode using `esp_light_sleep_start()`, UART FIFOs will not be flushed. Instead, UART output will be suspended, and remaining characters in the FIFO will be sent out after wakeup from Light-sleep.

Checking Sleep Wakeup Cause

`esp_sleep_get_wakeup_cause()` function can be used to check which wakeup source has triggered wakeup from sleep mode.

For touchpad, it is possible to identify which touch pin has caused wakeup using `esp_sleep_get_touchpad_wakeup_status()` functions.

For ext1 wakeup sources, it is possible to identify which touch pin has caused wakeup using `esp_sleep_get_ext1_wakeup_status()` functions.

Application Example

- `protocols/sntp`: the implementation of basic functionality of Deep-sleep, where ESP module is periodically waken up to retrieve time from NTP server.
- `wifi/power_save`: the usage of Wi-Fi Modem-sleep mode and automatic Light-sleep feature to maintain Wi-Fi connections.
- `bluetooth/nimble/power_save`: the usage of Bluetooth Modem-sleep mode and automatic Light-sleep feature to maintain Bluetooth connections.
- `system/deep_sleep`: the usage of various Deep-sleep wakeup triggers and ULP coprocessor programming.

API Reference

Header File

- `components/esp_hw_support/include/esp_sleep.h`
- This header file can be included with:

```c
#include "esp_sleep.h"
```

Functions

- `esp_err_t esp_sleep_disable_wakeup_source(esp_sleep_source_t source)`
  Disable wakeup source.
  
  This function is used to deactivate wake up trigger for source defined as parameter of the function.

  See docs/sleep-modes.rst for details.

  **Note:** This function does not modify wake up configuration in RTC. It will be performed in esp_deep_sleep_start/esp_light_sleep_start function.

  **Parameters** `source` -- number of source to disable of type `esp_sleep_source_t`
  **Returns**
  - ESP_OK on success
  - ESP_ERR_INVALID_STATE if trigger was not active
**esp_err_t esp_sleep_enable_ulp_wakeup (void)**
Enable wakeup by ULP coprocessor.

**Note:** On ESP32, ULP wakeup source cannot be used when RTC_PERIPH power domain is forced, to be powered on (ESP_PD_OPTION_ON) or when ext0 wakeup source is used.

**Returns**
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if additional current by touch (CONFIG_RTC_EXT_CRYST_ADDIT_CURRENT) is enabled.
- ESP_ERR_INVALID_STATE if ULP co-processor is not enabled or if wakeup triggers conflict

**esp_err_t esp_sleep_enable_timer_wakeup (uint64_t time_in_us)**
Enable wakeup by timer.

**Parameters**
- time_in_us – time before wakeup, in microseconds

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if value is out of range (TBD)

**esp_err_t esp_sleep_enable_touchpad_wakeup (void)**
Enable wakeup by touch sensor.

**Note:** On ESP32, touch wakeup source cannot be used when RTC_PERIPH power domain is forced to be powered on (ESP_PD_OPTION_ON) or when ext0 wakeup source is used.

**Returns**
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if additional current by touch (CONFIG_RTC_EXT_CRYST_ADDIT_CURRENT) is enabled.
- ESP_ERR_INVALID_STATE if wakeup triggers conflict

**touch_pad_t esp_sleep_get_touchpad_wakeup_status (void)**
Get the touch pad which caused wakeup.

If wakeup was caused by another source, this function will return TOUCH_PAD_MAX;

**Returns**
touch pad which caused wakeup

**bool esp_sleep_is_valid_wakeup_gpio (gpio_num_t gpio_num)**
Returns true if a GPIO number is valid for use as wakeup source.

**Note:** For SoCs with RTC IO capability, this can be any valid RTC IO input pin.

**Parameters**
- gpio_num – Number of the GPIO to test for wakeup source capability

**Returns**
- True if this GPIO number will be accepted as a sleep wakeup source.
**esp_err_t esp_sleep_enable_ext0_wakeup** (gpio_num_t gpio_num, int level)

Enable wakeup using a pin.

This function uses external wakeup feature of RTC IO peripheral. It will work only if RTC peripherals are kept on during sleep.

This feature can monitor any pin which is an RTC IO. Once the pin transitions into the state given by level argument, the chip will be woken up.

**Note:** This function does not modify pin configuration. The pin is configured in esp_deep_sleep_start/esp_light_sleep_start, immediately before entering sleep mode.

**Note:** ESP32: ext0 wakeup source cannot be used together with touch or ULP wakeup sources.

**Parameters**

- **gpio_num** – GPIO number used as wakeup source. Only GPIOs with the RTC functionality can be used. For different SoCs, the related GPIOs are:
  - ESP32: 0, 2, 4, 12-15, 25-27, 32-39;
  - ESP32-S2: 0-21;
  - ESP32-S3: 0-21.
- **level** – input level which will trigger wakeup (0=low, 1=high)

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the selected GPIO is not an RTC GPIO, or the mode is invalid
- ESP_ERR_INVALID_STATE if wakeup triggers conflict

**esp_err_t esp_sleep_enable_ext1_wakeup** (uint64_t io_mask, esp_sleep_ext1_wakeup_mode_t level_mode)

Enable wakeup using multiple pins.

This function uses external wakeup feature of RTC controller. It will work even if RTC peripherals are shut down during sleep.

This feature can monitor any number of pins which are in RTC IOs. Once selected pins go into the state given by level_mode argument, the chip will be woken up.

**Note:** This function does not modify pin configuration. The pins are configured in esp_deep_sleep_start/esp_light_sleep_start, immediately before entering sleep mode.

**Note:** Internal pullups and pulldowns don’t work when RTC peripherals are shut down. In this case, external resistors need to be added. Alternatively, RTC peripherals (and pullups/pulldowns) may be kept enabled using esp_sleep_pd_config function. If we turn off the RTC_PERIPH domain or certain chips lack the RTC_PERIPH domain, we will use the HOLD feature to maintain the pull-up and pull-down on the pins during sleep. HOLD feature will be acted on the pin internally before the system entering sleep, and this can further reduce power consumption.

**Parameters**

- **io_mask** – Bit mask of GPIO numbers which will cause wakeup. Only GPIOs which have RTC functionality can be used in this bit map. For different SoCs, the related GPIOs are:
  - ESP32: 0, 2, 4, 12-15, 25-27, 32-39
  - ESP32-S2: 0-21
  - ESP32-S3: 0-21
- ESP32-C6: 0-7
- ESP32-H2: 7-14

- **level_mode** - Select logic function used to determine wakeup condition: When target chip is ESP32:
  - ESP_EXT1_WAKEUP_ALL_LOW: wake up when all selected GPIOs are low
  - ESP_EXT1_WAKEUP_ANY_HIGH: wake up when any of the selected GPIOs is high

  When target chip is ESP32-S2, ESP32-S3, ESP32-C6 or ESP32-H2:
  - ESP_EXT1_WAKEUP_ANY_LOW: wake up when any of the selected GPIOs is low
  - ESP_EXT1_WAKEUP_ANY_HIGH: wake up when any of the selected GPIOs is high

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if any of the selected GPIOs is not an RTC GPIO, or mode is invalid

```c
esp_err_t esp_sleep_enable_gpio_wakeup (void)
```

Enable wakeup from light sleep using GPIOs.

Each GPIO supports wakeup function, which can be triggered on either low level or high level. Unlike EXT0 and EXT1 wakeup sources, this method can be used both for all IOs: RTC IOs and digital IOs. It can only be used to wakeup from light sleep though.

To enable wakeup, first call gpio_wakeup_enable, specifying gpio number and wakeup level, for each GPIO which is used for wakeup. Then call this function to enable wakeup feature.

**Note:** On ESP32, GPIO wakeup source can not be used together with touch or ULP wakeup sources.

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_STATE if wakeup triggers conflict

```c
esp_err_t esp_sleep_enable_uart_wakeup (int uart_num)
```

Enable wakeup from light sleep using UART.

Use uart_set_wakeup_threshold function to configure UART wakeup threshold.

Wakeup from light sleep takes some time, so not every character sent to the UART can be received by the application.

**Note:** ESP32 does not support wakeup from UART2.

**Parameters**
- **uart_num** - UART port to wake up from

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if wakeup from given UART is not supported

```c
esp_err_t esp_sleep_enable_bt_wakeup (void)
```

Enable wakeup by bluetooth.

**Returns**
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if wakeup from bluetooth is not supported

```c
esp_err_t esp_sleep_disable_bt_wakeup (void)
```

Disable wakeup by bluetooth.

**Returns**
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if wakeup from bluetooth is not supported
**esp_err_t esp_sleep_enable_wifi_wakeup**(void)

Enable wakeup by WiFi MAC.

**Returns**
- ESP_OK on success

**esp_err_t esp_sleep_disable_wifi_wakeup**(void)

Disable wakeup by WiFi MAC.

**Returns**
- ESP_OK on success

**esp_err_t esp_sleep_enable_wifi_beacon_wakeup**(void)

Enable beacon wakeup by WiFi MAC, it will wake up the system into modem state.

**Returns**
- ESP_OK on success

**esp_err_t esp_sleep_disable_wifi_beacon_wakeup**(void)

Disable beacon wakeup by WiFi MAC.

**Returns**
- ESP_OK on success

**uint64_t esp_sleep_get_ext1_wakeup_status**(void)

Get the bit mask of GPIOs which caused wakeup (ext1)

If wakeup was caused by another source, this function will return 0.

**Returns**
bit mask, if GPIO caused wakeup, BIT(n) will be set

**esp_err_t esp_sleep_pd_config**(esp_sleep_pd_domain_t domain, esp_sleep_pd_option_t option)

Set power down mode for an RTC power domain in sleep mode.

If not set set using this API, all power domains default to ESP_PD_OPTION_AUTO.

**Parameters**
- **domain** - power domain to configure
- **option** - power down option (ESP_PD_OPTION_OFF, ESP_PD_OPTION_ON, or ESP_PD_OPTION_AUTO)

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if either of the arguments is out of range

**esp_err_t esp_deep_sleep_try_to_start**(void)

Enter deep sleep with the configured wakeup options.

The reason for the rejection can be such as a short sleep time.

**Note:** In general, the function does not return, but if the sleep is rejected, then it returns from it.

**Returns**
- No return - If the sleep is not rejected.
- ESP_ERR_SLEEP_REJECT sleep request is rejected(wakeup source set before the sleep request)

**void esp_deep_sleep_start**(void)

Enter deep sleep with the configured wakeup options.
Note: The function does not do a return (no rejection). Even if wakeup source set before the sleep request it goes to deep sleep anyway.

**esp_err_t esp_light_sleep_start (void)**
Enter light sleep with the configured wakeup options.

**Returns**
- ESP_OK on success (returned after wakeup)
- ESP_ERR_SLEEP_REJECT sleep request is rejected (wakeup source set before the sleep request)
- ESP_ERR_SLEEP_TOO_SHORT_SLEEP_DURATION after deducting the sleep flow overhead, the final sleep duration is too short to cover the minimum sleep duration of the chip, when rtc timer wakeup source enabled

**esp_err_t esp_deep_sleep_try (uint64_t time_in_us)**
Enter deep-sleep mode.
The device will automatically wake up after the deep-sleep time Upon waking up, the device calls deep sleep wake stub, and then proceeds to load application.
Call to this function is equivalent to a call to esp_deep_sleep_enable_timer_wakeup followed by a call to esp_deep_sleep_start.

The reason for the rejection can be such as a short sleep time.

Note: In general, the function does not return, but if the sleep is rejected, then it returns from it.

**Parameters**
- time_in_us - deep-sleep time, unit: microsecond

**Returns**
- No return - If the sleep is not rejected.
- ESP_ERR_SLEEP_REJECT sleep request is rejected (wakeup source set before the sleep request)

**void esp_deep_sleep (uint64_t time_in_us)**
Enter deep-sleep mode.
The device will automatically wake up after the deep-sleep time Upon waking up, the device calls deep sleep wake stub, and then proceeds to load application.
Call to this function is equivalent to a call to esp_deep_sleep_enable_timer_wakeup followed by a call to esp_deep_sleep_start.

Note: The function does not do a return (no rejection). Even if wakeup source set before the sleep request it goes to deep sleep anyway.

**Parameters**
- time_in_us - deep-sleep time, unit: microsecond

**esp_err_t esp_deep_sleep_register_hook (esp_deep_sleep_cb_t new_dslp_cb)**
Register a callback to be called from the deep sleep prepare.

Warning: deepsleep callbacks should without parameters, and MUST NOT, UNDER ANY CIRCUMSTANCES, CALL A FUNCTION THAT MIGHT BLOCK.
Parameters `new_dslp_cb` – Callback to be called

Returns
- ESP_OK: Callback registered to the deepsleep misc_modules_sleep_prepare
- ESP_ERR_NO_MEM: No more hook space for register the callback

void `esp_deep_sleep_deregister_hook` (`esp_deep_sleep_cb_t` `old_dslp_cb`)  
Unregister an deepsleep callback.

Parameters `old_dslp_cb` – Callback to be unregistered

`esp_sleep_wakeup_cause_t` `esp_sleep_get_wakeup_cause` (void)
Get the wakeup source which caused wakeup from sleep.

Returns cause of wake up from last sleep (deep sleep or light sleep)

void `esp_wake_deep_sleep` (void)
Default stub to run on wake from deep sleep.

Allows for executing code immediately on wake from sleep, before the software bootloader or ESP-IDF app has started up.

This function is weak-linked, so you can implement your own version to run code immediately when the chip wakes from sleep.

See docs/deep-sleep-stub.rst for details.

void `esp_set_deep_sleep_wake_stub` (`esp_deep_sleep_wake_stub_fn_t` `new_stub`)  
Install a new stub at runtime to run on wake from deep sleep.

If implementing esp_wake_deep_sleep() then it is not necessary to call this function.

However, it is possible to call this function to substitute a different deep sleep stub. Any function used as a deep sleep stub must be marked RTC_IRAM_ATTR, and must obey the same rules given for esp_wake_deep_sleep().

void `esp_set_deep_sleep_wake_stub_default_entry` (void)
Set wake stub entry to default `esp_wake_stub_entry`

`esp_deep_sleep_wake_stub_fn_t` `esp_get_deep_sleep_wakeStub` (void)
Get current wake from deep sleep stub.

Returns Return current wake from deep sleep stub, or NULL if no stub is installed.

void `esp_default_wake_deep_sleep` (void)
The default esp-idf-provided `esp_wake_deep_sleep` stub.

See docs/deep-sleep-stub.rst for details.

void `esp_deep_sleep_disable_rom_logging` (void)
Disable logging from the ROM code after deep sleep.

Using LSB of RTC_STORE4.

void `esp_sleep_config_gpio_isolate` (void)
Configure to isolate all GPIO pins in sleep state.

void `esp_sleep_enable_gpio_switch` (bool enable)
Enable or disable GPIO pins status switching between slept status and waked status.

Parameters `enable` – decide whether to switch status or not

Macros

`ESP_PD_DOMAIN_RTC8M`
Type Definitions

typedef void (*esp_deep_sleep_cb_t)(void)

typedef esp_sleep_source_t esp_sleep_wakeup_cause_t

typedef void (*esp_deep_sleep_wake_stub_fn_t)(void)

Function type for stub to run on wake from sleep.

Enumerations

enum esp_sleep_ext1_wakeup_mode_t
    Logic function used for EXT1 wakeup mode.
    
    Values:

    enumerator ESP_EXT1_WAKEUP_ALL_LOW
        Wake the chip when all selected GPIOs go low.

    enumerator ESP_EXT1_WAKEUP_ANY_HIGH
        Wake the chip when any of the selected GPIOs go high.

enum esp_sleep_pd_domain_t
    Power domains which can be powered down in sleep mode.
    
    Values:

    enumerator ESP_PD_DOMAIN_RTC_PERIPH
        RTC IO, sensors and ULP co-processor.

    enumerator ESP_PD_DOMAIN_RTC_SLOW_MEM
        RTC slow memory.

    enumerator ESP_PD_DOMAIN_RTC_FAST_MEM
        RTC fast memory.

    enumerator ESP_PD_DOMAIN_XTAL
        XTAL oscillator.

    enumerator ESP_PD_DOMAIN_RC_FAST
        Internal Fast oscillator.

    enumerator ESP_PD_DOMAIN_VDDSDIO
        VDD_SDIO.

    enumerator ESP_PD_DOMAIN_MODEM
        MODEM, includes WiFi, Bluetooth and IEEE802.15.4.

    enumerator ESP_PD_DOMAIN_MAX
        Number of domains.
enum esp_sleep_pd_option_t
    Power down options.
    
    Values:
    
    enumerator ESP_PD_OPTION_OFF
        Power down the power domain in sleep mode.
    
    enumerator ESP_PD_OPTION_ON
        Keep power domain enabled during sleep mode.
    
    enumerator ESP_PD_OPTION_AUTO
        Keep power domain enabled in sleep mode, if it is needed by one of the wakeup options. Otherwise
        power it down.

enum esp_sleep_source_t
    Sleep wakeup cause.
    
    Values:
    
    enumerator ESP_SLEEP_WAKEUP_UNDEFINED
        In case of deep sleep, reset was not caused by exit from deep sleep.
    
    enumerator ESP_SLEEP_WAKEUP_ALL
        Not a wakeup cause, used to disable all wakeup sources with esp_sleep_disable_wakeup_source.
    
    enumerator ESP_SLEEP_WAKEUP_EXT0
        Wakeup caused by external signal using RTC_IO.
    
    enumerator ESP_SLEEP_WAKEUP_EXT1
        Wakeup caused by external signal using RTC_CNTL.
    
    enumerator ESP_SLEEP_WAKEUP_TIMER
        Wakeup caused by timer.
    
    enumerator ESP_SLEEP_WAKEUP_TOUCHPAD
        Wakeup caused by touchpad.
    
    enumerator ESP_SLEEP_WAKEUP_U1P
        Wakeup caused by ULP program.
    
    enumerator ESP_SLEEP_WAKEUP_GPIO
        Wakeup caused by GPIO (light sleep only on ESP32, S2 and S3)
    
    enumerator ESP_SLEEP_WAKEUP_UART
        Wakeup caused by UART (light sleep only)
    
    enumerator ESP_SLEEP_WAKEUP_WIFI
        Wakeup caused by WIFI (light sleep only)
enumerator `ESP_SLEEP_WAKEUP_COCPU`
   Wakeup caused by COCPU int.

enumerator `ESP_SLEEP_WAKEUP_COCPU_TRAP_TRIG`
   Wakeup caused by COCPU crash.

enumerator `ESP_SLEEP_WAKEUP_BT`
   Wakeup caused by BT (light sleep only)

enum `esp_sleep_mode_t`
   Sleep mode.
   Values:

   enumerator `ESP_SLEEP_MODE_LIGHT_SLEEP`
      light sleep mode

   enumerator `ESP_SLEEP_MODE_DEEP_SLEEP`
      deep sleep mode

enum [anonymous]
   Values:

   enumerator `ESP_ERR_SLEEP_REJECT`

   enumerator `ESP_ERR_SLEEP_TOO_SHORT_SLEEP_DURATION`

2.10.29 SoC Capabilities

This section lists the macro definitions of the ESP32’s SoC hardware capabilities. These macros are commonly used by conditional-compilation directives (e.g., `#if`) in ESP-IDF to determine which hardware-dependent features are supported, thus control what portions of code are compiled.

**Warning:** These macro definitions are currently not considered to be part of the public API, and may be changed in a breaking manner (see ESP-IDF Versions for more details).

Support to connect an external low frequency crystal

SOC_SDMMC_USE_IOMUX

SOC_SDMMC_NUM_SLOTS

SOC_WIFI_WAPI_SUPPORT
Support WAPI

SOC_WIFI_CSI_SUPPORT
Support CSI

SOC_WIFI_MESH_SUPPORT
Support WIFI MESH

SOC_WIFI_SUPPORT_VARIABLE_BEACON_WINDOW
Support delta early time for rf phy on/off

SOC_WIFI_NAN_SUPPORT
Support WIFI Aware (NAN)

SOC_BLE_SUPPORTED
Support Bluetooth Low Energy hardware

SOC_BLE_MESH_SUPPORTED
Support BLE MESH

SOC_BT_CLASSIC_SUPPORTED
Support Bluetooth Classic hardware

SOC_BLE_DEVICE_PRIVACY_SUPPORTED
Support BLE device privacy mode

SOC_BLUFI_SUPPORTED
Support BLUFI

SOC_ULP_HAS_ADC

SOC_PHY_COMBO_MODULE
Support Wi-Fi, BT and BLE

2.10.30 System Time
Overview

ESP32 uses two hardware timers for the purpose of keeping system time. System time can be kept by using either one or both of the hardware timers depending on the application’s purpose and accuracy requirements for system time. The two hardware timers are:

- **RTC timer**: This timer allows time keeping in various sleep modes, and can also persist time keeping across any resets (with the exception of power-on resets which reset the RTC timer). The frequency deviation depends on the RTC Timer Clock Sources and affects the accuracy only in sleep modes, in which case the time will be measured at 6.6667 μs resolution.

- **High-resolution timer**: This timer is not available in sleep modes and will not persist over a reset, but has greater accuracy. The timer uses the APB_CLK clock source (typically 80 MHz), which has a frequency deviation of less than ±10 ppm. Time will be measured at 1 μs resolution.

The possible combinations of hardware timers used to keep system time are listed below:

- RTC and high-resolution timer (default)
- RTC
- High-resolution timer
- None

It is recommended that users stick to the default option as it provides the highest accuracy. However, users can also select a different setting via the `CONFIG_NEWLIB_TIME_SYSCALL` configuration option.

**RTC Timer Clock Sources**

The RTC timer has the following clock sources:

- **Internal 150 kHz RC oscillator** (default): Features the lowest Deep-sleep current consumption and no dependence on any external components. However, the frequency stability of this clock source is affected by temperature fluctuations, so time may drift in both Deep-sleep and Light-sleep modes.

- **External 32 kHz crystal**: Requires a 32 kHz crystal to be connected to the 32K_XP and 32K_XN pins. This source provides a better frequency stability at the expense of a slightly higher (by 1 μA) Deep-sleep current consumption.

- **External 32 kHz oscillator at 32K_XN pin**: Allows using 32 kHz clock generated by an external circuit. The external clock signal must be connected to the 32K_XN pin. The amplitude should be less than 1.2 V for sine wave signal and less than 1 V for square wave signal. Common mode voltage should be in the range of 0.1 < Vcm < 0.5xVamp, where Vamp stands for signal amplitude. In this case, the 32K_XN pin cannot be used as a GPIO pin.

- **Internal 8.5 MHz oscillator, divided by 256 (about 33 kHz)**: Provides better frequency stability than the Internal 150 kHz RC oscillator at the expense of a higher (by 5 μA) Deep-sleep current consumption. It also does not require external components.

The choice depends on your requirements for system time accuracy and power consumption in sleep modes. To modify the RTC clock source, set `CONFIG_RTC_CLK_SRC` in project configuration.

More details about the wiring requirements for the external crystal or external oscillator, please refer to ESP32 Hardware Design Guidelines.

**Get Current Time**

To get the current time, use the POSIX function `gettimeofday()`. Additionally, you can use the following standard C library functions to obtain time and manipulate it:

```c
gettimeofday
time
asctime
clock
```

(continues on next page)
ctime
difftime
gmtime
localtime
mktime
strftime
adjtime

To stop smooth time adjustment and update the current time immediately, use the POSIX function `settimeofday()`.

If you need to obtain time with one second resolution, use the following code snippet:

```c
time_t now;
char strftime_buf[64];
struct tm timeinfo;
time(&now);
// Set timezone to China Standard Time
setenv("TZ", "CST-8", 1);
tzset();
localtime_r(&now, &timeinfo);
strftime(strftime_buf, sizeof(strftime_buf), "%c", &timeinfo);
ESP_LOGI(TAG, "The current date/time in Shanghai is: %s", strftime_buf);
```

If you need to obtain time with one microsecond resolution, use the code snippet below:

```c
struct timeval tv_now;
gettimeofday(&tv_now, NULL);
int64_t time_us = (int64_t)tv_now.tv_sec * 1000000L + (int64_t)tv_now.tv_usec;
```

**SNTP Time Synchronization**

To set the current time, you can use the POSIX functions `settimeofday()` and `adjtime()`. They are used internally in the lwIP SNTP library to set current time when a response from the NTP server is received. These functions can also be used separately from the lwIP SNTP library.

Some lwIP APIs, including SNTP functions, are not thread safe, so it is recommended to use `esp_netif component` when interacting with SNTP module.

To initialize a particular SNTP server and also start the SNTP service, simply create a default SNTP server configuration with a particular server name, then call `esp_netif_sntp_init()` to register that server and start the SNTP service.

```c
esp_sntp_config_t config = ESP_NETIF_SNTP_DEFAULT_CONFIG("pool.ntp.org");
esp_netif_sntp_init(&config);
```

This code automatically performs time synchronization once a reply from the SNTP server is received. Sometimes it is useful to wait until the time gets synchronized, `esp_netif_sntp_sync_wait()` can be used for this purpose:

```c
if (esp_netif_sntp_sync_wait(pdMS_TO_TICKS(10000)) != ESP_OK) {
    printf("Failed to update system time within 10s timeout");
}
```

To configure multiple NTP servers (or use more advanced settings, such as DHCP provided NTP servers), please refer to the detailed description of **SNTP API** in `esp_netif` documentation.

The lwIP SNTP library could work in one of the following sync modes:
• **SNTP_SYNC_MODE_IMMED** (default): Updates system time immediately upon receiving a response from the SNTP server after using `settimeofday()`.
• **SNTP_SYNC_MODE_SMOOTH**: Updates time smoothly by gradually reducing time error using the function `adjtime()`. If the difference between the SNTP response time and system time is more than 35 minutes, update system time immediately by using `settimeofday()`.

If you want to choose the **SNTP_SYNC_MODE_SMOOTH** mode, please set the `esp_sntp_config::smooth` to `true` in the SNTP configuration struct. Otherwise (and by default) the **SNTP_SYNC_MODE_IMMED** mode will be used.

For setting a callback function that is called when time gets synchronized, use the `esp_sntp_config::sync_cb` field in the configuration struct.

An application with this initialization code periodically synchronizes the time. The time synchronization period is determined by `CONFIG_LWIP_SNTP_UPDATE_DELAY` (the default value is one hour). To modify the variable, set `CONFIG_LWIP_SNTP_UPDATE_DELAY` in project configuration.

A code example that demonstrates the implementation of time synchronization based on the lwIP SNTP library is provided in the `protocols/sntp` directory.

Note that it is also possible to use lwIP API directly, but care must be taken to thread safety. Here we list the thread-safe APIs:

- `snntp_set_time_sync_notification_cb()` can be used to set a callback function that notifies of the time synchronization process.
- `snntp_get_sync_status()` and `snntp_set_sync_status()` can be used to get/set time synchronization status.
- `snntp_set_sync_mode()` can be used to set the synchronization mode.
- `esp_snntp_setoperatingmode()` sets the preferred operating mode.:
- `esp_snntp_init()` initializes SNTP module.
- `esp_snntp_setservername()` configures one SNTP server.

### Timezones

To set the local timezone, use the following POSIX functions:

1. Call `setenv()` to set the `TZ` environment variable to the correct value based on the device location. The format of the time string is the same as described in the GNU libc documentation (although the implementation is different).
2. Call `tzset()` to update C library runtime data for the new timezone.

Once these steps are completed, call the standard C library function `localtime()`, and it returns the correct local time taking into account the timezone offset and daylight saving time.

### Year 2036 and 2038 Overflow Issues

**SNTP/NTP 2036 Overflow**  SNTP/NTP timestamps are represented as 64-bit unsigned fixed point numbers, where the first 32 bits represent the integer part, and the last 32 bits represent the fractional part. The 64-bit unsigned fixed point number represents the number of seconds since 00:00 on 1st of January 1900, thus SNTP/NTP times will overflow in the year 2036.

To address this issue, lifetime of the SNTP/NTP timestamps has been extended by convention by using the MSB (bit 0 by convention) of the integer part to indicate time ranges between years 1968 to 2104 (see [RFC2030](https://tools.ietf.org/html/rfc2030) for more details). This convention is implemented in lwIP library SNTP module. Therefore SNTP-related functions in ESP-IDF are future-proof until year 2104.

**Unix Time 2038 Overflow**  Unix time (type `time_t`) was previously represented as a 32-bit signed integer, leading to an overflow in year 2038 (i.e., [Y2K38 issue](https://en.wikipedia.org/wiki/Y2K38_issue)). To address the Y2K38 issue, ESP-IDF uses a 64-bit signed integer to represent `time_t` starting from release v5.0, thus deferring `time_t` overflow for another 292 billion years.
API Reference

Header File

- components/lwip/include/apps/esp_sntp.h
  - This header file can be included with:
    ```
    #include "esp_sntp.h"
    ```
  - This header file is a part of the API provided by the lwip component. To declare that your component depends on lwip, add the following to your CMakeLists.txt:
    ```
    REQUIRES lwip
    or
    PRIV_REQUIRES lwip
    ```

Functions

**void sntp_sync_time (struct timeval *tv)**

This function updates the system time.

This is a weak-linked function. It is possible to replace all SNTP update functionality by placing a sntp_sync_time() function in the app firmware source. If the default implementation is used, calling sntp_set_sync_mode() allows the time synchronization mode to be changed to instant or smooth. If a callback function is registered via sntp_set_time_sync_notification_cb(), it will be called following time synchronization.

**Parameters**

- tv – Time received from SNTP server.

**void sntp_set_sync_mode (sntp_sync_mode_t sync_mode)**

Set the sync mode.

**Parameters**

- sync_mode – Sync mode.

**sntp_sync_mode_t sntp_get_sync_mode (void)**

Get set sync mode.

**Returns**

- SNTP_SYNC_MODE_IMMED: Update time immediately.
- SNTP_SYNC_MODE_SMOOTH: Smooth time updating.

**sntp_sync_status_t sntp_get_sync_status (void)**

Get status of time sync.

After the update is completed, the status will be returned as SNTP_SYNC_STATUS_COMPLETED. After that, the status will be reset to SNTP_SYNC_STATUS_RESET. If the update operation is not completed yet, the status will be SNTP_SYNC_STATUS_RESET. If a smooth mode was chosen and the synchronization is still continuing (adjtime works), then it will be SNTP_SYNC_STATUS_IN_PROGRESS.

**Returns**

- SNTP_SYNC_STATUS_RESET: Reset status. SNTP_SYNC_STATUS_COMPLETED: Time is synchronized. SNTP_SYNC_STATUS_IN_PROGRESS: Smooth time sync in progress.

**void sntp_set_sync_status (sntp_sync_status_t sync_status)**

Set status of time sync.

**Parameters**

- sync_status – status of time sync (see sntp_sync_status_t)

**void sntp_set_time_sync_notification_cb (sntp_time_sync_cb_t callback)**

Set a callback function for time synchronization notification.

**Parameters**

- callback – a callback function
void `sntp_set_sync_interval` (uint32_t interval_ms)
Set the sync interval of SNTP operation.

Note: SNTPv4 RFC 4330 enforces a minimum sync interval of 15 seconds. This sync interval will be used in the next attempt update time through SNTP. To apply the new sync interval call the `sntp_restart()` function, otherwise, it will be applied after the last interval expired.

**Parameters**
- `interval_ms` - The sync interval in ms. It cannot be lower than 15 seconds, otherwise 15 seconds will be set.

`uint32_t sntp_get_sync_interval` (void)
Get the sync interval of SNTP operation.

**Returns**
- the sync interval

`bool sntp_restart` (void)
Restart SNTP.

**Returns**
- True - Restart
- False - SNTP was not initialized yet

void `esp_sntp_setoperatingmode` (`esp_sntp_operatingmode_t` operating_mode)
Sets SNTP operating mode. The mode has to be set before init.

**Parameters**
- `operating_mode` - Desired operating mode

void `esp_sntp_init` (void)
Init and start SNTP service.

void `esp_sntp_stop` (void)
Stops SNTP service.

void `esp_sntp_setserver` (u8_t idx, const ip_addr_t *addr)
Sets SNTP server address.

**Parameters**
- `idx` - Index of the server
- `addr` - IP address of the server

void `esp_sntp_setservername` (u8_t idx, const char *server)
Sets SNTP hostname.

**Parameters**
- `idx` - Index of the server
- `server` - Name of the server

`const char *esp_sntp_getservername` (u8_t idx)
Gets SNTP server name.

**Parameters**
- `idx` - Index of the server

`Returns` Name of the server

`const ip_addr_t *esp_sntp_getserver` (u8_t idx)
Get SNTP server IP.

**Parameters**
- `idx` - Index of the server

`Returns` IP address of the server

`bool esp_sntp_enabled` (void)
Checks if sntp is enabled.

**Returns**
- true if sntp module is enabled

static inline void `sntp_setoperatingmode` (u8_t operating_mode)
if not build within lwip, provide translating inlines, that will warn about thread safety
Chapter 2. API Reference

static inline void sntp_servermode_dhcp (int set_servers_from_dhcp)
static inline void sntp_setservername (u8_t idx, const char *server)
static inline void sntp_init (void)
static inline const char *sntp_getservername (u8_t idx)
static inline const ip_addr_t *sntp_getserver (u8_t idx)

Macros

esp_sntp_sync_time
  Aliases for esp_sntp prefixed API (inherently thread safe)

esp_sntp_set_sync_mode

esp_sntp_get_sync_mode

esp_sntp_get_sync_status

esp_sntp_set_sync_status

esp_sntp_set_time_sync_notification_cb

esp_sntp_set_sync_interval

esp_sntp_get_sync_interval

esp_sntp_restart

SNTP_OPMODE_POLL

Type Definitions

typedef void (*sntp_sync_time_cb_t)(struct timeval *tv)
   SNTP callback function for notifying about time sync event.
   
   Param tv Time received from SNTP server.

Enumerations

gen snntp_sync_mode_t
   SNTP time update mode.
   
   Values:

   enumerator snntp_sync_mode_t IMMED
      Update system time immediately when receiving a response from the SNTP server.

   enumerator snntp_sync_mode_t SMOOTH
      Smooth time updating. Time error is gradually reduced using adjtime function. If the difference between
      SNTP response time and system time is large (more than 35 minutes) then update immediately.
enum `sntp_sync_status_t`

SNTP sync status.

Values:

- `SNTP_SYNC_STATUS_RESET`
- `SNTP_SYNC_STATUS_COMPLETED`
- `SNTP_SYNC_STATUS_IN_PROGRESS`

enum `esp_sntp_operatingmode_t`

SNTP operating modes per lwip SNTP module.

Values:

- `ESP_SNTP_OPMODE_POLL`
- `ESP_SNTP_OPMODE_LISTENONLY`

### 2.10.31 Himem

**Overview**

For external memories that are <= 4 MiB, the MMU is configured to use a “unity mapping”, meaning that each CPU address is mapped 1-to-1 to the external SPI RAM address, thus allowing external memory to be accessed transparently. However, because the address space for external memory is limited to 4 MiB, only SPI RAM chips that are <= 4 MiB in size can be used fully transparently.

It is still possible for ESP32 to use SPI RAM chips >= 4 MiB in size. However, the memory on these chips needs to be accessed using a bank switching scheme. ESP-IDF provides the Himem API to control this bank switching. More specifically, the Himem API allows particular 32 K banks within 4 MiB address switch mappings at run time, thus allowing access to more than 4 MiB of external memory.

**Usage**

In order to use the Himem API, you have to enable it in the menuconfig using `CONFIG_SPIRAM_BANKSWITCH_ENABLE`, as well as set the amount of banks reserved for this in `CONFIG_SPIRAM_BANKSWITCH_RESERVE`. This decreases the amount of external memory allocated by functions like `malloc()`, but it allows you to use the Himem API to map any of the remaining memory into the reserved banks.

The Himem API is more-or-less an abstraction of the bank switching scheme: it allows you to claim one or more banks of address space (called ‘regions’ in the API) as well as one or more of banks of memory to map into the ranges.

**Example**

An example doing a simple memory test of the high memory range is available in ESP-IDF: `system/himem`
API Reference

Header File

- components/esp_psram/include/esp32/himem.h
  - This header file can be included with:
    
    ```
    #include "esp32/himem.h"
    ```
  - This header file is a part of the API provided by the esp_psram component. To declare that your component depends on esp_psram, add the following to your CMakeLists.txt:
    
    ```
    REQUIRES esp_psram
    ```
    or
    ```
    PRIV_REQUIRES esp_psram
    ```

Functions

```
esp_err_t esp_himem_alloc(size_t size, esp_himem_handle_t *handle_out)
```
Allocate a block in high memory.

Parameters

- **size** - Size of the to-be-allocated block, in bytes. Note that this needs to be a multiple of the external RAM mmu block size (32K).
- **handle_out** - [out] Handle to be returned

Returns

- ESP_OK if successful
- ESP_ERR_NO_MEM if out of memory
- ESP_ERR_INVALID_SIZE if size is not a multiple of 32K

```
esp_err_t esp_himem_alloc_map_range(size_t size, esp_himem_rangehandle_t *handle_out)
```
Allocate a memory region to map blocks into.

This allocates a contiguous CPU memory region that can be used to map blocks of physical memory into.

Parameters

- **size** - Size of the range to be allocated. Note this needs to be a multiple of the external RAM mmu block size (32K).
- **handle_out** - [out] Handle to be returned

Returns

- ESP_OK if successful
- ESP_ERR_NO_MEM if out of memory or address space
- ESP_ERR_INVALID_SIZE if size is not a multiple of 32K

```
esp_err_t esp_himem_map(esp_himem_handle_t handle, esp_himem_rangehandle_t range, size_t ram_offset, size_t range_offset, size_t len, int flags, void **out_ptr)
```
Map a block of high memory into the CPUs address space.
This effectively makes the block available for read/write operations.

**Note:** The region to be mapped needs to have offsets and sizes that are aligned to the SPI RAM MMU block size (32K)

Parameters

- **handle** - Handle to the block of memory, as given by esp_himem Alloc
- **range** - Range handle to map the memory in
- **ram_offset** - Offset into the block of physical memory of the block to map
- **range_offset** - Offset into the address range where the block will be mapped
- **len** - Length of region to map
- **flags** - One of ESP_HIMEM_MAPFLAG_ *
- **out_ptr** - [out] Pointer to variable to store resulting memory pointer in
Returns - ESP_OK if the memory could be mapped
  • ESP_ERR_INVALID_ARG if offset, range or len aren’t MMU-block-aligned (32K)
  • ESP_ERR_INVALID_SIZE if the offsets/lengths don’t fit in the allocated memory or range
  • ESP_ERR_INVALID_STATE if a block in the selected ram offset/length is already mapped, or if a block in the selected range offset/length already has a mapping.

`esp_err_t esp_himem_free(esp_himem_handle_t handle)`
Free a block of physical memory.
This clears out the associated handle making the memory available for re-allocation again. This will only succeed if none of the memory blocks currently have a mapping.

Parameters handle – Handle to the block of memory, as given by esp_himem_alloc

Returns - ESP_OK if the memory is successfully freed
  • ESP_ERR_INVALID_ARG if the handle still is (partially) mapped

`esp_err_t esp_himem_free_map_range(esp_himem_rangehandle_t handle)`
Free a mapping range.
This clears out the associated handle making the range available for re-allocation again. This will only succeed if none of the range blocks currently are used for a mapping.

Parameters handle – Handle to the range block, as given by esp_himem_alloc_map_range

Returns - ESP_OK if the memory is successfully unmapped.
  • ESP_ERR_INVALID_ARG if the handle still is (partially) mapped to

`esp_err_t esp_himem_unmap(esp_himem_rangehandle_t range, void *ptr, size_t len)`
Unmap a region.

Parameters
  • range – Range handle
  • ptr – Pointer returned by esp_himem_map
  • len – Length of the block to be unmapped. Must be aligned to the SPI RAM MMU blocksize (32K)

Returns - ESP_OK if the memory is successfully unmapped.
  • ESP_ERR_INVALID_ARG if ptr or len are invalid.

`size_t esp_himem_get_phys_size(void)`
Get total amount of memory under control of himem API.

Returns Amount of memory, in bytes

`size_t esp_himem_get_free_size(void)`
Get free amount of memory under control of himem API.

Returns Amount of free memory, in bytes

`size_t esp_himem_reserved_area_size(void)`
Get amount of SPI memory address space needed for bankswitching.

Note: This is also weakly defined in esp32/spiram.c and returns 0 there, so if no other function in this file is used, no memory is reserved.

Returns Amount of reserved area, in bytes

**Macros**

`ESP_HIMEM_BLKSZ`
**ESP_HIMEM_MAPFLAG_RO**

Indicates that a mapping will only be read from. Note that this is unused for now.

**Type Definitions**

```c
typedef struct esp_himem_ramdata_t *esp_himem_handle_t

typedef struct esp_himem_rangedata_t *esp_himem_rangehandle_t
```

### 2.10.32 ULP Coprocessor Programming

The Ultra Low Power (ULP) coprocessor is a simple finite state machine (FSM) which is designed to perform measurements using the ADC, temperature sensor, and external I2C sensors, while the main processors are in Deep-sleep mode. The ULP coprocessor can access the RTC_SLOW_MEM memory region, and registers in the RTC_CNTL, RTC_IO, and SARADC peripherals. The ULP coprocessor uses fixed-width 32-bit instructions, 32-bit memory addressing, and has 4 general-purpose 16-bit registers. This coprocessor is referred to as ULP FSM in ESP-IDF.

**Installing the Toolchain**

The ULP FSM coprocessor code is written in assembly and compiled using the `binutils-esp32ulp toolchain`.

If you have already set up ESP-IDF with CMake build system according to the *Getting Started Guide*, then the ULP FSM toolchain will already be installed.

**Programming ULP FSM**

The ULP FSM can be programmed using the supported instruction set. Alternatively, the ULP FSM coprocessor can also be programmed using C Macros on the main CPU. These two methods are described in the following section:

**ESP32 ULP Coprocessor Instruction Set**

This document provides details about the instructions used by ESP32 ULP FSM coprocessor assembler.

ULP FSM coprocessor has 4 16-bit general purpose registers, labeled R0, R1, R2, R3. It also has an 8-bit counter register (`stage_cnt`) which can be used to implement loops. Stage count register is accessed using special instructions.

ULP coprocessor can access 8 K bytes of RTC_SLOW_MEM memory region. Memory is addressed in 32-bit word units. It can also access peripheral registers in RTC_CNTL, RTC_IO, and SENS peripherals.

All instructions are 32-bit. Jump instructions, ALU instructions, peripheral register and memory access instructions are executed in 1 cycle. Instructions which work with peripherals (TSENS, ADC, I2C) take variable number of cycles, depending on peripheral operation.

The instruction syntax is case insensitive. Upper and lower case letters can be used and intermixed arbitrarily. This is true both for register names and instruction names.

**Note About Addressing**

ESP32 ULP FSM coprocessor’s JUMP, ST, LD family of instructions expect the address argument to be expressed in the following way depending on the type of address argument used:

- When the address argument is presented as a label then the instruction expects the address to be expressed as 32-bit words.

Consider the following example program:
entry:
    NOP
    NOP
    NOP
    NOP
loop:
    MOVE R1, loop
    JUMP R1

When this program is assembled and linked, address of label loop will be equal to 16 (expressed in bytes). However JUMP instruction expects the address stored in register R1 to be expressed in 32-bit words. To account for this common use case, the assembler will convert the address of label loop from bytes to words when generating the MOVE instruction. Hence, the code generated code will be equivalent to:

0000  NOP
0004  NOP
0008  NOP
000c  NOP
0010  MOVE R1, 4
0014  JUMP R1

• The other case is when the argument of MOVE instruction is not a label but a constant. In this case, assembler will use the value as is, without any conversion:

.set    val, 0x10
MOVE    R1, val

In this case, value loaded into R1 will be 0x10. However, when an immediate value is used as an offset in LD and ST instructions, the assembler considers the address argument in bytes and converts it to 32-bit words before executing the instruction:

ST R1, R2, 4  // offset = 4 bytes; Mem[R2 + 4 / 4] = R1

In this case, the value in R1 is stored at the memory location pointed by [R2 + offset / 4]

Consider the following code:

.global array
array: .long 0
       .long 0
       .long 0
       .long 0

MOVE R1, array
MOVE R2, 0x1234
ST R2, R1, 0  // write value of R2 into the first array element,
              // i.e., array[0]
ST R2, R1, 4  // write value of R2 into the second array element
              // (4 byte offset), i.e., array[1]
ADD R1, R1, 2 // this increments address by 2 words (8 bytes)
ST R2, R1, 0  // write value of R2 into the third array element,
              // i.e., array[2]

Note About Instruction Execution Time

ULP coprocessor is clocked from RTC_FAST_CLK, which is normally derived from the internal 8MHz oscillator. Applications which need to know exact ULP clock frequency can calibrate it against the main XTAL clock:

#include "soc/rtc.h"

// calibrate 8M/256 clock against XTAL, get 8M/256 clock period
Chapter 2. API Reference

(continued from previous page)

```c
uint32_t rtc_8md256_period = rtc_clk_cal(RTC_CAL_8MD256, 100);
uint32_t rtc_fast_freq_hz = 1000000ULL * (1 << RTC_CLK_CAL_FRACT) * 256 / rtc_-
→8md256_period;
```

ULP coprocessor needs certain number of clock cycles to fetch each instruction, plus certain number of cycles to execute it, depending on the instruction. See description of each instruction below for details on the execution time.

Instruction fetch time is:

- 2 clock cycles — for instructions following ALU and branch instructions.
- 4 clock cycles — in other cases.

Note that when accessing RTC memories and RTC registers, ULP coprocessor has lower priority than the main CPUs. This means that ULP coprocessor execution may be suspended while the main CPUs access same memory region as the ULP.

The detailed description of all instructions is presented below:

**NOP - No Operation**  
**Syntax**

```
NOP
```

**Operands**

None

**Cycles**

2 cycle to execute, 4 cycles to fetch next instruction

**Description**

No operation is performed. Only the PC is incremented.

**Example:**

```
1: NOP
```

**ADD - Add to Register**  
**Syntax**

```
ADD Rdst, Rsr1, Rsr2
ADD Rdst, Rsr1, imm
```

**Operands**

- **Rdst** - Register R[0..3]
- **Rsrc1** - Register R[0..3]
- **Rsrc2** - Register R[0..3]
- **Imm** - 16-bit signed value

**Cycles**

2 cycles to execute, 4 cycles to fetch next instruction

**Description**

The instruction adds source register to another source register or to a 16-bit signed value and stores the result in the destination register.

**Examples:**

```
1: ADD R1, R2, R3    // R1 = R2 + R3
2: Add R1, R2, 0x1234 // R1 = R2 + 0x1234
```

(continues on next page)
SUB - Subtract from Register

Syntax

SUB Rdst, Rscl, RsC2

SUB Rdst, Rscl, imm

Operands

- Rdst - Register R[0..3]
- Rscl - Register R[0..3]
- RsC2 - Register R[0..3]
- Imm - 16-bit signed value

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction subtracts the source register from another source register or subtracts a 16-bit signed value from a source register, and stores the result to the destination register.

Examples:

1:  SUB R1, R2, R3 // R1 = R2 - R3
2:  sub R1, R2, 0x1234 // R1 = R2 - 0x1234
3:  .set value1, 0x03 // constant value1=0x03
    ADD R1, R2, value1 // R1 = R2 + value1
4:  .global label // declaration of variable label
    add R1, R2, label // R1 = R2 + label
    ...
    label: nop // definition of variable label

AND - Bitwise Logical AND of Two Operands

Syntax

AND Rdst, Rscl, RsC2

AND Rdst, Rscl, imm

Operands

- Rdst - Register R[0..3]
- Rscl - Register R[0..3]
- RsC2 - Register R[0..3]
- Imm - 16-bit signed value

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction does a bitwise logical AND of a source register and another source register or a 16-bit signed value and stores the result to the destination register.
Chapter 2. API Reference

Examples:

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:</td>
<td><code>AND R1, R2, R3</code> // R1 = R2 &amp; R3</td>
</tr>
<tr>
<td>2:</td>
<td><code>AND R1, R2, 0x1234</code> // R1 = R2 &amp; 0x1234</td>
</tr>
</tbody>
</table>
| 3:      | `.set value1, 0x03` // constant value1=0x03  
|         | `AND R1, R2, value1` // R1 = R2 & value1 |
| 4:      | `.global label` // declaration of variable label  
|         | `AND R1, R2, label` // R1 = R2 & label  
|         | `...` // definition of variable label |

OR - Bitwise Logical OR of Two Operands  

Syntax

`OR Rdst, Rsrc1, Rsrc2`  
`OR Rdst, Rsrc1, imm`

Operands

- **Rdst** - Register R[0..3]
- **Rs1c1** - Register R[0..3]
- **Rs1c2** - Register R[0..3]
- **Imm** - 16-bit signed value

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction does a bitwise logical OR of a source register and another source register or a 16-bit signed value and stores the result to the destination register.

Examples:

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:</td>
<td><code>OR R1, R2, R3</code> // R1 = R2</td>
</tr>
<tr>
<td>2:</td>
<td><code>OR R1, R2, 0x1234</code> // R1 = R2</td>
</tr>
</tbody>
</table>
| 3:      | `.set value1, 0x03` // constant value1=0x03  
|         | `OR R1, R2, value1` // R1 = R2 || value1 |
| 4:      | `.global label` // declaration of variable label  
|         | `OR R1, R2, label` // R1 = R2 || label  
|         | `...` // definition of variable label |

LSH - Logical Shift Left  

Syntax

`LSH Rdst, Rs1c1, Rs1c2`  
`LSH Rdst, Rs1c1, imm`

Operands

- **Rdst** - Register R[0..3]
- **Rs1c1** - Register R[0..3]
- **Rs1c2** - Register R[0..3]
- **Imm** - 16-bit signed value

Cycles

Chapter 2. API Reference

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction does a logical shift to the left of the source register by the number of bits from another source register or a 16-bit signed value and stores the result to the destination register.

Note: Shift operations which are greater than 15 bits have undefined results.

Examples:

1: LSH R1, R2, R3 // R1 = R2 << R3
2: LSH R1, R2, 0x03 // R1 = R2 << 0x03
3: .set value1, 0x03 // constant value1=0x03
   LSH R1, R2, value1 // R1 = R2 << value1
4: .global label // declaration of variable label
   LSH R1, R2, label // R1 = R2 << label
   ...
   label: nop // definition of variable label

RSH - Logical Shift Right Syntax

RSH Rdst, Rsrcl, Rsrcl2
RSH Rdst, Rsrcl, imm

Operands

Rdst - Register R[0..3] Rsrcl - Register R[0..3] Rsrcl2 - Register R[0..3] Imm - 16-bit signed value

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction does a logical shift to right of a source register by the number of bits from another source register or a 16-bit signed value and stores the result to the destination register.

Note: Shift operations which are greater than 15 bits have undefined results.

Examples:

1: RSH R1, R2, R3 // R1 = R2 >> R3
2: RSH R1, R2, 0x03 // R1 = R2 >> 0x03
3: .set value1, 0x03 // constant value1=0x03
   RSH R1, R2, value1 // R1 = R2 >> value1
4: .global label // declaration of variable label
   RSH R1, R2, label // R1 = R2 >> label
   ...
   label: nop // definition of variable label

MOVE – Move to Register Syntax

MOVE Rdst, Rsrcl
MOVE Rdst, imm
Operands

- **Rdst** – Register R[0..3]
- **Rsrc** – Register R[0..3]
- **Imm** – 16-bit signed value

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

**Description**

The instruction moves the value from the source register or a 16-bit signed value to the destination register.

**Note:** Note that when a label is used as an immediate, the address of the label will be converted from bytes to words. This is because LD, ST, and JUMP instructions expect the address register value to be expressed in words rather than bytes. See the section *Note About Addressing* for more details.

**Examples:**

1: `MOVE R1, R2`  // R1 = R2
2: `MOVE R1, 0x03`  // R1 = 0x03
3: `.set value1, 0x03`  // constant value1=0x03
   `MOVE R1, value1`  // R1 = value1
4: `.global label`  // declaration of label
   `MOVE R1, label`  // R1 = address_of(label) / 4
   ...  // definition of label

**ST – Store Data to the Memory**  Syntax

**ST Rsrc, Rdst, offset**

Operands

- **Rsrc** – Register R[0..3], holds the 16-bit value to store
- **Rdst** – Register R[0..3], address of the destination, in 32-bit words
- **Offset** – 13-bit signed value, offset in bytes

Cycles

4 cycles to execute, 4 cycles to fetch next instruction

**Description**

The instruction stores the 16-bit value of Rsrc to the lower half-word of memory with address Rdst+offset. The upper half-word is written with the current program counter (PC) (expressed in words, shifted left by 5 bits) OR’d with Rdst (0..3):

\[
\text{Mem}[\text{Rdst} + \text{offset} / 4]{31:0} = \{\text{PC}[10:0], 3'b0, \text{Rdst}, \text{Rsrc}[15:0]\}
\]

The application can use the higher 16 bits to determine which instruction in the ULP program has written any particular word into memory.

**Note:** Note that the offset specified in bytes is converted to a 32-bit word offset before execution. See the section *Note About Addressing* for more details.

**Examples:**
LD – Load Data from the Memory  

**Syntax**

LD Rdst, Rsrc, offset

**Operands**

- **Rdst** – Register R[0..3], destination
- **Rscc** – Register R[0..3], holds address of destination, in 32-bit words
- **Offset** – 13-bit signed value, offset in bytes

**Cycles**

4 cycles to execute, 4 cycles to fetch next instruction

**Description**

The instruction loads the lower 16-bit half-word from memory with address [Rscc + offset / 4] into the destination register Rdst:

\[
\text{Rdst}[15:0] = \text{Mem[Rsrc + offset / 4][15:0]}
\]

**Note:** Note that the offset specified in bytes is converted to a 32-bit word offset before execution. See the section [Note About Addressing](#) for more details.

**Examples:**

1:  

LD R1, R2, 0x12  // R1 = MEM[R2 + 0x12 / 4]

2:  

.data  // Data section definition

**JUMP – Jump to an Absolute Address**  

**Syntax**

JUMP Rdst

JUMP ImmAddr

JUMP Rdst, Condition

JUMP ImmAddr, Condition

**Operands**

- **Rdst** – Register R[0..3] containing address to jump to (expressed in 32-bit words)
Chapter 2. API Reference

- **ImmAddr**: 13 bits address (expressed in bytes), aligned to 4 bytes
- **Condition**:  
  - EQ – jump if last ALU operation result was zero  
  - OV – jump if last ALU has set overflow flag

### Cycles

2 cycles to execute, 2 cycles to fetch next instruction

### Description

The instruction makes jump to the specified address. Jump can be either unconditional or based on an ALU flag.

### Examples:

<p>| | | |</p>

#### JUMPR – Jump to a Relative Offset (Condition Based on R0) Syntax

**JUMPR Step, Threshold, Condition**

### Operands

- **Step** – relative shift from current position, in bytes  
- **Threshold** – threshold value for branch condition  
- **Condition**:  
  - EQ (equal) – jump if value in R0 == threshold  
  - LT (less than) – jump if value in R0 < threshold  
  - LE (less or equal) – jump if value in R0 <= threshold  
  - GT (greater than) – jump if value in R0 > threshold  
  - GE (greater or equal) – jump if value in R0 >= threshold

### Cycles

Conditions LT, GE, LE and GT: 2 cycles to execute, 2 cycles to fetch next instruction  
Conditions LE and GT are implemented in the assembler using one JUMPR instruction:

```plaintext
// JUMPR target, threshold, GT is implemented as:
JUMPR target, threshold+1, GE
```

```plaintext
// JUMPR target, threshold, LE is implemented as:
JUMPR target, threshold + 1, LT
```

Conditions EQ is implemented in the assembler using two JUMPR instructions:
// JUMPR target, threshold, EQ is implemented as:
JUMPR next, threshold + 1, GE
JUMPR target, threshold, GE

next:

**Description**

The instruction makes a jump to a relative address if condition is true. Condition is the result of comparison of R0 register value and the threshold value.

**Examples:**

1: pos: JUMPR 16, 20, GE // Jump to address (position + 16 bytes) if...
   \_value in R0 >= 20

2: // Down counting loop using R0 register
   MOVE R0, 16 // load 16 into R0
   label: SUB R0, R0, 1 // R0--
   NOP // do something
   JUMPR label, 1, GE // jump to label if R0 >= 1

**JUMPS** – Jump to a Relative Address (Condition Based on Stage Count)  Syntax

**JUMPS Step, Threshold, Condition**

**Operands**

- **Step** – relative shift from current position, in bytes
- **Threshold** – threshold value for branch condition
- **Condition:**
  - EQ (equal) – jump if value in stage_cnt == threshold
  - LT (less than) – jump if value in stage_cnt < threshold
  - LE (less or equal) – jump if value in stage_cnt <= threshold
  - GT (greater than) – jump if value in stage_cnt > threshold
  - GE (greater or equal) – jump if value in stage_cnt >= threshold

**Cycles**

Conditions LE, LT, GE: 2 cycles to execute, 2 cycles to fetch next instruction

Conditions EQ, GT are implemented in the assembler using two JUMPS instructions:

// JUMPS target, threshold, EQ is implemented as:
JUMPS next, threshold, LT
JUMPS target, threshold, LE
next:

// JUMPS target, threshold, GT is implemented as:
JUMPS next, threshold, LE
JUMPS target, threshold, GE
next:

Therefore the execution time depends on the branches taken: either 2 cycles to execute + 2 cycles to fetch, or 4 cycles to execute + 4 cycles to fetch.

**Description**

The instruction makes a jump to a relative address if condition is true. Condition is the result of comparison of count register value and threshold value.

**Examples:**
Chapter 2. API Reference

1:pos: JUMPS 16, 20, EQ // Jump to (position + 16 bytes) if stage_cnt_ -= 20

2: // Up counting loop using stage count register
   STAGE_RST // set stage_cnt to 0
   label: STAGE_INC 1 // stage_cnt++
   NOP // do something
   JUMPS label, 16, LT // jump to label if stage_cnt < 16

STAGE_RST – Reset Stage Count Register

Syntax

STAGE_RST

Operands
No operands

Description
The instruction sets the stage count register to 0

Cycles
2 cycles to execute, 4 cycles to fetch next instruction

Examples:

1: STAGE_RST // Reset stage count register

STAGE_INC – Increment Stage Count Register

Syntax

STAGE_INC Value

Operands
• Value – 8 bits value

Cycles
2 cycles to execute, 4 cycles to fetch next instruction

Description
The instruction increments the stage count register by the given value.

Examples:

1: STAGE_INC 10 // stage_cnt += 10

2: // Up counting loop example:
   STAGE_RST // set stage_cnt to 0
   label: STAGE_INC 1 // stage_cnt++
   NOP // do something
   JUMPS label, 16, LT // jump to label if stage_cnt < 16

STAGE_DEC – Decrement Stage Count Register

Syntax

STAGE_DEC Value

Operands
• Value – 8 bits value

Cycles
2 cycles to execute, 4 cycles to fetch next instruction
Chapter 2. API Reference

Description

The instruction decrements the stage count register by the given value.

Examples:

```
1:   STAGE_DEC 10  // stage_cnt -= 10;
2:   // Down counting loop example
    STAGE_RST  // set stage_cnt to 0
    STAGE_INC 16  // increment stage_cnt to 16
    label: STAGE_DEC 1  // stage_cnt--;
    NOP  // do something
    JUMPS label, 0, GT  // jump to label if stage_cnt > 0
```

HALT -End the Program

Syntax

HALT

Operands

No operands

Cycles

2 cycles to execute

Description

The instruction halts the ULP coprocessor and restarts the ULP wake up timer, if it is enabled.

Examples:

```
1:   HALT  // Halt the coprocessor
```

WAKE -Wake up the Chip

Syntax

WAKE

Operands

No operands

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction sends an interrupt from the ULP coprocessor to the RTC controller.

- If the SoC is in deep sleep mode, and ULP wakeup is enabled, this causes the SoC to wake up.
- If the SoC is not in deep sleep mode, and ULP interrupt bit (RTC_CNTL_ULP_CP_INT_ENA) is set in RTC_CNTL_INT_ENA_REG register, RTC interrupt will be triggered.

Note:

Note that before using WAKE instruction, ULP program may need to wait until RTC controller is ready to wake up the main CPU. This is indicated using RTC_CNTL_RDY_FOR_WAKEUP bit of RTC_CNTL_LOW_POWER_ST_REG register. If WAKE instruction is executed while RTC_CNTL_RDY_FOR_WAKEUP is zero, it has no effect (wake up does not occur). If the WAKE instruction is intended to be used while the main CPU is not in sleep mode then the RTC_CNTL_MAIN_STATE_IN_IDLE (bit 27) of RTC_CNTL_LOW_POWER_ST_REG can be used to check whether main CPU is in normal mode or sleep mode.

Examples:
Chapter 2. API Reference

1: is_rdy_for_wakeup:  // Read RTC_CNTL_RDY_FOR_WAKEUP bit
    READ_RTC_FIELD(RTC_CNTL_LOW_POWER_ST_REG, RTC_CNTL_RDY_FOR_WAKEUP)
    AND r0, r0, 1
    JUMP is_rdy_for_wakeup, eq  // Retry until the bit is set
    WAKE  // Trigger wake up
REG_WR 0x006, 24, 24, 0  // Stop ULP timer (clear RTC_CNTL_ULP_CP_
→SLP_TIMER_EN)
    HALT  // Stop the ULP program
    // After these instructions, SoC will wake up,
    // and ULP will not run again until started by the main program.

1: check_wakeup:  // Read RTC_CNTL_RDY_FOR_WAKEUP and RTC_
→CNTL_MAIN_STATE_IN_IDLE bit
    READ_RTC_REG(RTC_CNTL_LOW_POWER_ST_REG, 27, 1)
    MOVE r1, r0  // Copy result in to r1
    READ_RTC_FIELD(RTC_CNTL_LOW_POWER_ST_REG, RTC_CNTL_RDY_FOR_WAKEUP)
    OR r0, r0, r1
    JUMP check_wakeup, eq  // Retry until either of the bit are set
    WAKE  // Trigger wake up
    HALT  // Stop the ULP program

SLEEP –Set ULP Wakeup Timer Period  Syntax

SLEEP sleep_reg

Operands
- sleep_reg –0..4, selects one of SENS_ULP_CP_SLEEP_CYCx_REG registers.

Cycles
- 2 cycles to execute, 4 cycles to fetch next instruction

Description
The instruction selects which of the SENS_ULP_CP_SLEEP_CYCx_REG (x = 0..4) register values is to be used by the ULP wakeup timer as wakeup period. By default, the value from SENS_ULP_CP_SLEEP_CYC0_REG is used.

Examples:

1: SLEEP 1  // Use period set in SENS_ULP_CP_SLEEP_CYC1_REG
2: .set sleep_reg, 4  // Set constant
   SLEEP sleep_reg  // Use period set in SENS_ULP_CP_SLEEP_CYC4_REG

WAIT –Wait Some Number of Cycles  Syntax

WAIT Cycles

Operands
- Cycles –number of cycles for wait

Cycles
- 2 + Cycles cycles to execute, 4 cycles to fetch next instruction

Description
The instruction delays for given number of cycles.

Examples:
Chapter 2. API Reference

ADC – Do Measurement with ADC  
**Syntax**
- ADC Rdst, Sar_sel, Mux
- ADC Rdst, Sar_sel, Mux, 0 — deprecated form

**Operands**
- **Rdst** — Destination Register R[0..3], result will be stored to this register
- **Sar_sel** — Select ADC: 0 = SARADC1, 1 = SARADC2
- **Mux** — Enable ADC channel. Channel number is [Mux-1]. If the user passes Mux value 1, then ADC channel 0 gets used.

**Cycles**
23 + max(1, SAR_AMP_WAIT1) + max(1, SAR_AMP_WAIT2) + max(1, SAR_AMP_WAIT3) + SARx_SAMPLE_CYCLE + SARx_SAMPLE_BIT cycles to execute, 4 cycles to fetch next instruction

**Description**
The instruction makes measurements from ADC.

**Examples:**
```
.. only:: esp32

1: ADC R1, 0, 1 // Measure value using ADC1 channel 0 and store result into R1
```

I2C_RD - Read Single Byte from I2C Slave  
**Syntax**
- I2C_RD Sub_addr, High, Low, Slave_sel

**Operands**
- **Sub_addr** — Address within the I2C slave to read.
- **High**, **Low** — Define range of bits to read. Bits outside of [High, Low] range are masked.
- **Slave_sel** — Index of I2C slave address to use.

**Cycles**
Execution time mostly depends on I2C communication time. 4 cycles to fetch next instruction.

**Description**
I2C_RD instruction reads one byte from I2C slave with index Slave_sel. Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == Slave_sel. 8 bits of read result is stored into R0 register.

**Examples:**
```
1: I2C_RD 0x10, 7, 0, 0 // Read byte from sub-address 0x10 of slave with address set in SENS_I2C_SLAVE_ADDR0
```

I2C_WR - write single byte to I2C slave  
**Syntax**
- I2C_WR Sub_addr, Value, High, Low, Slave_sel

**Operands**
Chapter 2. API Reference

- **Sub_addr** – Address within the I2C slave to write.
- **Value** – 8-bit value to be written.
- **High, Low** – Define range of bits to write. Bits outside of [High, Low] range are masked.
- **Slave_sel** – Index of I2C slave address to use.

**Cycles**

Execution time mostly depends on I2C communication time. 4 cycles to fetch next instruction.

**Description**

I2C_WR instruction writes one byte to I2C slave with index Slave_sel. Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == Slave_sel.

**Examples**:

```plaintext
1: I2C_WR 0x20, 0x33, 7, 0, 1 // Write byte 0x33 to sub-address\-
   → 0x20 of slave with address set in SENS_I2C_SLAVE_ADDR1.
```

**REG_RD – Read from Peripheral Register**

**Syntax**

REG_RD Addr, High, Low

**Operands**

- **Addr** – Register address, in 32-bit words
- **High** – Register end bit number
- **Low** – Register start bit number

**Cycles**

4 cycles to execute, 4 cycles to fetch next instruction

**Description**

The instruction reads up to 16 bits from a peripheral register into a general purpose register: R0 = REG[Addr][High:Low].

This instruction can access registers in RTC_CNTL, RTC_IO, SENS, and RTC_I2C peripherals. Address of the register, as seen from the ULP, can be calculated from the address of the same register on the DPORT bus as follows:

```
addr_ulp = (addr_dport - DR_REG_RTCCNTL_BASE) / 4
```

**Examples**:

```plaintext
1: REG_RD 0x120, 7, 4 // load 4 bits: R0 = {12'b0, REG[0x120][7:4]}
```

**REG_WR – Write to Peripheral Register**

**Syntax**

REG_WR Addr, High, Low, Data

**Operands**

- **Addr** – Register address, in 32-bit words.
- **High** – Register end bit number
- **Low** – Register start bit number
- **Data** – Value to write, 8 bits

**Cycles**

8 cycles to execute, 4 cycles to fetch next instruction

**Description**
The instruction writes up to 8 bits from an immediate data value into a peripheral register:

\[ \text{REG}[\text{Addr}][\text{High:Low}] = \text{data}. \]

This instruction can access registers in RTC_CNTL, RTC_IO, SENS, and RTC_I2C peripherals. Address of the register, as seen from the ULP, can be calculated from the address of the same register on the DPORT bus as follows:

\[ \text{addr}_\text{ulp} = \left( \text{addr}_\text{dport} - \text{DR_REG_RTC_CNTL_BASE} \right) / 4 \]

**Examples:**

1: \( \text{REG}_\text{WR} 0x120, 7, 0, 0x10 \) // set 8 bits: \( \text{REG}[0x120][7:0] = 0x10 \)

**Convenience Macros for Peripheral Registers Access**

ULP source files are passed through C preprocessor before the assembler. This allows certain macros to be used to facilitate access to peripheral registers.

Some existing macros are defined in `soc/soc_ulp.h` header file. These macros allow access to the fields of peripheral registers by their names. Peripheral registers names which can be used with these macros are the ones defined in `soc/rtc_CNTL_reg.h`, `soc/rtc_GPIO_reg.h`, `soc/sens_reg.h`, and `soc/rtc_i2c_reg.h`.

**READ_RTC_REG**

\( \text{READ_RTC_REG}(\text{rtc_reg}, \text{low_bit}, \text{bit_width}) \)

Read up to 16 bits from \( \text{rtc_reg}[_{\text{low_bit + bit_width} - 1 : \text{low_bit}}] \) into R0. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/rtc_CNTL_reg.h"

/* Read 16 lower bits of RTC_CNTL_TIME0_REG into R0 */
READ_RTC_REG(RTC_CNTL_TIME0_REG, 0, 16)
```

**READ_RTC_FIELD**

\( \text{READ_RTC_FIELD}(\text{rtc_reg}, \text{field}) \)

Read from a field in \( \text{rtc_reg} \) into R0, up to 16 bits. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/sens_reg.h"

/* Read 8-bit SENS_TSENS_OUT field of SENS_SAR_SLAVE_ADDR3_REG into R0 */
READ_RTC_FIELD(SENS_SAR_SLAVE_ADDR3_REG, SENS_TSENS_OUT)
```

**WRITE_RTC_REG**

\( \text{WRITE_RTC_REG}(\text{rtc_reg}, \text{low_bit}, \text{bit_width}, \text{value}) \)

Write immediate value into \( \text{rtc_reg}[_{\text{low_bit + bit_width} - 1 : \text{low_bit}}] \), bit_width <= 8. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/rtc_GPIO_reg.h"

/* Set BIT(2) of RTC_GPIO_OUT_DATA_W1TS field in RTC_GPIO_OUT_W1TS_REG */
WRITE_RTC_REG(RTC_GPIO_OUT_W1TS_REG, RTC_GPIO_OUT_DATA_W1TS_S + 2, 1, 1)
```

**WRITE_RTC_FIELD**

\( \text{WRITE_RTC_FIELD}(\text{rtc_reg}, \text{field}, \text{value}) \)

Write immediate value into a field in \( \text{rtc_reg} \), up to 8 bits. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/rtc_CNTL_reg.h"

/* Set RTC_CNTL_ULP_CP_SLP_TIMER_EN field of RTC_CNTL_STATE0_REG to 0 */
WRITE_RTC_FIELD(RTC_CNTL_STATE0_REG, RTC_CNTL_ULP_CP_SLP_TIMER_EN, 0)
```

**Programming ULP FSM Coprocessor Using C Macros (Legacy)**

In addition to the existing binutils port for the ESP32 ULP coprocessor, it is possible to generate programs for the ULP FSM coprocessor by embedding assembly-like macros into an ESP32 application. Here is an example how this can be done:
The program array is an array of ulp_insn_t, i.e., ULP coprocessor instructions. Each I_XXX preprocessor define translates into a single 32-bit instruction. Arguments of these preprocessor defines can be register numbers (R0—R3) and literal constants. See the API reference section at the end of this guide for descriptions of instructions and arguments they take.

**Note:** Because some of the instruction macros expand to inline function calls, defining such array in global scope will cause the compiler to produce an “initializer element is not constant” error. To fix this error, move the definition of instructions array into local scope.

**Note:** Load, store and move instructions use *addresses expressed in 32-bit words*. Address 0 corresponds to the first word of RTC_SLOW_MEM. This is different to how address arguments are handled in assembly code of the same instructions. See the section *Note About Addressing* for more details for reference.

To generate branch instructions, special M_ preprocessor defines are used. M_LABEL define can be used to define a branch target. Label identifier is a 16-bit integer. M_Bxxx defines can be used to generate branch instructions with target set to a particular label.

Implementation note: these M_ preprocessor defines will be translated into two ulp_insn_t values: one is a token value which contains label number, and the other is the actual instruction. ulp_process_macros_and_load function resolves the label number to the address, modifies the branch instruction to use the correct address, and removes the extra ulp_insn_t token which contains the label numer.

Here is an example of using labels and branches:

```c
const ulp_insn_t program[] = {
    I_MOVI(R0, 34),       // R0 <- 34
    M_LABEL(1),           // label_1
    I_MOVI(R1, 32),       // R1 <- 32
    I_LD(R1, R1, 0),      // R1 <- RTC_SLOW_MEM[R1]
    I_MOVI(R2, 33),       // R2 <- 33
    I_LD(R2, R2, 0),      // R2 <- RTC_SLOW_MEM[R2]
    I_SUBR(R3, R1, R2),   // R3 <- R1 - R2
    I_ST(R3, R0, 0),      // R3 -> RTC_SLOW_MEM[R0 + 0]
    I_ADDI(R0, R0, 1),    // R0++
    M_BL(1, 64),          // if (R0 < 64) goto label_1
    I_HALT(),             //
};
RTC_SLOW_MEM[32] = 42;
RTC_SLOW_MEM[33] = 18;
size_t load_addr = 0;
size_t size = sizeof(program)/sizeof(ulp_insn_t);
ulp_process_macros_and_load(load_addr, program, &size);
ulp_run(load_addr);
```

**API Reference**
Chapter 2. API Reference

Header File

- components/ulp/ulp_fsm/include/esp32/ulp.h
- This header file can be included with:

```
#include "ulp.h"
```
- This header file is a part of the API provided by the ulp component. To declare that your component depends on ulp, add the following to your CMakeLists.txt:

```
REQUIRES ulp
```
or
```
PRIV_REQUIRES ulp
```

Functions

static inline uint32_t SOC_REG_TO_U LP_PER I PH_SEL(uint32_t reg)

Map SoC peripheral register to periph_sel field of RD_REG and WR_REG instructions.

Parameters reg - peripheral register in RTC_CNTL_, RTC_IO_, SENS_, RTC_I2C peripherals.

Returns periph_sel value for the peripheral to which this register belongs.

Unions

union ulp_insn

```
#include <ulp.h>
```

Instruction format structure.

All ULP instructions are 32 bit long. This union contains field layouts used by all of the supported instructions. This union also includes a special “macro” instruction layout. This is not a real instruction which can be executed by the CPU. It acts as a token which is removed from the program by the ulp_process_macros_and_load function.

These structures are not intended to be used directly. Preprocessor definitions provided below fill the fields of these structure with the right arguments.

Public Members

SUB_OPCODE_MACRO_LABEL or SUB_OPCODE_MACRO_BRANCH or SUB_OPCODE_MACRO_LABELPC

struct ulp_insn::[anonymous] st
  Format of ST instruction

struct ulp_insn::[anonymous] ld
  Format of LD instruction

struct ulp_insn::[anonymous] halt
  Format of HALT instruction

uint32_t addr
  Target PC, expressed in words (used if .reg == 0)
  Address within either RTC_CNTL, RTC_IO, or SARADC

uint32_t reg
  Target PC in register (1) or immediate (0)

uint32_t type
  Jump condition (BX_JUMP_TYPE_xxx)

struct ulp_insn::[anonymous] bx
  Format of BRANCH instruction (absolute address)

uint32_t imm
  Immediate value to compare against
  Immediate value of operand
  Immediate value of operand B

uint32_t cmp
  Comparison to perform: B_CMP_L or B_CMP_GE
  Comparison to perform: JUMPS_LT, JUMPS_GE or JUMPS_LE

uint32_t sign
  Sign of target PC offset: 0: positive, 1: negative

struct ulp_insn::[anonymous] b
  Format of BRANCH instruction (relative address, conditional on R0)

struct ulp_insn::[anonymous] bs
  Format of BRANCH instruction (relative address, conditional on the stage counter)

uint32_t treg
  Register with operand B

uint32_t sel
  Operation to perform, one of ALU_SEL_xxx
  Operation to perform, one of ALU_SEL_Sxxx
struct *ulp_insn::[anonymous] *alu_reg
    Format of ALU instruction (both sources are registers)

struct *ulp_insn::[anonymous] *alu_reg_s
    Format of ALU instruction (stage counter and an immediate)

struct *ulp_insn::[anonymous] *alu_imm
    Format of ALU instruction (one source is an immediate)

uint32_t *periph_sel
    Select peripheral: RTC_CNTL (0), RTC_IO(1), SARADC(2)

uint32_t *data
    8 bits of data to write
    8 bits of data for write operation

uint32_t *low
    Low bit

uint32_t *high
    High bit

struct *ulp_insn::[anonymous] *wr_reg
    Format of WR_REG instruction

struct *ulp_insn::[anonymous] *rd_reg
    Format of RD_REG instruction

uint32_t *mux
    Select SARADC pad (mux + 1)

uint32_t *sar_sel
    Select SARADC0 (0) or SARADC1 (1)

struct *ulpInsn::[anonymous] *adc
    Format of ADC instruction

uint32_t *wait_delay
    Cycles to wait after measurement is done

uint32_t *reserved
    Reserved, set to 0

struct *ulp_insn::[anonymous] *tsens
    Format of TSENS instruction

uint32_t *i2c_addr
    I2C slave address
**uint32_t low_bits**

low bit of range for write operation (lower bits are masked)

**uint32_t high_bits**

high bit of range for write operation (higher bits are masked)

**uint32_t i2c_sel**

index of slave address register [7:0]

**uint32_t rw**

Write (1) or read (0)

**struct ulp_insn::[anonymous] i2c**

Format of I2C instruction

**uint32_t wakeup**

Set to 1 to wake up chip

**struct ulp_insn::[anonymous] end**

Format of END instruction with wakeup

**uint32_t cycle_sel**

Select which one of SARADC_ULP_CP_SLEEP_CYCx_REG to get the sleep duration from

**struct ulp_insn::[anonymous] sleep**

Format of END instruction with sleep

**uint32_t label**

Label number

**struct ulp_insn::[anonymous] macro**

Format of tokens used by MACROs

**uint32_t instruction**

Encoded instruction for ULP coprocessor

**Macros**

**R0**

general purpose register 0

**R1**

general purpose register 1

**R2**

general purpose register 2

**R3**

general purpose register 3
Chapter 2. API Reference

**OPCODE_WR_REG**
Instruction: write peripheral register (RTC_CNTL/RTC_IO/SARADC)

**OPCODE_RD_REG**
Instruction: read peripheral register (RTC_CNTL/RTC_IO/SARADC)

**RD_REG_PERIPH_RTC_CNTL**
Identifier of RTC_CNTL peripheral for RD_REG and WR_REG instructions

**RD_REG_PERIPH_RTC_IO**
Identifier of RTC_IO peripheral for RD_REG and WR_REG instructions

**RD_REG_PERIPH_SENS**
Identifier of SARADC peripheral for RD_REG and WR_REG instructions

**RD_REG_PERIPH_RTC_I2C**
Identifier of RTC_I2C peripheral for RD_REG and WR_REG instructions

**OPCODE_I2C**
Instruction: read/write I2C

**SUB_OPCODE_I2C_RD**
I2C read

**SUB_OPCODE_I2C_WR**
I2C write

**OPCODE_DELAY**
Instruction: delay (nop) for a given number of cycles

**OPCODE_ADC**
Instruction: SAR ADC measurement

**OPCODE_ST**
Instruction: store indirect to RTC memory

**SUB_OPCODE_ST**
Store 32 bits, 16 MSBs contain PC, 16 LSBs contain value from source register

**OPCODE_ALU**
Arithmetic instructions

**SUB_OPCODE_ALU_REG**
Arithmetic instruction, both source values are in register

**SUB_OPCODE_ALU_IMM**
Arithmetic instruction, one source value is an immediate
Chapter 2. API Reference

**SUB_OPCODE_ALU_CNT**

Arithmetic instruction, stage counter and an immediate

**ALU_SEL_ADD**

Addition

**ALU_SEL_SUB**

Subtraction

**ALU_SEL_AND**

Logical AND

**ALU_SEL_OR**

Logical OR

**ALU_SEL_MOV**

Copy value (immediate to destination register or source register to destination register)

**ALU_SEL_LSH**

Shift left by given number of bits

**ALU_SEL_RSH**

Shift right by given number of bits

**ALU_SEL_SINC**

Increment the stage counter

**ALU_SEL_SDEC**

Decrement the stage counter

**ALU_SEL_SRST**

Reset the stage counter

**OPCODE_BRANCH**

Branch instructions

**SUB_OPCODE_BX**

Branch to absolute PC (immediate or in register)

**SUB_OPCODE_BR**

Branch to relative PC, conditional on R0

**SUB_OPCODE_BS**

Branch to relative PC, conditional on the stage counter

**BX_JUMP_TYPE_DIRECT**

Unconditional jump
**Chapter 2. API Reference**

**BX_JUMP_TYPE_ZERO**
Branch if last ALU result is zero

**BX_JUMP_TYPE_OVF**
Branch if last ALU operation caused and overflow

**SUB_OPCODE_B**
Branch to a relative offset

**B_CMP_L**
Branch if R0 is less than an immediate

**B_CMP_GE**
Branch if R0 is greater than or equal to an immediate

**JUMPS_LT**
Branch if the stage counter <

**JUMPS_GE**
Branch if the stage counter >=

**JUMPS_LE**
Branch if the stage counter <=

**OPCODE_END**
Stop executing the program

**SUB_OPCODE_END**
Stop executing the program and optionally wake up the chip

**SUB_OPCODE_SLEEP**
Stop executing the program and run it again after selected interval

**OPCODE_TSENS**
Instruction: temperature sensor measurement. Poor accuracy, not recommended for most use-cases

**OPCODE_HALT**
Halt the coprocessor

**OPCODE_LD**
Indirect load lower 16 bits from RTC memory

**OPCODE_MACRO**
Not a real opcode. Used to identify labels and branches in the program

**SUB_OPCODE_MACRO_LABEL**
Label macro
**SUB_OPCODE_MACRO_BRANCH**

Branch macro

**SUB_OPCODE_MACRO_LABELPC**

Label pointer macro

**I_DELAY (cycles_)**

Delay (nop) for a given number of cycles

**I_HALT ()**

Halt the coprocessor.

This instruction halts the coprocessor, but keeps ULP timer active. As such, ULP program will be restarted again by timer. To stop the program and prevent the timer from restarting the program, use I_END(0) instruction.

**I_WR_REG (reg, low_bit, high_bit, val)**

Write literal value to a peripheral register

\[ \text{reg}[\text{high_bit : low_bit}] = \text{val} \]

This instruction can access RTC_CNTL_, RTC_IO_, SENS_, and RTC_I2C peripheral registers.

**I_RD_REG (reg, low_bit, high_bit)**

Read from peripheral register into R0

\[ \text{R0} = \text{reg}[\text{high_bit : low_bit}] \]

This instruction can access RTC_CNTL_, RTC_IO_, SENS_, and RTC_I2C peripheral registers.

**I_WR_REG_BIT (reg, shift, val)**

Set or clear a bit in the peripheral register.

Sets bit \((1 \ll \text{shift})\) of register \(\text{reg}\) to value \(\text{val}\). This instruction can access RTC_CNTL_, RTC_IO_, SENS_, and RTC_I2C peripheral registers.

**I_WAKE ()**

Wake the SoC from deep sleep.

This instruction initiates wake up from deep sleep. Use esp_deep_sleep_enable_ulp_wakeup to enable deep sleep wakeup triggered by the ULP before going into deep sleep. Note that ULP program will still keep running until the I_HALT instruction, and it will still be restarted by timer at regular intervals, even when the SoC is woken up.

To stop the ULP program, use I_HALT instruction.

To disable the timer which starts ULP program, use I_END() instruction. I_END instruction clears the RTC_CNTL_ULP_CP_SLP_TIMER_EN_S bit of RTC_CNTL_STATE0_REG register, which controls the ULP timer.

**I_END ()**

Stop ULP program timer.

This is a convenience macro which disables the ULP program timer. Once this instruction is used, ULP program will not be restarted anymore until ulp_run function is called.

ULP program will continue running after this instruction. To stop the currently running program, use I_HALT().

**I_SLEEP_CYCLE_SEL (timer_idx)**

Select the time interval used to run ULP program.

This instructions selects which of the SENS_SLEEP_CYCLES_Sx registers’ value is used by the ULP program timer. When the ULP program stops at I_HALT instruction, ULP program timer start counting. When
the counter reaches the value of the selected SENS_SLEEP_CYCLES_Sx register, ULP program start running again from the start address (passed to the ulp_run function). There are 5 SENS_SLEEP_CYCLES_Sx registers, so 0 <= timer_idx < 5.

By default, SENS_SLEEP_CYCLES_S0 register is used by the ULP program timer.

I_TSENS (reg_dest, delay)
Perform temperature sensor measurement and store it into reg_dest.
Delay can be set between 1 and ((1 << 14) - 1). Higher values give higher measurement resolution.

I_ADC (reg_dest, adc_idx, pad_idx)
Perform ADC measurement and store result in reg_dest.
adc_idx selects ADC (0 or 1). pad_idx selects ADC pad (0 - 7).

I_ST (reg_val, reg_addr, offset_)
Store value from register reg_val into RTC memory.
The value is written to an offset calculated by adding value of reg_addr register and offset_field (this offset is expressed in 32-bit words). 32 bits written to RTC memory are built as follows:
- bits [31:21] hold the PC of current instruction, expressed in 32-bit words
- bits [20:18] = 3’b0
- bits [17:16] reg_addr (0..3)
- bits [15:0] are assigned the contents of reg_val

RTC_SLOW_MEM[addr + offset_] = { insn_PC[10:0], 3’b0, reg_addr, reg_val[15:0] }

I_LD (reg_dest, reg_addr, offset_)
Load value from RTC memory into reg_dest register.
Loads 16 LSBs from RTC memory word given by the sum of value in reg_addr and value of offset_.

I_BL (pc_offset, imm_value)
Branch relative if R0 less than immediate value.
pc_offset is expressed in words, and can be from -127 to 127 imm_value is a 16-bit value to compare R0 against

I_BGE (pc_offset, imm_value)
Branch relative if R0 greater or equal than immediate value.
pc_offset is expressed in words, and can be from -127 to 127 imm_value is a 16-bit value to compare R0 against

I_BXR (reg_pc)
Unconditional branch to absolute PC, address in register.
reg_pc is the register which contains address to jump to. Address is expressed in 32-bit words.

I_BXI (imm_pc)
Unconditional branch to absolute PC, immediate address.
Address imm_pc is expressed in 32-bit words.

I_BXZR (reg_pc)
Branch to absolute PC if ALU result is zero, address in register.
reg_pc is the register which contains address to jump to. Address is expressed in 32-bit words.

I_BXZI (imm_pc)
Branch to absolute PC if ALU result is zero, immediate address.
Address imm_pc is expressed in 32-bit words.
\textbf{I\_BXFR} (\texttt{reg\_pc})

Branch to absolute PC if ALU overflow, address in register

\texttt{reg\_pc} is the register which contains address to jump to. Address is expressed in 32-bit words.

\textbf{I\_BXFI} (\texttt{imm\_pc})

Branch to absolute PC if ALU overflow, immediate address

Address \texttt{imm\_pc} is expressed in 32-bit words.

\textbf{I\_ADDR} (\texttt{reg\_dest, reg\_src1, reg\_src2})

Addition: \texttt{dest = src1 + src2}

\textbf{I\_SUBR} (\texttt{reg\_dest, reg\_src1, reg\_src2})

Subtraction: \texttt{dest = src1 - src2}

\textbf{I\_ANDR} (\texttt{reg\_dest, reg\_src1, reg\_src2})

Logical AND: \texttt{dest = src1 \& src2}

\textbf{I\_ORR} (\texttt{reg\_dest, reg\_src1, reg\_src2})

Logical OR: \texttt{dest = src1 | src2}

\textbf{I\_MOVR} (\texttt{reg\_dest, reg\_src})

Copy: \texttt{dest = src}

\textbf{I\_LSHR} (\texttt{reg\_dest, reg\_src, reg\_shift})

Logical shift left: \texttt{dest = src << shift}

\textbf{I\_RSHR} (\texttt{reg\_dest, reg\_src, reg\_shift})

Logical shift right: \texttt{dest = src >> shift}

\textbf{I\_ADDI} (\texttt{reg\_dest, reg\_src, imm\_})

Add register and an immediate value: \texttt{dest = src1 + imm}

\textbf{I\_SUBI} (\texttt{reg\_dest, reg\_src, imm\_})

Subtract register and an immediate value: \texttt{dest = src - imm}

\textbf{I\_ANDI} (\texttt{reg\_dest, reg\_src, imm\_})

Logical AND register and an immediate value: \texttt{dest = src \& imm}

\textbf{I\_ORI} (\texttt{reg\_dest, reg\_src, imm\_})

Logical OR register and an immediate value: \texttt{dest = src \| imm}

\textbf{I\_MOVI} (\texttt{reg\_dest, imm\_})

Copy an immediate value into register: \texttt{dest = imm}

\textbf{I\_LSHI} (\texttt{reg\_dest, reg\_src, imm\_})

Logical shift left register value by an immediate: \texttt{dest = src << imm}

\textbf{I\_RSHI} (\texttt{reg\_dest, reg\_src, imm\_})

Logical shift right register value by an immediate: \texttt{dest = val >> imm}

\textbf{M\_LABEL} (\texttt{label\_num})

Define a label with number \texttt{label\_num}.

This is a macro which doesn’t generate a real instruction. The token generated by this macro is removed by \texttt{ulp_process_macros_and_load} function. Label defined using this macro can be used in branch macros defined below.

\textbf{M\_BRANCH} (\texttt{label\_num})

Token macro used by \texttt{M\_B} and \texttt{M\_BX} macros. Not to be used directly.

\textbf{M\_LABELPC} (\texttt{label\_num})

Token macro used by \texttt{M\_MOVL} macro. Not to be used directly.
M_MOVL (reg_dest, label_num)
Macro: Move the program counter at the given label into the register. This address can then be used with I_BXR, I_BXZR, I_BXFR, etc.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BL (label_num, imm_value)
Macro: branch to label label_num if R0 is less than immediate value.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BGE (label_num, imm_value)
Macro: branch to label label_num if R0 is greater or equal than immediate value.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BX (label_num)
Macro: unconditional branch to label
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BXZ (label_num)
Macro: branch to label if ALU result is zero.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BXF (label_num)
Macro: branch to label if ALU overflow.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

I_STAGE_INC (imm_)
Increment the stage counter by immediate value

I_STAGE_DEC (imm_)
Decrement the stage counter by immediate value

I_STAGE_RST ()
Reset the stage counter

M_BSLT (label_num, imm_value)
Macro: branch to label if the stage counter is less than immediate value.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BSGE (label_num, imm_value)
Macro: branch to label if the stage counter is greater than or equal to immediate value.
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.
M_BSE (label_num, imm_value)
Macro: branch to label if the stage counter is less than or equal to immediate value

This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BSEQ (label_num, imm_value)
Macro: branch to label if the stage counter is equal to immediate value. Implemented using two JUMPS instructions: JUMPS next, imm_value, LT JUMPS label_num, imm_value, LE

This macro generates three ulp_insn_t values separated by commas, and should be used when defining contents of ulp_insn_t arrays. Second value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BSGT (label_num, imm_value)
Macro: branch to label if the stage counter is greater than immediate value. Implemented using two instructions: JUMPS next, imm_value, LE JUMPS label_num, imm_value, GE

This macro generates three ulp_insn_t values separated by commas, and should be used when defining contents of ulp_insn_t arrays. Second value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

I_JUMPS (pc_offset, imm_value, comp_type)
Branch relative if (stage counter [comp_type][imm_value]) evaluates to true.

pc_offset is expressed in words, and can be from -127 to 127 imm_value is an 8-bit value to compare the stage counter against comp_type is the type of comparison to perform: JUMPS_LT(<), JUMPS_GE (>=) or JUMPS_LE (<=)

I_I2C_RW (sub_addr, val, low_bit, high_bit, slave_sel, rw_bit)
Perform an I2C transaction with a slave device. I_I2C_READ and I_I2C_WRITE are provided for convenience, instead of using this directly.

Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == slave_sel. For read operations, 8 bits of read result is stored into R0 register. For write operations, val will be written to sub_addr at [high_bit:low_bit]. Bits outside of this range are masked.

I_I2C_READ (slave_sel, sub_addr)
Read a byte from the sub address of an I2C slave, and store the result in R0.

Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == slave_sel.

I_I2C_WRITE (slave_sel, sub_addr, val)
Write a byte to the sub address of an I2C slave.

Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == slave_sel.

Compiling the ULP Code

To compile the ULP FSM code as part of the component, the following steps must be taken:

1. The ULP FSM code, written in assembly, must be added to one or more files with .S extension. These files must be placed into a separate directory inside the component directory, for instance, ulp/.

Note: When registering the component (via idf_component_register), this directory should not be added to the SRC_DIRS argument. The logic behind this is that the ESP-IDF build system will compile files found in SRC_DIRS based on their extensions. For .S files, xtensa-esp32-elf-as assembler is used. This is not desirable for ULP FSM assembly files, so the easiest way to achieve the distinction is by placing ULP FSM assembly
files into a separate directory. The ULP FSM assembly source files should also not be added to SRCS for the same reason. See the steps below for how to properly add ULP FSM assembly source files.

2. Call `ulp_embed_binary` from the component CMakeLists.txt after registration. For example:

```cmake
... idf_component_register()
set(ulp_app_name ulp_${COMPONENT_NAME})
set(ulp_s_sources ulp/ulp_assembly_source_file.S)
set(ulp_exp_dep_srcs "ulp_c_source_file.c")
ulp_embed_binary(${ulp_app_name} "${ulp_s_sources}" "${ulp_exp_dep_srcs}"
```

The first argument to `ulp_embed_binary` specifies the ULP FSM binary name. The name specified here will also be used by other generated artifacts such as the ELF file, map file, header file and linker export file. The second argument specifies the ULP FSM assembly source files. Finally, the third argument specifies the list of component source files which include the header file to be generated. This list is needed to build the dependencies correctly and ensure that the generated header file will be created before any of these files are compiled. See the section below for the concept of generated header files for ULP applications.

3. Build the application as usual (e.g., `idf.py app`). Inside, the build system will take the following steps to build ULP FSM program:
   1. **Run each assembly file (foo.S) through the C preprocessor.** This step generates the preprocessed assembly files (foo.ulp.S) in the component build directory. This step also generates dependency files (foo.ulp.d).
   2. **Run preprocessed assembly sources through the assembler.** This produces object (foo.ulp.o) and listing (foo.ulp.lst) files. Listing files are generated for debugging purposes and are not used at later stages of the build process.
   3. **Run the linker script template through the C preprocessor.** The template is located in components/ulp/ld directory.
   4. **Link the object files into an output ELF file (ulp_app_name.elf).** The Map file (ulp_app_name.map) generated at this stage may be useful for debugging purposes.
   5. **Dump the contents of the ELF file into a binary (ulp_app_name.bin) which can then be embedded into the application.**
   6. **Generate a list of global symbols (ulp_app_name.sym) in the ELF file using esp32ulp-elf-nm.**
   7. **Create an LD export script and a header file (ulp_app_name.ld and ulp_app_name.h) containing the symbols from ulp_app_name.sym.** This is done using the esp32ulp_mapgen.py utility.
   8. **Add the generated binary to the list of binary files** to be embedded into the application.

**Accessing the ULP FSM Program Variables**

Global symbols defined in the ULP FSM program may be used inside the main program.

For example, the ULP FSM program may define a variable `measurement_count` which will define the number of ADC measurements the program needs to make before waking up the chip from Deep-sleep:

```assembly
.globl measurement_count
measurement_count:
    .long 0

    // later, use measurement_count
    move r3, measurement_count
    ld r3, r3, 0
```

The main program needs to initialize this variable before the ULP program is started. The build system makes this possible by generating the `${ULP_APP_NAME}.h` and `${ULP_APP_NAME}.ld` files which define the global symbols present in the ULP program. Each global symbol defined in the ULP program is included in these files and are prefixed with `ulp_`. 
Chapter 2. API Reference

The header file contains the declaration of the symbol:

```c
extern uint32_t ulp_measurement_count;
```

Note that all symbols (variables, arrays, functions) are declared as `uint32_t`. For functions and arrays, take the address of the symbol and cast it to the appropriate type.

The generated linker script file defines the locations of symbols in RTC_SLOW_MEM:

```makefile
PROVIDE ( ulp_measurement_count = 0x50000060 );
```

To access the ULP program variables from the main program, the generated header file should be included using an `#include` statement. This will allow the ULP program variables to be accessed as regular variables:

```c
#include "ulp_app_name.h"
// later
void init_ulp_vars() {
  ulp_measurement_count = 64;
}
```

Note that the ULP FSM program can only use the lower 16 bits of each 32-bit word in RTC memory, because the registers are 16-bit, and there is no instruction to load from the high part of the word. Likewise, the ULP store instruction writes register values into the lower 16 bits of the 32-bit word in RTC memory. The upper 16 bits are written with a value which depends on the address of the store instruction, thus when reading variables written by the ULP coprocessor, the main application needs to mask the upper 16 bits, e.g.:

```c
printf("Last measurement value: %d\n", ulp_last_measurement & UINT16_MAX);
```

Starting the ULP FSM Program

To run a ULP FSM program, the main application needs to load the ULP program into RTC memory using the `ulp_load_binary()` function, and then start it using the `ulp_run()` function.

Note that the Enable Ultra Low Power (ULP) Coprocessor option must be enabled in menuconfig to work with ULP. To select the type of ULP to be used, the ULP Co-processor type option must be set. To reserve memory for the ULP, the RTC slow memory reserved for coprocessor option must be set to a value big enough to store ULP code and data. If the application components contain multiple ULP programs, then the size of the RTC memory must be sufficient to hold the largest one.

Each ULP program is embedded into the ESP-IDF application as a binary blob. The application can reference this blob and load it in the following way (suppose ULP_APP_NAME was defined to `ulp_app_name`):

```c
extern const uint8_t bin_start[] asm("_binary_ulp_app_name_bin_start");
extern const uint8_t bin_end[] asm("_binary_ulp_app_name_bin_end");
void start_ulp_program() {
  ESP_ERROR_CHECK( ulp_load_binary( 
      0, /* load address, set to 0 when using default linker scripts */
      bin_start, 
      (bin_end - bin_start) / sizeof(uint32_t) ));
}
```

Once the program is loaded into RTC memory, the application can start it by passing the address of the entry point to the `ulp_run()` function:

```c
ESP_ERROR_CHECK( ulp_run(&ulp_entry - RTC_SLOW_MEM) );
```

Declaration of the entry point symbol comes from the generated header file mentioned above, `${ULP_APP_NAME}.h`. In the assembly source of the ULP FSM application, this symbol must be marked as `.global`.
Chapter 2. API Reference

ESP32 ULP Program Flow

ESP32 ULP coprocessor is started by a timer. The timer is started once `ulp_run()` is called. The timer counts a number of RTC_SLOW_CLK ticks (by default, produced by an internal 150 kHz RC oscillator). The number of ticks is set using `SENS_ULP_CP_SLEEP_CYCx_REG` registers (x = 0..4). When starting the ULP for the first time, `SENS_ULP_CP_SLEEP_CYC0_REG` will be used to set the number of timer ticks. Later the ULP program can select another `SENS_ULP_CP_SLEEP_CYCx_REG` register using `sleep` instruction.

The application can set ULP timer period values (`SENS_ULP_CP_SLEEP_CYCx_REG`, x = 0..4) using `ulp_set_wakeup_period` function.

Once the timer counts the number of ticks set in the selected `SENS_ULP_CP_SLEEP_CYCx_REG` register, ULP coprocessor powers up and starts running the program from the entry point set in the call to `ulp_run()`.

The program runs until it encounters a `halt` instruction or an illegal instruction. Once the program halts the ULP coprocessor powers down and the timer is started again.

To disable the timer (effectively preventing the ULP program from running again), clear the `RTC_CNTL_ULP_CP_SLP_TIMER_EN` bit in the `RTC_CNTL_STATE0_REG` register. This can be done both from ULP code and from the main program.

Application Examples

- ULP FSM Coprocessor counts pulses on an IO while main CPU is in Deep-sleep: `system/ulp/ulp_fsm/ulp`
- ULP FSM Coprocessor polls ADC in while main CPU is in Deep-sleep: `system/ulp/ulp_fsm/ulp_adc`

API Reference

Header File

- `components/ulp/ulp_fsm/include/ulp_fsm_common.h`

This header file can be included with:

```
#include "ulp_fsm_common.h"
```

This header file is a part of the API provided by the `ulp` component. To declare that your component depends on `ulp`, add the following to your CMakelists.txt:

```cmake
REQUIRES ulp
```

or

```cmake
PRIV_REQUIRES ulp
```

Functions

```c
esp_err_t ulp_isr_register (intr_handler_t fn, void *arg)
```

Register ULP wakeup signal ISR.

**Note:** The ISR routine will only be active if the main CPU is not in deepsleep

Parameters

- `fn` - ISR callback function
Chapter 2. API Reference

- **arg** – ISR callback function arguments

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if callback function is NULL
- ESP_ERR_NO_MEM if heap memory cannot be allocated for the interrupt

```c
esp_err_t ulp_isr_deregister(intr_handler_t fn, void *arg)
```
Deregister ULP wakeup signal ISR.

**Parameters**
- `fn` – ISR callback function
- `arg` – ISR callback function arguments

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if callback function is NULL
- ESP_ERR_INVALID_STATE if a handler matching both callback function and its arguments isn’t registered

```c
esp_err_t ulp_process_macros_and_load(uint32_t load_addr, const ulp_insn_t *program, size_t *psize)
```
Resolve all macro references in a program and load it into RTC memory.

**Parameters**
- `load_addr` – address where the program should be loaded, expressed in 32-bit words
- `program` – ulp_insn_t array with the program
- `psize` – size of the program, expressed in 32-bit words

**Returns**
- ESP_OK on success
- ESP_ERR_NO_MEM if auxiliary temporary structure cannot be allocated
- one of ESP_ERR_ULP_xxx if program is not valid or can not be loaded

```c
esp_err_t ulp_load_binary(uint32_t load_addr, const uint8_t* program_binary, size_t program_size)
```
Load ULP program binary into RTC memory.

ULP program binary should have the following format (all values little-endian):

a. MAGIC, (value 0x00706c75, 4 bytes)
b. TEXT_OFFSET, offset of .text section from binary start (2 bytes)
c. TEXT_SIZE, size of .text section (2 bytes)
d. DATA_SIZE, size of .data section (2 bytes)
e. BSS_SIZE, size of .bss section (2 bytes)
f. (TEXT_OFFSET - 12) bytes of arbitrary data (will not be loaded into RTC memory)
g. .text section
h. .data section

Linker script in components/ulp/ld/esp32.ulp.ld produces ELF files which correspond to this format. This linker script produces binaries with load_addr == 0.

**Parameters**
- `load_addr` – address where the program should be loaded, expressed in 32-bit words
- `program_binary` – pointer to program binary
- `program_size` – size of the program binary

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if load_addr is out of range
- ESP_ERR_INVALID_SIZE if program_size doesn’t match (TEXT_OFFSET + TEXT_SIZE + DATA_SIZE)
- ESP_ERR_NOT_SUPPORTED if the magic number is incorrect

```c
esp_err_t ulp_run(uint32_t entry_point)
```
Run the program loaded into RTC memory.

---

Espressif Systems 2469 Release v5.3-dev-277-gc8243465e4 Submit Document Feedback
Chapter 2. API Reference

Parameters entry_point

Parameters entry_point – entry point, expressed in 32-bit words

Returns ESP_OK on success

Macros

ESP_ERR_ULT_BASE

Offset for ULP-related error codes

ESP_ERR_ULT_SIZE_TOO_BIG

Program doesn’t fit into RTC memory reserved for the ULP

ESP_ERR_ULT_INVALID_LOAD_ADDR

Load address is outside of RTC memory reserved for the ULP

ESP_ERR_ULT_DUPLICATE_LABEL

More than one label with the same number was defined

ESP_ERR_ULT_UNDEFINED_LABEL

Branch instructions references an undefined label

ESP_ERR_ULT_BRANCH_OUT_OF_RANGE

Branch target is out of range of B instruction (try replacing with BX)

Type Definitions

typedef union ulp_insn ulpInsn_t

Header File

• components/ulp/ulp_common/include/ulp_common.h

• This header file can be included with:

    #include "ulp_common.h"

• This header file is a part of the API provided by the ulp component. To declare that your component depends on ulp, add the following to your CMakeLists.txt:

    REQUIRES ulp

    or

    PRIV_REQUIRES ulp

Functions

esp_err_t ulp_set_wakeup_period (size_t period_index, uint32_t period_us)

Set one of ULP wakeup period values.

ULP coprocessor starts running the program when the wakeup timer counts up to a given value (called period). There are 5 period values which can be programmed into SENS_ULT_CP_SLEEP_CYCx_REG registers, x = 0..4 for ESP32, and one period value which can be programmed into RTC_CNTL_ULT_CP_TIMER_1_REG register for ESP32-S2/S3. By default, for ESP32, wakeup timer will use the period set into SENS_ULT_CP_SLEEP_CYC0_REG, i.e. period number 0. ULP program code can use SLEEP instruction to select which of the SENS_ULT_CP_SLEEP_CYCx_REG should be used for subsequent wakeups.

However, please note that SLEEP instruction issued (from ULP program) while the system is in deep sleep mode does not have effect, and sleep cycle count 0 is used.
For ESP32-S2/S3 the SLEEP instruction not exist. Instead a WAKE instruction will be used.

**Note:** The ULP FSM requires two clock cycles to wakeup before being able to run the program. Then additional 16 cycles are reserved after wakeup waiting until the 8M clock is stable. The FSM also requires two more clock cycles to go to sleep after the program execution is halted. The minimum wakeup period that may be set up for the ULP is equal to the total number of cycles spent on the above internal tasks. For a default configuration of the ULP running at 150kHz it makes about 133us.

**Parameters**

- **period_index** – wakeup period setting number (0 - 4)
- **period_us** – wakeup period, us

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if period_index is out of range

```c
void ulp_timer_stop (void)
Stop the ULP timer.
```

**Note:** This will stop the ULP from waking up if halted, but will not abort any program currently executing on the ULP.

```c
void ulp_timer_resume (void)
Resume the ULP timer.
```

**Note:** This will resume an already configured timer, but does no other configuration

**Header File**

- components/ulp/ulp_common/include/esp32/ulp_common_defs.h
- This header file can be included with:

  ```c
  #include "ulp_common_defs.h"

  ```cmake
  REQUIRES ulp
  
or
  PRIV_REQUIRES ulp
  ```

**Macros**

**RTC_SLOW_MEM**

RTC slow memory, 8k size

**2.10.33 Watchdogs**
Overview

ESP-IDF supports multiple types of watchdogs:

- Interrupt Watchdog Timer (IWDT)
- Task Watchdog Timer (TWDT)

The Interrupt Watchdog is responsible for ensuring that ISRs (Interrupt Service Routines) are not blocked for a prolonged period of time. The TWDT is responsible for detecting instances of tasks running without yielding for a prolonged period.

The various watchdog timers can be enabled using the Project Configuration Menu. However, the TWDT can also be enabled during runtime.

Interrupt Watchdog Timer (IWDT)

The purpose of the IWDT is to ensure that interrupt service routines (ISRs) are not blocked from running for a prolonged period of time (i.e., the IWDT timeout period). Preventing ISRs from running in a timely manner is undesirable as it can increase ISR latency, and also prevent task switching (as task switching is executed form an ISR). The things that can block ISRs from running include:

- Disabling interrupts
- Critical Sections (also disables interrupts)
- Other same/higher priority ISRs which block same/lower priority ISRs from running

The IWDT utilizes the watchdog timer in Timer Group 1 as its underlying hardware timer and leverages the FreeRTOS tick interrupt on each CPU to feed the watchdog timer. If the tick interrupt on a particular CPU is not run at within the IWDT timeout period, it is indicative that something is blocking ISRs from being run on that CPU (see the list of reasons above).

When the IWDT times out, the default action is to invoke the panic handler and display the panic reason as Interrupt wdt timeout on CPU0 or Interrupt wdt timeout on CPU1 (as applicable). Depending on the panic handler’s configured behavior (see CONFIG_ESP_SYSTEM_PANIC), users can then debug the source of the IWDT timeout (via the backtrace, OpenOCD, gdbstub etc) or simply reset the chip (which may be preferred in a production environment).

If for whatever reason the panic handler is unable to run after an IWDT timeout, the IWDT has a second stage timeout that will hard-reset the chip (i.e., a system reset).

Configuration

- The IWDT is enabled by default via the CONFIG_ESP_INT_WDT option.
- The IWDT’s timeout is configured by setting the CONFIG_ESP_INT_WDT_TIMEOUT_MS option.
  - Note that the default timeout is higher if PSRAM support is enabled, as a critical section or interrupt routine that accesses a large amount of PSRAM takes longer to complete in some circumstances.
  - The timeout should always at least twice longer than the period between FreeRTOS ticks (see CONFIG_FREERTOS_HZ).

Tuning  If you find the IWDT timeout is triggered because an interrupt or critical section is running longer than the timeout period, consider rewriting the code:

- Critical sections should be made as short as possible. Any non-critical code/computation should be placed outside the critical section.
- Interrupt handlers should also perform the minimum possible amount of computation. Users can consider deferring any computation to a task by having the ISR push data to a task using queues.

Neither critical sections or interrupt handlers should ever block waiting for another event to occur. If changing the code to reduce the processing time is not possible or desirable, it is possible to increase the CONFIG_ESP_INT_WDT_TIMEOUT_MS setting instead.
**Task Watchdog Timer (TWDT)**

The Task Watchdog Timer (TWDT) is used to monitor particular tasks, ensuring that they are able to execute within a given timeout period. The TWDT primarily watches the Idle Tasks of each CPU, however any task can subscribe to be watched by the TWDT. By watching the Idle Tasks of each CPU, the TWDT can detect instances of tasks running for a prolonged period of time without yielding. This can be an indicator of poorly written code that spin loops on a peripheral, or a task that is stuck in an infinite loop.

The TWDT is built around the Hardware Watchdog Timer in Timer Group 0. When a timeout occurs, an interrupt is triggered.

Users can define the function `esp_task_wdt_isr_user_handler` in the user code, in order to receive the timeout event and extend the default behavior.

**Usage** The following functions can be used to watch tasks using the TWDT:

- `esp_task_wdt_init()` to initialize the TWDT and subscribe the idle tasks.
- `esp_task_wdt_add()` subscribes other tasks to the TWDT.
- Once subscribed, `esp_task_wdt_reset()` should be called from the task to feed the TWDT.
- `esp_task_wdt_delete()` unsubscribes a previously subscribed task.
- `esp_task_wdt_deinit()` unsubscribes the idle tasks and deinitializes the TWDT.

In the case where applications need to watch at a more granular level (i.e., ensure that a particular function/stub/code-path is called), the TWDT allows subscription of users.

- `esp_task_wdt_add_user()` to subscribe an arbitrary user of the TWDT. This function returns a user handle to the added user.
- `esp_task_wdt_reset_user()` must be called using the user handle in order to prevent a TWDT timeout.
- `esp_task_wdt_delete_user()` unsubscribes an arbitrary user of the TWDT.

**Configuration** The default timeout period for the TWDT is set using config item `CONFIG_ESP_TASK_WDT_TIMEOUT_S`. This should be set to at least as long as you expect any single task needs to monopolize the CPU (for example, if you expect the app will do a long intensive calculation and should not yield to other tasks). It is also possible to change this timeout at runtime by calling `esp_task_wdt_init()`.

**Note:** Erasing large flash areas can be time consuming and can cause a task to run continuously, thus triggering a TWDT timeout. The following two methods can be used to avoid this:

- Increase `CONFIG_ESP_TASK_WDT_TIMEOUT_S` in menuconfig for a larger watchdog timeout period.
- You can also call `esp_task_wdt_init()` to increase the watchdog timeout period before erasing a large flash area.

For more information, you can refer to **SPI Flash API**.

The following config options control TWDT configuration. They are all enabled by default:

- `CONFIG_ESP_TASK_WDT_EN` - enables TWDT feature. If this option is disabled, TWDT cannot be used, even if initialized at runtime.
- `CONFIG_ESP_TASK_WDT_INIT` - the TWDT is initialized automatically during startup. If this option is disabled, it is still possible to initialize the Task WDT at runtime by calling `esp_task_wdt_init()`.
- `CONFIG_ESP_TASK_WDT_CHECK_IDLE_TASK_CPU0` - CPU0 Idle task is subscribed to the TWDT during startup. If this option is disabled, it is still possible to subscribe the idle task by calling `esp_task_wdt_init()` again.
- `CONFIG_ESP_TASK_WDT_CHECK_IDLE_TASK_CPU1` - CPU1 Idle task is subscribed to the TWDT during startup.
Chapter 2. API Reference

**Note:** On a TWDT timeout the default behaviour is to simply print a warning and a backtrace before continuing running the app. If you want a timeout to cause a panic and a system reset then this can be configured through `CONFIG_ESP_TASK_WDT_PANIC`.

**JTAG & Watchdogs**

While debugging using OpenOCD, the CPUs are halted every time a breakpoint is reached. However if the watchdog timers continue to run when a breakpoint is encountered, they will eventually trigger a reset making it very difficult to debug code. Therefore OpenOCD will disable the hardware timers of both the interrupt and task watchdogs at every breakpoint. Moreover, OpenOCD will not reenable them upon leaving the breakpoint. This means that interrupt watchdog and task watchdog functionality will essentially be disabled. No warnings or panics from either watchdogs will be generated when the ESP32 is connected to OpenOCD via JTAG.

**API Reference**

**Task Watchdog** A full example using the Task Watchdog is available in esp-idf: `system/task_watchdog`

**Header File**

- `components/esp_system/include/esp_task_wdt.h`
- This header file can be included with:

```
#include "esp_task_wdt.h"
```

**Functions**

`esp_err_t esp_task_wdt_init (const esp_task_wdt_config_t *config)`

Initialize the Task Watchdog Timer (TWDT)

This function configures and initializes the TWDT. This function will subscribe the idle tasks if configured to do so. For other tasks, users can subscribe them using `esp_task_wdt_add()` or `esp_task_wdt_add_user()`. This function won’t start the timer if no task have been registered yet.

**Note:** `esp_task_wdt_init()` must only be called after the scheduler is started. Moreover, it must not be called by multiple tasks simultaneously.

**Parameters**

- `config` – Configuration structure

**Returns**

- ESP_OK: Initialization was successful
- ESP_ERR_INVALID_STATE: Already initialized
- Other: Failed to initialize TWDT

`esp_err_t esp_task_wdt_reconfigure (const esp_task_wdt_config_t *config)`

Reconfigure the Task Watchdog Timer (TWDT)

The function reconfigures the running TWDT. It must already be initialized when this function is called.

**Note:** `esp_task_wdt_reconfigure()` must not be called by multiple tasks simultaneously.

**Parameters**

- `config` – Configuration structure

**Returns**

- ESP_OK: Reconfiguring was successful
Chapter 2. API Reference

- ESP_ERR_INVALID_STATE: TWDT not initialized yet
- Other: Failed to initialize TWDT

`esp_err_t esp_task_wdt_deinit (void)`

Deinitialize the Task Watchdog Timer (TWDT)

This function will deinitialize the TWDT, and unsubscribe any idle tasks. Calling this function whilst other tasks are still subscribed to the TWDT, or when the TWDT is already deinitialized, will result in an error code being returned.

**Note:** `esp_task_wdt_deinit()` must not be called by multiple tasks simultaneously.

**Returns**
- ESP_OK: TWDT successfully deinitialized
- Other: Failed to deinitialize TWDT

`esp_err_t esp_task_wdt_add (TaskHandle_t task_handle)`

Subscribe a task to the Task Watchdog Timer (TWDT)

This function subscribes a task to the TWDT. Each subscribed task must periodically call `esp_task_wdt_reset()` to prevent the TWDT from elapsing its timeout period. Failure to do so will result in a TWDT timeout.

**Parameters**
- `task_handle` - Handle of the task. Input NULL to subscribe the current running task to the TWDT

**Returns**
- ESP_OK: Successfully subscribed the task to the TWDT
- Other: Failed to subscribe task

`esp_err_t esp_task_wdt_add_user (const char* user_name, esp_task_wdt_user_handle_t* user_handle_ret)`

Subscribe a user to the Task Watchdog Timer (TWDT)

This function subscribes a user to the TWDT. A user of the TWDT is usually a function that needs to run periodically. Each subscribed user must periodically call `esp_task_wdt_reset_user()` to prevent the TWDT from elapsing its timeout period. Failure to do so will result in a TWDT timeout.

**Parameters**
- `user_name` - [in] String to identify the user
- `user_handle_ret` - [out] Handle of the user

**Returns**
- ESP_OK: Successfully subscribed the user to the TWDT
- Other: Failed to subscribe user

`esp_err_t esp_task_wdt_reset (void)`

Reset the Task Watchdog Timer (TWDT) on behalf of the currently running task.

This function will reset the TWDT on behalf of the currently running task. Each subscribed task must periodically call this function to prevent the TWDT from timing out. If one or more subscribed tasks fail to reset the TWDT on their own behalf, a TWDT timeout will occur.

**Returns**
- ESP_OK: Successfully reset the TWDT on behalf of the currently running task
- Other: Failed to reset

`esp_err_t esp_task_wdt_reset_user (esp_task_wdt_user_handle_t user_handle)`

Reset the Task Watchdog Timer (TWDT) on behalf of a user.

This function will reset the TWDT on behalf of a user. Each subscribed user must periodically call this function to prevent the TWDT from timing out. If one or more subscribed users fail to reset the TWDT on their own behalf, a TWDT timeout will occur.
**Parameters**

`user_handle` [in] User handle

- ESP_OK: Successfully reset the TWDT on behalf of the user
- Other: Failed to reset

**esp_err_t** `esp_task_wdt_delete` *(TaskHandle_t task_handle)*

Unsubscribes a task from the Task Watchdog Timer (TWDT)

This function will unsubscribe a task from the TWDT. After being unsubscribed, the task should no longer call `esp_task_wdt_reset()`.

**Parameters**

`task_handle` [in] Handle of the task. Input NULL to unsubscribe the current running task.

**Returns**

- ESP_OK: Successfully unsubscribed the task from the TWDT
- Other: Failed to unsubscribe task

**esp_err_t** `esp_task_wdt_delete_user` *(esp_task_wdt_user_handle_t user_handle)*

Unsubscribes a user from the Task Watchdog Timer (TWDT)

This function will unsubscribe a user from the TWDT. After being unsubscribed, the user should no longer call `esp_task_wdt_reset_user()`.

**Parameters**

`user_handle` [in] User handle

**Returns**

- ESP_OK: Successfully unsubscribed the user from the TWDT
- Other: Failed to unsubscribe user

**esp_err_t** `esp_task_wdt_status` *(TaskHandle_t task_handle)*

Query whether a task is subscribed to the Task Watchdog Timer (TWDT)

This function will query whether a task is currently subscribed to the TWDT, or whether the TWDT is initialized.

**Parameters**

`task_handle` [in] Handle of the task. Input NULL to query the current running task.

**Returns**

- ESP_OK: The task is currently subscribed to the TWDT
- ESP_ERR_NOT_FOUND: The task is not subscribed
- ESP_ERR_INVALID_STATE: TWDT was never initialized

**void** `esp_task_wdt_isr_user_handler` *(void)*

User ISR callback placeholder.

This function is called by `task_wdt_isr` function (ISR for when TWDT times out). It can be defined in user code to handle TWDT events.

---

**Note:** It has the same limitations as the interrupt function. Do not use ESP_LOGx functions inside.

---

**Structures**

**struct** `esp_task_wdt_config_t`

Task Watchdog Timer (TWDT) configuration structure.

**Public Members**

`uint32_t timeout_ms`

TWDT timeout duration in milliseconds
uint32_t idle_core_mask
    Bitmask of the core whose idle task should be subscribed on initialization where \(1 \ll i\) means that core i’s idle task will be monitored by the TWDT

bool trigger_panic
    Trigger panic when timeout occurs

Type Definitions

typedef struct esp_task_wdt_user_handle_s *esp_task_wdt_user_handle_t
    Task Watchdog Timer (TWDT) user handle.
Code examples for this API section are provided in the system directory of ESP-IDF examples.

API Guides

4.1 Application Level Tracing Library

4.1.1 Overview

ESP-IDF provides a useful feature for program behavior analysis: application level tracing. It is implemented in the corresponding library and can be enabled in menuconfig. This feature allows to transfer arbitrary data between host and ESP32 via JTAG, UART, or USB interfaces with small overhead on program execution. It is possible to use JTAG and UART interfaces simultaneously. The UART interface is mostly used for connection with SEGGER SystemView tool (see SystemView).

Developers can use this library to send application-specific state of execution to the host and receive commands or other types of information from the opposite direction at runtime. The main use cases of this library are:

1. Collecting application-specific data. See Application Specific Tracing.
2. Lightweight logging to the host. See Logging to Host.

Tracing components used when working over JTAG interface are shown in the figure below.

4.1.2 Modes of Operation

The library supports two modes of operation:

**Post-mortem mode:** This is the default mode. The mode does not need interaction with the host side. In this mode, tracing module does not check whether the host has read all the data from HW UP BUFFER, but directly overwrites old data with the new ones. This mode is useful when only the latest trace data is interesting to the user, e.g., for analyzing program’s behavior just before the crash. The host can read the data later on upon user request, e.g., via special OpenOCD command in case of working via JTAG interface.

**Streaming mode:** Tracing module enters this mode when the host connects to ESP32. In this mode, before writing new data to HW UP BUFFER, the tracing module checks that whether there is enough space in it and if necessary, waits for the host to read data and free enough memory. Maximum waiting time is controlled via timeout values passed by users to corresponding API routines. So when application tries to write data to the trace buffer using the finite value of the maximum waiting time, it is possible that this data will be dropped. This is especially true for tracing from time critical code (ISRs, OS scheduler code, etc.) where infinite timeouts can lead to system malfunction. In order to avoid loss of such critical data, developers can enable additional data buffering via menuconfig option.
**CONFIG_APPTRACE_PENDING_DATA_SIZE_MAX.** This macro specifies the size of data which can be buffered in above conditions. The option can also help to overcome situation when data transfer to the host is temporarily slowed down, e.g., due to USB bus congestions. But it will not help when the average bit rate of the trace data stream exceeds the hardware interface capabilities.

### 4.1.3 Configuration Options and Dependencies

Using of this feature depends on two components:

1. **Host side:** Application tracing is done over JTAG, so it needs OpenOCD to be set up and running on host machine. For instructions on how to set it up, please see [JTAG Debugging](https:// Espressif Systems 2482 Release v5.3-dev-277-gc8243465e4) for details.

2. **Target side:** Application tracing functionality can be enabled in menuconfig. Please go to Component config > Application Level Tracing menu, which allows selecting destination for the trace data (hardware interface for transport: JTAG or/and UART). Choosing any of the destinations automatically enables the `CONFIG_APPTRACE_ENABLE` option. For UART interfaces, users have to define baud rate, TX and RX pins numbers, and additional UART-related parameters.

**Note:** In order to achieve higher data rates and minimize the number of dropped packets, it is recommended to optimize the setting of JTAG clock frequency, so that it is at maximum and still provides stable operation of JTAG. See [Optimize JTAG Speed](https:// Espressif Systems 2482 Release v5.3-dev-277-gc8243465e4).

There are two additional menuconfig options not mentioned above:

1. **Threshold for flushing last trace data to host on panic (CONFIG_APPTRACE_POSTMORTEM_FLUSH_THRESH).** This option is necessary due to the nature of working over JTAG. In this mode, trace data is exposed to the host in 16 KB blocks. In post-mortem mode, when one block is filled, it is exposed to the host and the previous one becomes unavailable. In other words, the trace data is overwritten in 16 KB granularity. On panic, the latest data from the current input block is exposed to the host and the host can read them for post-analysis. System panic may occur when a very small amount of data are not exposed to the host yet. In this case, the previous 16 KB of collected data will be lost and the host will see the latest, but very small piece of the trace.
It can be insufficient to diagnose the problem. This menuconfig option allows avoiding such situations. It controls the threshold for flushing data in case of panic. For example, users can decide that it needs no less than 512 bytes of the recent trace data, so if there is less then 512 bytes of pending data at the moment of panic, they will not be flushed and will not overwrite the previous 16 KB. The option is only meaningful in post-mortem mode and when working over JTAG.

2. **Timeout for flushing last trace data to host on panic (CONFIG_APPTRACE_ONPANIC_HOST_FLUSH_TMO).** The option is only meaningful in streaming mode and it controls the maximum time that the tracing module will wait for the host to read the last data in case of panic.

3. **UART RX/TX ring buffer size (CONFIG_APPTRACE_UART_TX_BUFF_SIZE).** The size of the buffer depends on the amount of data transferred through the UART.

4. **UART TX message size (CONFIG_APPTRACE_UART_TX_MSG_SIZE).** The maximum size of the single message to transfer.

### 4.1.4 How to Use This Library

This library provides APIs for transferring arbitrary data between the host and ESP32. When enabled in menuconfig, the target application tracing module is initialized automatically at the system startup, so all what the user needs to do is to call corresponding APIs to send, receive or flush the data.

#### Application Specific Tracing

In general, users should decide what type of data should be transferred in every direction and how these data must be interpreted (processed). The following steps must be performed to transfer data between the target and the host:

1. **On the target side,** users should implement algorithms for writing trace data to the host. Piece of code below shows an example on how to do this.

   ```c
   #include "esp_app_trace.h"
   ...
   char buf[] = "Hello World!";
   esp_err_t res = esp_apptrace_write(ESP_APPTRACE_DEST_TRAX, buf,
   strlen(buf), ESP_APPTRACE_TMO_INFINITE);
   if (res != ESP_OK) {
     ESP_LOGE(TAG, "Failed to write data to host!");
     return res;
   }
   
   esp_apptrace_write() function uses memcpy to copy user data to the internal buffer. In some cases, it can be more optimal to use esp_apptrace_buffer_get() and esp_apptrace_buffer_put() functions. They allow developers to allocate buffer and fill it themselves. The following piece of code shows how to do this.

   ```c
   #include "esp_app_trace.h"
   ...
   int number = 10;
   char *ptr = (char *)esp_apptrace_buffer_get(ESP_APPTRACE_DEST_TRAX, 32,
   100/"tmo in us"/);
   if (ptr == NULL) {
     ESP_LOGE(TAG, "Failed to get buffer!");
     return ESP_FAIL;
   }
   
   sprintf(ptr, "Here is the number %d", number);
   esp_err_t res = esp_apptrace_buffer_put(ESP_APPTRACE_DEST_TRAX, ptr,
   100/"tmo in us"/);
   if (res != ESP_OK) {
     /* in case of error host tracing tool (e.g., OpenOCD) will report...
     incomplete user buffer */
     ESP_LOGE(TAG, "Failed to put buffer!");
     return res;
   }
   ```

Espressif Systems 2483 Release v5.3-dev-277-gc8243465e4

Submit Document Feedback
Also according to his needs, the user may want to receive data from the host. Piece of code below shows an example on how to do this.

```c
#include "esp_app_trace.h"
...
char buf[32];
char down_buf[32];
sizet sz = sizeof(buf);

/* config down buffer */
esp_apptrace_down_buffer_config(down_buf, sizeof(down_buf));
/* check for incoming data and read them if any */
esp_err_t res = esp_apptrace_read(ESP_APPTRACE_DEST_TRAX, buf, &sz, 0/
"do not wait");
if (res != ESP_OK) {
    ESP_LOGE(TAG, "Failed to read data from host!");
    return res;
}
if (sz > 0) {
    /* we have data, process them */
    ...
}
```

The `esp_apptrace_read()` function uses `memcpy` to copy host data to user buffer. In some casesm it can be more optimal to use `esp_apptrace_down_buffer_get()` and `esp_apptrace_down_buffer_put()` functions. They allow developers to occupy chunk of read buffer and process it in-place. The following piece of code shows how to do this.

```c
#include "esp_app_trace.h"
...
char down_buf[32];
uint32_t *number;
sizet sz = 32;

/* config down buffer */
esp_apptrace_down_buffer_config(down_buf, sizeof(down_buf));
char *ptr = (char *)esp_apptrace_down_buffer_get(ESP_APPTRACE_DEST__
TRAX, &sz, 100/*tmo in us*/);
if (ptr == NULL) {
    ESP_LOGE(TAG, "Failed to get buffer!");
    return ESP_FAIL;
}
if (sz > 4) {
    number = (uint32_t *)ptr;
    printf("Here is the number %d", *number);
} else {
    printf("No data");
}
esp_err_t res = esp_apptrace_down_buffer_put(ESP_APPTRACE_DEST_TRAX,
"ptr, 100/*tmo in us*/");
if (res != ESP_OK) {
    /* in case of error host tracing tool (e.g., OpenOCD) will report
    incomplete user buffer */
    ESP_LOGE(TAG, "Failed to put buffer!");
    return res;
}
```

2. The next step is to build the program image and download it to the target as described in the Getting Started Guide.
3. Run OpenOCD (see JTAG Debugging).
4. Connect to OpenOCD telnet server. It can be done using the following command in terminal `telnet <oocd_host> 4444`. If telnet session is opened on the same machine which runs OpenOCD, you can use `localhost` as `<oocd_host>` in the command above.
5. Start trace data collection using special OpenOCD command. This command will transfer tracing data and 
redirect them to the specified file or socket (currently only files are supported as trace data destination). For 
description of the corresponding commands, see OpenOCD Application Level Tracing Commands.
6. The final step is to process received data. Since the format of data is defined by users, the processing stage is out 
of the scope of this document. Good starting points for data processor are python scripts in $IDF_PATH/
tools/esp_app_trace: apptrace_proc.py (used for feature tests) and logtrace_proc.py 
(see more details in section Logging to Host).

OpenOCD Application Level Tracing Commands  HW UP BUFFER is shared between user data blocks and the 
filling of the allocated memory is performed on behalf of the API caller (in task or ISR context). In multithreading 
environment, it can happen that the task/ISR which fills the buffer is preempted by another high priority task/ISR. 
So it is possible that the user data preparation process is not completed at the moment when that chunk is read by 
the host. To handle such conditions, the tracing module prepends all user data chunks with header which contains 
the allocated user buffer size (2 bytes) and the length of the actually written data (2 bytes). So the total length of 
the header is 4 bytes. OpenOCD command which reads trace data reports error when it reads incomplete user data 
chunk, but in any case, it puts the contents of the whole user chunk (including unfilled area) to the output file.

Below is the description of available OpenOCD application tracing commands.

**Note:** Currently, OpenOCD does not provide commands to send arbitrary user data to the target.

Command usage:

```
esp aptrace [start <options>] | [stop] | [status] | [dump <cores_num> <outfile>]
```

Sub-commands:

- **start**  Start tracing (continuous streaming).
- **stop** Stop tracing.
- **status** Get tracing status.
- **dump** Dump all data from (post-mortem dump).

Start command syntax:

```
start <outfile> [poll_period [trace_size [stop_tmo [wait4halt  
[skip_size]]]]]
```

- **outfile**  Path to file to save data from both CPUs. This argument should have the following format: file:// 
  path/to/file.
- **poll_period**  Data polling period (in ms) for available trace data. If greater than 0, then command runs in non- 
  blocking mode. By default, 1 ms.
- **trace_size**  Maximum size of data to collect (in bytes). Tracing is stopped after specified amount of data is 
  received. By default, -1 (trace size stop trigger is disabled).
- **stop_tmo**  Idle timeout (in sec). Tracing is stopped if there is no data for specified period of time. By default, -1 
  (disable this stop trigger). Optionally set it to value longer than longest pause between tracing commands from 
  target.
- **wait4halt**  If 0, start tracing immediately, otherwise command waits for the target to be halted (after reset, by 
  breakpoint etc.) and then automatically resumes it and starts tracing. By default, 0.
- **skip_size**  Number of bytes to skip at the start. By default, 0.

**Note:** If poll_period is 0, OpenOCD telnet command line will not be available until tracing is stopped. You 
must stop it manually by resetting the board or pressing Ctrl+C in OpenOCD window (not one with the telnet session). 
Another option is to set trace_size and wait until this size of data is collected. At this point, tracing stops 
automatically.

Command usage examples:
Chapter 4. API Guides

1. Collect 2048 bytes of tracing data to the file `trace.log`. The file will be saved in the `openocd-esp32` directory.

   ```
   esp aptrace start file://trace.log 1 2048 5 0 0
   ```

   The tracing data will be retrieved and saved in non-blocking mode. This process will stop automatically after 2048 bytes are collected, or if no data are available for more than 5 seconds.

   **Note:** Tracing data is buffered before it is made available to OpenOCD. If you see “Data timeout!” message, then it is likely that the target is not sending enough data to empty the buffer to OpenOCD before the timeout. Either increase the timeout or use the function `esp_aptrace_flush()` to flush the data on specific intervals.

2. Retrieve tracing data indefinitely in non-blocking mode.

   ```
   esp aptrace start file://trace.log 1 -1 -1 0 0
   ```

   There is no limitation on the size of collected data and there is no data timeout set. This process may be stopped by issuing `esp aptrace stop` command on OpenOCD telnet prompt, or by pressing Ctrl+C in OpenOCD window.

3. Retrieve tracing data and save them indefinitely.

   ```
   esp aptrace start file://trace.log 0 -1 -1 0 0
   ```

   OpenOCD telnet command line prompt will not be available until tracing is stopped. To stop tracing, press Ctrl+C in the OpenOCD window.

4. Wait for the target to be halted. Then resume the target’s operation and start data retrieval. Stop after collecting 2048 bytes of data:

   ```
   esp aptrace start file://trace.log 0 2048 -1 1 0
   ```

   To configure tracing immediately after reset, use the OpenOCD `reset halt` command.

**Logging to Host**

ESP-IDF implements a useful feature: logging to the host via application level tracing library. This is a kind of semihosting when all `ESP_LOGx` calls send strings to be printed to the host instead of UART. This can be useful because “printing to host” eliminates some steps performed when logging to UART. Most part of the work is done on the host.

By default, ESP-IDF’s logging library uses `vprintf`-like function to write formatted output to dedicated UART. In general, it involves the following steps:

1. Format string is parsed to obtain type of each argument.
2. According to its type, every argument is converted to string representation.
3. Format string combined with converted arguments is sent to UART.

Though the implementation of the `vprintf`-like function can be optimized to a certain level, all steps above have to be performed in any case and every step takes some time (especially item 3). So it frequently occurs that with additional log added to the program to identify the problem, the program behavior is changed and the problem cannot be reproduced. And in the worst cases, the program cannot work normally at all and ends up with an error or even hangs.

Possible ways to overcome this problem are to use higher UART bitrates (or another faster interface) and/or to move string formatting procedure to the host.

The application level tracing feature can be used to transfer log information to the host using `esp_aptrace_vprintf` function. This function does not perform full parsing of the format string and arguments. Instead, it just calculates the number of arguments passed and sends them along with the format string address to the host. On the host, log data is processed and printed out by a special Python script.

**Limitations** Current implementation of logging over JTAG has some limitations:
Chapter 4. API Guides

1. No support for tracing from ESP_EARLY_LOGx macros.
2. No support for printf arguments whose size exceeds 4 bytes (e.g., `double` and `uint64_t`).
3. Only strings from the .rodata section are supported as format strings and arguments.
4. The maximum number of printf arguments is 256.

**How To Use It**

In order to use logging via trace module, users need to perform the following steps:

1. On the target side, the special vprintf-like function `esp_apptrace_vprintf()` needs to be installed. It sends log data to the host. An example is `esp_log_set_vprintf(esp_apptrace_vprintf);`. To send log data to UART again, use `esp_log_set_vprintf(vprintf);`.
2. Follow instructions in items 2-5 in Application Specific Tracing.
3. To print out collected log records, run the following command in terminal:
   ```
   $IDF_PATH/tools/esp_app_trace/logtrace_proc.py /path/to/trace/file /path/to/program/elf/file.
   ```

**Log Trace Processor Command Options**

Command usage:

```logtrace_proc.py [-h] [--no-errors] <trace_file> <elf_file>```

Positional arguments:

- `trace_file` Path to log trace file.
- `elf_file` Path to program ELF file.

Optional arguments:

- `-h, --help` Show this help message and exit.
- `--no-errors, -n` Do not print errors.

**System Behavior Analysis with SEGGER SystemView**

Another useful ESP-IDF feature built on top of application tracing library is the system level tracing which produces traces compatible with SEGGER SystemView tool (see SystemView). SEGGER SystemView is a real-time recording and visualization tool that allows to analyze runtime behavior of an application. It is possible to view events in real-time through the UART interface.

**How To Use It**

Support for this feature is enabled by `Component config > Application Level Tracing > FreeRTOS SystemView Tracing (CONFIG_APPTRACE_SV_ENABLE)` menuconfig option. There are several other options enabled under the same menu:

1. SystemView destination. Select the destination interface: JTAG or UART. In case of UART, it will be possible to connect SystemView application to the ESP32 directly and receive data in real-time.
2. ESP32 timer to use as SystemView timestamp source: (`CONFIG_APPTRACE_SV_TS_SOURCE`) selects the source of timestamps for SystemView events. In the single core mode, timestamps are generated using ESP32 internal cycle counter running at maximum 240 Mhz (about 4 ns granularity). In the dual-core mode, external timer working at 40 MHz is used, so the timestamp granularity is 25 ns.
3. Individually enabled or disabled collection of SystemView events (`CONFIG_APPTRACE_SV_EVT_XXX`):
   - Trace Buffer Overflow Event
   - ISR Enter Event
   - ISR Exit Event
   - ISR Exit to Scheduler Event
   - Task Start Execution Event
   - Task Stop Execution Event
   - Task Start Ready State Event
   - Task Stop Ready State Event
   - Task Create Event
   - Task Terminate Event
   - System Idle Event
   - Timer Enter Event
• Timer Exit Event

ESP-IDF has all the code required to produce SystemView compatible traces, so users can just configure necessary project options (see above), build, download the image to target, and use OpenOCD to collect data as described in the previous sections.

4. Select Pro or App CPU in menuconfig options Component config > Application Level Tracing > FreeRTOS SystemView Tracing to trace over the UART interface in real-time.

**OpenOCD SystemView Tracing Command Options**

Command usage:

```plaintext
esp sysview [start <options>] | [stop] | [status]
```

Sub-commands:

- **start** Start tracing (continuous streaming).
- **stop** Stop tracing.
- **status** Get tracing status.

Start command syntax:

```plaintext
start <outfile1> [outfile2] [poll_period [trace_size [stop_tmo]]]
```

- **outfile1** Path to file to save data from PRO CPU. This argument should have the following format: `file://path/to/file`.
- **outfile2** Path to file to save data from APP CPU. This argument should have the following format: `file://path/to/file`.
- **poll_period** Data polling period (in ms) for available trace data. If greater than 0, then command runs in non-blocking mode. By default, 1 ms.
- **trace_size** Maximum size of data to collect (in bytes). Tracing is stopped after specified amount of data is received. By default, -1 (trace size stop trigger is disabled).
- **stop_tmo** Idle timeout (in sec). Tracing is stopped if there is no data for specified period of time. By default, -1 (disable this stop trigger).

**Note:** If **poll_period** is 0, OpenOCD telnet command line will not be available until tracing is stopped. You must stop it manually by resetting the board or pressing Ctrl+C in the OpenOCD window (not the one with the telnet session). Another option is to set **trace_size** and wait until this size of data is collected. At this point, tracing stops automatically.

Command usage examples:

1. Collect SystemView tracing data to files `pro-cpu.SVDat` and `app-cpu.SVDat`. The files will be saved in openocd-esp32 directory.

   ```plaintext
   esp sysview start file://pro-cpu.SVDat file://app-cpu.SVDat
   ```

   The tracing data will be retrieved and saved in non-blocking mode. To stop this process, enter `esp sysview stop` command on OpenOCD telnet prompt, optionally pressing Ctrl+C in the OpenOCD window.

2. Retrieve tracing data and save them indefinitely.

   ```plaintext
   esp sysview start file://pro-cpu.SVDat file://app-cpu.SVDat 0 -1 -1
   ```

   OpenOCD telnet command line prompt will not be available until tracing is stopped. To stop tracing, press Ctrl+C in the OpenOCD window.

**Data Visualization**

After trace data are collected, users can use a special tool to visualize the results and inspect behavior of the program.

Unfortunately, SystemView does not support tracing from multiple cores. So when tracing from ESP32 with JTAG interfaces in the dual-core mode, two files are generated: one for PRO CPU and another for APP CPU. Users can load each file into separate instances of the tool. For tracing over UART, users can select Component config
Chapter 4. API Guides

> Application Level Tracing > FreeRTOS SystemView Tracing in menuconfig Pro or App to choose which CPU has to be traced.

It is uneasy and awkward to analyze data for every core in separate instance of the tool. Fortunately, there is an Eclipse plugin called Impulse which can load several trace files, thus making it possible to inspect events from both cores in one view. Also, this plugin has no limitation of 1,000,000 events as compared to the free version of SystemView.

Good instructions on how to install, configure, and visualize data in Impulse from one core can be found here.

**Note:** ESP-IDF uses its own mapping for SystemView FreeRTOS events IDs, so users need to replace the original file mapping `$SYSVIEW_INSTALL_DIR/Description/SYSVIEW_FreeRTOS.txt` with `$IDF_PATH/tools/esp_app_trace/SYSVIEW_FreeRTOS.txt`. Also, contents of that ESP-IDF-specific file should be used when configuring SystemView serializer using the above link.

---

**Configure Impulse for Dual Core Traces**  
After installing Impulse and ensuring that it can successfully load trace files for each core in separate tabs, users can add special Multi Adapter port and load both files into one view. To do this, users need to do the following steps in Eclipse:

1. Open the Signal Ports view. Go to Windows > Show View > Other menu. Find the Signal Ports view in Impulse folder and double-click it.
2. In the Signal Ports view, right-click Ports and select Add > New Multi Adapter Port.
3. In the open dialog box, click Add and select New Pipe/File.
4. In the open dialog box, select SystemView Serializer as Serializer and set path to PRO CPU trace file. Click OK.
5. Repeat the steps 3-4 for APP CPU trace file.
6. Double-click the created port. View for this port should open.
7. Click the Start/Stop Streaming button. Data should be loaded.
8. Use the Zoom Out, Zoom In and Zoom Fit buttons to inspect data.
9. For settings measurement cursors and other features, please see Impulse documentation).

**Note:** If you have problems with visualization (no data is shown or strange behaviors of zoom action are observed), you can try to delete current signal hierarchy and double-click on the necessary file or port. Eclipse will ask you to create a new signal hierarchy.

---

**Gcov (Source Code Coverage)**

**Basics of Gcov and Gcovr**  
Source code coverage is data indicating the count and frequency of every program execution path that has been taken within a program’s runtime. *Gcov* is a GCC tool that, when used in concert with the compiler, can generate log files indicating the execution count of each line of a source file. The *Gcovr* tool is a utility for managing Gcov and generating summarized code coverage results.

Generally, using Gcov to compile and run programs on the host will undergo these steps:

1. Compile the source code using GCC with the --coverage option enabled. This will cause the compiler to generate a .gcno notes files during compilation. The notes files contain information to reconstruct execution path block graphs and map each block to source code line numbers. Each source file compiled with the --coverage option should have their own .gcno file of the same name (e.g., a main.c will generate a main.gcno when compiled).
2. Execute the program. During execution, the program should generate .gcda data files. These data files contain the counts of the number of times an execution path was taken. The program will generate a .gcda file for each source file compiled with the --coverage option (e.g., main.c will generate a main.gcda).
3. Gcov or Gcovr can be used to generate a code coverage report based on the .gcno, .gcda, and source files. Gcov will generate a text-based coverage report for each source file in the form of a .gcov file, whilst Gcovr will generate a coverage report in HTML format.
Gcov and Gcovr in ESP-IDF

Using Gcov in ESP-IDF is complicated due to the fact that the program is running remotely from the host (i.e., on the target). The code coverage data (i.e., the .gcda files) is initially stored on the target itself. OpenOCD is then used to dump the code coverage data from the target to the host via JTAG during runtime. Using Gcov in ESP-IDF can be split into the following steps.

1. Setting Up a Project for Gcov
2. Dumping Code Coverage Data
3. Generating Coverage Report

Setting Up a Project for Gcov

Compiler Option

In order to obtain code coverage data in a project, one or more source files within the project must be compiled with the --coverage option. In ESP-IDF, this can be achieved at the component level or the individual source file level:

- To cause all source files in a component to be compiled with the --coverage option, you can add `target_compile_options(${COMPONENT_LIB} PRIVATE --coverage)` to the CMakeLists.txt file of the component.
- To cause a select number of source files (e.g., `source1.c` and `source2.c`) in the same component to be compiled with the --coverage option, you can add `set_source_files_properties(source1.c source2.c PROPERTIES COMPILE_FLAGS --coverage)` to the CMakeLists.txt file of the component.

When a source file is compiled with the --coverage option (e.g., `gcov_example.c`), the compiler will generate the `gcov_example.gcno` file in the project’s build directory.

Project Configuration

Before building a project with source code coverage, make sure that the following project configuration options are enabled by running `idf.py menuconfig`.

- Enable the application tracing module by selecting Trace Memory for the `CONFIG_APPTRACE_DESTINATION1` option.
- Enable Gcov to the host via the `CONFIG_APPTRACE_GCOV_ENABLE` option.

Dumping Code Coverage Data

Once a project has been compiled with the --coverage option and flashed onto the target, code coverage data will be stored internally on the target (i.e., in trace memory) whilst the application runs. The process of transferring code coverage data from the target to the host is known as dumping.

The dumping of coverage data is done via OpenOCD (see JTAG Debugging on how to setup and run OpenOCD). A dump is triggered by issuing commands to OpenOCD, therefore a telnet session to OpenOCD must be opened to issue such commands (run `telnet localhost 4444`). Note that GDB could be used instead of telnet to issue commands to OpenOCD, however all commands issued from GDB will need to be prefixed as `mon <oocd_command>`.

When the target dumps code coverage data, the `.gcda` files are stored in the project’s build directory. For example, if `gcov_example_main.c` of the main component is compiled with the --coverage option, then dumping the code coverage data would generate a `gcov_example_main.gcda` in `build/esp-idf/main/CMakeFiles/__idf_main.dir/gcov_example_main.c.gcda`. Note that the `.gcno` files produced during compilation are also placed in the same directory.

The dumping of code coverage data can be done multiple times throughout an application’s lifetime. Each dump will simply update the `.gcda` file with the newest code coverage information. Code coverage data is accumulative, thus the newest data will contain the total execution count of each code path over the application’s entire lifetime.

ESP-IDF supports two methods of dumping code coverage data form the target to the host:

- Instant Run-Time Dumpgit
- Hard-coded Dump
**Instant Run-Time Dump**  An Instant Run-Time Dump is triggered by calling the ESP32 `gcov` OpenOCD command (via a telnet session). Once called, OpenOCD will immediately preempt the ESP32’s current state and execute a built-in ESP-IDF Gcov debug stub function. The debug stub function will handle the dumping of data to the host. Upon completion, the ESP32 will resume its current state.

**Hard-coded Dump**  A Hard-coded Dump is triggered by the application itself by calling `esp_gcov_dump()` from somewhere within the application. When called, the application will halt and wait for OpenOCD to connect and retrieve the code coverage data. Once `esp_gcov_dump()` is called, the host must execute the `esp gcov dump` OpenOCD command (via a telnet session). The `esp gcov dump` command will cause OpenOCD to connect to the ESP32, retrieve the code coverage data, then disconnect from the ESP32, thus allowing the application to resume. Hard-coded Dumps can also be triggered multiple times throughout an application’s lifetime.

Hard-coded Dumps are useful if code coverage data is required at certain points of an application’s lifetime by placing `esp_gcov_dump()` where necessary (e.g., after application initialization, during each iteration of an application’s main loop).

GDB can be used to set a breakpoint on `esp_gcov_dump()`, then call `mon esp gcov dump` automatically via the use a gdbinit script (see Using GDB from Command Line).

The following GDB script will add a breakpoint at `esp_gcov_dump()`, then call the `mon esp gcov dump` OpenOCD command.

```plaintext
b esp_gcov_dump
commands
mon esp gcov dump
end
```

**Note:** Note that all OpenOCD commands should be invoked in GDB as: `mon <oocd_command>`.

**Generating Coverage Report**  Once the code coverage data has been dumped, the `.gcno`, `.gcda` and the source files can be used to generate a code coverage report. A code coverage report is simply a report indicating the number of times each line in a source file has been executed.

Both Gcov and Gcovr can be used to generate code coverage reports. Gcov is provided along with the Xtensa toolchain, whilst Gcovr may need to be installed separately. For details on how to use Gcov or Gcovr, refer to Gcov documentation and Gcovr documentation.

**Adding Gcovr Build Target to Project**  To make report generation more convenient, users can define additional build targets in their projects such that the report generation can be done with a single build command.

Add the following lines to the CMakeLists.txt file of your project.

```plaintext
include($ENV{IDF_PATH}/tools/cmake/gcov.cmake)
idf_create_coverage_report(${CMAKE_CURRENT_BINARY_DIR}/coverage_report)
idf_clean_coverage_report(${CMAKE_CURRENT_BINARY_DIR}/coverage_report)
```

The following commands can now be used:
- `cmake --build build/ --target gcovr-report` will generate an HTML coverage report in
  `$BUILDDIR_BASE/coverage_report/html` directory.
- `cmake --build build/ --target cov-data-clean` will remove all coverage data files.

### 4.2 Application Startup Flow

This note explains various steps which happen before `app_main` function of an ESP-IDF application is called.
The high level view of startup process is as follows:

1. **First Stage Bootloader** in ROM loads second-stage bootloader image to RAM (IRAM & DRAM) from flash offset 0x1000.
2. **Second Stage Bootloader** loads partition table and main app image from flash. Main app incorporates both RAM segments and read-only segments mapped via flash cache.
3. **Application Startup** executes. At this point the second CPU and RTOS scheduler are started.

This process is explained in detail in the following sections.

### 4.2.1 First Stage Bootloader

After SoC reset, PRO CPU will start running immediately, executing reset vector code, while APP CPU will be held in reset. During startup process, PRO CPU does all the initialization. APP CPU reset is de-asserted in the call_start_cpu0 function of application startup code. Reset vector code is located in the mask ROM of the ESP32 chip and cannot be modified.

Startup code called from the reset vector determines the boot mode by checking GPIO Strap register for bootstrap pin states. Depending on the reset reason, the following takes place:

1. **Reset from deep sleep**: if the value in RTC_CNTL_STORE6_REG is non-zero, and CRC value of RTC memory in RTC_CNTL_STORE7_REG is valid, use RTC_CNTL_STORE6_REG as an entry point address and jump immediately to it. If RTC_CNTL_STORE6_REG is zero, or RTC_CNTL_STORE7_REG contains invalid CRC, or once the code called via RTC_CNTL_STORE6_REG returns, proceed with boot as if it was a power-on reset. **Note**: to run customized code at this point, a deep sleep stub mechanism is provided. Please see deep sleep documentation for this.

2. **For power-on reset, software SoC reset, and watchdog SoC reset**: check the GPIO Strap register if a custom boot mode (such as UART Download Mode) is requested. If this is the case, this custom loader mode is executed from ROM. Otherwise, proceed with boot as if it was due to software CPU reset. Consult ESP32 datasheet for a description of SoC boot modes and how to execute them.

3. **For software CPU reset and watchdog CPU reset**: configure SPI flash based on EFUSE values, and attempt to load the code from flash. This step is described in more detail in the next paragraphs.

**Note**: During normal boot modes the RTC watchdog is enabled when this happens, so if the process is interrupted or stalled then the watchdog will reset the SOC automatically and repeat the boot process. This may cause the SoC to strap into a new boot mode, if the strapping GPIOs have changed.

Second stage bootloader binary image is loaded from flash starting at address 0x1000. If Secure Boot is in use then the first 4 KB sector of flash is used to store secure boot IV and digest of the bootloader image. Otherwise, this sector is unused.

### 4.2.2 Second Stage Bootloader

In ESP-IDF, the binary image which resides at offset 0x1000 in flash is the second stage bootloader. Second stage bootloader source code is available in components/bootloader directory of ESP-IDF. Second stage bootloader is used in ESP-IDF to add flexibility to flash layout (using partition tables), and allow for various flows associated with flash encryption, secure boot, and over-the-air updates (OTA) to take place.

When the first stage bootloader is finished checking and loading the second stage bootloader, it jumps to the second stage bootloader entry point found in the binary image header.

Second stage bootloader reads the partition table found by default at offset 0x8000 (configurable value). See partition tables documentation for more information. The bootloader finds factory and OTA app partitions. If OTA app partitions are found in the partition table, the bootloader consults the odata partition to determine which one should be booted. See Over The Air Updates (OTA) for more information.

For a full description of the configuration options available for the ESP-IDF bootloader, see **Bootloader**.
For the selected partition, second stage bootloader reads the binary image from flash one segment at a time:

- For segments with load addresses in internal IRAM (Instruction RAM) or DRAM (Data RAM), the contents are copied from flash to the load address.
- For segments which have load addresses in DROM (Data Stored in flash) or IROM (Code Executed from flash) regions, the flash MMU is configured to provide the correct mapping from the flash to the load address.

Note that the second stage bootloader configures flash MMU for both PRO and APP CPUs, but it only enables flash MMU for PRO CPU. Reason for this is that second stage bootloader code is loaded into the memory region used by APP CPU cache. The duty of enabling cache for APP CPU is passed on to the application.

Once all segments are processed - meaning code is loaded and flash MMU is set up, second stage bootloader verifies the integrity of the application and then jumps to the application entry point found in the binary image header.

### 4.2.3 Application Startup

Application startup covers everything that happens after the app starts executing and before the app_main function starts running inside the main task. This is split into three stages:

- Port initialization of hardware and basic C runtime environment.
- System initialization of software services and FreeRTOS.
- Running the main task and calling app_main.

**Note:** Understanding all stages of ESP-IDF app initialization is often not necessary. To understand initialization from the application developer’s perspective only, skip forward to Running the Main Task.

#### Port Initialization

ESP-IDF application entry point is call_start_cpu0 function found in components/esp_system/port/cpu_start.c. This function is executed by the second stage bootloader, and never returns.

This port-layer initialization function initializes the basic C Runtime Environment ("CRT") and performs initial configuration of the SoC’s internal hardware:

- Reconfigure CPU exceptions for the app (allowing app interrupt handlers to run, and causing Fatal Errors to be handled using the options configured for the app rather than the simpler error handler provided by ROM).
- If the option CONFIG_BOOTLOADER_WDT_ENABLE is not set then the RTC watchdog timer is disabled.
- Initialize internal memory (data & bss).
- Finish configuring the MMU cache.
- Enable PSRAM if configured.
- Set the CPU clocks to the frequencies configured for the project.
- Reconfigure the main SPI flash based on the app header settings (necessary for compatibility with bootloader versions before ESP-IDF V4.0, see Bootloader Compatibility).
- If the app is configured to run on multiple cores, start the other core and wait for it to initialize as well (inside the similar “port layer” initialization function call_start_cpu1).

Once call_start_cpu0 completes running, it calls the “system layer” initialization function start_cpu0 found in components/esp_system/startup.c. Other cores will also complete port-layer initialization and call start_other_cores found in the same file.

#### System Initialization

The main system initialization function is start_cpu0. By default, this function is weak-linked to the function start_cpu0_default. This means that it is possible to override this function to add some additional initialization steps.

The primary system initialization stage includes:
• Log information about this application (project name, App Version, etc.) if default log level enables this.
• Initialize the heap allocator (before this point all allocations must be static or on the stack).
• Initialize newlib component syscalls and time functions.
• Configure the brownout detector.
• Setup libc stdin, stdout, and stderr according to the serial console configuration.
• Perform any security-related checks, including burning efuses that should be burned for this configuration (including disabling ROM download mode on ESP32 V3, CONFIG_ESP32_DISABLE_BASIC_ROM_CONSOLE).
• Initialize SPI flash API support.
• Call global C++ constructors and any C functions marked with __attribute__((constructor)).

Secondary system initialization allows individual components to be initialized. If a component has an initialization function annotated with the ESP_SYSTEM_INIT_FN macro, it will be called as part of secondary initialization. Component initialization functions have priorities assigned to them to ensure the desired initialization order. The priorities are documented in esp_system/system_init_fn.txt and ESP_SYSTEM_INIT_FN definition in source code are checked against this file.

Running the Main Task

After all other components are initialized, the main task is created and the FreeRTOS scheduler starts running.

After doing some more initialization tasks (that require the scheduler to have started), the main task runs the application-provided function app_main in the firmware.

The main task that runs app_main has a fixed RTOS priority (one higher than the minimum) and a configurable stack size.

The main task core affinity is also configurable: CONFIG_ESP_MAIN_TASK_AFFINITY.

Unlike normal FreeRTOS tasks (or embedded C main functions), the app_main task is allowed to return. If this happens, The task is cleaned up and the system will continue running with other RTOS tasks scheduled normally. Therefore, it is possible to implement app_main as either a function that creates other application tasks and then returns, or as a main application task itself.

Second Core Startup

A similar but simpler startup process happens on the APP CPU:

When running system initialization, the code on PRO CPU sets the entry point for APP CPU, de-asserts APP CPU reset, and waits for a global flag to be set by the code running on APP CPU, indicating that it has started. Once this is done, APP CPU jumps to call_start_cpu1 function in components/esp_system/port/cpu_start.c.

While PRO CPU does initialization in start_cpu0 function, APP CPU runs start_cpu_other_cores function. Similar to start_cpu0, this function is weak-linked and defaults to the start_cpu_other_cores_default function but can be replaced with a different function by the application.

The start_cpu_other_cores_default function does some core-specific system initialization and then waits for the PRO CPU to start the FreeRTOS scheduler, at which point it executes esp_startup_start_app_other_cores which is another weak-linked function defaulting to esp_startup_start_app_other_cores_default.

By default esp_startup_start_app_other_cores_default does nothing but spin in a busy-waiting loop until the scheduler of the PRO CPU triggers an interrupt to start the RTOS scheduler on the APP CPU.

4.3 BluFi
4.3.1 Overview

The BluFi for ESP32 is a Wi-Fi network configuration function via Bluetooth channel. It provides a secure protocol to pass Wi-Fi configuration and credentials to ESP32. Using this information, ESP32 can then connect to an AP or establish a SoftAP.

Fragmenting, data encryption, and checksum verification in the BluFi layer are the key elements of this process. You can customize symmetric encryption, asymmetric encryption, and checksum support customization. Here we use the DH algorithm for key negotiation, 128-AES algorithm for data encryption, and CRC16 algorithm for checksum verification.

4.3.2 The BluFi Flow

The BluFi networking flow includes the configuration of the SoftAP and Station.

The following uses Station as an example to illustrate the core parts of the procedure, including broadcast, connection, service discovery, negotiation of the shared key, data transmission, and connection status backhaul.

1. Set the ESP32 into GATT Server mode and then it will send broadcasts with specific advertising data. You can customize this broadcast as needed, which is not a part of the BluFi Profile.
2. Use the App installed on the mobile phone to search for this particular broadcast. The mobile phone will connect to ESP32 as the GATT Client once the broadcast is confirmed. The App used during this part is up to you.
3. After the GATT connection is successfully established, the mobile phone will send a data frame for key negotiation to ESP32 (see the section The Frame Formats Defined in BluFi for details).
4. After ESP32 receives the data frame of key negotiation, it will parse the content according to the user-defined negotiation method.
5. The mobile phone works with ESP32 for key negotiation using the encryption algorithms, such as DH, RSA, or ECC.
6. After the negotiation process is completed, the mobile phone will send a control frame for security-mode setup to ESP32.
7. When receiving this control frame, ESP32 will be able to encrypt and decrypt the communication data using the shared key and the security configuration.
8. The mobile phone sends the data frame defined in the section of The Frame Formats Defined in BluFi, with the Wi-Fi configuration information to ESP32, including SSID, password, etc.
9. The mobile phone sends a control frame of Wi-Fi connection request to ESP32. When receiving this control frame, ESP32 will regard the communication of essential information as done and get ready to connect to the Wi-Fi.
10. After connecting to the Wi-Fi, ESP32 will send a control frame of Wi-Fi connection status report to the mobile phone. At this point, the networking procedure is completed.

Note:

1. After ESP32 receives the control frame of security-mode configuration, it will execute the operations in accordance with the defined security mode.
2. The data lengths before and after symmetric encryption/decryption must stay the same. It also supports in-place encryption and decryption.

4.3.3 The Flow Chart of BluFi

4.3.4 The Frame Formats Defined in BluFi

The frame formats for the communication between the mobile phone App and ESP32 are defined as follows:

The frame format with no fragment:
Fig. 2: BluFi Flow Chart

Phone

ESP32

Advertising

Create GATT connection

Negotiate key procedure

Negotiate key procedure

CTRL: Set ESP32 to Phone Security mode

DATA: SSID

DATA: Password

DATA: Other information, such as CA certification

CTRL: Connect to AP

DATA: Connection State Report
If the frag frame bit in the **Frame Control** field is enabled, there would be a 2-byte **Total Content Length** field in the **Data** field. This **Total Content Length** field indicates the length of the remaining part of the frame and also tells the remote how much memory needs to be allocated.

The frame format with fragments:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value (Byte)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type (Least Significant Bit)</strong></td>
<td>1</td>
</tr>
<tr>
<td>Frame Control</td>
<td>1</td>
</tr>
<tr>
<td>Sequence Number</td>
<td>1</td>
</tr>
<tr>
<td>Data Length</td>
<td>1</td>
</tr>
<tr>
<td>Data</td>
<td>${\text{Data Length}}$</td>
</tr>
<tr>
<td>CheckSum (Most Significant Bit)</td>
<td>2</td>
</tr>
</tbody>
</table>

Normally, the control frame does not contain data bits, except for ACK Frame.

The format of ACK Frame:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value (Byte)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type - ACK (Least Significant Bit)</strong></td>
<td>1</td>
</tr>
<tr>
<td>Frame Control</td>
<td>1</td>
</tr>
<tr>
<td>Sequence Number</td>
<td>1</td>
</tr>
<tr>
<td>Data Length</td>
<td>1</td>
</tr>
<tr>
<td>Data</td>
<td>Acked Sequence Number: 2</td>
</tr>
<tr>
<td>CheckSum (Most Significant Bit)</td>
<td>2</td>
</tr>
</tbody>
</table>

1. **Type** field takes 1 byte and is divided into **Type** and **Subtype**. **Type** uses the lower two bits, indicating whether the frame is a data frame or a control frame. **Subtype** uses the upper six bits, indicating the specific meaning of this data frame or control frame.
   - The control frame is not encrypted for the time being and supports to be verified.
   - The data frame supports to be encrypted and verified.

1.1 Control Frame (Binary: 0x0 b’ 00)
<table>
<thead>
<tr>
<th>Control Frame</th>
<th>Implication</th>
<th>Explanation</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0 (b’000000)</td>
<td>ACK</td>
<td>The data field of the ACK frame uses the same sequence value of the frame to reply to.</td>
<td>The data field consumes a byte and its value is the same as the sequence field of the frame to reply to.</td>
</tr>
<tr>
<td>0x1 (b’000001)</td>
<td>Set the ESP device to the security mode.</td>
<td>To inform the ESP device of the security mode to use when sending data, which is allowed to be reset multiple times during the process. Each setting affects the subsequent security mode used. If it is not set, the ESP device will send the control frame and data frame with no checksum and encryption by default. The data transmission from the mobile phone to the ESP device is controlled by this control frame.</td>
<td>The data field consumes a byte. The higher four bits are for the security mode setting of the control frame, and the lower four bits are for the security mode setting of the data frame.</td>
</tr>
<tr>
<td>0x2 (b’000010)</td>
<td>Set the opmode of Wi-Fi.</td>
<td>The frame contains opmode settings for configuring the Wi-Fi mode of the ESP device.</td>
<td>data[0] is for opmode settings, including:</td>
</tr>
<tr>
<td>0x3 (b’000011)</td>
<td>Connect the ESP device to the AP.</td>
<td>To notify the ESP device that the essential information has been sent and it is allowed to connect to the AP.</td>
<td>No data field is contained.</td>
</tr>
<tr>
<td>0x4 (b’000100)</td>
<td>Disconnect the ESP device from the AP.</td>
<td>No data field is contained.</td>
<td></td>
</tr>
<tr>
<td>0x5 (b’000101)</td>
<td>To get the information of the ESP device’s Wi-Fi mode and it’s status.</td>
<td>No data field is contained. When receiving this control frame, the ESP device will send back a follow-up frame of Wi-Fi connection state report to the mobile phone with the information of the current opmode, connection status, SSID, and so on.</td>
<td></td>
</tr>
<tr>
<td>0x6 (b’000110)</td>
<td>Disconnect the STA device from the SoftAP (in SoftAP mode).</td>
<td>Data[0-5] is taken as the MAC address for the STA device. If there is a second STA device, then it uses data[6-11] and the rest can be done in the same manner.</td>
<td></td>
</tr>
<tr>
<td>0x7 (b’000111)</td>
<td>Get the version information.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x8 (b’001000)</td>
<td>Disconnect the BLE GATT link.</td>
<td>The ESP device will disconnect the BLE GATT link after receives this command.</td>
<td></td>
</tr>
<tr>
<td>0x9 (b’001001)</td>
<td>Get the Wi-Fi list.</td>
<td>To get the ESP device to scan the Wi-Fi access points around.</td>
<td>No data field is contained. When receiving this control frame, the ESP device will send back a follow-up frame of Wi-Fi list report to the mobile phone.</td>
</tr>
</tbody>
</table>
1.2 Data Frame (Binary: 0x1b’01)
<table>
<thead>

</tbody>
</table>
Chapter 4. API Guides

Note:

• Note 1: The length of the data depends on the data length field. When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
• Note 2: The length of the data depends on the data length field. The frame supports to be fragmented if the data length is not long enough.

2. Frame Control
The Frame Control field takes one byte and each bit has a different meaning.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x01</td>
<td>Indicates whether the frame is encrypted.</td>
</tr>
<tr>
<td></td>
<td>• 1 means encrypted.</td>
</tr>
<tr>
<td></td>
<td>• 0 means unencrypted.</td>
</tr>
<tr>
<td></td>
<td>The encrypted part of the frame includes the full clear data before the DATA field is encrypted (no checksum). Control frame is not encrypted, so this bit is 0.</td>
</tr>
<tr>
<td>0x02</td>
<td>Indicates whether a frame contains a checksum (such as SHA1, MD5, CRC) for the end of the frame. Data field includes sequence, data length, and clear text. Both the control frame and the data frame can choose whether to contain a check bit or not.</td>
</tr>
<tr>
<td>0x04</td>
<td>Indicates the data direction.</td>
</tr>
<tr>
<td></td>
<td>• 0 means from the mobile phone to the ESP device.</td>
</tr>
<tr>
<td></td>
<td>• 1 means from the ESP device to the mobile phone.</td>
</tr>
<tr>
<td>0x08</td>
<td>Indicates whether the other person is required to reply to an ACK.</td>
</tr>
<tr>
<td></td>
<td>• 0 indicates not required to reply to an ACK.</td>
</tr>
<tr>
<td></td>
<td>• 1 indicates required to reply to an ACK.</td>
</tr>
<tr>
<td>0x10</td>
<td>Indicates whether there are subsequent data fragments.</td>
</tr>
<tr>
<td></td>
<td>• 0 indicates that there is no subsequent data fragment for this frame.</td>
</tr>
<tr>
<td></td>
<td>• 1 indicates that there are subsequent data fragments which used to transmit longer data.</td>
</tr>
<tr>
<td></td>
<td>In the case of a frag frame, the total length of the current content section + subsequent content section is given in the first two bytes of the data field (that is, the content data of the maximum support 64 K).</td>
</tr>
<tr>
<td>0x10~0x80</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

3. Sequence Number
The Sequence Number field is the field for sequence control. When a frame is sent, the value of this field is automatically incremented by 1 regardless of the type of frame, which prevents Replay Attack. The sequence would be cleared after each reconnection.

4. Data Length
The Data Length field indicates the length of the data field, which does not include CheckSum.

5. Data
Content of the Data field can be different according to various values of Type or Subtype. Please refer to the table above.

6. CheckSum
The CheckSum field takes two bytes, which is used to check “sequence + data length + clear text data”.

4.3.5 The Security Implementation of ESP32

1. Securing Data
To ensure that the transmission of the Wi-Fi SSID and password is secure, the message needs to be encrypted using symmetric encryption algorithms, such as AES, DES, and so on. Before using symmetric encryption algorithms, the devices are required to negotiate (or generate) a shared key using an asymmetric encryption algorithm (DH, RSA, ECC, etc).

2. Ensuring Data Integrity
To ensure data integrity, you need to add a checksum algorithm, such as SHA1, MD5, CRC, etc.

3. Securing Identity (Signature)
   Algorithm like RSA can be used to secure identity. But for DH, it needs other algorithms as a companion for signature.

4. Replay Attack Prevention
   It is added to the Sequence Number field and used during the checksum verification.
   For the coding of ESP32, you can determine and develop the security processing, such as key negotiation. The mobile application sends the negotiation data to ESP32, and then the data will be sent to the application layer for processing. If the application layer does not process it, you can use the DH encryption algorithm provided by BluFi to negotiate the key.

   The application layer needs to register several security-related functions to BluFi:

   ```c
   typedef void (*esp_blufi_negotiate_data_handler_t)(uint8_t *data, int len, uint8_t *output_data, int *output_len, bool *need_free);
   ```

   This function is for ESP32 to receive normal data during negotiation. After processing is completed, the data will be transmitted using Output_data and Output_len.

   BluFi will send output_data from Negotiate_data_handler after Negotiate_data_handler is called.

   Here are two "*", which means the length of the data to be emitted is unknown. Therefore, it requires the function to allocate itself (malloc) or point to the global variable to inform whether the memory needs to be freed by NEED_FREE.

   ```c
   typedef int (*esp_blufi_encrypt_func_t)(uint8_t iv8, uint8_t *crypt_data, int *crypt_len);
   ```

   The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as a 8-bit of IV.

   ```c
   typedef int (*esp_blufi_decrypt_func_t)(uint8_t iv8, uint8_t *crypt_data, int *crypt_len);
   ```

   The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as an 8-bit of IV.

   ```c
   typedef uint16_t (*esp_blufi_checksum_func_t)(uint8_t iv8, uint8_t *data, int len);
   ```

   This function is used to compute CheckSum and return a value of CheckSum. BluFi uses the returned value to compare the CheckSum of the frame.

### 4.3.6 GATT Related Instructions

**UUID**

BluFi Service UUID: 0xFFFF, 16 bit
BluFi (the mobile > ESP32): 0xFF01, writable
Blufi (ESP32 > the mobile phone): 0xFF02, readable and callable

### 4.4 Bluetooth® Overview

This document provides an architecture overview of the Bluetooth stack in ESP-IDF and some quick links to related documents and application examples.

ESP32 supports Dual-Mode Bluetooth 4.2 and is certified for Bluetooth 4.2.
The Bluetooth stack in ESP-IDF is a layered architecture that enables Bluetooth functionality on ESP32 chip series. The table below shows its architecture.

![Fig. 3: ESP32 Bluetooth Stack Architecture](image)

The table below shows whether the Bluetooth modules are supported in a specific chip series.

<table>

</tbody>
</table>

The following sections briefly describe each layer and provide quick links to the related documents and application examples.

### 4.4.1 ESP Bluetooth Controller

At the bottom layer is ESP Bluetooth Controller, which encompasses various modules such as PHY, Baseband, Link Controller, Link Manager, Device Manager, and HCI. It handles hardware interface management and link management. It provides functions in the form of libraries and is accessible through APIs. This layer directly interacts with the hardware and low-level Bluetooth protocols.

- **API reference**
- **Application examples**

### 4.4.2 Hosts

There are two hosts, ESP-Bluedroid and ESP-NimBLE. The major difference between them is as follows:

- Although both support Bluetooth LE, ESP-NimBLE requires less heap and flash size.
- ESP-Bluedroid supports both Classic Bluetooth and Bluetooth LE, while ESP-NimBLE only supports Bluetooth LE.
ESP-Bluedroid

ESP-Bluedroid is a modified version of the native Android Bluetooth stack, Bluedroid. It consists of two layers: the Bluetooth Upper Layer (BTU) and the Bluetooth Transport Controller layer (BTC). The BTU layer is responsible for processing bottom layer Bluetooth protocols such as L2CAP, GATT/ATT, SMP, GAP, and other profiles. The BTU layer provides an interface prefixed with “bta”. The BTC layer is mainly responsible for providing a supported interface, prefixed with “esp”, to the application layer, processing GATT-based profiles and handling miscellaneous tasks. All the APIs are located in the ESP_API layer. Developers should use the Bluetooth APIs prefixed with “esp”.

ESP-Bluedroid for ESP32 supports Classic Bluetooth and Bluetooth LE.

- API references
  - Bluetooth® Common
  - Bluetooth LE
  - Classic Bluetooth®
- Application examples

ESP-NimBLE

ESP-NimBLE is a host stack built on top of the NimBLE host stack developed by Apache Mynewt. The NimBLE host stack is ported for ESP32 chip series and FreeRTOS. The porting layer is kept clean by maintaining all the existing APIs of NimBLE along with a single ESP-NimBLE API for initialization, making it simpler for the application developers.

ESP-NimBLE supports Bluetooth LE only. Classic Bluetooth is not supported.

- Apache Mynewt NimBLE User Guide
- API references
  - NimBLE API references
  - ESP-NimBLE API references for initialization
- Application examples

4.4.3 Profiles

Above the host stacks are the profile implementations by Espressif and some common profiles. Depending on your configuration, these profiles can run on ESP-Bluedroid or ESP-NimBLE.

ESP-BLE-MESH

Built on top of Zephyr Bluetooth Mesh stack, the ESP-BLE-MESH implementation supports device provisioning and node control. It also supports such node features as Proxy, Relay, Low power and Friend.

- ESP-BLE-MESH documentation: feature list, get started, architecture, description of application examples, frequently asked questions, etc.
- Application examples

BluFi

The BluFi for ESP32 is a Wi-Fi network configuration function via Bluetooth channel. It provides a secure protocol to pass Wi-Fi configuration and credentials to ESP32. Using this information, ESP32 can then connect to an AP or establish a softAP.

- BluFi documentation
- Application examples
4.4.4 Applications

At the uppermost layer are applications. You can build your own applications on top of the ESP-Bluedroid and ESP-NimBLEstacks, leveraging the provided APIs and profiles to create Bluetooth-enabled applications tailored to specific use cases.

4.5 Bootloader

The ESP-IDF Software Bootloader performs the following functions:

1. Minimal initial configuration of internal modules;
2. Initialize Flash Encryption and/or Secure features, if configured;
3. Select the application partition to boot, based on the partition table and ota_data (if any);
4. Load this image to RAM (IRAM & DRAM) and transfer management to the image that was just loaded.

Bootloader is located at the address 0x1000 in the flash.

For a full description of the startup process including the ESP-IDF bootloader, see Application Startup Flow.

4.5.1 Bootloader Compatibility

It is recommended to update to newer versions of ESP-IDF; when they are released. The OTA (over the air) update process can flash new apps in the field but cannot flash a new bootloader. For this reason, the bootloader supports booting apps built from newer versions of ESP-IDF.

The bootloader does not support booting apps from older versions of ESP-IDF. When updating ESP-IDF manually on an existing product that might need to downgrade the app to an older version, keep using the older ESP-IDF bootloader binary as well.

**Note:** If testing an OTA update for an existing product in production, always test it using the same ESP-IDF bootloader binary that is deployed in production.

Before ESP-IDF V2.1

Bootloaders built from very old versions of ESP-IDF (before ESP-IDF V2.1) perform less hardware configuration than newer versions. When using a bootloader from these early ESP-IDF versions and building a new app, enable the config option `CONFIG_APP_COMPATIBLE_PRE_V2_1_BOOTLOADERS`.

Before ESP-IDF V3.1

Bootloaders built from versions of ESP-IDF before V3.1 do not support MD5 checksums in the partition table binary. When using a bootloader from these ESP-IDF versions and building a new app, enable the config option `CONFIG_APP_COMPATIBLE_PRE_V3_1_BOOTLOADERS`.

Before ESP-IDF V5.1

Bootloaders built from versions of ESP-IDF prior to V5.1 do not support `CONFIG_ESP_SYSTEM_ESP32_SRAM1_REGION_AS_IRAM`. When using a bootloader from these ESP-IDF versions and building a new app, you should not use this option.
SPI Flash Configuration

Each ESP-IDF application or bootloader .bin file contains a header with `CONFIG_ESPTOOLPY_FLASHMODE`, `CONFIG_ESPTOOLPY_FLASHFREQ`, `CONFIG_ESPTOOLPY_FLASHSIZE` embedded in it. These are used to configure the SPI flash during boot.

The First Stage Bootloader in ROM reads the Second Stage Bootloader header information from flash and uses this information to load the rest of the Second Stage Bootloader from flash. However, at this time the system clock speed is lower than configured and not all flash modes are supported. When the Second Stage Bootloader then runs, it will reconfigure the flash using values read from the currently selected app binary’s header (and NOT from the Second Stage Bootloader header). This allows an OTA update to change the SPI flash settings in use.

Bootloaders prior to ESP-IDF V4.0 used the bootloader’s own header to configure the SPI flash, meaning these values could not be changed in an update. To maintain compatibility with older bootloaders, the app re-initializes the flash settings during app startup using the configuration found in the app header.

4.5.2 Log Level

The default bootloader log level is “Info”. By setting the `CONFIG_BOOTLOADER_LOG_LEVEL` option, it is possible to increase or decrease this level. This log level is separate from the log level used in the app (see Logging library).

Reducing bootloader log verbosity can improve the overall project boot time by a small amount.

4.5.3 Factory Reset

Sometimes it is desirable to have a way for the device to fall back to a known-good state, in case of some problem with an update.

To roll back to the original “factory” device configuration and clear any user settings, configure the config item `CONFIG_BOOTLOADER_FACTORY_RESET` in the bootloader.

The factory reset mechanism allows the device to be factory reset in two ways:

- Clear one or more data partitions. The `CONFIG_BOOTLOADER_DATA_FACTORY_RESET` option allows users to specify which data partitions will be erased when the factory reset is executed. Users can specify the names of partitions as a comma-delimited list with optional spaces for readability. (Like this: `nvs, phy_init, nvs_custom`). Make sure that the names of partitions specified in the option are the same as those found in the partition table. Partitions of type “app” cannot be specified here.
- Boot from “factory” app partition. Enabling the `CONFIG_BOOTLOADER_OTA_DATA_ERASE` option will cause the device to boot from the default “factory” app partition after a factory reset (or if there is no factory app partition in the partition table then the default ota app partition is selected instead). This reset process involves erasing the OTA data partition which holds the currently selected OTA partition slot. The “factory” app partition slot (if it exists) is never updated via OTA, so resetting to this allows reverting to a “known good” firmware application.

Either or both of these configuration options can be enabled independently.

In addition, the following configuration options control the reset condition:

- `CONFIG_BOOTLOADER_NUM_PIN_FACTORY_RESET` - The input GPIO number used to trigger a factory reset. This GPIO must be pulled low or high (configurable) on reset to trigger this.
- `CONFIG_BOOTLOADER_HOLD_TIME_GPIO` - this is hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.
- `CONFIG_BOOTLOADER_FACTORY_RESET_PIN_LEVEL` - configure whether a factory reset should trigger on a high or low level of the GPIO. If the GPIO has an internal pullup then this is enabled before the pin is sampled, consult the ESP32 datasheet for details on pin internal pullups.
If an application needs to know if the factory reset has occurred, users can call the function `bootloader_common_get_rtc_retain_mem_factory_reset_state()`.  

- If the status is read as true, the function will return the status, indicating that the factory reset has occurred. The function then resets the status to false for subsequent factory reset judgement.
- If the status is read as false, the function will return the status, indicating that the factory reset has not occurred, or the memory where this status is stored is invalid.

Note that this feature reserves some RTC FAST memory (the same size as the `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` feature).

### 4.5.4 Boot from Test Firmware

It is possible to write a special firmware app for testing in production, and boot this firmware when needed. The project partition table will need a dedicated app partition entry for this testing app, type `app` and subtype `test` (see [Partition Tables](#)).

Implementing a dedicated test app firmware requires creating a totally separate ESP-IDF project for the test app (each project in ESP-IDF only builds one app). The test app can be developed and tested independently of the main project, and then integrated at production testing time as a pre-compiled .bin file which is flashed to the address of the main project’s test app partition.

To support this functionality in the main project’s bootloader, set the configuration item `CONFIG_BOOTLOADER_APP_TEST` and configure the following three items:

- `CONFIG_BOOTLOADER_NUM_PIN_APP_TEST` - GPIO number to boot test partition. The selected GPIO will be configured as an input with internal pull-up enabled. This GPIO must be pulled low or high (configurable) on reset to trigger this.
  
  Once the GPIO input is released and the device has been rebooted, the default boot sequence will be enabled again to boot the factory partition or any OTA app partition slot.

- `CONFIG_BOOTLOADER_HOLD_TIME_GPIO` - this is the hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.

- `CONFIG_BOOTLOADER_APP_TEST_PIN_LEVEL` - configure whether a test partition boot should trigger on a high or low level of the GPIO. If the GPIO has an internal pull-up, then this is enabled before the pin is sampled. Consult the ESP32 datasheet for details on pin internal pull-ups.

### 4.5.5 Rollback

Rollback and anti-rollback features must be configured in the bootloader as well.

Consult the [App Rollback](#) and [Anti-rollback](#) sections in the [OTA API reference document](#).

### 4.5.6 Watchdog

By default, the hardware RTC Watchdog timer remains running while the bootloader is running and will automatically reset the chip if no app has successfully started after 9 seconds.

- The timeout period can be adjusted by setting `CONFIG_BOOTLOADER_WDT_TIME_MS` and recompiling the bootloader.

- The app’s behaviour can be adjusted so the RTC Watchdog remains enabled after app startup. The Watchdog would need to be explicitly reset (i.e., fed) by the app to avoid a reset. To do this, set the `CONFIG_BOOTLOADER_WDT_DISABLE_IN_USER_CODE` option, modify the app as needed, and then recompile the app.

- The RTC Watchdog can be disabled in the bootloader by disabling the `CONFIG_BOOTLOADER_WDT_ENABLE` setting and recompiling the bootloader. This is not recommended.
4.5.7 Bootloader Size

When enabling additional bootloader functions, including Flash Encryption or Secure Boot, and especially if setting a high CONFIG_BOOTLOADER_LOG_LEVEL level, then it is important to monitor the bootloader .bin file’s size.

When using the default CONFIG_PARTITION_TABLE_OFFSET value 0x8000, the size limit is 0x8000 bytes. If the bootloader binary is too large, then the bootloader build will fail with an error “Bootloader binary size [...] is too large for partition table offset”. If the bootloader binary is flashed anyhow then the ESP32 will fail to boot - errors will be logged about either invalid partition table or invalid bootloader checksum.

Options to work around this are:

- Set bootloader compiler optimization back to “Size” if it has been changed from this default value.
- Reduce bootloader log level. Setting log level to Warning, Error or None all significantly reduce the final binary size (but may make it harder to debug).
- Set CONFIG_PARTITION_TABLE_OFFSET to a higher value than 0x8000, to place the partition table later in the flash. This increases the space available for the bootloader. If the partition table CSV file contains explicit partition offsets, they will need changing so no partition has an offset lower than CONFIG_PARTITION_TABLE_OFFSET + 0x1000. (This includes the default partition CSV files supplied with ESP-IDF.)

When Secure Boot V2 is enabled, there is also an absolute binary size limit of 48 KB (0xC000 bytes) (excluding the 4 KB signature), because the bootloader is first loaded into a fixed size buffer for verification.

4.5.8 Fast Boot from Deep-Sleep

The bootloader has the CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP option which allows the wake-up time from Deep-sleep to be reduced (useful for reducing power consumption). This option is available when CONFIG_SECURE_BOOT option is disabled. Reduction of time is achieved due to the lack of image verification. During the first boot, the bootloader stores the address of the application being launched in the RTC FAST memory. And during the awakening, this address is used for booting without any checks, thus fast loading is achieved.

4.5.9 Custom Bootloader

The current bootloader implementation allows a project to extend it or modify it. There are two ways of doing it: by implementing hooks or by overriding it. Both ways are presented in custom_bootloader folder in ESP-IDF examples:

- bootloader_hooks which presents how to connect some hooks to the bootloader initialization
- bootloader_override which presents how to override the bootloader implementation

In the bootloader space, you cannot use the drivers and functions from other components. If necessary, then the required functionality should be placed in the project’s bootloader_components directory (note that this will increase its size).

If the bootloader grows too large then it can collide with the partition table, which is flashed at offset 0x8000 by default. Increase the partition table offset value to place the partition table later in the flash. This increases the space available for the bootloader.

4.6 Build System

This document explains the implementation of the ESP-IDF build system and the concept of “components”. Read this document if you want to know how to organize and build a new ESP-IDF project or component.
4.6.1 Overview

An ESP-IDF project can be seen as an amalgamation of a number of components. For example, for a web server that shows the current humidity, there could be:

- The ESP-IDF base libraries (libc, ROM bindings, etc)
- The Wi-Fi drivers
- A TCP/IP stack
- The FreeRTOS operating system
- A web server
- A driver for the humidity sensor
- Main code tying it all together

ESP-IDF makes these components explicit and configurable. To do that, when a project is compiled, the build system will look up all the components in the ESP-IDF directories, the project directories and (optionally) in additional custom component directories. It then allows the user to configure the ESP-IDF project using a text-based menu system to customize each component. After the components in the project are configured, the build system will compile the project.

Concepts

- A “project” is a directory that contains all the files and configuration to build a single “app” (executable), as well as additional supporting elements such as a partition table, data/filesystem partitions, and a bootloader.
- “Project configuration” is held in a single file called sdkconfig in the root directory of the project. This configuration file is modified via idf.py menuconfig to customize the configuration of the project. A single project contains exactly one project configuration.
- An “app” is an executable that is built by ESP-IDF. A single project will usually build two apps - a “project app” (the main executable, i.e., your custom firmware) and a “bootloader app” (the initial bootloader program which launches the project app).
- “Components” are modular pieces of standalone code that are compiled into static libraries (.a files) and linked to an app. Some are provided by ESP-IDF itself, others may be sourced from other places.
- “Target” is the hardware for which an application is built. A full list of supported targets in your version of ESP-IDF can be seen by running idf.py --list-targets.

Some things are not part of the project:

- “ESP-IDF” is not part of the project. Instead, it is standalone, and linked to the project via the IDF_PATH environment variable which holds the path of the esp-idf directory. This allows the ESP-IDF framework to be decoupled from your project.
- The toolchain for compilation is not part of the project. The toolchain should be installed in the system command line PATH.

4.6.2 Using the Build System

**idf.py**

The idf.py command-line tool provides a front-end for easily managing your project builds. It manages the following tools:

- CMake, which configures the project to be built
- Ninja which builds the project
- esptool.py for flashing the target.

You can read more about configuring the build system using idf.py here.

Using CMake Directly

idf.py is a wrapper around CMake for convenience. However, you can also invoke CMake directly if you prefer.
When `idf.py` does something, it prints each command that it runs for easy reference. For example, the `idf.py build` command is the same as running these commands in a bash shell (or similar commands for Windows Command Prompt):

```
mkdir -p build
cd build
cmake .. -G Ninja  # or 'Unix Makefiles'
ninja
```

In the above list, the `cmake` command configures the project and generates build files for use with the final build tool. In this case, the final build tool is **Ninja**: running `ninja` actually builds the project.

It’s not necessary to run `cmake` more than once. After the first build, you only need to run `ninja` each time. `ninja` will automatically re-invoke `cmake` if the project needs reconfiguration.

If using CMake with `ninja` or `make`, there are also targets for more of the `idf.py` sub-commands. For example, running `make menuconfig` or `ninja menuconfig` in the build directory will work the same as `idf.py menuconfig`.

**Note:** If you’re already familiar with CMake, you may find the ESP-IDF CMake-based build system unusual because it wraps a lot of CMake’s functionality to reduce boilerplate. See [writing pure CMake components](#) for some information about writing more “CMake style” components.

### Flashing with Ninja or Make

It’s possible to build and flash directly from `ninja` or `make` by running a target like:

```
ninja flash
```

Or:

```
make app-flash
```

Available targets are: `flash`, `app-flash` (app only), `bootloader-flash` (bootloader only).

When flashing this way, optionally set the `ESPPORT` and `ESPBAUD` environment variables to specify the serial port and baud rate. You can set environment variables in your operating system or IDE project. Alternatively, set them directly on the command line:

```
ESPPORT=/dev/ttyUSB0 ninja flash
```

**Note:** Providing environment variables at the start of the command like this is Bash shell Syntax. It will work on Linux and macOS. It won’t work when using Windows Command Prompt, but it will work when using Bash-like shells on Windows.

Or:

```
make -j3 app-flash ESPPORT=COM4 ESPBAUD=2000000
```

**Note:** Providing variables at the end of the command line is `make` syntax, and works for `make` on all platforms.

### Using CMake in an IDE

You can also use an IDE with CMake integration. The IDE will want to know the path to the project’s `CMakeLists.txt` file. IDEs with CMake integration often provide their own build tools (CMake calls these “generators”) to build the source files as part of the IDE.
When adding custom non-build steps like “flash” to the IDE, it is recommended to execute `idf.py` for these “special” commands.

For more detailed information about integrating ESP-IDF with CMake into an IDE, see `Build System Metadata`.

### Setting up the Python Interpreter

ESP-IDF works well with Python version 3.8+.

`idf.py` and other Python scripts will run with the default Python interpreter, i.e., `python`. You can switch to a different one like `python3 $IDF_PATH/tools/idf.py ...`, or you can set up a shell alias or another script to simplify the command.

If using CMake directly, running `cmake -D PYTHON=python3 ...` will cause CMake to override the default Python interpreter.

If using an IDE with CMake, setting the `PYTHON` value as a CMake cache override in the IDE UI will override the default Python interpreter.

To manage the Python version more generally via the command line, check out the tools `pyenv` or `virtualenv`. These let you change the default Python version.

### 4.6.3 Example Project

An example project directory tree might look like this:

```
- myProject/
  - CMakeLists.txt
  - sdkconfig
  - bootloader_components/
    - boot_component/
      - CMakeLists.txt
      - Kconfig
      - src1.c
  - components/
    - component1/
      - CMakeLists.txt
      - Kconfig
      - src1.c
    - component2/
      - CMakeLists.txt
      - Kconfig
      - src1.c
      - include/
        - component2.h
  - main/
    - CMakeLists.txt
    - src1.c
    - src2.c
  - build/
```

This example “myProject” contains the following elements:

- A top-level project `CMakeLists.txt` file. This is the primary file which CMake uses to learn how to build the project; and may set project-wide CMake variables. It includes the file `/tools/cmake/project.cmake` which implements the rest of the build system. Finally, it sets the project name and defines the project.
- “sdkconfig” project configuration file. This file is created/updated when `idf.py menuconfig` runs, and holds the configuration for all of the components in the project (including ESP-IDF itself). The `sdkconfig` file may or may not be added to the source control system of the project.
- Optional “bootloader_components” directory contains components that need to be compiled and linked inside the bootloader project. A project does not have to contain custom bootloader components of this kind, but it can be useful in case the bootloader needs to be modified to embed new features.
- Optional “components” directory contains components that are part of the project. A project does not have to contain custom components of this kind, but it can be useful for structuring reusable code or including third-party components that aren’t part of ESP-IDF. Alternatively, `EXTRA_COMPONENT_DIRS` can be set in the top-level `CMakeLists.txt` to look for components in other places.
• “main” directory is a special component that contains source code for the project itself. “main” is a default name, the CMake variable COMPONENT_DIRS includes this component but you can modify this variable. See the renaming main section for more info. If you have a lot of source files in your project, we recommend grouping most into components instead of putting them all in “main”. 
• “build” directory is where the build output is created. This directory is created by idf.py if it doesn’t already exist. CMake configures the project and generates interim build files in this directory. Then, after the main build process is run, this directory will also contain interim object files and libraries as well as final binary output files. This directory is usually not added to source control or distributed with the project source code.

Component directories each contain a component CMakeLists.txt file. This file contains variable definitions to control the build process of the component, and its integration into the overall project. See Component CMakeLists Files for more details.

Each component may also include a Kconfig file defining the component configuration options that can be set via menuconfig. Some components may also include Kconfig.projbuild and project_include.cmake files, which are special files for overriding parts of the project.

### 4.6.4 Project CMakeLists File

Each project has a single top-level CMakeLists.txt file that contains build settings for the entire project. By default, the project CMakeLists can be quite minimal.

**Minimal Example CMakeLists**

Minimal project:

```cmake
cmake_minimum_required(VERSION 3.16)
include(${ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)
```

**Mandatory Parts**

The inclusion of these three lines, in the order shown above, is necessary for every project:

• cmake_minimum_required(VERSION 3.16) tells CMake the minimum version that is required to build the project. ESP-IDF is designed to work with CMake 3.16 or newer. This line must be the first line in the CMakeLists.txt file.
• include(${ENV{IDF_PATH}/tools/cmake/project.cmake) pulls in the rest of the CMake functionality to configure the project, discover all the components, etc.
• project(myProject) creates the project itself, and specifies the project name. The project name is used for the final binary output files of the app - ie myProject.elf, myProject.bin. Only one project can be defined per CMakeLists file.

**Optional Project Variables**

These variables all have default values that can be overridden for custom behavior. Look in /tools/cmake/project.cmake for all of the implementation details.

• COMPONENT_DIRS: Directories to search for components. Defaults to IDF_PATH/components, PROJECT_DIR/components, and EXTRA_COMPONENT_DIRS. Override this variable if you don’t want to search for components in these places.
• EXTRA_COMPONENT_DIRS: Optional list of additional directories to search for components. Paths can be relative to the project directory, or absolute.
• COMPONENTS: A list of component names to build into the project. Defaults to all components found in the COMPONENT_DIRS directories. Use this variable to “trim down” the project for faster build times. Note that any component which “requires” another component via the REQUIRES or PRIV_REQUIRES arguments
on component registration will automatically have it added to this list, so the COMPONENTS list can be very short.

- **BOOTLOADER_IGNORE_EXTRA_COMPONENT**: A list of components, placed in bootloader_components/, that should be ignored by the bootloader compilation. Use this variable if a bootloader component needs to be included conditionally inside the project.

Any paths in these variables can be absolute paths, or set relative to the project directory.

To set these variables, use the `cmake set command` ie `set(VARIABLE "VALUE")`. The `set()` commands should be placed after the `cmake_minimum(...) line but before the include(...) line.

### Renaming main Component

The build system provides special treatment to the `main` component. It is a component that gets automatically added to the build provided that it is in the expected location, `PROJECT_DIR/main`. All other components in the build are also added as its dependencies, saving the user from hunting down dependencies and providing a build that works right out of the box. Renaming the `main` component causes the loss of these behind-the-scenes heavy lifting, requiring the user to specify the location of the newly renamed component and manually specify its dependencies. Specifically, the steps to renaming `main` are as follows:

1. Rename `main` directory.
2. Set `EXTRA_COMPONENT_DIRS` in the project CMakeLists.txt to include the renamed `main` directory.
3. Specify the dependencies in the renamed component’s CMakeLists.txt file via `REQUIRES` or `PRIV_REQUIRES` arguments on component registration.

### Overriding Default Build Specifications

The build sets some global build specifications (compile flags, definitions, etc.) that gets used in compiling all sources from all components.

For example, one of the default build specifications set is the compile option `-Wextra`. Suppose a user wants to use override this with `-Wno-extra`, it should be done after `project()`:

```
cmake_minimum_required(VERSION 3.16)
#include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)

idf_build_set_property(COMPILE_OPTIONS "-Wno-error" APPEND)
```

This ensures that the compile options set by the user won’t be overridden by the default build specifications, since the latter are set inside `project()`.

### 4.6.5 Component CMakeLists Files

Each project contains one or more components. Components can be part of ESP-IDF, part of the project’s own components directory, or added from custom component directories (see above).

A component is any directory in the COMPONENT_DIRS list which contains a CMakeLists.txt file.

### Searching for Components

The list of directories in COMPONENT_DIRS is searched for the project’s components. Directories in this list can either be components themselves (ie they contain a CMakeLists.txt file), or they can be top-level directories whose sub-directories are components.

When CMake runs to configure the project, it logs the components included in the build. This list can be useful for debugging the inclusion/exclusion of certain components.
Multiple Components with the Same Name

When ESP-IDF is collecting all the components to compile, it will do this in the order specified by COMPO-
NENT_DIRS; by default, this means ESP-IDF’s internal components first (IDF_PATH/components), then
any components in directories specified in EXTRA_COMPONENT_DIRS, and finally the project’s components
(PROJECT_DIR/components). If two or more of these directories contain component sub-directories with the
same name, the component in the last place searched is used. This allows, for example, overriding ESP-IDF com-
ponents with a modified version by copying that component from the ESP-IDF components directory to the project
components directory and then modifying it there. If used in this way, the ESP-IDF directory itself can remain
untouched.

Note: If a component is overridden in an existing project by moving it to a new location, the project will not
automatically see the new component path. Run idf.py reconfigure (or delete the project build folder) and
then build again.

Minimal Component CMakeLists

The minimal component CMakeLists.txt file simply registers the component to the build system using
idf_component_register:

```
idf_component_register(SRCS "foo.c" "bar.c"
  INCLUDE_DIRS "include"
  REQUIRES mbedtls)
```

- SRCS is a list of source files (*.c, *.cpp, *.cc, *.S). These source files will be compiled into the com-
  ponent library.
- INCLUDE_DIRS is a list of directories to add to the global include search path for any component which
  requires this component, and also the main source files.
- REQUIRES is not actually required, but it is very often required to declare what other components this com-
  ponent will use. See component requirements.

A library with the name of the component will be built and linked to the final app.

Directories are usually specified relative to the CMakeLists.txt file itself, although they can be absolute.

There are other arguments that can be passed to idf_component_register. These arguments are discussed
here.

See example component requirements and example component CMakeLists for more complete component CMake-
Lists.txt examples.

Preset Component Variables

The following component-specific variables are available for use inside component CMakeLists, but should not be
modified:

- COMPONENT_DIR: The component directory. Evaluates to the absolute path of the directory contain-
  ing CMakeLists.txt. The component path cannot contain spaces. This is the same as the
  CMAKE_CURRENT_SOURCE_DIR variable.
- COMPONENT_NAME: Name of the component. Same as the name of the component directory.
- COMPONENT_ALIAS: Alias of the library created internally by the build system for the component.
- COMPONENT_LIB: Name of the library created internally by the build system for the component.

The following variables are set at the project level, but available for use in component CMakeLists:

- CONFIG_*: Each value in the project configuration has a corresponding variable available in cmake. All
  names begin with CONFIG_. More information here.
- ESP_PLATFORM: Set to 1 when the CMake file is processed within the ESP-IDF build system.
Chapter 4. API Guides

Build/Project Variables

The following are some project/build variables that are available as build properties and whose values can be queried using `idf_build_get_property` from the component CMakeLists.txt:

- **PROJECT_NAME**: Name of the project, as set in project CMakeLists.txt file.
- **PROJECT_DIR**: Absolute path of the project directory containing the project CMakeLists. Same as the `CMAKE_SOURCE_DIR` variable.
- **COMPONENTS**: Names of all components that are included in this build, formatted as a semicolon-delimited CMake list.
- **IDF_VER**: Git version of ESP-IDF (produced by `git describe`).
- **IDF_VERSION_MAJOR, IDF_VERSION_MINOR, IDF_VERSION_PATCH**: Components of ESP-IDF version, to be used in conditional expressions. Note that this information is less precise than that provided by `IDF_VER` variable. v4.0-dev-*, v4.0-beta1, v4.0-rc1 and v4.0 will all have the same values of `IDF_VERSION_*` variables, but different `IDF_VER` values.
- **IDF_TARGET**: Name of the target for which the project is being built.
- **PROJECT_VER**: Project version.
  - If `CONFIG_APP_PROJECT_VER_FROM_CONFIG` option is set, the value of `CONFIG_APP_PROJECT_VER` will be used.
  - Else, if `PROJECT_VER` variable is set in project CMakeLists.txt file, its value will be used.
  - Else, if the `PROJECT_DIR/version.txt` exists, its contents will be used as `PROJECT_VER`.
  - Else, if the project is located inside a Git repository, the output of git description will be used.
  - Otherwise, `PROJECT_VER` will be “1”.
- **EXTRA_PARTITION_SUBTYPES**: CMake list of extra partition subtypes. Each subtype description is a comma-separated string with `type_name, subtype_name, numeric_value` format. Components may add new subtypes by appending them to this list.

Other build properties are listed here.

Controlling Component Compilation

To pass compiler options when compiling source files belonging to a particular component, use the `target_compile_options` function:

```
target_compile_options(${COMPONENT_LIB} PRIVATE -Wno-unused-variable)
```

To apply the compilation flags to a single source file, use the CMake `set_source_files_properties` command:

```
set_source_files_properties(mysrc.c
  PROPERTIES COMPILE_FLAGS
  -Wno-unused-variable
)
```

This can be useful if there is upstream code that emits warnings.

**Note:** CMake `set_source_files_properties` command is not applicable when the source files have been populated with help of the `SRC_DIRS` variable in `idf_component_register`. See File Globbing & Incremental Builds for more details.

When using these commands, place them after the call to `idf_component_register` in the component CMakeLists file.

4.6.6 Component Configuration

Each component can also have a Kconfig file, alongside CMakeLists.txt. This contains configuration settings to add to the configuration menu for this component.

These settings are found under the “Component Settings” menu when menuconfig is run.
To create a component Kconfig file, it is easiest to start with one of the Kconfig files distributed with ESP-IDF.
For an example, see *Adding conditional configuration*.

### 4.6.7 Preprocessor Definitions

The ESP-IDF build system adds the following C preprocessor definitions on the command line:

- **ESP_PLATFORM**: Can be used to detect that build happens within ESP-IDF.
- **IDF_VER**: Defined to a git version string. E.g. `v2.0` for a tagged release or `v1.0-275-g0efaa4f` for an arbitrary commit.

### 4.6.8 Component Requirements

When compiling each component, the ESP-IDF build system recursively evaluates its dependencies. This means each component needs to declare the components that it depends on ("requires").

**When Writing a Component**

```c
idf_component_register(...
    REQUIRES mbedtls
    PRIV_REQUIRES console spiffs)
```

- **REQUIRES** should be set to all components whose header files are #included from the *public* header files of this component.
- **PRIV_REQUIRES** should be set to all components whose header files are #included from *any source files* in this component, unless already listed in **REQUIRES**. Also, any component which is required to be linked in order for this component to function correctly.
- The values of **REQUIRES** and **PRIV_REQUIRES** should not depend on any configuration choices (**CONFIG_xxx** macros). This is because requirements are expanded before the configuration is loaded. Other component variables (like include paths or source files) can depend on configuration choices.
- Not setting either or both **REQUIRES** variables is fine. If the component has no requirements except for the *Common component requirements* needed for RTOS, libc, etc.

If a component only supports some target chips (values of **IDF_TARGET**) then it can specify **REQUIRED_IDF_TARGETS** in the `idf_component_register` call to express these requirements. In this case, the build system will generate an error if the component is included in the build, but does not support the selected target.

**Note**: In CMake terms, **REQUIRES** & **PRIV_REQUIRES** are approximate wrappers around the CMake functions `target_link_libraries(... PUBLIC ...)` and `target_link_libraries(... PRIVATE ..)`.

**Example of Component Requirements**

Imagine there is a `car` component, which uses the `engine` component, which uses the `sparkplug` component:

```
- autoProject/
    - CMakeLists.txt
    - components/ - car/ - CMakeLists.txt
        - car.c
        - car.h
    - engine/ - CMakeLists.txt
        - engine.c
        - include/ - engine.h
```

(continues on next page)
Car Component  The `car.h` header file is the public interface for the `car` component. This header includes `engine.h` directly because it uses some declarations from this header:

```c
/* car.h */
#include "engine.h"

#ifdef ENGINE_IS_HYBRID
#define CAR_MODEL "Hybrid"
#endif
```

And `car.c` includes `car.h` as well:

```c
/* car.c */
#include "car.h"
```

This means the `car/CMakeLists.txt` file needs to declare that `car` requires `engine`:

```c
idf_component_register(SRCS "car.c"
  INCLUDE_DIRS "."
  REQUIRES engine)
```

- `SRCS` gives the list of source files in the `car` component.
- `INCLUDE_DIRS` gives the list of public include directories for this component. Because the public interface is `car.h`, the directory containing `car.h` is listed here.
- `REQUIRES` gives the list of components required by the public interface of this component. Because `car.h` is a public header and includes a header from `engine`, we include `engine` here. This makes sure that any other component which includes `car.h` will be able to recursively include the required `engine.h` also.

Engine Component  The `engine` component also has a public header file `include/engine.h`, but this header is simpler:

```c
/* engine.h */
#define ENGINE_IS_HYBRID

void engine_start (void);
```

The implementation is in `engine.c`:

```c
/* engine.c */
#include "engine.h"
#include "spark_plug.h"
...
```

In this component, `engine` depends on `spark_plug` but this is a private dependency. `spark_plug.h` is needed to compile `engine.c`, but not needed to include `engine.h`.

This means that the `engine/CMakeLists.txt` file can use `PRIV_REQUIRES`:

```c
idf_component_register(SRCS "engine.c"
  INCLUDE_DIRS "include"
  PRIV_REQUIRES spark_plug)
```
As a result, source files in the car component don’t need the spark_plug include directories added to their compiler search path. This can speed up compilation, and stops compiler command lines from becoming longer than necessary.

**Spark Plug Component**  The spark_plug component doesn’t depend on anything else. It has a public header file spark_plug.h, but this doesn’t include headers from any other components. This means that the spark_plug/CMakeLists.txt file doesn’t need any REQUIRES or PRIV_REQUIRES clauses:

```
idf_component_register(SRCS "spark_plug.c"
INCLUDE_DIRS ".")
```

**Source File Include Directories**

Each component’s source file is compiled with these include path directories, as specified in the passed arguments to idf_component_register:

```
idf_component_register(.
   INCLUDE_DIRS "include"
   PRIV_INCLUDE_DIRS "other")
```

- The current component’s INCLUDE_DIRS and PRIV_INCLUDE_DIRS.
- The INCLUDE_DIRS belonging to all other components listed in the REQUIRES and PRIV_REQUIRES parameters (ie all the current component’s public and private dependencies).
- Recursively, all of the INCLUDE_DIRS of those components REQUIRES lists (ie all public dependencies of this component’s dependencies, recursively expanded).

**Main Component Requirements**

The component named main is special because it automatically requires all other components in the build. So it’s not necessary to pass REQUIRES or PRIV_REQUIRES to this component. See renaming main for a description of what needs to be changed if no longer using the main component.

**Common Component Requirements**

To avoid duplication, every component automatically requires some “common” IDF components even if they are not mentioned explicitly. Headers from these components can always be included.

The list of common components is: cxx, newlib, freertos, esp_hw_support, heap, log, soc, hal, esp_rom, esp_common, esp_system, xtensa/riscv.

**Including Components in the Build**

- By default, every component is included in the build.
- If you set the COMPONENTS variable to a minimal list of components used directly by your project, then the build will expand to also include required components. The full list of components will be:
  - Components mentioned explicitly in COMPONENTS.
  - Those components’ requirements (evaluated recursively).
  - The “common” components that every component depends on.
- Setting COMPONENTS to the minimal list of required components can significantly reduce compile times.
Circular Dependencies

It’s possible for a project to contain Component A that requires (REQUIRES or PRIV_REQUIRES) Component B, and Component B that requires Component A. This is known as a dependency cycle or a circular dependency.

CMake will usually handle circular dependencies automatically by repeating the component library names twice on the linker command line. However this strategy doesn’t always work, and the build may fail with a linker error about “Undefined reference to …”, referencing a symbol defined by one of the components inside the circular dependency. This is particularly likely if there is a large circular dependency, i.e., A > B > C > D > A.

The best solution is to restructure the components to remove the circular dependency. In most cases, a software architecture without circular dependencies has desirable properties of modularity and clean layering and will be more maintainable in the long term. However, removing circular dependencies is not always possible.

To bypass a linker error caused by a circular dependency, the simplest workaround is to increase the CMake LINK_INTERFACE_MULTIPLICITY property of one of the component libraries. This causes CMake to repeat this library and its dependencies more than two times on the linker command line.

For example:

```cmake
set_property(TARGET ${COMPONENT_LIB} APPEND PROPERTY LINK_INTERFACE_MULTIPLICITY 3)
```

- This line should be placed after idf_component_register in the component CMakeLists.txt file.
- If possible, place this line in the component that creates the circular dependency by depending on a lot of other components. However, the line can be placed inside any component that is part of the cycle. Choosing the component that owns the source file shown in the linker error message, or the component that defines the symbol(s) mentioned in the linker error message, is a good place to start.
- Usually increasing the value to 3 (default is 2) is enough, but if this doesn’t work then try increasing the number further.
- Adding this option will make the linker command line longer, and the linking stage slower.

Advanced Workaround: Undefined Symbols

If only one or two symbols are causing a circular dependency, and all other dependencies are linear, then there is an alternative method to avoid linker errors: Specify the specific symbols required for the “reverse” dependency as undefined symbols at link time.

For example, if component A depends on component B but component B also needs to reference reverse_ops from component A (but nothing else), then you can add a line like the following to the component B CMakeLists.txt to resolve the cycle at link time:

```cmake
# This symbol is provided by 'Component A' at link time
target_link_libraries(${COMPONENT_LIB} INTERFACE "-u reverse_ops")
```

- The -u argument means that the linker will always include this symbol in the link, regardless of dependency ordering.
- This line should be placed after idf_component_register in the component CMakeLists.txt file.
- If ‘Component B’ doesn’t need to access any headers of ‘Component A’, only link to a few symbol(s), then this line can be used instead of any REQUIRES from B to A. This further simplifies the component structure in the build system.

See the `target_link_libraries` documentation for more information about this CMake function.

Requirements in the Build System Implementation

- Very early in the CMake configuration process, the script `expand_requirements.cmake` is run. This script does a partial evaluation of all component CMakeLists.txt files and builds a graph of component requirements (this graph may have cycles). The graph is used to generate a file `component_depends.cmake` in the build directory.
- The main CMake process then includes this file and uses it to determine the list of components to include in the build (internal BUILD_COMPONENTS variable). The BUILD_COMPONENTS variable is sorted so dependencies are listed first, however, as the component dependency graph has cycles this cannot be guaranteed.
for all components. The order should be deterministic given the same set of components and component dependencies.

- The value of `BUILD_COMPONENTS` is logged by CMake as “Component names: “
- Configuration is then evaluated for the components included in the build.
- Each component is included in the build normally and the CMakeLists.txt file is evaluated again to add the component libraries to the build.

### Component Dependency Order

The order of components in the `BUILD_COMPONENTS` variable determines other orderings during the build:

- Order that `Project_include.cmake` files are included in the project.
- Order that the list of header paths is generated for compilation (via `-I` argument). (Note that for a given component’s source files, only that component’s dependency’s header paths are passed to the compiler.)

### Adding Link-Time Dependencies

The ESP-IDF CMake helper function `idf_component_add_link_dependency` adds a link-only dependency between one component and another. In almost all cases, it is better to use the `PRIV_REQUIRES` feature in `idf_component_register` to create a dependency. However, in some cases, it’s necessary to add the link-time dependency of another component to this component, i.e., the reverse order to `PRIV_REQUIRES` (for example: Overriding Default Chip Drivers).

To make another component depend on this component at link time:

```
idf_component_add_link_dependency(FROM other_component)
```

Place this line after the line with `idf_component_register`. It’s also possible to specify both components by name:

```
idf_component_add_link_dependency(FROM other_component TO that_component)
```

### 4.6.9 Overriding Parts of the Project

#### Project_include.cmake

For components that have build requirements that must be evaluated before any component CMakeLists files are evaluated, you can create a file called `project_include.cmake` in the component directory. This CMake file is included when `project.cmake` is evaluating the entire project.

`project_include.cmake` files are used inside ESP-IDF, for defining project-wide build features such as `esp tool.py` command line arguments and the bootloader “special app”.

Unlike component CMakeLists.txt files, when including a `project_include.cmake` file the current source directory (CMAKE_CURRENT_SOURCE_DIR and working directory) is the project directory. Use the variable `COMPONENT_DIR` for the absolute directory of the component.

Note that `project_include.cmake` isn’t necessary for the most common component uses, such as adding include directories to the project, or `LDFLAGS` to the final linking step. These values can be customized via the CMakeLists.txt file itself. See [Optional Project Variables](#optional-project-variables) for details.

`project_include.cmake` files are included in the order given in `BUILD.Components` variable (as logged by CMake). This means that a component’s `project_include.cmake` file will be included after its all dependencies’ `project_include.cmake` files, unless both components are part of a dependency cycle. This is important if a `project_include.cmake` file relies on variables set by another component. See also [above](#above).

Take great care when setting variables or targets in a `project_include.cmake` file. As the values are included in the top-level project CMake pass, they can influence or break functionality across all components!
**KConfig.projbuild**

This is an equivalent to `project_include.cmake` for Component Configuration KConfig files. If you want to include configuration options at the top level of menuconfig, rather than inside the “Component Configuration” sub-menu, then these can be defined in the KConfig.projbuild file alongside the CMakeLists.txt file.

Take care when adding configuration values in this file, as they will be included across the entire project configuration. Where possible, it’s generally better to create a KConfig file for Component Configuration.

`project_include.cmake` files are used inside ESP-IDF, for defining project-wide build features such as `esptool.py` command line arguments and the bootloader “special app”.

**Wrappers to Redefine or Extend Existing Functions**

Thanks to the linker’s `wrap` feature, it is possible to redefine or extend the behavior of an existing ESP-IDF function. To do so, you will need to provide the following CMake declaration in your project’s `CMakeLists.txt` file:

```
target_link_libraries(${COMPONENT_LIB} INTERFACE "-Wl,--wrap=function_to_redefine")
```

Where `function_to_redefine` is the name of the function to redefine or extend. This option will let the linker replace all the calls to `function_to_redefine` functions in the binary libraries with calls to `__wrap_function_to_redefine` function. Thus, you must define this new symbol in your application.

The linker will provide a new symbol named `__real_function_to_redefine` which points to the former implementation of the function to redefine. It can be called from the new implementation, making it an extension of the former one.

This mechanism is shown in the example `build_system/wrappers`. Check `examples/build_system/wrappers/README.md` for more details.

**Override the Default Bootloader**

Thanks to the optional `bootloader_components` directory present in your ESP-IDF project, it is possible to override the default ESP-IDF bootloader. To do so, a new `bootloader_components/main` component should be defined, which will make the project directory tree look like the following:

- **myProject/**
  - CMakelists.txt
  - sdkconfig
  - `bootloader_components` - main/ - CMakelists.txt
    - Kconfig
    - my_bootloader.c
  - main/ - CMakelists.txt
    - app_main.c
  - build/

Here the `my_bootloader.c` file becomes source code for the new bootloader, which means that it will need to perform all the required operations to set up and load the main application from flash.

It is also possible to conditionally replace the bootloader depending on a certain condition, such as the target for example. This can be achieved thanks to the `BOOTLOADER_IGNORE_EXTRA_COMPONENT` CMake variable. This list can be used to tell the ESP-IDF bootloader project to ignore and not compile the given components present in `bootloader_components`. For example, if one wants to use the default bootloader for ESP32 target, then `myProject/CMakeLists.txt` should look like the following:

```
include($ENV{IDF_PATH}/tools/cmake/project.cmake)

if(${IDF_TARGET} STREQUAL "esp32")
  set(BOOTLOADER_IGNORE_EXTRA_COMPONENT "main")
endif()
```

(continues on next page)
It is important to note that this can also be used for any other bootloader components than main. In all cases, the prefix bootloader_component must not be specified.

See custom_bootloader/bootloader_override for an example of overriding the default bootloader.

### 4.6.10 Configuration-Only Components

Special components which contain no source files, only `Kconfig.projbuild` and `KConfig`, can have a one-line `CMakeLists.txt` file which calls the function `idf_component_register()` with no arguments specified. This function will include the component in the project build, but no library will be built and no header files will be added to any included paths.

### 4.6.11 Debugging CMake

For full details about CMake and CMake commands, see the CMake v3.16 documentation.

Some tips for debugging the ESP-IDF CMake-based build system:

- When CMake runs, it prints quite a lot of diagnostic information including lists of components and component paths.
- Running `cmake -DDEBUG=1` will produce more verbose diagnostic output from the IDF build system.
- Running `cmake` with the `--trace` or `--trace-expand` options will give a lot of information about control flow. See the `cmake` command line documentation.

When included from a project `CMakeLists.txt` file, the `project.cmake` file defines some utility modules and global variables and then sets `IDF_PATH` if it was not set in the system environment.

It also defines an overridden custom version of the built-in CMake `project` function. This function is overridden to add all of the ESP-IDF specific project functionality.

**Warning On Undefined Variables**

By default, the function of warnings on undefined variables is disabled.

To enable this function, we can pass the `--warn-uninitialized` flag to CMake or pass the `--cmake-warn-uninitialized` flag to `idf.py` so it will print a warning if an undefined variable is referenced in the build. This can be very useful to find buggy CMake files.

Browse the `/tools/cmake/project.cmake` file and supporting functions in `/tools/cmake/` for more details.

### 4.6.12 Example Component CMakeLists

Because the build environment tries to set reasonable defaults that will work most of the time, component `CMakeLists.txt` can be very small or even empty (see Minimal Component CMakeLists). However, overriding `preset_component_variables` is usually required for some functionality.

Here are some more advanced examples of component `CMakeLists` files.

**Adding Conditional Configuration**

The configuration system can be used to conditionally compile some files depending on the options selected in the project configuration.

`Kconfig:`
config FOO_ENABLE_BAR
  bool "Enable the BAR feature."
  help
  This enables the BAR feature of the FOO component.

CMakeLists.txt:

```cmake
set(srcs "foo.c" "more_foo.c")
if(CONFIG_FOO_ENABLE_BAR)
  list(APPEND srcs "bar.c")
endif()
idf_component_register(SRCS "${{srcs}}"
  ...
)
```

This example makes use of the CMake if function and list APPEND function.

This can also be used to select or stub out an implementation, as such:

Kconfig:

```cmake
cfg ENABLE_LCD_OUTPUT
  bool "Enable LCD output."
  help
  Select this if your board has an LCD.

cfg ENABLE_LCD_CONSOLE
  bool "Output console text to LCD"
  depends on ENABLE_LCD_OUTPUT
  help
  Select this to output debugging output to the LCD

cfg ENABLE_LCD_PLOT
  bool "Output temperature plots to LCD"
  depends on ENABLE_LCD_OUTPUT
  help
  Select this to output temperature plots
```

CMakeLists.txt:

```cmake
if(CONFIG_ENABLE_LCD_OUTPUT)
  set(srcs lcd-real.c lcd-spi.c)
else()
  set(srcs lcd-dummy.c)
endif()

# We need font if either console or plot is enabled
if(CONFIG_ENABLE_LCD_CONSOLE OR CONFIG_ENABLE_LCD_PLOT)
  list(APPEND srcs "font.c")
endif()

idf_component_register(SRCS "${{srcs}}"
  ...
)
```

Conditions Which Depend on the Target

The current target is available to CMake files via IDF_TARGET variable.

In addition to that, if target xyz is used (IDF_TARGET=xyz), then Kconfig variable CONFIG_IDF_TARGET_xyz will be set.
Note that component dependencies may depend on IDF_TARGET variable, but not on Kconfig variables. Also one can not use Kconfig variables in include statements in CMake files, but IDF_TARGET can be used in such context.

### Source Code Generation

Some components will have a situation where a source file isn’t supplied with the component itself but has to be generated from another file. Say our component has a header file that consists of the converted binary data of a BMP file, converted using a hypothetical tool called bmp2h. The header file is then included in as C source file called graphics_lib.c:

```makefile
add_custom_command(
  OUTPUT logo.h
  COMMAND bmp2h -i ${COMPONENT_DIR}/logo.bmp -o log.h
  DEPENDS ${COMPONENT_DIR}/logo.bmp
  VERBATIM)
add_custom_target(logo DEPENDS logo.h)
add_dependencies(${COMPONENT_LIB} logo)
set_property(DIRECTORY "${COMPONENT_DIR}" APPEND PROPERTY ADDITIONAL_CLEAN_FILES logo.h)
```

This answer is adapted from the [CMake FAQ entry](#), which contains some other examples that will also work with ESP-IDF builds.

In this example, logo.h will be generated in the current directory (the build directory) while logo.bmp comes with the component and resides under the component path. Because logo.h is a generated file, it should be cleaned when the project is cleaned. For this reason, it is added to the ADDITIONAL_CLEAN_FILES property.

**Note:** If generating files as part of the project CMakeLists.txt file, not a component CMakeLists.txt, then use build property PROJECT_DIR instead of ${COMPONENT_DIR} and ${PROJECT_NAME}.elf instead of ${COMPONENT_LIB}.

If a source file from another component included logo.h, then add_dependencies would need to be called to add a dependency between the two components, to ensure that the component source files were always compiled in the correct order.

### Embedding Binary Data

Sometimes you have a file with some binary or text data that you’d like to make available to your component, but you don’t want to reformat the file as a C source.

You can specify argument EMBED_FILES in the component registration, giving space-delimited names of the files to embed:

```makefile
idf_component_register(...
  EMBED_FILES server_root_cert.der)
```

Or if the file is a string, you can use the variable EMBED_TXTFILES. This will embed the contents of the text file as a null-terminated string:

```makefile
idf_component_register(...
  EMBED_TXTFILES server_root_cert.pem)
```

The file’s contents will be added to the .rodata section in flash, and are available via symbol names as follows:

```c
extern const uint8_t server_root_cert_pem_start[] asm("_binary_server_root_cert_pem_start");
extern const uint8_t server_root_cert_pem_end[] asm("_binary_server_root_cert_pem_end");
```
Chapter 4. API Guides

The names are generated from the full name of the file, as given in EMBED_FILES. Characters /., etc. are replaced with underscores. The _binary prefix in the symbol name is added by objcopy and is the same for both text and binary files.

To embed a file into a project, rather than a component, you can call the function target_add_binary_data like this:

```
target_add_binary_data(myproject.elf "main/data.bin" TEXT)
```

Place this line after the `project()` line in your project CMakeLists.txt file. Replace myproject.elf with your project name. The final argument can be TEXT to embed a null-terminated string, or BINARY to embed the content as-is.

For an example of using this technique, see the "main" component of the file_serving example protocols/http_server/file_serving/main/CMakeLists.txt - two files are loaded at build time and linked into the firmware.

It is also possible to embed a generated file:

```
add_custom_command(OUTPUT my_processed_file.bin COMMAND my_process_file_cmd my_unprocessed_file.bin)
target_add_binary_data(my_target "my_processed_file.bin" BINARY)
```

In the example above, my_processed_file.bin is generated from my_unprocessed_file.bin through some command my_process_file_cmd, then embedded into the target.

To specify a dependence on a target, use the DEPENDS argument:

```
add_custom_target(my_process COMMAND ...)
target_add_binary_data(my_target "my_embed_file.bin" BINARY DEPENDS my_process)
```

The DEPENDS argument to `target_add_binary_data` ensures that the target executes first.

**Code and Data Placements**

ESP-IDF has a feature called linker script generation that enables components to define where its code and data will be placed in memory through linker fragment files. These files are processed by the build system, and is used to augment the linker script used for linking app binary. See Linker Script Generation for a quick start guide as well as a detailed discussion of the mechanism.

**Fully Overriding the Component Build Process**

Obviously, there are cases where all these recipes are insufficient for a certain component, for example when the component is basically a wrapper around another third-party component not originally intended to be compiled under this build system. In that case, it’s possible to forego the ESP-IDF build system entirely by using a CMake feature called ExternalProject. Example component CMakeLists:

```cmake
# External build process for quirc, runs in source dir and # produces libquirc.a
externalproject_add(quirc_build
  PREFIX ${COMPONENT_DIR}
  SOURCE_DIR ${COMPONENT_DIR}/quirc
  CONFIGURE_COMMAND ""
  BUILD_IN_SOURCE 1
  BUILD_COMMAND make CC=${CMAKE_C_COMPILER} libquirc.a
  INSTALL_COMMAND ""
)
# Add libquirc.a to the build process
add_library(quirc STATIC IMPORTED GLOBAL)
add_dependencies(quirc quirc_build)
```

(continues on next page)
set_target_properties(quirc PROPERTIES IMPORTED_LOCATION 
    ${COMPONENT_DIR}/quirc/libquirc.a)

set_target_properties(quirc PROPERTIES INTERFACE_INCLUDE_DIRECTORIES 
    ${COMPONENT_DIR}/quirc/lib)

set_directory_properties( PROPERTIES ADDITIONAL_CLEAN_FILES 
    "${COMPONENT_DIR}/quirc/libquirc.a")

(The above CMakeLists.txt can be used to create a component named quirc that builds the quirc project using its own Makefile.)

- externalproject_add defines an external build system.
  - SOURCE_DIR, CONFIGURE_COMMAND, BUILD_COMMAND and INSTALL_COMMAND should always be set. CONFIGURE_COMMAND can be set to an empty string if the build system has no “configure” step. INSTALL_COMMAND will generally be empty for ESP-IDF builds.
  - Setting BUILD_IN_SOURCE means the build directory is the same as the source directory. Otherwise, you can set BUILD_DIR.
  - Consult the ExternalProject documentation for more details about externalproject_add()

- The second set of commands adds a library target, which points to the imported library file built by the external system. Some properties need to be set in order to add includedirectories and tell CMake where this file is.
- Finally, the generated library is added to ADDITIONAL_CLEAN_FILES. This means make clean will delete this library. (Note that the other object files from the build won’t be deleted.)

Note: When using an external build process with PSRAM, remember to add -mfix-esp32-psram-cache-issue to the C compiler arguments. See CONFIG_SPIRAM_CACHE_WORKAROUND for details of this flag.

ExternalProject Dependencies and Clean Builds CMake has some unusual behavior around external project builds:

- ADDITIONAL_CLEAN_FILES only works when “make” or “ninja” is used as the build system. If an IDE build system is used, it won’t delete these files when cleaning.
- However, the ExternalProject configure & build commands will always be re-run after a clean is run.
- Therefore, there are two alternative recommended ways to configure the external build command:
  1. Have the external BUILD_COMMAND run a full clean compile of all sources. The build command will be run if any of the dependencies passed to externalproject_add with DEPENDS have changed, or if this is a clean build (ie any of idf.py clean, ninja clean, or make clean was run.)
  2. Have the external BUILD_COMMAND be an incremental build command. Pass the parameter BUILD_ALWAYS 1 to externalproject_add. This means the external project will be built each time a build is run, regardless of dependencies. This is only recommended if the external project has correct incremental build behavior, and doesn’t take too long to run.

The best of these approaches for building an external project will depend on the project itself, its build system, and whether you anticipate needing to frequently recompile the project.

4.6.13 Custom Sdkconfig Defaults

For example projects or other projects where you don’t want to specify a full sdkconfig configuration, but you do want to override some key values from the ESP-IDF defaults, it is possible to create a file sdkconfig.defaults in the project directory. This file will be used when creating a new config from scratch, or when any new config value hasn’t yet been set in the sdkconfig file.

To override the name of this file or to specify multiple files, set the SDKCONFIG_DEFAULTS environment variable or set SDKCONFIG_DEFAULTS in top-level CMakeLists.txt. File names that are not specified as full paths
are resolved relative to current project’s directory.

When specifying multiple files, use a semicolon as the list separator. Files listed first will be applied first. If a particular key is defined in multiple files, the definition in the latter file will override definitions from former files.

Some of the IDF examples include a `sdkconfig.ci` file. This is part of the continuous integration (CI) test framework and is ignored by the normal build process.

**Target-dependentSdkconfig Defaults**

If and only if an `sdkconfig.defaults` file exists, the build system will also attempt to load defaults from an `sdkconfig.defaults.TARGET_NAME` file, where `TARGET_NAME` is the value of `IDF_TARGET`. For example, for `esp32` target, default settings will be taken from `sdkconfig.defaults` first, and then from `sdkconfig.defaults.esp32`. If there are no generic default settings, an empty `sdkconfig.defaults` still needs to be created if the build system should recognize any additional target-dependent `sdkconfig.defaults.TARGET_NAME` files.

If `SDKCONFIG_DEFAULTS` is used to override the name of defaults file/files, the name of target-specific defaults file will be derived from `SDKCONFIG_DEFAULTS` value/values using the rule above. When there are multiple files in `SDKCONFIG_DEFAULTS`, target-specific file will be applied right after the file bringing it in, before all latter files in `SDKCONFIG_DEFAULTS`.

For example, if `SDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig_devkit1"`, and there is a file `sdkconfig.defaults.esp32` in the same folder, then the files will be applied in the following order: (1) `sdkconfig.defaults` (2) `sdkconfig.defaults.esp32` (3) `sdkconfig_devkit1`.

**4.6.14 Flash Arguments**

There are some scenarios that we want to flash the target board without IDF. For this case we want to save the built binaries, esptool.py and esptool.write flash arguments. It’s simple to write a script to save binaries and esptool.py.

After running a project build, the build directory contains binary output files (.bin files) for the project and also the following flashing data files:

- `flash_project_args` contains arguments to flash the entire project (app, bootloader, partition table, PHY data if this is configured).
- `flash_app_args` contains arguments to flash only the app.
- `flash_bootloader_args` contains arguments to flash only the bootloader.

You can pass any of these flasher argument files to `esptool.py` as follows:

```python
esptool.py --chip esp32 write_flash @build/flash_project_args
```

Alternatively, it is possible to manually copy the parameters from the argument file and pass them on the command line.

The build directory also contains a generated file `flasher_args.json` which contains project flash information, in JSON format. This file is used by `idf.py` and can also be used by other tools which need information about the project build.

**4.6.15 Building the Bootloader**

The bootloader is a special “subproject” inside `/components/bootloader/subproject`. It has its own project CMake-Lists.txt file and builds separate .ELF and .BIN files to the main project. However, it shares its configuration and build directory with the main project.

The subproject is inserted as an external project from the top-level project, by the file `/components/bootloader/project_include.cmake`. The main build process runs CMake for the subproject, which includes discovering components (a subset of the main components) and generating a bootloader-specific config (derived from the main `sdkconfig`).

Espressif Systems 2527 Release v5.3-dev-277-gc8243465e4
4.6.16 Writing Pure CMake Components

The ESP-IDF build system “wraps” CMake with the concept of “components”, and helper functions to automatically integrate these components into a project build.

However, underneath the concept of “components” is a full CMake build system. It is also possible to make a component which is pure CMake.

Here is an example minimal “pure CMake” component CMakeLists file for a component named json:

```cmake
add_library(json STATIC cJSON/cJSON.c cJSON/cJSON_Utils.c)
target_include_directories(json PUBLIC cJSON)
```

- This is actually an equivalent declaration to the IDF json component `/components/json/CMakeLists.txt`.
- This file is quite simple as there are not a lot of source files. For components with a large number of files, the globbing behavior of ESP-IDF’s component logic can make the component CMakeLists style simpler.
- Any time a component adds a library target with the component name, the ESP-IDF build system will automatically add this to the build, expose public include directories, etc. If a component wants to add a library target with a different name, dependencies will need to be added manually via CMake commands.

4.6.17 Using Third-Party CMake Projects with Components

CMake is used for a lot of open-source C and C++ projects — code that users can tap into for their applications. One of the benefits of having a CMake build system is the ability to import these third-party projects, sometimes even without modification! This allows for users to be able to get functionality that may not yet be provided by a component, or use another library for the same functionality.

Importing a library might look like this for a hypothetical library foo to be used in the main component:

```cmake
# Register the component
idf_component_register(...)

# Set values of hypothetical variables that control the build of ‘foo’
set(FOO_BUILD_STATIC OFF)
set(FOO_BUILD_TESTS OFF)

# Create and import the library targets
add_subdirectory(foo)

# Publicly link ‘foo’ to ‘main’ component
target_link_libraries(main PUBLIC foo)
```

For an actual example, take a look at `build_system/cmake/import_lib`. Take note that what needs to be done in order to import the library may vary. It is recommended to read up on the library’s documentation for instructions on how to import it from other projects. Studying the library’s CMakeLists.txt and build structure can also be helpful.

It is also possible to wrap a third-party library to be used as a component in this manner. For example, the mbedtls component is a wrapper for Espressif’s fork of mbedtls. See its component CMakeLists.txt.

The CMake variable `ESP_PLATFORM` is set to 1 whenever the ESP-IDF build system is being used. Tests such as `if(ESP_PLATFORM)` can be used in generic CMake code if special IDF-specific logic is required.

Using ESP-IDF Components from External Libraries

The above example assumes that the external library foo (or tinyxml in the case of the import_lib example) doesn’t need to use any ESP-IDF APIs apart from common APIs such as libc, libstdc++, etc. If the external library needs to use APIs provided by other ESP-IDF components, this needs to be specified in the external CMakeLists.txt file by adding a dependency on the library target `idf::<componentname>`.
For example, in the foo/CMakeLists.txt file:

```cmake
add_library(foo bar.c fizz.cpp buzz.cpp)
if(ESP_PLATFORM)
    # On ESP-IDF, bar.c needs to include esp_flash.h from the spi_flash component
    target_link_libraries(foo PRIVATE idf::spi_flash)
endif()
```

### 4.6.18 Using Prebuilt Libraries with Components

Another possibility is that you have a prebuilt static library (.a file), built by some other build process.

The ESP-IDF build system provides a utility function `add_prebuilt_library` for users to be able to easily import and use prebuilt libraries:

```cmake
add_prebuilt_library(target_name lib_path
                      [REQUIRES req1 req2 ...]
                      [PRIV_REQUIRES req1 req2 ...])
```

where:
- `target_name`- name that can be used to reference the imported library, such as when linking to other targets
- `lib_path`- path to prebuilt library; may be an absolute or relative path to the component directory

Optional arguments `REQUIRES` and `PRIV_REQUIRES` specify dependency on other components. These have the same meaning as the arguments for `idf_component_register`.

Take note that the prebuilt library must have been compiled for the same target as the consuming project. Configuration relevant to the prebuilt library must also match. If not paid attention to, these two factors may contribute to subtle bugs in the app.

For an example, take a look at `build_system/cmake/import_prebuilt`.

### 4.6.19 Using ESP-IDF in Custom CMake Projects

ESP-IDF provides a template CMake project for easily creating an application. However, in some instances the user might already have an existing CMake project or may want to create a custom one. In these cases it is desirable to be able to consume IDF components as libraries to be linked to the user’s targets (libraries/executables).

It is possible to do so by using the `build system APIs provided` by `tools/cmake/idf.cmake`. For example:

```cmake
cmake_minimum_required(VERSION 3.16)
project(my_custom_app C)

# Include CMake file that provides ESP-IDF CMake build system APIs.
include(${ENV{IDF_PATH}}/tools/cmake/idf.cmake)

# Include ESP-IDF components in the build, may be thought as an equivalent of
# add_subdirectory() but with some additional processing and magic for ESP-IDF
# build
# specific build processes.
idf_build_process(esp32)

# Create the project executable and plainly link the newlib component to it using
# its alias, idf::newlib.
add_executable(${CMAKE_PROJECT_NAME}.elf main.c)
target_link_libraries(${CMAKE_PROJECT_NAME}.elf idf::newlib)

# Let the build system know what the project executable is to attach more targets,
# dependencies, etc.
idf_build_executable(${CMAKE_PROJECT_NAME}.elf)
```
The example in `build_system/cmake/idf_as_lib` demonstrates the creation of an application equivalent to `hello world` application using a custom CMake project.

**Note:** The IDF build system can only set compiler flags for source files that it builds. When an external CMake-Lists.txt file is used and PSRAM is enabled, remember to add `-mfix-esp32-psram-cache-issue` to the C compiler arguments. See `CONFIG_SPIRAM_CACHE_WORKAROUND` for details of this flag.

### 4.6.20 ESP-IDF CMake Build System API

**Idf-build-commands**

```cmake
idf_build_get_property(var property [GENERATOR_EXPRESSION])
```

Retrieve a **build property** `property` and store it in `var` accessible from the current scope. Specifying `GENERATOR_EXPRESSION` will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.

```cmake
idf_build_set_property(property val [APPEND])
```

Set a **build property** `property` with value `val`. Specifying `APPEND` will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

```cmake
idf_build_component(component_dir)
```

Present a directory `component_dir` that contains a component to the build system. Relative paths are converted to absolute paths with respect to current directory. All calls to this command must be performed before `idf_build_process`.

This command does not guarantee that the component will be processed during build (see the `COMPONENTS` argument description for `idf_build_process`)

```cmake
idf_build_process(target

[PROJECT_DIR project_dir]
[PROJECT_VER project_ver]
[PROJECT_NAME project_name]
[SDKCONFIG sdkconfig]
[SDKCONFIG_DEFAULTS sdkconfig_defaults]
[BUILD_DIR build_dir]
[COMPONENTS component1 component2 ...])
```

Performs the bulk of the behind-the-scenes magic for including ESP-IDF components such as component configuration, libraries creation, dependency expansion and resolution. Among these functions, perhaps the most important from a user’s perspective is the libraries creation by calling each component’s `idf_component_register`. This command creates the libraries for each component, which are accessible using aliases in the form `idf::component_name`. These aliases can be used to link the components to the user’s own targets, either libraries or executables.

The call requires the target chip to be specified with `target` argument. Optional arguments for the call include:

- `PROJECT_DIR` - directory of the project; defaults to `CMAKE_SOURCE_DIR`
- `PROJECT_NAME` - name of the project; defaults to `CMAKE_PROJECT_NAME`
- `PROJECT_VER` - version/revision of the project; defaults to “1”
- `SDKCONFIG` - output path of generated sdkconfig file; defaults to `PROJECT_DIR/sdkconfig` or `CMAKE_SOURCE_DIR/sdkconfig` depending if `PROJECT_DIR` is set
- `SDKCONFIG_DEFAULTS` - list of files containing default config to use in the build (list must contain full paths); defaults to empty. For each value `filename` in the list, the config from file `filename.target`, if it exists, is also loaded.
Chapter 4. API Guides

- **BUILD_DIR** - directory to place ESP-IDF build-related artifacts, such as generated binaries, text files, components; defaults to CMAKE_BINARY_DIR
- **COMPONENTS** - select components to process among the components known by the build system (added via `idf_build_component`). This argument is used to trim the build. Other components are automatically added if they are required in the dependency chain, i.e., the public and private requirements of the components in this list are automatically added, and in turn the public and private requirements of those requirements, so on and so forth. If not specified, all components known to the build system are processed.

```cpp
idf_build_executable(executable)
```

Specify the executable `executable` for ESP-IDF build. This attaches additional targets such as dependencies related to flashing, generating additional binary files, etc. Should be called after `idf_build_process`.

```cpp
idf_build_get_config(var config [GENERATOR_EXPRESSION])
```

Get the value of the specified config. Much like build properties, specifying `GENERATOR_EXPRESSION` will retrieve the generator expression string for that config, instead of the actual value, which can be used with CMake commands that support generator expressions. Actual config values are only known after call to `idf_build_process`, however.

### Idf-build-properties

These are properties that describe the build. Values of build properties can be retrieved by using the build command `idf_build_get_property`. For example, to get the Python interpreter used for the build:

```cpp
idf_build_get_property(python PYTHON)
message(STATUS "The Python interpreter is: \${python}"")
```

- **BUILD_DIR** - build directory; set from `idf_build_process BUILD_DIR` argument
- **BUILD_COMPONENTS** - list of components included in the build; set by `idf_build_process`
- **BUILD_COMPONENT_ALIASES** - list of library alias of components included in the build; set by `idf_build_process`
- **C_COMPILE_OPTIONS** - compile options applied to all components’ C source files
- **COMPILE_OPTIONS** - compile options applied to all components’ source files, regardless of it being C or C++
- **COMPILE_DEFINITIONS** - compile definitions applied to all component source files
- **CXX_COMPILE_OPTIONS** - compile options applied to all components’ C++ source files
- **DEPENDENCIES_LOCK** - lock file path used in component manager. The default value is `dependencies.lock` under the project path.
- **EXECUTABLE** - project executable; set by call to `idf_build_executable`
- **EXECUTABLE_NAME** - name of project executable without extension; set by call to `idf_build_executable`
- **EXECUTABLE_DIR** - path containing the output executable
- **IDF_COMPONENT_MANAGER** - the component manager is enabled by default, but if this property is set to 0 it was disabled by the IDF_COMPONENT_MANAGER environment variable
- **IDF_PATH** - ESP-IDF path; set from IDF_PATH environment variable, if not, inferred from the location of `idf.cmake`
- **IDF_TARGET** - target chip for the build; set from the required target argument for `idf_build_process`
- **IDF_VER** - ESP-IDF version; set from either a version file or the Git revision of the IDF_PATH repository
- **INCLUDE_DIRECTORIES** - include directories for all component source files
- **KCONFIGS** - list of Kconfig files found in components in build; set by `idf_build_process`
- **KCONFIG_PROJBUILDS** - list of Kconfig.projbuild files found in components in build; set by `idf_build_process`
- **PROJECT_NAME** - name of the project; set from `idf_build_process PROJECT_NAME` argument
- **PROJECT_DIR** - directory of the project; set from `idf_build_process PROJECT_DIR` argument
- **PROJECT_VER** - version of the project; set from `idf_build_process PROJECT_VER` argument
- **PYTHON** - Python interpreter used for the build; set from PYTHON environment variable if available, if not “python” is used
Chapter 4. API Guides

- **SDKCONFIG** - full path to output config file; set from `idf_build_process` `SDKCONFIG` argument
- **SDKCONFIG_DEFAULTS** - list of files containing default config to use in the build; set from `idf_build_process` `SDKCONFIG_DEFAULTS` argument
- **SDKCONFIG_HEADER** - full path to C/C++ header file containing component configuration; set by `idf_build_process`
- **SDKCONFIG_CMAKE** - full path to CMake file containing component configuration; set by `idf_build_process`
- **SDKCONFIG_JSON** - full path to JSON file containing component configuration; set by `idf_build_process`
- **SDKCONFIG_JSON_MENUS** - full path to JSON file containing config menus; set by `idf_build_process`

**Idf-component-commands**

```
idf_component_get_property(var component property [GENERATOR_EXPRESSION])
```

Retrieve a specified component’s `component property` and store it in `var` accessible from the current scope. Specifying `GENERATOR_EXPRESSION` will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.

```
idf_component_set_property(component property val [APPEND])
```

Set a specified component’s `component property` with value `val`. Specifying `APPEND` will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

```
idf_component_register([[[SRCS src1 src2 ...] | [[SRC_DIRS dir1 dir2 ...] [EXCLUDE_\nSRCS src1 src2 ...]])
  [INCLUDE_DIRS dir1 dir2 ...]
  [PRIV_INCLUDE_DIRS dir1 dir2 ...]
  [REQUIRES component1 component2 ...]
  [PRIV.Requires component1 component2 ...]
  [LDFRAGMENTS ldfragment1 ldfragment2 ...]
  [REQUIRED_IDF_TARGETS target1 target2 ...]
  [EMBED_FILES file1 file2 ...]
  [EMBED_TXTFILES file1 file2 ...]
  [KCONFIG kconfig]
  [KCONFIG_PROJBUILD kconfig_projbuild]
  [WHOLE_ARCHIVE])
```

Register a component to the build system. Much like the `project()` CMake command, this should be called from the component’s `CMakeLists.txt` directly (not through a function or macro) and is recommended to be called before any other command. Here are some guidelines on what commands can **not** be called before `idf_component_register`:

- commands that are not valid in CMake script mode
- custom commands defined in `project_include.cmake`
- build system API commands except `idf_build_get_property`; although consider whether the property may not have been set yet

Commands that set and operate on variables are generally okay to call before `idf_component_register`.

The arguments for `idf_component_register` include:

- **SRCS** - component source files used for creating a static library for the component; if not specified, component is treated as a config-only component and an interface library is created instead.
- **SRC_DIRS, EXCLUDE_SRCS** - used to glob source files (.c, .cpp, .S) by specifying directories, instead of specifying source files manually via SRCS. Note that this is subject to the **limitations of globbing in CMake**. Source files specified in `EXCLUDE_SRCS` are removed from the globbed files.
- **INCLUDE_DIRS** - paths, relative to the component directory, which will be added to the include search path for all other components which require the current component
• PRIV_INCLUDE_DIRS - directory paths, must be relative to the component directory, which will be added to the include search path for this component’s source files only
• REQUIRE - public component requirements for the component
• PRIV_REQUIRES - private component requirements for the component; ignored on config-only components
• LDFRAGMENTS - component linker fragment files
• REQUIRED_IDF_TARGETS - specify the only target the component supports
• KCONFIG - override the default Kconfig file
• KCONFIG_PROJBUILD - override the default Kconfig.projobuild file
• WHOLE_ARCHIVE - if specified, the component library is surrounded by -Wl,--whole-archive, -Wl,--no-whole-archive when linked. This has the same effect as setting WHOLE_ARCHIVE component property.

The following are used for embedding data into the component, and is considered as source files when determining if a component is config-only. This means that even if the component does not specify source files, a static library is still created internally for the component if it specifies either:

• EMBED_FILES - binary files to be embedded in the component
• EMBED_TXTFILES - text files to be embedded in the component

Idf-component-properties

These are properties that describe a component. Values of component properties can be retrieved by using the build command idf_component_get_property. For example, to get the directory of the freertos component:

```
idf_component_get_property(dir freertos COMPONENT_DIR)
message(STATUS "The 'freertos' component directory is: ${dir}")
```

• COMPONENT_ALIAS - alias for COMPONENT_LIB used for linking the component to external targets; set by idf_build_component and alias library itself is created by idf_component_register
• COMPONENT_DIR - component directory; set by idf_build_component
• COMPONENT_OVERRIDEN_DIR - contains the directory of the original component if this component overrides another component
• COMPONENT_LIB - name for created component static/interface library; set by idf_build_component and library itself is created by idf_component_register
• COMPONENT_NAME - name of the component; set by idf_build_component based on the component directory name
• COMPONENT_TYPE - type of the component, whether LIBRARY or CONFIG_ONLY. A component is of type LIBRARY if it specifies source files or embeds a file
• EMBED_FILES - list of files to embed in component; set from idf_component_register EMBED_FILES argument
• EMBED_TXTFILES - list of text files to embed in component; set from idf_component_register EMBED_TXTFILES argument
• INCLUDE_DIRS - list of component include directories; set from idf_component_register INCLUDE_DIRS argument
• KCONFIG - component Kconfig file; set by idf_build_component
• KCONFIG_PROJBUILD - component Kconfig.projobuild; set by idf_build_component
• LDFRAGMENTS - list of component linker fragment files; set from idf_component_register LDFRAGMENTS argument
• MANAGED_PRIV_REQUIRES - list of private component dependencies added by the IDF component manager from dependencies in idf_component.yml manifest file
• MANAGED_REQUIRES - list of public component dependencies added by the IDF component manager from dependencies in idf_component.yml manifest file
• PRIV_INCLUDE_DIRS - list of component private include directories; set from idf_component_register PRIV_INCLUDE_DIRS on components of type LIBRARY
• PRIV_REQUIRES - list of private component dependencies; set from value of idf_component_register PRIV_REQUIRES argument and dependencies in idf_component.yml manifest file
• REQUIRED_IDF_TARGETS - list of targets the component supports; set from idf_component_register EMBED_TXTFILES argument
• REQUIRES - list of public component dependencies; set from value of `idf_component_register REQUIRES` argument and dependencies in `idf_component.yml` manifest file
• SRCS - list of component source files; set from `SRCS` or `SRC_DIRS/EXCLUDE_SRCS` argument of `idf_component_register`
• WHOLE_ARCHIVE - if this property is set to TRUE (or any boolean “true” CMake value: I, ON, YES, Y), the component library is surrounded by `-Wl,-whole-archive, -Wl,-no-whole-archive` when linked. This can be used to force the linker to include every object file into the executable, even if the object file doesn’t resolve any references from the rest of the application. This is commonly used when a component contains plugins or modules which rely on link-time registration. This property is FALSE by default. It can be set to TRUE from the component CMakeLists.txt file.

### 4.6.21 File Globbing & Incremental Builds

The preferred way to include source files in an ESP-IDF component is to list them manually via `SRCS` argument to `idf_component_register`:

```bash
idf_component_register(SRCS library/a.c library/b.c platform/platform.c ...
```

This preference reflects the CMake best practice of manually listing source files. This could, however, be inconvenient when there are lots of source files to add to the build. The ESP-IDF build system provides an alternative way for specifying source files using `SRC_DIRS`:

```bash
idf_component_register(SRC_DIRS library platform ...
```

This uses globbing behind the scenes to find source files in the specified directories. Be aware, however, that if a new source file is added and this method is used, then CMake won’t know to automatically re-run and this file won’t be added to the build.

The trade-off is acceptable when you’re adding the file yourself, because you can trigger a clean build or run `idf.py reconfigure` to manually re-run CMake. However, the problem gets harder when you share your project with others who may check out a new version using a source control tool like Git...

For components which are part of ESP-IDF, we use a third party Git CMake integration module (`/tools/cmake/third_party/GetGitRevisionDescription.cmake`) which automatically re-runs CMake any time the repository commit changes. This means if you check out a new ESP-IDF version, CMake will automatically re-run.

For project components (not part of ESP-IDF), there are a few different options:

• If keeping your project file in Git, ESP-IDF will automatically track the Git revision and re-run CMake if the revision changes.
• If some components are kept in a third git repository (not the project repository or ESP-IDF repository), you can add a call to the `git_describe` function in a component CMakeLists file in order to automatically trigger re-runs of CMake when the Git revision changes.
• If not using Git, remember to manually run `idf.py reconfigure` whenever a source file may change.
• To avoid this problem entirely, use `SRCS` argument to `idf_component_register` to list all source files in project components.

The best option will depend on your particular project and its users.

### 4.6.22 Build System Metadata

For integration into IDEs and other build systems, when CMake runs the build process generates a number of metadata files in the `build/` directory. To regenerate these files, run `cmake` or `idf.py reconfigure` (or any other `idf.py` build command).

• `compile_commands.json` is a standard format JSON file which describes every source file which is compiled in the project. A CMake feature generates this file, and many IDEs know how to parse it.
• project_description.json contains some general information about the ESP-IDF project, configured paths, etc.
• flasher_args.json contains esptool.py arguments to flash the project’s binary files. There are also flash_*_args files which can be used directly with esptool.py. See Flash arguments.
• CMakeCache.txt is the CMake cache file which contains other information about the CMake process, toolchain, etc.
• config/sdkconfig.json is a JSON-formatted version of the project configuration values.
• config/kconfig_menus.json is a JSON-formatted version of the menus shown in menuconfig, for use in external IDE UIs.

JSON Configuration Server

A tool called kconfserver is provided to allow IDEs to easily integrate with the configuration system logic. kconfserver is designed to run in the background and interact with a calling process by reading and writing JSON over process stdin & stdout.

You can run kconfserver from a project via idf.py confserver or ninja kconfserver, or a similar target triggered from a different build generator.

For more information about kconfserver, see the esp-idf-kconfig documentation.

4.6.23 Build System Internals

Build Scripts

The list files for the ESP-IDF build system reside in /tools/cmake. The modules which implement core build system functionality are as follows:

• build.cmake - Build related commands i.e., build initialization, retrieving/setting build properties, build processing.
• component.cmake - Component related commands i.e., adding components, retrieving/setting component properties, registering components.
• kconfig.cmake - Generation of configuration files (sdkconfig, sdkconfig.h, sdkconfig.cmake, etc.) from Kconfig files.
• ldgen.cmake - Generation of final linker script from linker fragment files.
• target.cmake - Setting build target and toolchain file.
• utilities.cmake - Miscellaneous helper commands.

Aside from these files, there are two other important CMake scripts in /tools/cmake:

• idf.cmake - Sets up the build and includes the core modules listed above. Included in CMake projects in order to access ESP-IDF build system functionality.
• project.cmake - Includes idf.cmake and provides a custom project() command that takes care of all the heavy lifting of building an executable. Included in the top-level CMakeLists.txt of standard ESP-IDF projects.

The rest of the files in /tools/cmake are support or third-party scripts used in the build process.

Build Process

This section describes the standard ESP-IDF application build process. The build process can be broken down roughly into four phases:

Initialization This phase sets up necessary parameters for the build.

• Upon inclusion of idf.cmake in project.cmake, the following steps are performed:
  – Set IDF_PATH from environment variable or inferred from path to project.cmake included in the top-level CMakeLists.txt.
Fig. 4: ESP-IDF Build System Process

- Add \tools/cmake to CMAKE_MODULE_PATH and include core modules plus the various helper/third-party scripts.
- Set build tools/executables such as default Python interpreter.
- Get ESP-IDF git revision and store as IDF_VER.
- Set global build specifications i.e., compile options, compile definitions, include directories for all components in the build.
- Add components in \components to the build.

• The initial part of the custom project() command performs the following steps:
  - Set IDF_TARGET from environment variable or CMake cache and the corresponding CMAKE_TOOLCHAIN_FILE to be used.
  - Add components in EXTRA_COMPONENT_DIRS to the build.
  - Prepare arguments for calling command idf_build_process() from variables such as COMPONENTS/EXCLUDE_COMPONENTS, SDKCONFIG, SDKCONFIG_DEFAULTS.

The call to idf_build_process() command marks the end of this phase.

Enumeration

This phase builds a final list of components to be processed in the build, and is performed in the first half of idf_build_process().

• Retrieve each component’s public and private requirements. A child process is created which executes each component’s CMakeLists.txt in script mode. The values of idf_component_register REQUIRES and PRIV_REQUIRES argument is returned to the parent build process. This is called early expansion. The variable CMAKE_BUILD_EARLY_EXPANSION is defined during this step.
• Recursively include components based on public and private requirements.

Processing

This phase processes the components in the build, and is the second half of idf_build_process().

• Load project configuration from sdkconfig file and generate an sdkconfig.cmake and sdkconfig.h header. These define configuration variables/macros that are accessible from the build scripts and C/C++ source/header files, respectively.
• Include each component’s project_include.cmake.
• Add each component as a subdirectory, processing its CMakeLists.txt. The component CMakeLists.txt calls the registration command, idf_component_register which adds source files, include directories, creates component library, links dependencies, etc.

Finalization

This phase is everything after idf_build_process().

• Create executable and link the component libraries to it.
• Generate project metadata files such as project_description.json and display relevant information about the project built.

Browse /tools/cmake/project.cmake for more details.
4.6.24 Migrating from ESP-IDF GNU Make System

Some aspects of the CMake-based ESP-IDF build system are very similar to the older GNU Make-based system. The developer needs to provide values the include directories, source files etc. There is a syntactical difference, however, as the developer needs to pass these as arguments to the registration command, \texttt{idf\_component\_register}.

Automatic Conversion Tool

An automatic project conversion tool is available in \texttt{tools/make/convert\_to\_cmake.py} in ESP-IDF v4.x releases. The script was removed in v5.0 because of its \texttt{make} build system dependency.

No Longer Available in CMake

Some features are significantly different or removed in the CMake-based system. The following variables no longer exist in the CMake-based build system:

- \texttt{COMPONENT\_BUILD\_DIR}: Use \texttt{CMAKE\_CURRENT\_BINARY\_DIR} instead.
- \texttt{COMPONENT\_LIBRARY}: Defaulted to \texttt{$\{COMPONENT\_NAME\}.a}, but the library name could be overridden by the component. The name of the component library can no longer be overridden by the component.
- \texttt{CC, LD, AR, OBJCOPY}: Full paths to each tool from the gcc xtensa cross-toolchain. Use \texttt{CMAKE\_C\_COMPILER}, \texttt{CMAKE\_C\_LINK\_EXECUTABLE}, \texttt{CMAKE\_OBJCOPY}, etc instead. \texttt{Full list here.}
- \texttt{HOSTCC, HOSTLD, HOSTAR}: Full names of each tool from the host native toolchain. These are no longer provided, external projects should detect any required host toolchain manually.
- \texttt{COMPONENT\_ADD\_LDFLAGS}: Used to override linker flags. Use the CMake \texttt{target\_link\_libraries} command instead.
- \texttt{COMPONENT\_ADD\_LINKER\_DEPS}: List of files that linking should depend on. \texttt{target\_link\_libraries} will usually infer these dependencies automatically. For linker scripts, use the provided custom CMake function \texttt{target\_linker\_scripts}.
- \texttt{COMPONENT\_SUBMODULES}: No longer used, the build system will automatically enumerate all submodules in the ESP-IDF repository.
- \texttt{COMPONENT\_EXTRA\_INCLUDES}: Used to be an alternative to \texttt{COMPONENT\_PRIV\_INCLUDEDIRS} for absolute paths. Use \texttt{PRIV\_INCLUDE\_DIRS} argument to \texttt{idf\_component\_register} for all cases now (can be relative or absolute).
- \texttt{COMPONENT\_OBJEXCLUDE}: Previously, component sources could be specified as a list of object files. Now they can be specified as a list of source files via \texttt{SRCS} argument to \texttt{idf\_component\_register}.
- \texttt{COMPONENT\_EXCLUDE\_SRCS}: Has been replaced with \texttt{EXCLUDE\_SRCS} argument to \texttt{idf\_component\_register}. Specify source files (as absolute paths or relative to component directory), instead.
- \texttt{COMPONENT\_EXTRA\_CLEAN}: Set property \texttt{ADDITIONAL\_CLEAN\_FILES} instead but note \texttt{CMake} has some restrictions around this functionality.
- \texttt{COMPONENT\_OWNBUILDTARGET} \& \texttt{COMPONENT\_OWNCLEANTARGET}: Use CMake \texttt{ExternalProject} instead. See \texttt{Fully Overriding the Component Build Process} for full details.
- \texttt{COMPONENT\_CONFIG\_ONLY}: Call \texttt{idf\_component\_register} without any arguments instead. See \texttt{Configuration-Only Components}.
- \texttt{CFLAGS, CPPFLAGS, CXXFLAGS}: Use equivalent CMake commands instead. See \texttt{Controlling Component Compilation}.

No Default Values

Unlike in the legacy Make-based build system, the following have no default values:

- Source directories (\texttt{COMPONENT\_SRC\_DIRS} variable in Make, \texttt{SRC\_DIRS} argument to \texttt{idf\_component\_register} in CMake)
- Include directories (\texttt{COMPONENT\_ADD\_INCLUDEDIRS} variable in Make, \texttt{INCLUDE\_DIRS} argument to \texttt{idf\_component\_register} in CMake)
Chapter 4. API Guides

No Longer Necessary

- In the legacy Make-based build system, it is required to also set COMPONENT_SRCDIRS if COMPONENT_SRCS is set. In CMake, the equivalent is not necessary i.e., specifying SRC_DIRS to idf_component_register if SRCS is also specified (in fact, SRCS is ignored if SRC_DIRS is specified).

Flashing from Make

make flash and similar targets still work to build and flash. However, project sdkconfig no longer specifies serial port and baud rate. Environment variables can be used to override these. See Flashing with Ninja or Make for more details.

4.7 RF Coexistence

4.7.1 Overview

ESP32 has only one 2.4 GHz ISM band RF module, which is shared by Bluetooth (BT & BLE) and Wi-Fi, so Bluetooth can’t receive or transmit data while Wi-Fi is receiving or transmitting data and vice versa. Under such circumstances, ESP32 uses the time-division multiplexing method to receive and transmit packets.

4.7.2 Supported Coexistence Scenario for ESP32

4.7.3 Coexistence Mechanism and Policy

Coexistence Mechanism

The RF resource allocation mechanism is based on priority. As shown below, both Bluetooth module and Wi-Fi module request RF resources from the coexistence module, and the coexistence module decides who will use the RF resource based on their priority.

![Coexistence Mechanism Diagram]

**Coexistence Policy**

**Coexistence Period and Time Slice**  Wi-Fi, BT, and BLE have their fixed time slice to use the RF. A coexistence period is divided into 3 time slices in the order of Wi-Fi, BT, and BLE. In the Wi-Fi slice, Wi-Fi’s request to the coexistence arbitration module will have higher priority. Similarly, BT/BL can enjoy higher priority at their own time slices. The duration of the coexistence period and the proportion of each time slice are divided into four categories according to the Wi-Fi status:

1) **IDLE** status: the coexistence of BT and BLE is controlled by Bluetooth module.
2) **CONNECTED** status: the coexistence period starts at the Target Beacon Transmission Time (TBTT) and is more than 100 ms.
3) **SCAN** status: Wi-Fi slice and coexistence period are longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.
4) **CONNECTING** status: Wi-Fi slice is longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.

According to the coexistence logic, different coexistence periods and time slice strategies will be selected based on the Wi-Fi and Bluetooth usage scenarios. A Coexistence policy corresponding to a certain usage scenarios is called a “coexistence scheme”. For example, the scenario of Wi-Fi CONNECTED and BLE CONNECTED has a corresponding coexistence scheme. In this scheme, the time slices of Wi-Fi and BLE in a coexistence period each account for 50%. The time allocation is shown in the following figure:

**Dynamic Priority**  The coexistence module assigns different priorities to different status of Wi-Fi and Bluetooth. And the priority for each status is dynamic. For example, in every N BLE Advertising events, there is always one
event with high priority. If a high-priority BLE Advertising event occurs within the Wi-Fi time slice, the right to use the RF may be preempted by BLE.

**Wi-Fi Connectionless Modules Coexistence** To some extent, some combinations of connectionless power-saving parameters `Window` and `Interval` would lead to extra Wi-Fi priority request out of Wi-Fi time slice. It’s for obtaining RF resources at coexistence for customized parameters, while leading to impact on Bluetooth performance.

If connectionless power-saving parameters are configured with default values, the coexistence module would perform in stable mode and the behaviour above would not happen. So please configure Wi-Fi connectionless power-saving parameters to default values unless you have plenty of coexistence performance tests for customized parameters.

Please refer to connectionless module power save to get more detail.

### 4.7.4 How to Use the Coexistence Feature

**Coexistence API**

For most coexistence cases, ESP32 will switch the coexistence status automatically without calling API. However, ESP32 provides two APIs for the coexistence of BLE MESH and Wi-Fi. When the status of BLE MESH changes, call `esp_coex_status_bit_clear` to clear the previous status first and then call `esp_coex_status_bit_set` to set the current status.

**BLE MESH Coexistence Status** As the firmware of Wi-Fi and Bluetooth are not aware of the current scenario of the upper layer application, some coexistence schemes require application code to call the coexistence API to take effect. The application layer needs to pass the working status of BLE MESH to the coexistence module for selecting the coexistence scheme.

- `ESP_COEX_BLE_ST_MESH_CONFIG`: network is provisioning
- `ESP_COEX_BLE_ST_MESH_TRAFFIC`: data is transmitting
- `ESP_COEX_BLE_ST_MESH_STANDBY`: in idle status with no significant data interaction

**Coexistence API Error Codes**

All coexistence APIs have custom return values, i.e., error codes. These error codes can be categorized as:

- No error. For example, the return value `ESP_OK` signifies the API returned successfully.
- Recoverable errors. For example, the return value `ESP_ERR_INVALID_ARG` signifies API parameter errors.

**Setting Coexistence Compile-time Options**

- After writing the coexistence program, you must check `CONFIG_ESP_COEX_SW_COEXIST_ENABLE` option through menuconfig to open coexistence configuration on software, otherwise the coexistence function mentioned above cannot be used.
To ensure better communication performance of Wi-Fi and Bluetooth in the case of coexistence, run the task of the Wi-Fi protocol stack, the task of the Bluetooth Controller and Host protocol stack on different CPUs. You can use `CONFIG_BTDM_CTRL_PINNED_TO_CORE_CHOICE` and `CONFIG_BT_BLUEDROID_PINNED_TO_CORE_CHOICE` (or `CONFIG_BT_NIMBLE_PINNED_TO_CORE_CHOICE`) to put the tasks of the Bluetooth controller and the host protocol stack on the same CPU, and then use `CONFIG_ESP_WIFI_TASK_CORE_ID` to place the task of the Wi-Fi protocol stack on another CPU.

In the case of coexistence, BLE SCAN may be interrupted by Wi-Fi and Wi-Fi releases RF resources before the end of the current BLE scan window. In order to make BLE acquire RF resources again within the current scan window, you can check the FULL SCAN configuration option through `CONFIG_BTDM_CTRL_FULL_SCAN_SUPPORTED`.

You can reduce the memory consumption by configuring the following options on menuconfig.

1. `CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY`: enable the configuration of dynamic memory for Bluetooth protocol stack.
2. `CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM`: reduce the number of Wi-Fi static RX buffers.
3. `CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM`: reduce the number of Wi-Fi dynamic RX buffers.
4. `CONFIG_ESP_WIFI_TX_BUFFER`: enable the configuration of dynamic allocation TX buffers.
5. `CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM`: reduce the number of Wi-Fi dynamic TX buffers.
6. `CONFIG_ESP_WIFI_TX_BA_WIN`: reduce the number of Wi-Fi Block Ack TX windows.
7. `CONFIG_ESP_WIFI_RX_BA_WIN`: reduce the number of Wi-Fi Block Ack RX windows.
8. `CONFIG_ESP_WIFI_MGMT_SBUF_NUM`: reduce the number of Wi-Fi Management Short Buffer.
9. `CONFIG_ESP_WIFI_RX_IRAM_OPT`: turning off this configuration option will reduce the IRAM memory by approximately 17 KB.
10. `CONFIG_LWIP_TCP_SND_BUF_DEFAULT`: reduce the default TX buffer size for TCP sockets.
11. `CONFIG_LWIP_TCP_WND_DEFAULT`: reduce the default size of the RX window for TCP sockets.
12. `CONFIG_LWIP_TCP_RECVMBX_SIZE`: reduce the size of the TCP receive mailbox.
13. `CONFIG_LWIP_UDP_RECVMBX_SIZE`: reduce the size of the UDP receive mailbox.
14. `CONFIG_LWIP_TCPIP_RECVMBX_SIZE`: reduce the size of TCPIP task receive mailbox.

**Note**: Since the coexistence configuration option depends on the Bluetooth configuration option, please turn on the Bluetooth configuration option first before configuring the coexistence feature in the Wi-Fi configuration option.

### 4.8 Core Dump

#### 4.8.1 Overview

A core dump is a set of software state information that is automatically saved by the panic handler when a fatal error occurs. Core dumps are useful for conducting post-mortem analysis of the software’s state at the moment of failure. ESP-IDF provides support for generating core dumps.

A core dump contains snapshots of all tasks in the system at the moment of failure, where each snapshot includes a task’s control block (TCB) and stack. By analyzing the task snapshots, it is possible to find out what task, at what instruction (line of code), and what call stack of that task lead to the crash. It is also possible to dump the contents of variables on demand, provided those variables are assigned special core dump attributes.

Core dump data is saved to a core dump file according to a particular format, see `Core dump internals` for more details. However, ESP-IDF’s `idf.py` command provides special subcommands to decode and analyze the core dump file.

#### 4.8.2 Configurations
**Destination**

The `CONFIG_ESP_COREDUMP_TO_FLASH_OR_UART` option enables or disables core dump, and selects the core dump destination if enabled. When a crash occurs, the generated core dump file can either be saved to flash, or output to a connected host over UART.

**Format & Size**

The `CONFIG_ESP_COREDUMP_DATA_FORMAT` option controls the format of the core dump file, namely ELF format or Binary format.

The ELF format contains extended features and allows more information regarding erroneous tasks and crashed software to be saved. However, using the ELF format causes the core dump file to be larger. This format is recommended for new software designs and is flexible enough to be extended in future revisions to save more information.

The Binary format is kept for compatibility reasons. Binary format core dump files are smaller while provide better performance.

The `CONFIG_ESP_COREDUMP_MAX_TASKS_NUM` option configures the number of task snapshots saved by the core dump.

Core dump data integrity checking is supported via the Components > Core dump > Core dump data integrity check option.

**Data Integrity Check**

Core dump files include a checksum, which can be used to verify the integrity of the core dump file, i.e., the file has not been corrupted. The `CONFIG_ESP_COREDUMP_CHECKSUM` option controls the type of checksum, namely CRC32 or SHA256 (only supported in the ELF format).

The CRC32 option provides better calculation performance and consumes less memory for storage.

The SHA256 hash algorithm provides a greater probability of detecting corruption than a CRC32 with multiple-bit errors.

**Reserved Stack Size**

Core dump routines run from a separate stack due to core dump itself needing to parse and save all other task stacks. The `CONFIG_ESP_COREDUMP_STACK_SIZE` option controls the size of the core dump’s stack in number of bytes.

Setting this option to 0 bytes will cause the core dump routines to run from the ISR stack, thus saving a bit of memory. Setting the option greater than zero will cause a separate stack to be instantiated.

---

**Note:** If a separate stack is used, the recommended stack size should be larger than 800 bytes to ensure that the core dump routines themselves do not cause a stack overflow.

### 4.8.3 Core Dump to Flash

When the core dump file is saved to flash, the file is saved to a special core dump partition in flash. Specifying the core dump partition will reserve space on the flash chip to store the core dump file.

The core dump partition is automatically declared when using the default partition table provided by ESP-IDF. However, when using a custom partition table, you need to declare the core dump partition, as illustrated below:
# Name, Type, SubType, Offset, Size
# Note: if you have increased the bootloader size, make sure to update the offsets to avoid overlap
nvs, data, nvs, 0x9000, 0x6000
phy_init, data, phy, 0xf000, 0x1000
factory, app, factory, 0x10000, 1M
coredump, data, coredump,, 64K

Important: If Flash Encryption is enabled on the device, please add an encrypted flag to the core dump partition declaration.
coredump, data, coredump,, 64K, encrypted

There are no special requirements for the partition name. It can be chosen according to the application’s needs, but the partition type should be data and the sub-type should be coredump. Also, when choosing partition size, note that the core dump file introduces a constant overhead of 20 bytes and a per-task overhead of 12 bytes. This overhead does not include the size of TCB and stack for every task. So the partition size should be at least 20 + max tasks number x (12 + TCB size + max task stack size) bytes.

An example of the generic command to analyze core dump from flash is:

```
idf.py coredump-info
```
or

```
idf.py coredump-debug
```

## 4.8.4 Core Dump to UART

When the core dump file is output to UART, the output file is Base64-encoded. The `CONFIG_ESP_COREDUMP_DECODE` option allows for selecting whether the output file is automatically decoded by the ESP-IDF monitor or kept encoded for manual decoding.

### Automatic Decoding

If `CONFIG_ESP_COREDUMP_DECODE` is set to automatically decode the UART core dump, ESP-IDF monitor will automatically decode the data, translate any function addresses to source code lines, and display it in the monitor. The output to ESP-IDF monitor would resemble the following output:

The `CONFIG_ESP_COREDUMP_UART_DELAY` allows for an optional delay to be added before the core dump file is output to UART.

</tbody>
</table>

------------------------ ESP32 CORE DUMP END ------------------------
```

### Manual Decoding

If you set `CONFIG_ESP_COREDUMP_DECODE` to no decoding, then the raw Base64-encoded body of core dump is output to UART between the following header and footer of the UART output:

```
============== CORE DUMP START ===============

<body of Base64-encoded core dump, save it to file on disk>

============== CORE DUMP END ===============
```

It is advised to manually save the core dump text body to a file. The `CORE DUMP START` and `CORE DUMP END` lines must not be included in a core dump text file. The saved text can then be decoded using the following command:

```
idf.py coredump-info -c </path/to/saved/base64/text>
```

or

```
idf.py coredump-debug -c </path/to/saved/base64/text>
```

### 4.8.5 Core Dump Commands

ESP-IDF provides special commands to help to retrieve and analyze core dumps:

- `idf.py coredump-info` - prints crashed task’s registers, call stack, list of available tasks in the system, memory regions, and contents of memory stored in core dump (TCBs and stacks).
• idf.py coredump-debug - creates core dump ELF file and runs GDB debug session with this file. You can examine memory, variables, and task states manually. Note that since not all memory is saved in the core dump, only the values of variables allocated on the stack are meaningful.

4.8.6 ROM Functions in Backtraces

It is possible that at the moment of a crash, some tasks and/or the crashed task itself have one or more ROM functions in their call stacks. Since ROM is not part of the program ELF, it is impossible for GDB to parse such call stacks due to GDB analyzing functions’ prologues to decode backtraces. Thus, call stack parsing will break with an error message upon the first ROM function that is encountered.

To overcome this issue, the ROM ELF provided by Espressif is loaded automatically by ESP-IDF monitor based on the target and its revision. More details about ROM ELFs can be found in esp-rom-elfs.

4.8.7 Dumping Variables on Demand

Sometimes you want to read the last value of a variable to understand the root cause of a crash. Core dump supports retrieving variable data over GDB by applying special attributes to declared variables.

Supported Notations and RAM Regions

• COREDUMP_DRAM_ATTR places the variable into the DRAM area, which is included in the dump.
• COREDUMP_RTC_ATTR places the variable into the RTC area, which is included in the dump.
• COREDUMP_RTC_FAST_ATTR places the variable into the RTC_FAST area, which is included in the dump.

Example

1. In Project Configuration Menu, enable COREDUMP TO FLASH, then save and exit.
2. In your project, create a global variable in the DRAM area, such as:
   ```
   // uint8_t global_var;
   COREDUMP_DRAM_ATTR uint8_t global_var;
   ```

3. In the main application, set the variable to any value and assert(0) to cause a crash.
   ```
   global_var = 25;
   assert(0);
   ```

4. Build, flash, and run the application on a target device and wait for the dumping information.
5. Run the command below to start core dumping in GDB, where PORT is the device USB port:
   ```
   idf.py coredump-debug
   ```

6. In GDB shell, type p global_var to get the variable content:
   ```
   (gdb) p global_var
   $1 = 25 '\031'
   ```

4.8.8 Running idf.py coredump-info and idf.py coredump-debug

idf.py coredump-info --help and idf.py coredump-debug --help commands can be used to get more details on usage.

Anatomy of Core Dump Image

A core dump file’s format can be configured to use the ELF format, or a legacy binary format. The ELF format is recommended for all new designs as it provides more information regarding the software’s state at the moment the crash occurs, e.g., CPU registers and memory contents.

The memory state embeds a snapshot of all tasks mapped in the memory space of the program. The CPU state contains register values when the core dump has been generated. The core dump file uses a subset of the ELF structures to register this information.

Loadable ELF segments are used to store the process’ memory state, while ELF notes (ELF.PT_NOTE) are used to store the process’ metadata (e.g., PID, registers, signal etc). In particular, the CPU’s status is stored in a note with a special name and type (CORE, NT_PRSTATUS type).

Here is an overview of the core dump layout:

![Core Dump ELF Image Format](image)

**Fig. 7: Core Dump ELF Image Format**

**Note:** The format of the image file shown in the above pictures represents the current version of the image and can be changed in future releases.

Overview of Implementation The figure below describes some basic aspects related to the implementation of the core dump:
Chapter 4. API Guides

Fig. 8: Core Dump Binary Image Format

Fig. 9: Core Dump Implementation Overview
4.9 C++ Support

ESP-IDF is primarily written in C and provides C APIs. However, ESP-IDF supports development of applications in C++. This document covers various topics relevant to C++ development.

The following C++ features are supported:

- **Exception Handling**
- **Multithreading**
- **Runtime Type Information (RTTI)**
- **Thread Local Storage** (thread_local keyword)
- All C++ features implemented by GCC, except for some Limitations. See GCC documentation for details on features implemented by GCC.

4.9.1 esp-idf-cxx Component

esp-idf-cxx component provides higher-level C++ APIs for some of the ESP-IDF features. This component is available from the ESP-IDF Component Registry.

4.9.2 C++ Language Standard

By default, ESP-IDF compiles C++ code with C++23 language standard with GNU extensions (-std=gnu++23).

To compile the source code of a certain component using a different language standard, set the desired compiler flag in the component’s CMakeLists.txt file:

```cmake
idf_component_register( ... )
target_compile_options(${COMPONENT_LIB} PRIVATE -std=gnu++11)
```

Use PUBLIC instead of PRIVATE if the public header files of the component also need to be compiled with the same language standard.

4.9.3 Multithreading

C++ threads, mutexes, and condition variables are supported. C++ threads are built on top of pthreads, which in turn wrap FreeRTOS tasks.

See cxx/pthread for an example of creating threads in C++.

Note: The destructor of std::jthread can only safely be called from a task that has been created by Thread APIs or by the C++ threading library API.

4.9.4 Exception Handling

Support for C++ Exceptions in ESP-IDF is disabled by default, but can be enabled using the CONFIG_COMPILER_CXX.Exceptions option.
If an exception is thrown, but there is no catch block, the program is terminated by the abort function, and the backtrace is printed. See Fatal Errors for more information about backtraces.

C++ Exceptions should only be used for exceptional cases, i.e., something happening unexpectedly and occurs rarely, such as events that happen less frequently than 1/100 times. Do not use them for control flow (see also the section about resource usage below). For more information on how to use C++ Exceptions, see the ISO C++ FAQ and CPP Core Guidelines.

See cxx/exceptions for an example of C++ exception handling.

**C++ Exception Handling and Resource Usage**

Enabling exception handling normally increases application binary size by a few KB. Additionally, it may be necessary to reserve some amount of RAM for the exception emergency memory pool. The amount of memory in the emergency pool can be set using the CONFIG_COMPILER_CXX_EXCEPTIONS_EMG_POOL_SIZE variable.

Some additional stack memory (around 200 bytes) is also used if and only if a C++ Exception is actually thrown, because it requires calling some functions from the top of the stack to initiate exception handling.

The run time of code using C++ exceptions depends on what actually happens at run time.

- If no exception is thrown, the code tends to be somewhat faster since there is no need to check error codes.
- If an exception is thrown, the run time of the code that handles exceptions is orders of magnitude slower than code returning an error code.

If an exception is thrown, the run time of the code that unwinds the stack is orders of magnitude slower than code returning an error code. The significance of the increased run time will depend on the application’s requirements and implementation of error handling (e.g., requiring user input or messaging to a cloud). As a result, exception-throwing code should never be used in real-time critical code paths.

### 4.9.5 Runtime Type Information (RTTI)

Support for RTTI in ESP-IDF is disabled by default, but can be enabled using CONFIG_COMPILER_CXX_RTTI option.

Enabling this option compiles all C++ files with RTTI support enabled, which allows using dynamic_cast conversion and typeid operator. Enabling this option typically increases the binary size by tens of KB.

See cxx/rtti for an example of using RTTI in ESP-IDF.

### 4.9.6 Developing in C++

The following sections provide tips on developing ESP-IDF applications in C++.

**Combining C and C++ Code**

When an application is developed using both C and C++, it is important to understand the concept of language linkage. In order for a C++ function to be callable from C code, it has to be both declared and defined with C linkage (extern "C"):

```c
// declaration in the .h file:
#ifdef __cplusplus
extern "C" {
#endif
#endif
```

(continues on next page)
void my_cpp_func(void);

#ifdef __cplusplus
#endif

// definition in a .cpp file:
extern "C" void my_cpp_func(void) {
    // ...
}

In order for a C function to be callable from C++, it has to be declared with C linkage:

#ifndef __cplusplus
extern "C" {
#endif
void my_c_func(void);
#ifndef __cplusplus
}
#endif

// definition in a .c file:
void my_c_func(void) {
    // ...
}

Defining app_main in C++

ESP-IDF expects the application entry point, app_main, to be defined with C linkage. When app_main is defined in a .cpp source file, it has to be designated as extern "C":

extern "C" void app_main();
{
}

Designated Initializers

Many of the ESP-IDF components use Configuration Structures as arguments to the initialization functions. ESP-IDF examples written in C routinely use designated initializers to fill these structures in a readable and a maintainable way. C and C++ languages have different rules with regards to the designated initializers. For example, C++23 (currently the default in ESP-IDF) does not support out-of-order designated initialization, nested designated initialization, mixing of designated initializers and regular initializers, and designated initialization of arrays. Therefore, when porting ESP-IDF C examples to C++, some changes to the structure initializers may be necessary. See the C++ aggregate initialization reference for more details.

iostream

iostream functionality is supported in ESP-IDF, with a couple of caveats:

1. Normally, ESP-IDF build process eliminates the unused code. However, in the case of iostreams, simply including <iostream> header in one of the source files significantly increases the binary size by about 200 kB.
2. By default, ESP-IDF uses a simple non-blocking implementation of the standard input stream (stdin). To get the usual behavior of std::cin, the application has to initialize the UART driver and enable the blocking mode as shown in common_components/protocol_examples_common/stdio_out.c.

4.9.7 Limitations

- Linker script generator does not support function level placements for functions with C++ linkage.
- Various section attributes (such as IRAM_ATTR) are ignored when used with template functions.
- Vtables are placed into Flash and are not accessible when the flash cache is disabled. Therefore, virtual function calls should be avoided in IRAM-Safe Interrupt Handlers. Placement of Vtables cannot be adjusted using the linker script generator, yet.
- C++ filesystem (std::filesystem) features are not supported.

4.9.8 What to Avoid

Do not use setjmp/longjmp in C++. longjmp blindly jumps up the stack without calling any destructors, easily introducing undefined behavior and memory leaks. Use C++ exceptions instead, they guarantee correctly calling destructors. If you cannot use C++ exceptions, use alternatives (except setjmp/longjmp themselves) such as simple return codes.

4.10 Current Consumption Measurement of Modules

You may want to know the current consumption of a module in deep-sleep mode, other power-saving modes, and active mode to develop some applications sensitive to power consumption. This section introduces how to measure the current consumption of a module running such an application.

4.10.1 Notes to Measurement

Can We Use a Development Board?

For ESP32, using a development board directly to measure current consumption of the corresponding module is not recommended, as some circuits still consume power on the board even when you flash the chip with the deep_sleep example. Therefore, you need to cut off the power supply circuit to the module to measure the module’s current. This method is inconvenient and increases measurement costs.

How to Choose an Appropriate Ammeter?

In the deep_sleep example, the module will be woken up every 20 seconds. In deep-sleep mode, the current in the module is just several microamps (μA), while in active mode, the current is in the order of milliamps (mA). The high dynamic current range makes accurate measurement difficult. Ordinary ammeters cannot dynamically switch the measurement range fast enough.

Additionally, ordinary ammeters have a relatively high internal resistance, resulting in a significant voltage drop. This may cause the module to enter an unstable state, as it is powered by a voltage smaller than the minimum required voltage supply.

Therefore, an ammeter suitable for measuring current in deep-sleep mode should have low internal resistance and, ideally, switch current ranges dynamically. We recommend two options: the Joulescope ammeter and the Power Profiler Kit II from Nordic.
**Joulescope Ammeter**  The Joulescope ammeter combines high-speed sampling and rapid dynamic current range switching to provide accurate and seamless current and energy measurements, even for devices with rapidly varying current consumption. Joulescope accurately measures electrical current over nine orders of magnitude from amps down to nanamps. This wide range allows for accurate and precise current measurements for devices. Additionally, Joulescope has a total voltage drop of 25 mV at 1 A, which keeps the module running normally. These two features make Joulescope a perfect option for measuring the module switching between deep-sleep mode and wake-up mode. Joulescope has no display screen. You need to connect it to a PC to visualize the current waveforms of the measured module. For specific instructions, please follow the documentation provided by the manufacturer.

**Nordic Power Profiler Kit II**  The Nordic Power Profiler Kit II has an advanced analog measurement unit with a high dynamic measurement range. This allows for accurate power consumption measurements for the entire range typically seen in low-power embedded applications, all the way from single μAs to 1 A. The resolution varies between 100 nA and 1 mA, depending on the measurement range, and is high enough to detect small spikes often seen in low-power optimized systems.

### 4.10.2 Hardware Connection

To measure the power consumption of a bare module, you need an ESP-Prog to flash the `deep_sleep` example to the module and power the module during measurement, a suitable ammeter (here we use the Joulescope ammeter), a computer, and of course a bare module with necessary jumper wires. For the connection, please refer to the following figure.

Please connect the pins of UART TX, UART RX, SPI Boot, Enable, and Ground on the measured module with corresponding pins on ESP-Prog, and connect the VPROG pin on ESP-Prog with the IN+ port on the Joulescope ammeter and connect its OUT+ port with the Power supply (3V3) pin on the measured module. For the specific names of these pins in different modules, please refer to the list below.

<table>
<thead>
<tr>
<th>Function of Module Pin</th>
<th>Pin Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>UART TX</td>
<td>TXD0</td>
</tr>
<tr>
<td>UART RX</td>
<td>RXD0</td>
</tr>
<tr>
<td>SPI Boot</td>
<td>IO0</td>
</tr>
<tr>
<td>Enable</td>
<td>EN</td>
</tr>
<tr>
<td>Power Supply</td>
<td>3V3</td>
</tr>
<tr>
<td>Ground</td>
<td>GND</td>
</tr>
</tbody>
</table>

For modules based on the ESP32 chip, the names of UART TX and UART RX pins may also be U0TXD and U0RXD.

For details of the pin names, please refer to the datasheet of specific module.

### 4.10.3 Measurement Steps

ESP32-S3-WROOM-1 is used as an example in the measurement, and other modules can be measured similarly. For the specific current consumption of chips in different modes, please refer to the Current Consumption subsection in the corresponding chip datasheet.

You can refer to the following steps to measure the current in deep-sleep mode.

- Connect the aforementioned devices according to the hardware connection.
- Flash the `deep_sleep` example to the module. For details, please refer to Start a Project on Linux and macOS for a computer with Linux or macOS system or Start a Project on Windows for a computer with Windows system.

Please note that when you configure the example by running `idf.py menuconfig`, you need to disable Enable touch wake up in the Example Configuration to reduce the bottom current.
Fig. 10: Hardware Connection (click to enlarge)
For modules with an external resistor on GPIO12 (such as ESP32-WROVER-E/IE), you should call `rtc_gpio_isolate()` before going into deep sleep. This is to isolate the GPIO12 pin from external circuits to further minimize current consumption. Please note, for other modules, you do not have to call this function, otherwise, you may get abnormal results.

- By default, the module will be woken up every 20 seconds (you can change the timing by modifying the code of this example). To check if the example runs as expected, you can monitor the module operation by running `idf.py -p PORT monitor` (please replace PORT with your serial port name).
- Open the Joulescope software to see the current waveform as shown in the image below.

From the waveforms, you can obtain that the current of the module in deep-sleep mode is 8.14 µA. In addition, you can also see the current of the module in active mode, which is about 23.88 mA. The waveforms also show that the average power consumption during deep-sleep mode is 26.85 µW, and the average power consumption during active mode is 78.32 mW.

![Current Waveform of ESP32-S3-WROOM-1](image)

The figure below shows the total power consumption of one cycle is 6.37 mW.

By referring to these power consumption in different modes, you can estimate the power consumption of your applications and choose the appropriate power source.
Fig. 12: Power Consumption of ESP32-S3-WROOM-1 (click to enlarge)
4.11  Deep Sleep Wake Stubs

ESP32 supports running a “deep sleep wake stub” when coming out of deep sleep. This function runs immediately as soon as the chip wakes up - before any normal initialisation, bootloader, or ESP-IDF code has run. After the wake stub runs, the SoC can go back to sleep or continue to start ESP-IDF normally.

Deep sleep wake stub code is loaded into “RTC Fast Memory” and any data which it uses must also be loaded into RTC memory. RTC memory regions hold their contents during deep sleep.

4.11.1  Rules for Wake Stubs

Wake stub code must be carefully written:

- As the SoC has freshly woken from sleep, most of the peripherals are in reset states. The SPI flash is unmapped.
- The wake stub code can only call functions implemented in ROM or loaded into RTC Fast Memory (see below.)
- The wake stub code can only access data loaded in RTC memory. All other RAM will be unintialised and have random contents. The wake stub can use other RAM for temporary storage, but the contents will be overwritten when the SoC goes back to sleep or starts ESP-IDF.
- RTC memory must include any read-only data (.rodata) used by the stub.
- Data in RTC memory is initialsed whenever the SoC restarts, except when waking from deep sleep. When waking from deep sleep, the values which were present before going to sleep are kept.
- Wake stub code is a part of the main esp-idf app. During normal running of esp-idf, functions can call the wake stub functions or access RTC memory. It is as if these were regular parts of the app.

4.11.2  Implementing A Stub

The wake stub in esp-idf is called esp_wake_deep_sleep(). This function runs whenever the SoC wakes from deep sleep. There is a default version of this function provided in esp-idf, but the default function is weak-linked so if your app contains a function named esp_wake_deep_sleep() then this will override the default.

If supplying a custom wake stub, the first thing it does should be to call esp_default_wake_deep_sleep().

It is not necessary to implement esp_wake_deep_sleep() in your app in order to use deep sleep. It is only necessary if you want to have special behaviour immediately on wake.

If you want to swap between different deep sleep stubs at runtime, it is also possible to do this by calling the esp_set_deep_sleep_wake_stub() function. This is not necessary if you only use the default esp_wake_deep_sleep() function.

All of these functions are declared in the esp_sleep.h header under components/esp32.

4.11.3  Loading Code Into RTC Memory

Wake stub code must be resident in RTC Fast Memory. This can be done in one of two ways.

The first way is to use the RTC_IRAM_ATTR attribute to place a function into RTC memory:

```c
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    // Add additional functionality here
}
```

The second way is to place the function into any source file whose name starts with rtc_wake_stub. Files names rtc_wake_stub* have their contents automatically put into RTC memory by the linker.

The first way is simpler for very short and simple code, or for source files where you want to mix “normal” and “RTC” code. The second way is simpler when you want to write longer pieces of code for RTC memory.
4.11.4 Loading Data Into RTC Memory

Data used by stub code must be resident in RTC memory.

The data can be placed in RTC Fast memory or in RTC Slow memory which is also used by the ULP.

Specifying this data can be done in one of two ways:

The first way is to use the `RTC_DATA_ATTR` and `RTC_RODATA_ATTR` to specify any data (writeable or read-only, respectively) which should be loaded into RTC memory:

```c
RTC_DATA_ATTR int wake_count;
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    static RTC_RODATA_ATTR const char fmt_str[] = "Wake count %d\n";
    esp_rom_printf(fmt_str, wake_count + +);
}
```

The RTC memory area where this data will be placed can be configured via menuconfig option named `CONFIG_ESP32_RTCDATA_IN_FAST_MEM`. This option allows to keep slow memory area for ULP programs and once it is enabled the data marked with `RTC_DATA_ATTR` and `RTC_RODATA_ATTR` are placed in the RTC fast memory segment otherwise it goes to RTC slow memory (default option). This option depends on the `CONFIG_FREERTOS_UNICORE` because RTC fast memory can be accessed only by PRO_CPU.

The attributes `RTC_FAST_ATTR` and `RTC_SLOW_ATTR` can be used to specify data that will be force placed into RTC_FAST and RTC_SLOW memory respectively. Any access to data marked with `RTC_FAST_ATTR` is allowed by PRO_CPU only and it is responsibility of user to make sure about it.

Unfortunately, any string constants used in this way must be declared as arrays and marked with `RTC_RODATA_ATTR`, as shown in the example above.

The second way is to place the data into any source file whose name starts with `rtc_wake_stub`.

For example, the equivalent example in `rtc_wake_stub_counter.c`:

```c
int wake_count;
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    esp_rom_printf("Wake count %d\n", wake_count++);
}
```

The second way is a better option if you need to use strings, or write other more complex code.

To reduce wake-up time use the `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` Kconfig option, see more information in `Fast boot from Deep Sleep`.

4.11.5 CRC Check For Wake Stubs

During deep sleep, all RTC Fast memory areas will be validated with CRC. When ESP32 wakes up from deep sleep, the RTC fast memory will be validated with CRC again. If the validation passes, the wake stubs code will be executed. Otherwise, the normal initialization, bootloader and esp-idf codes will be executed.

**Note:** When the `CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP` option is enabled, all the RTC fast memory except the wake stubs area is added to the heap.

4.11.6 Example

ESP-IDF provides an example to show how to implement the Deep-sleep wake stub.
• system/deep_sleep_wake_stub

4.12 Error Handling

4.12.1 Overview

Identifying and handling run-time errors is important for developing robust applications. There can be multiple kinds of run-time errors:

• Recoverable errors:
  – Errors indicated by functions through return values (error codes)
  – C++ exceptions, thrown using throw keyword
• Unrecoverable (fatal) errors:
  – Failed assertions (using assert macro and equivalent methods, see Assertions) and abort() calls.
  – CPU exceptions: access to protected regions of memory, illegal instruction, etc.
  – System level checks: watchdog timeout, cache access error, stack overflow, stack smashing, heap corruption, etc.

This guide explains ESP-IDF error handling mechanisms related to recoverable errors, and provides some common error handling patterns.

For instructions on diagnosing unrecoverable errors, see Fatal Errors.

4.12.2 Error Codes

The majority of ESP-IDF-specific functions use esp_err_t type to return error codes. esp_err_t is a signed integer type. Success (no error) is indicated with ESP_OK code, which is defined as zero.

Various ESP-IDF header files define possible error codes using preprocessor defines. Usually these defines start with ESP_ERR_prefix. Common error codes for generic failures (out of memory, timeout, invalid argument, etc.) are defined in esp_err.h file. Various components in ESP-IDF may define additional error codes for specific situations.

For the complete list of error codes, see Error Code Reference.

4.12.3 Converting Error Codes to Error Messages

For each error code defined in ESP-IDF components, esp_err_t value can be converted to an error code name using esp_err_to_name() or esp_err_to_name_r() functions. For example, passing 0x101 to esp_err_to_name() will return “ESP_ERR_NO_MEM” string. Such strings can be used in log output to make it easier to understand which error has happened.

Additionally, esp_err_to_name_r() function will attempt to interpret the error code as a standard POSIX error code, if no matching ESP_ERR_ value is found. This is done using strerror_r function. POSIX error codes (such as EAGAIN, ENOMEM) are defined in errno.h and are typically obtained from errno variable. In ESP-IDF this variable is thread-local: multiple FreeRTOS tasks have their own copies of errno. Functions which set errno only modify its value for the task they run in.

This feature is enabled by default, but can be disabled to reduce application binary size. See CONFIG_ESP_ERR_TO_NAME_LOOKUP. When this feature is disabled, esp_err_to_name() and esp_err_to_name_r() are still defined and can be called. In this case, esp_err_to_name() will return UNKNOWN ERROR, and esp_err_to_name_r() will return Unknown error 0xXXXX(YYYYY), where 0xXXXX and YYYY are the hexadecimal and decimal representations of the error code, respectively.
4.12.4 ESP_ERROR_CHECK Macro

ESP_ERROR_CHECK macro serves similar purpose as assert, except that it checks esp_err_t value rather than a bool condition. If the argument of ESP_ERROR_CHECK is not equal ESP_OK, then an error message is printed on the console, and abort() is called.

Error message will typically look like this:

```
ESP_ERROR_CHECK failed: esp_err_t 0x107 (ESP_ERR_TIMEOUT) at 0x400d1fdf
file: "~/Users/user/esp/example/main/main.c" line 20
func: app_main
expression: sdmmc_card_init(host, &card)
Backtrace: 0x40086e7c 0x3ffb4ff0 0x40087328 0x3ffb5010 0x400d1fdf:0x3ffb5030...
```

**Note:** If ESP-IDF monitor is used, addresses in the backtrace will be converted to file names and line numbers.

- The first line mentions the error code as a hexadecimal value, and the identifier used for this error in source code. The latter depends on CONFIG_ESP_ERR_TO_NAME_LOOKUP option being set. Address in the program where error has occurred is printed as well.
- Subsequent lines show the location in the program where ESP_ERROR_CHECK macro was called, and the expression which was passed to the macro as an argument.
- Finally, backtrace is printed. This is part of panic handler output common to all fatal errors. See Fatal Errors for more information about the backtrace.

4.12.5 ESP_ERROR_CHECK_WITHOUT_ABORT Macro

ESP_ERROR_CHECK_WITHOUT_ABORT macro serves similar purpose as ESP_ERROR_CHECK, except that it will not call abort().

4.12.6 ESP_RETURN_ON_ERROR Macro

ESP_RETURN_ON_ERROR macro checks the error code, if the error code is not equal ESP_OK, it prints the message and returns.

4.12.7 ESP_GOTO_ON_ERROR Macro

ESP_GOTO_ON_ERROR macro checks the error code, if the error code is not equal ESP_OK, it prints the message, sets the local variable ret to the code, and then exits by jumping to goto_tag.

4.12.8 ESP_RETURN_ON_FALSE Macro

ESP_RETURN_ON_FALSE macro checks the condition, if the condition is not equal true, it prints the message and returns with the supplied err_code.

4.12.9 ESP_GOTO_ON_FALSE Macro

ESP_GOTO_ON_FALSE macro checks the condition, if the condition is not equal true, it prints the message, sets the local variable ret to the supplied err_code, and then exits by jumping to goto_tag.
### 4.12.10 CHECK MACROS Examples

Some examples:

```c
static const char* TAG = "Test";

esp_err_t test_func(void)
{
    esp_err_t ret = ESP_OK;

    ESP_ERROR_CHECK(x); // err message
    ESP_ERROR_CHECK WITHOUT_ABORT(x); // err message
    ESP_RETURN_ON_ERROR(x, TAG, "fail reason 1"); // err message
    ESP_RETURN_ON_ERROR(x, err, TAG, "fail reason 2"); // err message
    ESP_GOTO_ON_ERROR(x, err, TAG, "fail reason 3"); // err message
    ESP_GOTO_ON_FALSE(a, err_code, err, TAG, "fail reason 4"); // err message

    err:
    // clean up
    return ret;
}
```

**Note:** If the option `CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT` in Kconfig is enabled, the err message will be discarded, while the other action works as is.

The `ESP_RETURN_XX` and `ESP_GOTO_xx` macros cannot be called from ISR. While there are `xx_ISR` versions for each of them, e.g., `ESP_RETURN_ON_ERROR_ISR`, these macros could be used in ISR.

### 4.12.11 Error Handling Patterns

1. Attempt to recover. Depending on the situation, we may try the following methods:
   - retry the call after some time;
   - attempt to de-initialize the driver and re-initialize it again;
   - fix the error condition using an out-of-band mechanism (e.g. reset an external peripheral which is not responding).

   Example:

   ```c
   esp_err_t err;
   do {
       err = sdio_slave_send_queue(addr, len, arg, timeout);
       // keep retrying while the sending queue is full
   } while (err == ESP_ERR_TIMEOUT);
   if (err != ESP_OK) {
       // handle other errors
   }
   ```

2. Propagate the error to the caller. In some middleware components this means that a function must exit with the same error code, making sure any resource allocations are rolled back.

   Example:

   ```c
   sdmmc_card_t* card = calloc(1, sizeof(sdmmc_card_t));
   if (card == NULL) {
   (continues on next page)
return ESP_ERR_NO_MEM;
}
esp_err_t err = sdmmc_card_init(host, &card);
if (err != ESP_OK) {
    // Clean up
    free(card);
    // Propagate the error to the upper layer (e.g., to notify the user).
    // Alternatively, application can define and return custom error code.
    return err;
}

3. Convert into unrecoverable error, for example using ESP_ERROR_CHECK. See ESP_ERROR_CHECK macro section for details.
   Terminating the application in case of an error is usually undesirable behavior for middleware components, but
   is sometimes acceptable at application level.
   Many ESP-IDF examples use ESP_ERROR_CHECK to handle errors from various APIs. This is not the best
   practice for applications, and is done to make example code more concise.
   Example:

   ESP_ERROR_CHECK(spi_bus_initialize(host, bus_config, dma_chan));

4.12.12 C++ Exceptions

See Exception Handling.

4.13 ESP-BLE-MESH

Bluetooth® mesh networking enables many-to-many (m:m) device communications and is optimized for creating
large-scale device networks.

Devices may relay data to other devices not in direct radio range of the originating device. In this way, mesh networks
can span very large physical areas and contain large numbers of devices. It is ideally suited for building automation,
sensor networks, and other IoT solutions where tens, hundreds, or thousands of devices need to reliably and securely
communicate with one another.

Bluetooth mesh is not a wireless communications technology, but a networking technology. This technology is de-
pendent upon Bluetooth Low Energy (BLE) - a wireless communications protocol stack.

Built on top of Zephyr Bluetooth Mesh stack, the ESP-BLE-MESH implementation supports device provisioning and
node control. It also supports such node features as Proxy, Relay, Low power and Friend.

Please see the ESP-BLE-MESH Architecture for information about the implementation of ESP-BLE-MESH archite-
cture and ESP-BLE-MESH API Reference for information about respective API.

ESP-BLE-MESH is implemented and certified based on the latest Mesh Profile v1.0.1, users can refer here for the
certification details of ESP-BLE-MESH.

Note: If you are looking for Wi-Fi based implementation of mesh for ESP32, please check another product by
Espressif called ESP-WIFI-MESH. For more information and documentation see ESP-WIFI-MESH.

4.13.1 Getting Started with ESP-BLE-MESH

This section is intended to help you get started with ESP-BLE-MESH for the hardware based on the ESP32 chip by
Espressif.
We are going to demonstrate process of setting and operation of a small ESP-BLE-MESH network of three nodes. This process will cover device provisioning and node configuration, and then sending on/off commands to Generic OnOff Server Models on specific nodes.

If you are new to ESP-IDF, please first set up development environment, compile, flash and run example application following top level ESP-IDF Get Started documentation.

**What You Need**

**Hardware:**
- Three ESP32 boards, see options.
- USB cables to connect the boards.
- Computer configured with ESP-IDF.
- Mobile phone or tablet running Android or iOS.

**Software:**
- Example application bluetooth/esp_ble_mesh/onoff_models/onoff_server code to load to the ESP32 boards.
- Mobile App: nRF Mesh for Android or iOS. Optionally you can use some other Apps:
  - EspBleMesh Android App
  - Silicon Labs Android or iOS App

**Installation Step by Step**

This is a detailed roadmap to walk you through the installation process.

**Step 1. Check Hardware**  Both ESP32-DevKitC and ESP-WROVER-KIT development boards are supported for ESP-BLE-MESH implementation. You can choose particular board through menuconfig: idf.py menuconfig

> Example Configuration > Board selection for ESP-BLE-MESH

**Note:** If you plan to use ESP32-DevKitC, connect a RGB LED to GPIO pins 25, 26 and 27.

**Step 2. Configure Software**  Enter the bluetooth/esp_ble_mesh/onoff_models/onoff_server example directory, run idf.py menuconfig to select your board and then run idf.py build to compile the example.

**Step 3. Upload Application to Nodes**  After the bluetooth/esp_ble_mesh/onoff_models/onoff_server example is compiled successfully, users can run idf.py flash to upload the same generated binary files into each of the three development boards.

Once boards are powered on, the RGB LED on each board should turn **GREEN**.

**Step 4. Provision Nodes**  In this section, we will use the nRF Mesh Android App to demonstrate how to provision an unprovisioned device. Users can also get its iOS version from the App Store.

**4.1 Scanner**  The Scanner is App’s functionality to search for unprovisioned devices in range. Open the App, press **Scanner** at the bottom and the search will start. After a short while we should see three unprovisioned devices displayed.
Chapter 4. API Guides

Fig. 13: ESP-BLE-MESH Devices Power On

Fig. 14: nRF Mesh - Scanner
4.2 Identify  Users can select any unprovisioned device, then the App will try to set up a connection with the selected device. After the Bluetooth LE connection is established successfully (sometimes users need to try multiple times to get connected), and proper ESP-BLE-MESH GATT Service is discovered, users can see the IDENTIFY interface button on the screen. The IDENTIFY operation can be used to tell users which device is going to be provisioned.

Note: The IDENTIFY operation also needs some cooperation on the device side, then users can see which device is in the provisioning process. Currently when pressing the IDENTIFY interface button, no signs can be seen from the device except from the log on the serial monitor.

After the IDENTIFY interface button is pressed, users can see the PROVISION interface button.

![Fig. 15: nRF Mesh - IDENTIFY - PROVISION](image)

4.3 Provision  Then, the App will try to provision the unprovisioned device. When the device is provisioned successfully, the RGB LED on the board will turn off, and the App will implement the following procedures:

1. Disconnect with the node
2. Try to reconnect with the node
3. Connect successfully and discover ESP-BLE-MESH GATT Service
4. Get Composition Data of the node and add AppKey to it

When all the procedures are finished, the node is configured properly. And after pressing OK, users can see that unicast address is assigned, and Composition Data of the node is decoded successfully.

Sometimes in procedure 2, the App may fail to reconnect with the node. In this case, after pressing OK, users can see that only unicast address of the node has been assigned, but no Composition Data has been got. Then users need to press CONNECT on the top right, and the previously provisioned node will be displayed on the screen, and users need to choose it and try to connect with the node.

After connecting successfully, the App will show the interface buttons which can be used to get Composition Data and add AppKey.

If the device is the second or the third one which has been provisioned by the App, and after pressing CONNECT, users can see two or three nodes on the screen. In this situation, users can choose any device to connect with, once succeed then go back to the main screen to choose the node which needs to be configured.
Chapter 4. API Guides

Fig. 16: nRF Mesh - Configuration Complete

Fig. 17: nRF Mesh - Initial Configuration Failed
Fig. 18: nRF Mesh - Reconnect - Initial Configuration

Here an example of three devices listed.

- The left picture shows that the third device is provisioned successfully, but the App failed to connect with it. When it tries to reconnect with the third node, three nodes are displayed on the App.
- The right picture shows that after connecting with any node successfully, the App displays the information of the three nodes. Users can see that the App has got the Composition Data of the first and the second nodes, but for the third one, only the unicast address has been assigned to it while the Composition Data is unknown.

### 4.4 Configuration

When provisioning and initial configuration are finished, users can start to configure the node, such as binding AppKey with each model with the elements, setting publication information to it, etc.

Example below shows how to bind AppKey with Generic OnOff Server Model within the Primary Element.

**Note:** No need to bind AppKey with the Configuration Server Model, since it only uses the DevKey to encrypt messages in the Upper Transport Layer.

### Step 5. Operate Network

After all the Generic OnOff Server Models within the three elements are bound with proper AppKey, users can use the App to turn on/off the RGB LED.

In the `bluetooth/esp_ble_mesh/onoff_models/onoff_server` example, the first Generic OnOff Server Model is used to control the RED color, the second one is used to control the GREEN color and the third one is used to control the BLUE color.

The following screenshot shows different board with different color on.

**Note:** For nRF Mesh iOS App [version 1.0.4], when the node contains more than one element, the App is not behaving correctly. If users try to turn on/off the second or the third Generic OnOff Server Model, the message sent by the App is destined to the first Generic OnOff Server Model within the Primary Element.

4.13.2 ESP-BLE-MESH Examples

- **OnOff Server** - shows the use of ESP-BLE-MESH as a node having a Configuration Server model and a Generic OnOff Server model. A ESP-BLE-MESH Provisioner can then provision the unprovisioned device and control a RGB LED representing on/off state, see example code.
- **OnOff Client** - shows how a Generic OnOff Client model works within a node. The node has a Configuration Server model and a Generic OnOff Client model, see example code.
- **Provisioner** - shows how a device can act as an ESP-BLE-MESH Provisioner to provision devices. The Provisioner has a Configuration Server model, a Configuration Client model and a Generic OnOff Client model, see example code.
- **Fast Provisioning** - this example is used for showing how fast provisioning can be used in order to create a mesh network. It takes no more than 60 seconds to provision 100 devices, see example client code and example server code.
- **BLE-Mesh and Wi-Fi Coexistence** - an example that demonstrates the Wi-Fi and Bluetooth (BLE/BR/EDR) coexistence feature of ESP32. Simply put, users can use the Wi-Fi while operating Bluetooth, see example code.
- **Remote Provisioning (v1.1)** - this example is used to demonstrate the new remote provisioning feature introduced in the Mesh Protocol v1.1, see example client code, example server code and example device code.
- **Directed Forwarding (v1.1)** - this example is used to demonstrate the new directed forwarding feature introduced in the Mesh Protocol v1.1. Only nodes along the path will forward the directed messages, while other nodes will not actively participate in forwarding, see example client code and example server code.

ESP-BLE-MESH Architecture

This document introduces ESP-BLE-MESH architecture overview, ESP-BLE-MESH architecture implementation as well as ESP-BLE-MESH auxiliary routines.

• ESP-BLE-MESH Architecture Overview
  – Describes the five major parts of ESP-BLE-MESH architecture and the functionality of each part.

• ESP-BLE-MESH Architecture Implementation
  – Describes the basic functions of ESP-BLE-MESH files, the correspondence between files and ESP-BLE-MESH architecture, and the interface for calling among files.

• ESP-BLE-MESH Auxiliary Routines
  – Describe the auxiliary routines of ESP-BLE-MESH, such as Mesh network management, Mesh features, etc.

1. ESP-BLE-MESH Architecture Overview

Currently ESP-BLE-MESH has implemented most functions of Mesh Profile and all the Client Models defined in Mesh Model specification. Those missing functions/models are under development and will be provided soon. ESP-BLE-MESH architecture has been granted the official Bluetooth certification.

ESP-BLE-MESH architecture includes five key parts:

• Mesh Protocol Stack
  – Mesh Networking is responsible for processing of messages of ESP-BLE-MESH nodes.
  – Mesh Provisioning is responsible for provisioning flow of ESP-BLE-MESH devices.
  – Mesh Models is responsible for the implementation of SIG-defined models.

• Network Management
  – Implements several network management procedures, including node removal procedure, IV Index recovery procedure, etc.

• Features
  – Include several ESP-BLE-MESH features, e.g., Low Power feature, Friend feature, Relay feature, etc.

• Mesh Bearer Layer
  – Includes Advertising Bearer and GATT Bearer. The bearer layer is crucial to ESP-BLE-MESH protocol stack which is built on Bluetooth Low-Energy technology, because the protocol stack must make use of the bearer layer to transmit data via the BLE advertising channel and connection channel.

• Applications
  – Based on ESP-BLE-MESH protocol stack and Mesh Models.
Fig. 23: Figure 1.1 ESP-BLE-MESH Architecture Diagram
Chapter 4. API Guides

By calling API and handling Event, Applications interact with Mesh Networking and Mesh Provisioning in ESP-BLE-MESH protocol stack, as well as a series of Models provided by Mesh Models.

1.1 Mesh Protocol Stack

1.1.1 Mesh Networking  Mesh Networking in the protocol stack architecture implements the following functions:

- The communication between nodes in the Mesh network.
- Encryption and decryption of messages in the Mesh network.
- Management of Mesh network resources (Network Key, IV Index, etc.).
- Segmentation and reassembly of Mesh network messages.
- Model mapping of messages between different models.
- For more features, please see ESP-BLE-MESH Feature List.

The implementation of Mesh Networking functions is based on hierarchy structure. Functions of each layer are shown in Table 1.1:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Layer</td>
<td>Access Layer not only defines the format of application data, but also defines and controls the encryption and decryption of the data packets conducted by Upper Transport Layer.</td>
</tr>
<tr>
<td>Upper Transport Layer</td>
<td>Upper Transport Layer encrypts, decrypts, and authenticates application data to and from the access layer; it also handles special messages called “transport control messages”, including messages related to “friendship” and heartbeat messages.</td>
</tr>
<tr>
<td>Lower Transport Layer</td>
<td>Lower Transport Layer handles segmentation and reassembly of PDU.</td>
</tr>
<tr>
<td>Network Layer</td>
<td>Network Layer defines the address type and format of the network messages, and implements the relay function of the device.</td>
</tr>
</tbody>
</table>

1.1.2 Mesh Provisioning  Mesh Provisioning in the protocol stack architecture implements the following functions:

- Provisioning of unprovisioned devices.
- Allocation of Mesh network resources (unicast address, IV Index, NetKey, etc.).
- Four authentication methods support during provisioning.
- For more features, please see ESP-BLE-MESH Feature List.

The implementation of Mesh Provisioning functions is based on hierarchy structure. Functions of each layer are shown in Table 1.2:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provisioning PDUs</td>
<td>Provisioning PDUs from different layers are handled using provisioning protocol.</td>
</tr>
<tr>
<td>Generic Provisioning PDU/Proxy PDU</td>
<td>The Provisioning PDUs are transmitted to an unprovisioned device using a Generic Provisioning layer or Proxy protocol layer.</td>
</tr>
<tr>
<td>PB-ADV/PB-GATT</td>
<td>These layers define how the Provisioning PDUs are transmitted as transactions that can be segmented and reassembled.</td>
</tr>
<tr>
<td>Advertising/Provisioning Service</td>
<td>The provisioning bearers define how sessions are established such that the transactions from the generic provisioning layer can be delivered to a single device.</td>
</tr>
</tbody>
</table>

1.1.3 Mesh Models  Mesh Models in the protocol stack architecture implements the following functions:

- Configuration Client/Server Models
Chapter 4. API Guides

- Health Client/Server Models
- Generic Client/Server Models
- Sensor Client/Server Models
- Time and Scenes Client/Server Models
- Lighting Client/Server Models

Functions of each layer are shown in Table 1.3:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model Layer</td>
<td>Model Layer implements models used to standardize the operation of typical user scenarios, including Generic Client/Server Models, Sensor Client/Server Models, Time and Scenes Client/Server Models, Lighting Client/Server Models and several vendor models.</td>
</tr>
<tr>
<td>Foundation Model Layer</td>
<td>Foundation Model Layer implements models related to ESP-BLE-MESH configuration, management, self diagnosis, etc.</td>
</tr>
</tbody>
</table>

1.2 Mesh Network Management  
Network Management implements the following functions:

- Node removal procedure is used to remove a node from the network.
- IV Index recovery procedure is used to recover a node’s IV Index.
- IV update procedure is used to update the nodes’ IV Index.
- Key refresh procedure is used to update the nodes’ NetKey, AppKey, etc.
- Network creation procedure is used to create a mesh network.
- NVS storage is used to store node’s networking information.

1.3 Mesh Features  
Features includes the following options:

- Low Power feature is used to reduce node’s power consumption.
- Friend feature is used to store messages for Low Power nodes.
- Relay feature is used to relay/forward Network PDUs received by a node over the advertising bearer.
- Proxy Server/Client are two node roles in proxy protocol, which enable nodes to send and receive Network PDUs, mesh beacons, proxy configuration messages and Provisioning PDUs over a connection-oriented bearer.

1.4 Mesh Bearer Layer  
Bearers in the protocol stack architecture are responsible for passing of data between ESP-BLE-MESH protocol stack and Bluetooth Low Energy Core.

Bearers can be taken as a carrier layer based on Bluetooth Low Energy Core, which implements the function of receiving and transmitting data for the ESP-BLE-MESH protocol stack.

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>GATT Bearer</td>
<td>The GATT Bearer uses the Proxy protocol to transmit and receive Proxy PDUs between two devices over a GATT connection.</td>
</tr>
<tr>
<td>Advertising Bearer</td>
<td>When using the Advertising Bearer, a mesh packet shall be sent in the Advertising Data of a Bluetooth Low Energy advertising PDU using the Mesh Message AD Type.</td>
</tr>
</tbody>
</table>

1.5 Mesh Applications  
The Applications in the protocol stack architecture implement the corresponding functions by calling the API provided by the ESP-BLE-MESH protocol stack and processing the Event reported by the protocol stack. There are some common applications, such as gateway, lighting and etc.

Interaction between application layer (Applications) and API/Event

- Application layer calls API
  - Call the provisioning-related API for provisioning.
  - Call the model-related API to send messages.
  - Call the device-attributes-related API to get local information about the device.
• Application layer processes Event
  The application layer is designed based on events, which take parameters to the application layer. Events are mainly divided into two categories.
  – The events completed by calling API.
    • Such as nodes sending messages.
  – The events that the protocol stack actively reports to the application layer.
    • The Event that the protocol stack actively reports.
    • The Event that Model actively reports.
• The event is reported by the callback function registered by the application layer, and the callback function also contains the corresponding processing of the event.

Interaction between API / Event and ESP-BLE-MESH protocol stack
• API used by user mainly calls functions provided by Mesh Networking, Mesh Provisioning and Mesh Models.
• The interaction between API / Event and the protocol stack does not operate across the hierarchy of the protocol stack. For example, API does not call functions related to Network Layer.

2. ESP-BLE-MESH Architecture Implementation
The design and implementation of ESP-BLE-MESH architecture is based on layers and modules. In details, Section 2.1 (Mesh Networking Implementation), Section 2.2 (Mesh Provisioning Implementation) and Section 2.3 (Mesh Bearers Implementation) are based on layers, and Section 2.4 (Mesh Models Implementation) is on modules.

• Layer-based Approach: With Layer-based approach, the architecture is designed according to the layers specified in the Mesh Profile Specification. Each layer has its unique files which include APIs of this layer and etc. The specific design is shown in Figure 2.1.
• Module-based Approach: Every file implements an independent function that can be called by other programs.

The design of ESP-BLE-MESH architecture uses layer-based approach. The sequence of layers which data packets are processed through is fixed, i.e., the processing of packets will form a message flow. Thus, we could see flows of messages from the Protocol Stack Interface Diagram in Figure 2.1.

2.1 Mesh Protocol Stack Implementation

2.1.1 Mesh Networking Implementation
The list of files and the functions implemented in each file in Mesh Networking are shown in Table 2.1:

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>access.c</td>
<td>ESP-BLE-MESH Access Layer</td>
</tr>
<tr>
<td>transport.c</td>
<td>ESP-BLE-MESH Lower/Upper Transport Layer</td>
</tr>
<tr>
<td>net.c</td>
<td>ESP-BLE-MESH Network Layer</td>
</tr>
<tr>
<td>adv.c</td>
<td>A task used to send ESP-BLE-MESH advertising packets, a callback used to handle received advertising packets and APIs used to allocate adv buffers</td>
</tr>
</tbody>
</table>

2.1.2 Mesh Provisioning Implementation
The implementation of Mesh Provisioning is divided into two chunks due to the Node/Provisioner coexistence.

Specific files that provide implementation of provisioning of Node are shown in Table 2.2:
Chapter 4. API Guides

Fig. 24: ESP-BLE-MESH Architecture Implementation Diagram

</tbody>
</table>

2.2 Mesh Bearers Implementation

Portability is fully considered in the implementation of Mesh Bearers. When the ESP-BLE-MESH protocol stack is being ported to other platforms, users only need to modify adapter.c (example of NimBLE version).

Table 12: Table 2.5 Mesh Bearers File Description

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>adapter.c</td>
<td>ESP-BLE-MESH Bearer Layer adapter. This file provides the interfaces used to receive and send ESP-BLE-MESH ADV &amp; GATT related packets.</td>
</tr>
</tbody>
</table>

Note: adapter.c is the implementation of Advertising Bearer and GATT Bearer in Mesh Networking.
Chapter 4. API Guides

framework.

2.3 Mesh Applications Implementation We have provided a series of application examples for customer development, and users can develop products based on ESP-BLE-MESH Examples.

3. Auxiliary Routine Auxiliary routine refers to optional functions in the ESP-BLE-MESH protocol stack. The design of the auxiliary routine generally implement the truncation of code through CONFIG_BLE_MESH.

3.1 Features

- Low Power
- Friend
- Relay
- Proxy Client/Server

3.2 Network Management

- Node Removal procedure
- IV Index Recovery procedure
- IV Update procedure
- Key Refresh procedure
- Network Creation procedure
- NVS Storage

3.3 Auxiliary Routine Implementation When adopting the design of independent module, the two main factors should be considered:

- The module can not be implemented hierarchically, and it can be completely independent, which means it does not rely on the implementation of other modules.
- The functions in the module will be used repeatedly, so it is reasonable to design it into a module. Independent module is shown in Table 3.1:

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>lpn.c</td>
<td>ESP-BLE-MESH Low Power functionality</td>
</tr>
<tr>
<td>friend.c</td>
<td>ESP-BLE-MESH Friend functionality</td>

</tr>
<tr>
<td>proxy_client.c</td>
<td>ESP-BLE-MESH Proxy Client related functionalities</td>
</tr>
<tr>
<td>settings.c</td>
<td>ESP-BLE-MESH NVS storage functionality</td>
</tr>
<tr>
<td>main.c</td>
<td>ESP-BLE-MESH stack initialize, stack enable, node removal related functionalities</td>
</tr>
</tbody>
</table>

ESP-BLE-MESH FAQ

This document provides a summary of frequently asked questions about developing with ESP-BLE-MESH, and is divided into seven sections:

- 1. Provisioner Development
- 2. Node Development
- 3. ESP-BLE-MESH and Wi-Fi Coexistence
- 4. Fast Provisioning
Users could refer to the sections for quick answer to their questions. This document will be updated based on the feedback collected via various channels.

1. **Provisioner Development**

   Generally, a Provisioner is used to provision unprovisioned devices and form a mesh network. And after provisioning, roles of the unprovisioned devices will be changed to those of a node.

1.1 **What Is the Flow for an Unprovisioned Device to Join ESP-BLE-MESH Network?**

   There are two phases for a device to join ESP-BLE-MESH network via a Provisioner, namely, provisioning and configuration.

   - The phase of provisioning is to assign unicast address, add NetKey and etc. to a device. By provisioning, the device joins the ESP-BLE-MESH network and its role is changed from an unprovisioned device to a node.
   - The phase of configuration is to add AppKeys to the node and bind AppKeys to corresponding models. And some items are optional during configuration, including adding subscription addresses to the node, set publication information, etc. By configuration, the node can actually transmit messages to a Provisioner and receive messages from it.

1.2 **If a Provisioner Wants to Change States of a Node, What Requirements Should Be Met for a Provisioner?**

   - Client model that corresponds to server model of the node is required.
   - NetKey and AppKey used to encrypt messages shall be owned by both the node and the Provisioner.
   - The address owned by the node shall be known, which could be its unicast address or subscription address.

1.3 **How Can NetKey and AppKey Be Used?**

   - NetKey is used for encryption of messages in Network Layer. Nodes with the same NetKey are assumed to be in the same subnet while those with different NetKeys cannot communicate with each other.
   - AppKey is used for encryption of messages in Upper Transport Layer. If client model and server model are bound to different AppKeys, the communication cannot be achieved.

1.4 **How to Generate a NetKey or AppKey for Provisioner? Can We Use a Fixed NetKey or AppKey?**

   - The API `esp_ble_mesh_provisioner_add_local_net_key()` can be used to add a NetKey with a fixed or random value.
   - The API `esp_ble_mesh_provisioner_add_local_app_key()` can be used to add an AppKey with a fixed or random value.

1.5 **Is the Unicast Address of Provisioner Fixed?**

   The value of `prov_unicast_addr` in `esp_ble_prov_t` is used to set the unicast address of Provisioner, it can be set only once during initialization and cannot be changed afterwards.

1.6 **Can the Address of Provisioner Serve as Destination Address of the Node-reporting-status Message?**

   The unicast address of Provisioner can be set only once during initialization and cannot be changed afterwards. In theory, it can serve as the destination address of the node-reporting-status message, provided that the unicast address of the Provisioner is known by nodes. Nodes can know the unicast address of Provisioner during configuration since Provisioner sends messages to them with its unicast address used as the source address.

   Subscription address can also be used. Provisioner subscribes to a group address or virtual address, and nodes send messages to the subscription address.
1.7 Is the Unicast Address of the Node That Is Firstly Provisioned by Provisioner to ESP-BLE-MESH Network Fixed?

The value of `prov_start_address` in `esp_ble_mesh_prov_t` is used to set the starting address when the Provisioner provisions unprovisioned devices, i.e., the unicast address of the node it firstly provisioned. It can be set only once during initialization and cannot be changed afterwards.

1.8 Is the Unicast Address of the Node That Mobile App Firstly Provisioned Fixed?

The App will decide the unicast address, and currently most of them are fixed.

1.9 How to Know Which Unprovisioned Device Is the Provisioner That Is Provisioning Currently?

The value of `prov_attention` in `esp_ble_mesh_prov_t` is used by Provisioner set to unprovisioned device during provisioning. It can be set only once during initialization and cannot be changed afterwards. When the unprovisioned device is joining the mesh network, it can display in a specific way like flashing light to notify Provisioner that it is being provisioned.

1.10 How Many Ways to Authenticate the Devices During Provisioning? Which Way Was Used in the provided examples?

There are four authentication methods, i.e., No OOB, Static OOB, Output OOB and Input OOB. In the provided examples, No OOB is used.

1.11 What Information Can Be Carried by the Advertising Packets of the Unprovisioned Device Before Provisioning into the Network?

- Device UUID
- OOB Info
- URL Hash (optional)

1.12 Can Such Information Be Used for Device Identification?

For example, each unprovisioned device contains a unique Device UUID, which can be used for device identification.

1.13 How Is the Unicast Address Assigned When the Node Provisioned by Provisioner Contains Multiple Elements?

- Provisioner will assign an unicast address for the primary element of the node, and unicast address of the remaining elements are incremented one by one.
- For example: If an unprovisioned device has three elements, i.e., the primary element, the second element and the third element. After provisioning, the primary element address of the node is 0x0002 while the second element address is 0x0003, and the third element address is 0x0004.

1.14 How Can Provisioner Get and Parse the Composition Data of Nodes Through Configuration Client Model?

- Provisioner can get the Composition Data of nodes using the `Configuration Client Model` API `esp_ble_mesh_config_client_set_state()` with `comp_data_get` in the parameter `esp_ble_mesh_cfg_client_get_state_t` set properly.
- Users can refer to the following code to parse the Composition Data:

```c
#include <stdio.h>
#include <string.h>
#include <stdint.h>
```

    if (ret == -1) {
        printf("decode_comp_data error");
    }
}

1.15 How Can Provisioner Further Configure Nodes Through Obtained Composition Data?

Provisioner do the following configuration by calling the Configuration Client Model API esp_ble_mesh_config_client_set_state().

- Add AppKey to nodes with app_key_add in the parameter esp_ble_mesh_cfg_client_set_state_t set properly.
- Add subscription address to the models of nodes with model_sub_add in the parameter esp_ble_mesh_cfg_client_set_state_t set properly.
- Set publication information to the models of nodes with model_pub_set in the parameter esp_ble_mesh_cfg_client_set_state_t set properly.

1.16 Can Nodes Add Corresponding Configurations for Themselves?

This method can be used in special cases like testing period.

- Here is an example to show nodes add new group addresses for their models.

esp_err_t example_add_fast_prov_group_address(uint16_t model_id, uint16_t... group_addr)
{
    const esp_ble_mesh_comp_t *comp = NULL;
    esp_ble_mesh_elem_t *element = NULL;

(continues on next page)
Chapter 4. API Guides

esp_ble_mesh_model_t *model = NULL;
int i, j;

if (!ESP_BLE_MESH_ADDR_IS_GROUP(group_addr)) {
    return ESP_ERR_INVALID_ARG;
}

comp = esp_ble_mesh_get_composition_data();
if (!comp) {
    return ESP_FAIL;
}

for (i = 0; i < comp->element_count; i++) {
    element = &comp->elements[i];
    model = esp_ble_mesh_find_sig_model(element, model_id);
    if (!model) {
        continue;
    }
    for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
        if (model->groups[j] == group_addr) {
            break;
        }
    }
    if (j != ARRAY_SIZE(model->groups)) {
        ESP_LOGW(TAG, "%s: Group address already exists, element_index: %d", __func__, i);
        continue;
    }
    for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
        if (model->groups[j] == ESP_BLE_MESH_ADDR_UNASSIGNED) {
            model->groups[j] = group_addr;
            break;
        }
    }
    if (j == ARRAY_SIZE(model->groups)) {
        ESP_LOGE(TAG, "%s: Model is full of group addresses, element_index: %d", __func__, i);
    }
}

return ESP_OK;

Note: When the NVS storage of the node is enabled, group address added and AppKey bound by this method will not be saved in the NVS when the device is powered off currently. These configuration information can only be saved if they are configured by Configuration Client Model.

1.17 How Does Provisioner Control Nodes by Grouping?
Generally there are two approaches to implement group control in ESP-BLE-MESH network, group address approach and virtual address approach. And supposing there are 10 devices, i.e., five devices with blue lights and five devices with red lights.

- Method 1: 5 blue lights can subscribe to a group address, 5 red lights subscribe to another one. By sending messages to different group addresses, Provisioner can realize group control.
- Method 2: 5 blue lights can subscribe to a virtual address, 5 red lights subscribe to another one. By sending messages to different virtual addresses, Provisioner can realize group control.
1.18 How Does Provisioner Add Nodes to Multiple Subnets?

Provisioner can add multiple NetKeys to nodes during configuration, and nodes sharing the same NetKey belong to the same subnet. Provisioner can communicate with nodes on different subnets by using different NetKeys.

1.19 How Does Provisioner Know If a Node in the Mesh Network Is Offline?

Node offline is usually defined as: the condition that the node cannot be properly communicated with other nodes in the mesh network due to power failure or some other reasons.

There is no connection between nodes and nodes in the ESP-BLE-MESH network. They communicate with each other through advertising channels.

An example is given here to show how to detect a node is offline by Provisioner.

• The node can periodically send heartbeat messages to Provisioner. And if Provisioner failed to receive heartbeat messages in a certain period, the node is considered to be offline.

Note: The heartbeat message should be designed into a single package (less than 11 bytes), so the transmission and reception of it can be more efficient.

1.20 What Operations Should Be Performed When Provisioner Removes Nodes from the Network?

Usually when Provisioner tries to remove node from the mesh network, the procedure includes three main steps:

• Firstly, Provisioner adds the node that need to be removed to the “blacklist”.
• Secondly, Provisioner performs the Key Refresh procedure.
• Lastly, the node performs node reset procedure, and switches itself to an unprovisioned device.

1.21 In the Key Refresh Procedure, How Does Provisioner Update the Netkey Owned by Nodes?

- Provisioner updates the NetKey of nodes using the Configuration Client Model API esp_ble_mesh_config_client_set_state() with net_key_update in the parameter esp_ble_mesh_cfg_client_set_state_t set properly.
- Provisioner updates the AppKey of nodes using the Configuration Client Model API esp_ble_mesh_config_client_set_state() with app_key_update in the parameter esp_ble_mesh_cfg_client_set_state_t set properly.

1.22 How Does Provisioner Manage Nodes in the Mesh Network?

ESP-BLE-MESH implements several functions related to basic node management in the example, such as esp_ble_mesh_store_node_info(). And ESP-BLE-MESH also provides the API esp_ble_mesh_provisioner_set_node_name() which can be used to set the node’s local name and the API esp_ble_mesh_provisioner_get_node_name() which can be used to get the node’s local name.

1.23 What Does Provisioner Need When Trying to Control the Server Model of Nodes?

Provisioner must include corresponding client model before controlling the server model of nodes.

Provisioner shall add its local NetKey and AppKey.

• Provisioner add NetKey by calling the API esp_ble_mesh_provisioner_add_local_net_key().
• Provisioner add AppKey by calling the API esp_ble_mesh_provisioner_add_local_app_key().

Provisioner shall configure its own client model.
Chapter 4. API Guides

1.24 How Does Provisioner Control the Server Model of Nodes?

ESP-BLE-MESH supports all SIG-defined client models. Provisioner can use these client models to control the server models of nodes. And the client models are divided into 6 categories with each category has the corresponding functions.

- Configuration Client Model
  - The API `esp_ble_mesh_config_client_get_state()` can be used to get the `esp_ble_mesh_cfg_client_get_state_t` values of Configuration Server Model.
  - The API `esp_ble_mesh_config_client_set_state()` can be used to set the `esp_ble_mesh_cfg_client_set_state_t` values of Configuration Server Model.

- Health Client Model
  - The API `esp_ble_mesh_health_client_get_state()` can be used to get the `esp_ble_mesh_health_client_get_state_t` values of Health Server Model.
  - The API `esp_ble_mesh_health_client_set_state()` can be used to set the `esp_ble_mesh_health_client_set_state_t` values of Health Server Model.

- Generic Client Models
  - The API `esp_ble_mesh_generic_client_get_state()` can be used to get the `esp_ble_mesh_generic_client_get_state_t` values of Generic Server Models.
  - The API `esp_ble_mesh_generic_client_set_state()` can be used to set the `esp_ble_mesh_generic_client_set_state_t` values of Generic Server Models.

- Lighting Client Models
  - The API `esp_ble_mesh_light_client_get_state()` can be used to get the `esp_ble_mesh_light_client_get_state_t` values of Lighting Server Models.
  - The API `esp_ble_mesh_light_client_set_state()` can be used to set the `esp_ble_mesh_light_client_set_state_t` values of Lighting Server Models.

- Sensor Client Models
  - The API `esp_ble_mesh_sensor_client_get_state()` can be used to get the `esp_ble_mesh_sensor_client_get_state_t` values of Sensor Server Model.
  - The API `esp_ble_mesh_sensor_client_set_state()` can be used to set the `esp_ble_mesh_sensor_client_set_state_t` values of Sensor Server Model.

- Time and Scenes Client Models
  - The API `esp_ble_mesh_time_scene_client_get_state()` can be used to get the `esp_ble_mesh_time_scene_client_get_state_t` values of Time and Scenes Server Models.
  - The API `esp_ble_mesh_time_scene_client_set_state()` can be used to set the `esp_ble_mesh_time_scene_client_set_state_t` values of Time and Scenes Server Models.

2. Node Development

2.1 What Kind of Models Are Included by Nodes?

- In ESP-BLE-MESH, nodes are all composed of a series of models with each model implements some functions of the node.
- Model has two types, client model and server model. Client model can get and set the states of server model.
- Model can also be divided into SIG model and vendor model. All behaviors of SIG models are officially defined while behaviors of vendor models are defined by users.

2.2 Is the Format of Messages Corresponding to Each Model Fixed?

- Messages, which consist of opcode and payload, are divided by opcode.
• The type and the format of the messages corresponding to models are both fixed, which means the messages transmitted between models are fixed.

2.3 Which Functions Can Be Used to Send Messages with the Models of Nodes?

• For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` to send messages.
• For server models, users can use the API `esp_ble_mesh_server_model_send_msg()` to send messages.
• For publication, users call the API `esp_ble_mesh_model_publish()` to publish messages.

2.4 How to Achieve the Transmission of Messages Without Packet Loss?

Acknowledged message is needed if users want to transmit messages without packet loss. The default time to wait for corresponding response is set in `CONFIG_BLE_MESH_CLIENT_MSG_TIMEOUT`. If the sender waits for the response until the timer expires, the corresponding timeout event would be triggered.

Note: Response timeout can be set in the API `esp_ble_mesh_client_model_send_msg()`. The default value (4 seconds) would be applied if the parameter `msg_timeout` is set to 0.

2.5 How to Send Unacknowledged Messages?

For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` with the parameter `need_rsp` set to `false` to send unacknowledged messages.

For server models, the messages sent by using the API `esp_ble_mesh_server_model_send_msg()` are always unacknowledged messages.

2.6 How to Add Subscription Address to Models?

Subscription address can be added through Configuration Client Model.

2.7 What Is the Difference Between Messages Sent and Published by Models?

Messages sent by calling the API `esp_ble_mesh_client_model_send_msg()` or `esp_ble_mesh_server_model_send_msg()` will be sent in the duration determined by the Network Transmit state.

Messages published by calling the API `esp_ble_mesh_model_publish()` will be published determined by the Model Publication state. And the publication of messages is generally periodic or with a fixed number of counts. The publication period and publication count are controlled by the Model Publication state, and can be configured through Configuration Client Model.

2.8 How Many Bytes Can Be Carried When Sending Unsegmented Messages?

The total payload length (which can be set by users) of unsegmented message is 11 octets, so if the opcode of the message is 2 octets, then the message can carry 9-octets of valid information. For vendor messages, due to the 3-octets opcode, the remaining payload length is 8 octets.

2.9 When Should the Relay Feature of Nodes Be Enabled?

Users can enable the Relay feature of all nodes when nodes detected in the mesh network are sparse.

For dense mesh network, users can choose to just enable the Relay feature of several nodes.

And users can enable the Relay feature by default if the mesh network size is unknown.
2.10 When Should the Proxy Feature of Node Be Enabled?
If the unprovisioned device is expected to be provisioned by a phone, then it should enable the Proxy feature since almost all the phones do not support sending ESP-BLE-MESH packets through advertising bearer currently. And after the unprovisioned device is provisioned successfully and becoming a Proxy node, it will communicate with the phone using GATT bearer and using advertising bearer to communicate with other nodes in the mesh network.

2.11 How to Use the Proxy Filter?
The Proxy filter is used to reduce the number of Network PDUs exchanged between a Proxy Client (e.g., the phone) and a Proxy Server (e.g., the node). And with the Proxy filter, Proxy Client can explicitly request to receive only mesh messages with certain destination addresses from Proxy Server.

2.12 When a Message Can Be Relayed by a Relay Node?
If a message need to be relayed, the following conditions should be met.
- The message is in the mesh network.
- The message is not sent to the unicast address of the node.
- The value of TTL in the message is greater than 1.

2.13 If a Message Is Segmented into Several Segments, Should the Other Relay Nodes Just Relay When One of These Segments Is Received or Wait Until the Message Is Received Completely?
Relay nodes will forward segments when one of them are received rather than keeping waiting until all the segments are received.

2.14 What Is the Principle of Reducing Power Consumption Using Low Power Feature?
- When the radio is turned on for listening, the device is consuming energy. When low power feature of the node is enabled, it will turn off its radio in the most of the time.
- And cooperation is needed between low power node and friend node, thus low power node can receive messages at an appropriate or lower frequency without the need to keep listening.
- When there are some new messages for low power node, its friend node will store the messages for it. And low power node can poll friend nodes to see if there are new messages at a fixed interval.

2.15 How to Continue the Communication on the Network After Powering-down and Powering-up Again?
Enable the configuration Store ESP-BLE-MESH Node configuration persistently in menuconfig.

2.16 How to Send out the Self-test Results of Nodes?
It is recommended that nodes can publish its self-test results periodically through Health Server Model.

2.17 How to Transmit Information Between Nodes?
One possible application scenario for transmitting information between nodes is that spray nodes would be triggered once smoke alarm detected high smoke concentration. There are two approaches in implementation.
- Approach 1 is that spray node subscribes to a group address. When smoke alarm detects high smoke concentration, it will publish a message whose destination address is the group address which has been subscribed by spray node.
- Approach 2 is that Provisioner can configure the unicast address of spray node to the smoke alarm. When high smoke concentration is detected, smoke alarm can use send messages to the spray node with the spray node’s unicast address as the destination address.
2.18 Is Gateway a Must for Nodes Communication?

- Situation 1: nodes only communicate within the mesh network. In this situation, no gateway is needed. ESP-BLE-MESH network is a flooded network, messages in the network have no fixed paths, and nodes can communicate with each other freely.
- Situation 2: if users want to control the nodes remotely, for example turn on some nodes before getting home, then a gateway is needed.

2.19 When Will the IV Update Procedure Be Performed?

IV Update procedure would be performed once sequence number of messages sent detected by the bottom layer of node reached a critical value.

2.20 How to Perform IV Update Procedure?

Nodes can perform IV Update procedure with Secure Network Beacon.

3. ESP-BLE-MESH and Wi-Fi Coexistence

3.1 Which Modes Does Wi-Fi Support When it Coexists with ESP-BLE-MESH?

Currently only Wi-Fi station mode supports the coexistence.

3.2 Why Is the Wi-Fi Throughput So Low When Wi-Fi and ESP-BLE-MESH Coexist?

The ESP32-DevKitC board without PSRAM can run properly but the throughput of it is low since it has no PSRAM. When Bluetooth and Wi-Fi coexist, the throughput of ESP32-DevKitC with PSRAM can be stabilized to more than 1 Mbps.

Some configurations in menuconfig shall be enabled to support PSRAM.

- ESP32-specific > Support for external, SPI-connected RAM > Try to allocate memories of Wi-Fi and LWIP...
- Bluetooth > Bluedroid Enable > BT/BLE will first malloc the memory from the PSRAM
- Bluetooth > Bluedroid Enable > Use dynamic memory allocation in BT/BLE stack
- Bluetooth > Bluetooth controller > BLE full scan feature supported
- Wi-Fi > Software controls Wi-Fi/Bluetooth coexistence > Wi-Fi

4. Fast Provisioning

4.1 Why Is Fast Provisioning Needed?

Normally when they are several unprovisioned devices, users can provision them one by one. But when it comes to a large number of unprovisioned devices (e.g., 100), provisioning them one by one will take huge amount of time. With fast provisioning, users can provision 100 unprovisioned devices in about 50 seconds.

4.2 Why EspBleMesh App Would Wait for a Long Time During Fast Provisioning?

After the App provisioned one Proxy node, it will disconnect from the App during fast provisioning, and reconnect with the App when all the nodes are provisioned.
4.3 Why Is the Number of Node Addresses Displayed in the App More Than That of Existing Node Addresses?

Each time after a fast provisioning process, and before starting a new one, the node addresses in the App should be cleared, otherwise the number of the node address will be incorrect.

4.4 What Is the Usage of the count Value Which Was Input in EspBleMesh App?

The count value is provided to the Proxy node which is provisioned by the App so as to determine when to start Proxy advertising in advance.

4.5 When Will Configuration Client Model of the Node Running fast_prov_server Example Start to Work?

Configuration Client Model will start to work after the Temporary Provisioner functionality is enabled.

4.6 Will the Temporary Provisioner Functionality Be Enabled All the Time?

After the nodes receive messages used to turn on/off lights, all the nodes will disable its Temporary Provisioner functionality and become nodes.

5. Log Help

You can find meaning of errors or warnings when they appear at the bottom of ESP-BLE-MESH stack.

5.1 What Is the Meaning of Warning ran out of retransmit attempts?

When the node transmits a segmented message, and due to some reasons, the receiver does not receive the complete message. Then the node will retransmit the message. When the retransmission count reaches the maximum number, which is 4 currently, then this warning will appear.

5.2 What Is the Meaning of Warning Duplicate found in Network Message Cache?

When the node receives a message, it will compare the message with the ones stored in the network cache. If the same has been found in the cache, which means it has been received before, then the message will be dropped.

5.3 What Is the Meaning of Warning Incomplete timer expired?

When the node does not receive all the segments of a segmented message during a certain period (e.g., 10 seconds), then the Incomplete timer will expire and this warning will appear.

5.4 What Is the Meaning of Warning No matching TX context for ack?

When the node receives a segment ack and it does not find any self-send segmented message related with this ack, then this warning will appear.

5.5 What Is the Meaning of Warning No free slots for new incoming segmented messages?

When the node has no space for receiving new segmented message, this warning will appear. Users can make the space larger through the configuration CONFIG_BLE_MESH_RX_SEG_MSG_COUNT.

5.6 What Is the Meaning of Error Model not bound to Appkey 0x0000?

When the node sends messages with a model and the model has not been bound to the AppKey with AppKey Index 0x000, then this error will appear.
5.7 What Is the Meaning of Error Busy sending message to DST xxxx?

This error means client model of the node has transmitted a message to the target node and now is waiting for a response, users cannot send messages to the same node with the same unicast address. After the corresponding response is received or timer is expired, then another message can be sent.

6. Example Help

6.1 How Are the ESP-BLE-MESH Callback Functions Classified?

- The API `esp_ble_mesh_register_prov_callback()` is used to register callback function used to handle provisioning and networking related events.
- The API `esp_ble_mesh_register_config_client_callback()` is used to register callback function used to handle Configuration Client Model related events.
- The API `esp_ble_mesh_register_config_server_callback()` is used to register callback function used to handle Configuration Server Model related events.
- The API `esp_ble_mesh_register_health_client_callback()` is used to register callback function used to handle Health Client Model related events.
- The API `esp_ble_mesh_register_health_server_callback()` is used to register callback function used to handle Health Server Model related events.
- The API `esp_ble_mesh_register_generic_client_callback()` is used to register callback function used to handle Generic Client Models related events.
- The API `esp_ble_mesh_register_light_client_callback()` is used to register callback function used to handle Lighting Client Models related events.
- The API `esp_ble_mesh_register_sensor_client_callback()` is used to register callback function used to handle Sensor Client Model related events.
- The API `esp_ble_mesh_register_time_scene_client_callback()` is used to register callback function used to handle Time and Scenes Client Models related events.
- The API `esp_ble_mesh_register_custom_model_callback()` is used to register callback function used to handle vendor model and unrealized server models related events.

7. Others

7.1 How to Print the Message Context?

The examples use `ESP_LOG_BUFFER_HEX()` to print the message context while the ESP-BLE-MESH protocol stack uses `bt_hex()`.

7.2 Which API Can Be Used to Restart ESP32?

The API `esp_restart()`.

7.3 How to Monitor the Remaining Space of the Stack of a Task?

The API `vTaskList()` can be used to print the remaining space of the task stack periodically.

7.4 How to Change the Level of Log Without Changing the Menuconfig Output Level?

The API `esp_log_level_set()` can be used to change the log output level rather than using menu-config to change it.
## ESP-BLE-MESH Terminology

### Table 1: ESP-BLE-MESH Terminology - Role

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Un-provisioned Device</td>
<td>A device that is not a member of a mesh network is known as an unprovisioned device.</td>
<td>Examples: lighting devices, temperature control devices, manufacturing equipments and electric doors, etc.</td>
</tr>
<tr>
<td>Node</td>
<td>A node is a provisioned device.</td>
<td>The role of unprovisioned device will change to node after being provisioned to ESP-BLE-MESH network. Nodes (such as lighting devices, temperature control devices, manufacturing equipments, and electric doors) are devices that can send, receive, or relay messages in ESP-BLE-MESH network, and they can optionally support one or more subnets.</td>
</tr>
<tr>
<td>Relay Node</td>
<td>A node that supports the Relay feature and has the Relay feature enabled is known as a Relay node.</td>
<td>Relay nodes can receive and resend ESP-BLE-MESH messages, so the messages can be transferred further. Users can decide whether or not to enable forwarding function of nodes according to nodes’ status. Messages can be relayed for multiple times, and each relay is considered as a “hop”. Messages can hop up to 126 times, which is enough for message transmission in a wide area.</td>
</tr>
<tr>
<td>Proxy Node</td>
<td>A node that supports the Proxy feature and has the Proxy feature enabled is known as a Proxy node.</td>
<td>Proxy nodes receive messages from one bearer (it generally includes advertising bearer and GATT bearer) and resend it from another one. The purpose is to connect communication equipments that only support GATT bearer to ESP-BLE-MESH network. Generally, mobile apps need a Proxy node to access Mesh network. Without Proxy nodes, mobile apps cannot communicate with members in Mesh network.</td>
</tr>
<tr>
<td>Friend Node</td>
<td>A node that supports the Friend feature, has the Friend feature enabled, and has a friendship with a node that supports the Low Power feature is known as a Friend node.</td>
<td>Friend node, like the backup of Low Power node (LPN), can store messages that are sent to Low Power node and security updates; the stored information will be transferred to Low Power node when Low Power node needs it. Low Power node must establish “friendship” with another node that supports the Friend Feature to reduce duty cycle of its receiver, thus power consumption of Low Power node can be reduced. Low Power node needs to find a Friend node to establish a friendship with it. The process involved is called “friendship establishment”. Cooperation between Low Power node and Friend nodes enables Low Power node to schedule the use of the radio, thus Low Power node can receive messages at an appropriate or lower frequency without the need of keeping listening. Low Power node will poll Friend node to see if there is new message.</td>
</tr>
<tr>
<td>Low Power Node</td>
<td>A node that supports the Low Power feature and has a friendship with a node that supports the Friend feature is known as a Low Power node.</td>
<td>By polling, Low Power node gets information from Friend node, such as messages, security updates, and etc.</td>
</tr>
<tr>
<td>Provisoner</td>
<td>A node that is capable of adding a device to a mesh network.</td>
<td>The device that can provision unprovisioned devices is called a Provisioner. This process usually needs to be implemented through an app that is typically provided by the product manufacturer and can be used on a gateway, a smartphone, tablet or other carriers.</td>
</tr>
</tbody>
</table>
Table 15: Table 2 ESP-BLE-MESH Terminology - Composition

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>A value representing a condition of an element that is exposed by an element of a node.</td>
<td>Each node in a ESP-BLE-MESH network has an independent set of state values that indicate certain states of the device, like brightness, and color of lighting device. Change of state value will lead to change of the physical state of devices. For example, changing the on/off state of a device is actually turning on/off the device.</td>
</tr>
<tr>
<td>Model</td>
<td>A model defines the basic functionality of a node.</td>
<td>A node may contain multiple models, and each model defines basic functionalities of nodes, like the states needed by the nodes, the messages controlling the states, and actions resulted from messages handling. The function implementation of the nodes is based on models, which can be divided into SIG Model and Vendor Model, with the former defined by SIG and latter defined by users.</td>
</tr>
<tr>
<td>Element</td>
<td>An addressable entity within a device.</td>
<td>A node can contain one or more elements, with each having a unicast address and one or more models, and the models contained by the same element must not be the same.</td>
</tr>
<tr>
<td>Composition Data State</td>
<td>The Composition Data state contains information about a node, the elements it includes, and the supported models.</td>
<td>By reading the value of the Composition Data state, users can know basic information of the node, such as the number of elements, and the models in each element. Provisioner gets this message to further provision the device, such as configuring subscription address and publishing address of nodes.</td>
</tr>
</tbody>
</table>

Table 16: Table 3 ESP-BLE-MESH Terminology - Features

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low Power Feature</td>
<td>The ability to operate within a mesh network at significantly reduced receiver duty cycles only in conjunction with a node supporting the Friend feature.</td>
<td>Low Power feature reduces power consumption of nodes. When a Low Power node is searching for a Friend node, and there are multiple Friend nodes nearby, it selects the most suitable Friend node through algorithm.</td>
</tr>
<tr>
<td>Friend Feature</td>
<td>The ability to help a node supporting the Low Power feature to operate by storing messages destined for those nodes.</td>
<td>By enabling friend feature, the node can help to store information for Low Power node. The nodes enabled with friend feature may cause more power and memory consumption.</td>
</tr>
<tr>
<td>Relay Feature</td>
<td>The ability to receive and retransmit mesh messages over the advertising bearer to enable larger networks.</td>
<td>The relay feature enables ESP-BLE-MESH messages to hop among nodes for multiple times, and the transmission distance can exceed the range of direct radio transmission between two nodes, thereby covering the entire network. When a node is enabled with the relay feature to relay messages, it only relays the messages of its own subnet, and does not relay the messages of other subnets. The data integrity will not be considered when the node enabled with relay feature relays segmented messages. The node would relay every segmented message once it receives one rather than waiting for the complete message.</td>
</tr>
<tr>
<td>Proxy Feature</td>
<td>The ability to receive and retransmit mesh messages between GATT and advertising bearers.</td>
<td>The purpose of the proxy feature is to allow nodes without an advertising bearer to access the ESP-BLE-MESH network. The proxy feature is typically used in nodes that need to connect to mobile apps.</td>
</tr>
</tbody>
</table>
### Table 17: Table 4 ESP-BLE-MESH Terminology - Provisioning

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>PB-ADV</td>
<td>PB-ADV is a provisioning bearer used to provision a device using Generic Provisioning PDUs over the advertising channels.</td>
<td>PB-ADV transfers packets generated during the provisioning process over the advertising channels. This way can only be used for provisioning when provisioner and unprovisioned device both support PB-ADV.</td>
</tr>
<tr>
<td>PB-GATT</td>
<td>PB-GATT is a provisioning bearer used to provision a device using Proxy PDUs to encapsulate Provisioning PDUs within the Mesh Provisioning Service.</td>
<td>PB-GATT uses connection channels to transfer packets generated during the provisioning process. If an unprovisioned device wants to be provisioned through this method, it needs to implement the related Mesh Provisioning Service. Unprovisioned devices which don’t implement such service cannot be provisioned into mesh network through PB-GATT bearer.</td>
</tr>
<tr>
<td>PB-Remote</td>
<td>The PB-Remote provisioning bearer uses the existing mesh network to provision an unprovisioned device that is not within immediate radio range of the Provisioner.</td>
<td>PB-Remote uses the PB-ADV bearer or the PB-GATT bearer for the last hop to the unprovisioned device.</td>
</tr>
<tr>
<td>Provisioning</td>
<td>Provisioning is a process of adding an un provisioned device to a mesh network, managed by a Provisioner.</td>
<td>The process of provisioning turns the “unprovisioned device” into a “node”, making it a member of the ESP-BLE-MESH network.</td>
</tr>
<tr>
<td>Authentication Method</td>
<td>Authentication is a step during the provisioning of nodes.</td>
<td>There are four authentication methods for unprovisioned devices: Output OOB, Input OOB, Static OOB, and No OOB.</td>
</tr>
<tr>
<td>Input OOB</td>
<td>Input Out-of-Band</td>
<td>For example, a Provisioner generates and displays a random number, and then prompts users to take appropriate actions to input the random number into the unprovisioned device. Taking lighting switch as an example, users can press the button for several times in a certain period of time to input the random number displayed on the Provisioner. Authentication method of the Input OOB is similar to that of Output OOB, but the role of the device is reversed.</td>
</tr>
<tr>
<td>Output OOB</td>
<td>Output Out-of-Band</td>
<td>For example, an unprovisioned device will choose a random number and output the number in a way that is compatible with its functionality. If the unprovisioned device is a bulb, it can flash a specified number of times. If the unprovisioned device has an LCD screen, the random number can display as a multi-digit value. Users who start provisioning should input the observed number to authenticate the unprovisioned device.</td>
</tr>
<tr>
<td>Static OOB</td>
<td>Static Out-of-Band</td>
<td>Authentication method of Static OOB: use Static OOB information. Use 0 as Static OOB information if No OOB information is needed. Use Static OOB information to authenticate devices which are going through provisioning if OOB information is needed.</td>
</tr>
<tr>
<td>No OOB</td>
<td>No Out-of-Band</td>
<td>Authentication method of No OOB: Set the value of the Static OOB field to 0. Using this way is like not authenticating the unprovisioned devices.</td>
</tr>
<tr>
<td>Certificate-based Provisioning</td>
<td>Certificate-based Out-of-Band</td>
<td>The certificate-based provisioning feature makes use of Public Key Infrastructure to authenticate unprovisioned device’s public key and UUID information.</td>
</tr>
</tbody>
</table>
## API Guides

### Table 18: Table 5 ESP-BLE-MESH Terminology - Address

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Unassigned Address</strong></td>
<td>This is a special address type, with a value of 0x0000. Its use indicates that an Element has not yet been configured or had a Unicast Address assigned to it.</td>
<td>The addresses owned by elements which has not been configured yet or no address has been allocated are unassigned addresses. These elements will not be used for messages transfer because they have no fixed address. Unassigned address is recommended to set as the value of the address before setting the address of user code.</td>
</tr>
<tr>
<td><strong>Unicast Address</strong></td>
<td>A unicast address is a unique address allocated to each element.</td>
<td>During provisioning, the Provisioner will assign a unicast address to each element of node within the life cycle of the nodes in the network. A unicast address may appear in the source/destination address field of a message. Messages sent to a unicast address can only be processed by the element that owns the unicast address.</td>
</tr>
<tr>
<td><strong>Virtual Address</strong></td>
<td>A virtual address represents a set of destination addresses. Each virtual address logically represents a Label UUID, which is a 128-bit value that does not have to be managed centrally.</td>
<td>Associated with specific UUID labels, a virtual address may serve as the publishing or subscription address of the model. A UUID label is a 128-bit value associated with elements of one or more nodes. For virtual addresses, the 15th and 14th bits are set to 1 and 0 respectively; bits from 13th to 0 are set to hash values (providing 16384 hash values). The hash is a derivation of the Label UUID. To use subscribing elements to check the full 128-bit UUID is very inefficient while hash values provide a more efficient way to determine which elements that which messages are finally sent to.</td>
</tr>
<tr>
<td><strong>Group Address</strong></td>
<td>A group address is an address that is programmed into zero or more elements</td>
<td>Group address is another kind of multicast address in the ESP-BLE-MESH network, which is usually used to group nodes. A message sent to the allproxies address shall be processed by the primary element of all nodes that have the proxy functionality enabled. A message sent to the allfriends address shall be processed by the primary element of all nodes that have the friend functionality enabled. A message sent to the allrelays address shall be processed by the primary element of all nodes that have the relay functionality enabled. A message sent to the allnodes address shall be processed by the primary element of all nodes.</td>

Keys are usually updated after some nodes in the network are removed.</td>
</tr>
<tr>
<td>IV (Initialization Vector) Update Procedure</td>
<td>A node can also use an IV Update procedure to signal to peer nodes that it is updating the IV Index.</td>
<td>The IV Update procedure is used to update the value of ESP-BLE-MESH network’s IV Index. This value is related to the random number required for message encryption. To ensure that the value of the random number is not repeated, this value is periodically incremented. IV Index is a 32-bit value and a shared network resource. For example, all nodes in a mesh network share the same IV Index value. Starting from 0x00000000, the IV Index increments during the IV Update procedure and maintained by a specific process, ensuring the IV Index shared in the mesh network is the same. This can be done when the node believes that it has the risk of exhausting its sequence number, or when it determines that another node is nearly exhausting its sequence number. Note: The update time must not be less than 96 hours. It can be triggered when a secure network beacon is received, or when the node determines that its sequence number is greater than a certain value.</td>

**4.14 ESP-WIFI-MESH**

This guide provides information regarding the ESP-WIFI-MESH protocol. Please see the ESP-WIFI-MESH API Reference for more information about API usage.

**4.14.1 Overview**

ESP-WIFI-MESH is a networking protocol built atop the Wi-Fi protocol. ESP-WIFI-MESH allows numerous devices (henceforth referred to as nodes) spread over a large physical area (both indoors and outdoors) to be interconnected under a single WLAN (Wireless Local-Area Network). ESP-WIFI-MESH is self-organizing and self-healing meaning the network can be built and maintained autonomously.
The ESP-WIFI-MESH guide is split into the following sections:

1. Introduction
2. ESP-WIFI-MESH Concepts
3. Building a Network
4. Managing a Network
5. Data Transmission
6. Channel Switching
7. Performance
8. Further Notes

### 4.14.2 Introduction

![Fig. 25: Traditional Wi-Fi Network Architecture](image)

A traditional infrastructure Wi-Fi network is a point-to-multipoint network where a single central node known as the access point (AP) is directly connected to all other nodes known as stations. The AP is responsible for arbitrating and forwarding transmissions between the stations. Some APs also relay transmissions to/from an external IP network via a router. Traditional infrastructure Wi-Fi networks suffer the disadvantage of limited coverage area due to the requirement that every station must be in range to directly connect with the AP. Furthermore, traditional Wi-Fi networks are susceptible to overloading as the maximum number of stations permitted in the network is limited by the capacity of the AP.

ESP-WIFI-MESH differs from traditional infrastructure Wi-Fi networks in that nodes are not required to connect to a central node. Instead, nodes are permitted to connect with neighboring nodes. Nodes are mutually responsible for relaying each others transmissions. This allows an ESP-WIFI-MESH network to have much greater coverage area as nodes can still achieve interconnectivity without needing to be in range of the central node. Likewise, ESP-WIFI-MESH is also less susceptible to overloading as the number of nodes permitted on the network is no longer limited by a single central node.

### 4.14.3 ESP-WIFI-MESH Concepts

Tree Topology

ESP-WIFI-MESH is built atop the infrastructure Wi-Fi protocol and can be thought of as a networking protocol that combines many individual Wi-Fi networks into a single WLAN. In Wi-Fi, stations are limited to a single connection with an AP (upstream connection) at any time, whilst an AP can be simultaneously connected to multiple stations (downstream connections). However ESP-WIFI-MESH allows nodes to simultaneously act as a station and an AP.
Therefore a node in ESP-WIFI-MESH can have **multiple downstream connections using its softAP interface**, whilst simultaneously having a **single upstream connection using its station interface**. This naturally results in a tree network topology with a parent-child hierarchy consisting of multiple layers.

ESP-WIFI-MESH is a multiple hop (multi-hop) network meaning nodes can transmit packets to other nodes in the network through one or more wireless hops. Therefore, nodes in ESP-WIFI-MESH not only transmit their own packets, but simultaneously serve as relays for other nodes. Provided that a path exists between any two nodes on the physical layer (via one or more wireless hops), any pair of nodes within an ESP-WIFI-MESH network can communicate.

**Note:** The size (total number of nodes) in an ESP-WIFI-MESH network is dependent on the maximum number of layers permitted in the network, and the maximum number of downstream connections each node can have. Both of these variables can be configured to limit the size of the network.

**Node Types**

**Root Node:** The root node is the top node in the network and serves as the only interface between the ESP-WIFI-MESH network and an external IP network. The root node is connected to a conventional Wi-Fi router and relays packets to/from the external IP network to nodes within the ESP-WIFI-MESH network. **There can only be one root node within an ESP-WIFI-MESH network** and the root node’s upstream connection may only be with the router. Referring to the diagram above, node A is the root node of the network.

**Leaf Nodes:** A leaf node is a node that is not permitted to have any child nodes (no downstream connections). Therefore a leaf node can only transmit or receive its own packets, but cannot forward the packets of other nodes. If a node is situated on the network’s maximum permitted layer, it will be assigned as a leaf node. This prevents the node from forming any downstream connections thus ensuring the network does not add an extra layer. Some nodes without a softAP interface (station only) will also be assigned as leaf nodes due to the requirement of a softAP interface for any downstream connections. Referring to the diagram above, nodes L/M/N are situated on the networks maximum permitted layer hence have been assigned as leaf nodes.

**Intermediate Parent Nodes:** Connected nodes that are neither the root node or a leaf node are intermediate parent nodes. An intermediate parent node must have a single upstream connection (a single parent node), but can have zero to multiple downstream connections (zero to multiple child nodes). Therefore an intermediate parent node can transmit and receive packets, but also forward packets sent from its upstream and downstream connections. Referring to the diagram above, nodes B to J are intermediate parent nodes.
downstream connections such as nodes E/F/G/I/J are not equivalent to leaf nodes as they are still permitted to form downstream connections in the future.

Idle Nodes: Nodes that have yet to join the network are assigned as idle nodes. Idle nodes will attempt to form an upstream connection with an intermediate parent node or attempt to become the root node under the correct circumstances (see Automatic Root Node Selection). Referring to the diagram above, nodes K and O are idle nodes.

Beacon Frames & RSSI Thresholding

Every node in ESP-WIFI-MESH that is able to form downstream connections (i.e., has a softAP interface) will periodically transmit Wi-Fi beacon frames. A node uses beacon frames to allow other nodes to detect its presence and know of its status. Idle nodes will listen for beacon frames to generate a list of potential parent nodes, one of which the idle node will form an upstream connection with. ESP-WIFI-MESH uses the Vendor Information Element to store metadata such as:

- Node Type (Root, Intermediate Parent, Leaf, Idle)
- Current layer of Node
- Maximum number of layers permitted in the network
- Maximum number of child nodes
- Maximum number of downstream connections to accept

The signal strength of a potential upstream connection is represented by RSSI (Received Signal Strength Indication) of the beacon frames of the potential parent node. To prevent nodes from forming a weak upstream connection, ESP-WIFI-MESH implements an RSSI threshold mechanism for beacon frames. If a node detects a beacon frame with an RSSI below a preconfigured threshold, the transmitting node will be disregarded when forming an upstream connection.

Panel A of the illustration above demonstrates how the RSSI threshold affects the number of parent node candidates an idle node has.

Panel B of the illustration above demonstrates how an RF shielding object can lower the RSSI of a potential parent node. Due to the RF shielding object, the area in which the RSSI of node X is above the threshold is significantly...
reduced. This causes the idle node to disregard node X even though node X is physically adjacent. The idle node will instead form an upstream connection with the physically distant node Y due to a stronger RSSI.

Note: Nodes technically still receive all beacon frames on the MAC layer. The RSSI threshold is an ESP-WIFI-MESH feature that simply filters out all received beacon frames that are below the preconfigured threshold.

Preferred Parent Node

When an idle node has multiple parent nodes candidates (potential parent nodes), the idle node will form an upstream connection with the preferred parent node. The preferred parent node is determined based on the following criteria:

- Which layer the parent node candidate is situated on
- The number of downstream connections (child nodes) the parent node candidate currently has

The selection of the preferred parent node will always prioritize the parent node candidate on the shallowest layer of the network (including the root node). This helps minimize the total number of layers in an ESP-WIFI-MESH network when upstream connections are formed. For example, given a second layer node and a third layer node, the second layer node will always be preferred.

If there are multiple parent node candidates within the same layer, the parent node candidate with the least child nodes will be preferred. This criteria has the effect of balancing the number of downstream connections amongst nodes of the same layer.

Panel A of the illustration above demonstrates an example of how the idle node G selects a preferred parent node given the five parent node candidates B/C/D/E/F. Nodes on the shallowest layer are preferred, hence nodes B/C are prioritized since they are second layer nodes whereas nodes D/E/F are on the third layer. Node C is selected as the preferred parent node due it having fewer downstream connections (fewer child nodes) compared to node B.

Panel B of the illustration above demonstrates the case where the root node is within range of the idle node G. In other words, the root node’s beacon frames are above the RSSI threshold when received by node G. The root node is always the shallowest node in an ESP-WIFI-MESH network hence is always the preferred parent node given multiple parent node candidates.

Note: Users may also define their own algorithm for selecting a preferred parent node, or force a node to only
connect with a specific parent node (see the Mesh Manual Networking Example).

Routing Tables

Each node within an ESP-WIFI-MESH network will maintain its individual routing table used to correctly route ESP-WIFI-MESH packets (see ESP-WIFI-MESH Packet) to the correct destination node. The routing table of a particular node will consist of the MAC addresses of all nodes within the particular node’s subnetwork (including the MAC address of the particular node itself). Each routing table is internally partitioned into multiple subtables with each subtable corresponding to the subnetwork of each child node.

Using the diagram above as an example, the routing table of node B would consist of the MAC addresses of nodes B to I (i.e., equivalent to the subnetwork of node B). Node B’s routing table is internally partitioned into two subtables.
containing of nodes C to F and nodes G to I (i.e., equivalent to the subnetworks of nodes C and G respectively).

**ESP-WIFI-MESH utilizes routing tables to determine whether an ESP-WIFI-MESH packet should be forwarded upstream or downstream based on the following rules.**

1. If the packet’s destination MAC address is within the current node’s routing table and is not the current node, select the subtable that contains the destination MAC address and forward the data packet downstream to the child node corresponding to the subtable.

2. If the destination MAC address is not within the current node’s routing table, forward the data packet upstream to the current node’s parent node. Doing so repeatedly will result in the packet arriving at the root node where the routing table should contain all nodes within the network.

**Note:** Users can call `esp_mesh_get_routing_table()` to obtain a node’s routing table, or `esp_mesh_get_routing_table_size()` to obtain the size of a node’s routing table. `esp_mesh_get_subnet_nodes_list()` can be used to obtain the corresponding subtable of a specific child node. Likewise `esp_mesh_get_subnet_nodes_num()` can be used to obtain the size of the subtable.

### 4.14.4 Building a Network

**General Process**

**Warning:** Before the ESP-WIFI-MESH network building process can begin, certain parts of the configuration must be uniform across each node in the network (see `mesh_cfg_t`). Each node must be configured with the same Mesh Network ID, router configuration, and softAP configuration.

An ESP-WIFI-MESH network building process involves selecting a root node, then forming downstream connections layer by layer until all nodes have joined the network. The exact layout of the network can be dependent on factors such as root node selection, parent node selection, and asynchronous power-on reset. However, the ESP-WIFI-MESH network building process can be generalized into the following steps:

1. Root node selection or designation

2. Parent node selection

3. Intermediate node selection

4. Leaf node selection

Fig. 32: ESP-WIFI-MESH Network Building Process
Chapter 4. API Guides

1. Root Node Selection  The root node can be designated during configuration (see section on User Designated Root Node), or dynamically elected based on the signal strength between each node and the router (see Automatic Root Node Selection). Once selected, the root node will connect with the router and begin allowing downstream connections to form. Referring to the figure above, node A is selected to be the root node hence node A forms an upstream connection with the router.

2. Second Layer Formation  Once the root node has connected to the router, idle nodes in range of the root node will begin connecting with the root node thereby forming the second layer of the network. Once connected, the second layer nodes become intermediate parent nodes (assuming maximum permitted layers > 2) hence the next layer to form. Referring to the figure above, nodes B to D are in range of the root node. Therefore nodes B to D form upstream connections with the root node and become intermediate parent nodes.

3. Formation of Remaining Layers  The remaining idle nodes will connect with intermediate parent nodes within range thereby forming a new layer in the network. Once connected, the idles nodes become intermediate parent node or leaf nodes depending on the networks maximum permitted layers. This step is repeated until there are no more idle nodes within the network or until the maximum permitted layer of the network has been reached. Referring to the figure above, nodes E/F/G connect with nodes B/C/D respectively and become intermediate parent nodes themselves.

4. Limiting Tree Depth  To prevent the network from exceeding the maximum permitted number of layers, nodes on the maximum layer will automatically become leaf nodes once connected. This prevents any other idle node from connecting with the leaf node thereby prevent a new layer form forming. However if an idle node has no other potential parent node, it will remain idle indefinitely. Referring to the figure above, the network’s number of maximum permitted layers is set to four. Therefore when node H connects, it becomes a leaf node to prevent any downstream connections from forming.

Automatic Root Node Selection

The automatic selection of a root node involves an election process amongst all idle nodes based on their signal strengths with the router. Each idle node will transmit their MAC addresses and router RSSI values via Wi-Fi beacon frames. The MAC address is used to uniquely identify each node in the network whilst the router RSSI is used to indicate a node’s signal strength with reference to the router.

Each node will then simultaneously scan for the beacon frames from other idle nodes. If a node detects a beacon frame with a stronger router RSSI, the node will begin transmitting the contents of that beacon frame (i.e., voting for the node with the stronger router RSSI). The process of transmission and scanning will repeat for a preconfigured minimum number of iterations (10 iterations by default) and result in the beacon frame with the strongest router RSSI being propagated throughout the network.

After all iterations, each node will individually check for its vote percentage (number of votes/number of nodes participating in election) to determine if it should become the root node. If a node has a vote percentage larger than a preconfigured threshold (90% by default), the node will become a root node.

The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is automatically selected.

1. On power-on reset, each node begins transmitting beacon frames consisting of their own MAC addresses and their router RSSIs.

2. Over multiple iterations of transmission and scanning, the beacon frame with the strongest router RSSI is propagated throughout the network. Node C has the strongest router RSSI (-10 dB) hence its beacon frame is propagated throughout the network. All nodes participating in the election vote for node C thus giving node C a vote percentage of 100%. Therefore node C becomes a root node and connects with the router.

3. Once Node C has connected with the router, nodes A/B/D/E connect with node C as it is the preferred parent node (i.e., the shallowest node). Nodes A/B/D/E form the second layer of the network.

4. Node F and G connect with nodes D and E respectively and the network building process is complete.
Chapter 4. API Guides

Fig. 33: Root Node Election Example

Note: The minimum number of iterations for the election process can be configured using `esp_mesh_set_attempts()`. Users should adjust the number of iterations based on the number of nodes within the network (i.e., the larger the network the larger number of scan iterations required).

Warning: Vote percentage threshold can also be configured using `esp_mesh_set_vote_percentage()`. Setting a low vote percentage threshold can result in two or more nodes becoming root nodes within the same ESP-WIFI-MESH network leading to the building of multiple networks. If such is the case, ESP-WIFI-MESH has internal mechanisms to autonomously resolve the root node conflict. The networks of the multiple root nodes will be combined into a single network with a single root node. However, root node conflicts where two or more root nodes have the same router SSID but different router BSSID are not handled.

User Designated Root Node

The root node can also be designated by user which will entail the designated root node to directly connect with the router and forgo the election process. When a root node is designated, all other nodes within the network must also forgo the election process to prevent the occurrence of a root node conflict. The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is designated by the user.

1. Node A is designated the root node by the user therefore directly connects with the router. All other nodes forgo the election process.
2. Nodes C/D connect with node A as their preferred parent node. Both nodes form the second layer of the network.
3. Likewise, nodes B/E connect with node C, and node F connects with node D. Nodes B/E/F form the third layer of the network.
4. Node G connects with node E, forming the fourth layer of the network. However the maximum permitted number of layers in this network is configured as four, therefore node G becomes a leaf node to prevent any new layers from forming.
Chapter 4. API Guides

Fig. 34: Root Node Designation Example (Root Node = A, Max Layers = 4)

Note: When designating a root node, the root node should call \texttt{esp\_mesh\_set\_parent()} in order to directly connect with the router. Likewise, all other nodes should call \texttt{esp\_mesh\_fix\_root()} to forgo the election process.

Parent Node Selection

By default, ESP-WIFI-MESH is self organizing meaning that each node will autonomously select which potential parent node to form an upstream connection with. The autonomously selected parent node is known as the preferred parent node. The criteria used for selecting the preferred parent node is designed to reduce the number of layers in the ESP-WIFI-MESH network and to balance the number of downstream connections between potential parent nodes (see section on Preferred Parent Node).

However ESP-WIFI-MESH also allows users to disable self-organizing behavior which will allow users to define their own criteria for parent node selection, or to configure nodes to have designated parent nodes (see the Mesh Manual Networking Example).

Asynchronous Power-on Reset

ESP-WIFI-MESH network building can be affected by the order in which nodes power-on. If certain nodes within the network power-on asynchronously (i.e., separated by several minutes), the final structure of the network could differ from the ideal case where all nodes are powered on synchronously. Nodes that are delayed in powering on will adhere to the following rules:

Rule 1: If a root node already exists in the network, the delayed node will not attempt to elect a new root node, even if it has a stronger RSSI with the router. The delayed node will instead join the network like any other idle node by connecting with a preferred parent node. If the delayed node is the designated root node, all other nodes in the network will remain idle until the delayed node powers-on.

Rule 2: If a delayed node forms an upstream connection and becomes an intermediate parent node, it may also become the new preferred parent of other nodes (i.e., being a shallower node). This will cause the other nodes to switch their upstream connections to connect with the delayed node (see Parent Node Switching).
Rule 3: If an idle node has a designated parent node which is delayed in powering-on, the idle node will not attempt to form any upstream connections in the absence of its designated parent node. The idle node will remain idle indefinitely until its designated parent node powers-on.

The following example demonstrates the effects of asynchronous power-on with regards to network building.

1. Nodes A/C/D/F/G/H are powered-on synchronously and begin the root node election process by broadcasting their MAC addresses and router RSSIs. Node A is elected as the root node as it has the strongest RSSI.
2. Once node A becomes the root node, the remaining nodes begin forming upstream connections layer by layer with their preferred parent nodes. The result is a network with five layers.
3. Node B/E are delayed in powering-on but neither attempt to become the root node even though they have stronger router RSSIs (-20 dB and -10 dB) compared to node A. Instead both delayed nodes form upstream connections with their preferred parent nodes A and C respectively. Both nodes B/E become intermediate parent nodes after connecting.
4. Nodes D/G switch their upstream connections as node B is the new preferred parent node due to it being on a shallower layer (second layer node). Due to the switch, the resultant network has three layers instead of the original five layers.

Synchronous Power-On: Had all nodes powered-on synchronously, node E would have become the root node as it has the strongest router RSSI (-10 dB). This would result in a significantly different network layout compared to the network formed under the conditions of asynchronous power-on. However the synchronous power-on network layout can still be reached if the user manually switches the root node (see `esp_mesh_waive_root()`).

Note: Differences in parent node selection caused by asynchronous power-on are autonomously corrected for to some extent in ESP-WIFI-MESH (see Parent Node Switching)
Loop-back Avoidance, Detection, and Handling

A loop-back is the situation where a particular node forms an upstream connection with one of its descendant nodes (a node within the particular node’s subnetwork). This results in a circular connection path thereby breaking the tree topology. ESP-WIFI-MESH prevents loop-back during parent selection by excluding nodes already present in the selecting node’s routing table (see Routing Tables) thus prevents a particular node from attempting to connect to any node within its subnetwork.

In the event that a loop-back occurs, ESP-WIFI-MESH utilizes a path verification mechanism and energy transfer mechanism to detect the loop-back occurrence. The parent node of the upstream connection that caused the loop-back will then inform the child node of the loop-back and initiate a disconnection.

4.14.5 Managing a Network

ESP-WIFI-MESH is a self healing network meaning it can detect and correct for failures in network routing. Failures occur when a parent node with one or more child nodes breaks down, or when the connection between a parent node and its child nodes becomes unstable. Child nodes in ESP-WIFI-MESH will autonomously select a new parent node and form an upstream connection with it to maintain network interconnectivity. ESP-WIFI-MESH can handle both Root Node Failures and Intermediate Parent Node Failures.

Root Node Failure

If the root node breaks down, the nodes connected with it (second layer nodes) will promptly detect the failure of the root node. The second layer nodes will initially attempt to reconnect with the root node. However after multiple failed attempts, the second layer nodes will initialize a new round of root node election. The second layer node with the strongest router RSSI will be elected as the new root node whilst the remaining second layer nodes will form an upstream connection with the new root node (or a neighboring parent node if not in range).

If the root node and multiple downstream layers simultaneously break down (e.g., root node, second layer, and third layer), the shallowest layer that is still functioning will initialize the root node election. The following example illustrates an example of self healing from a root node break down.

1. Node C is the root node of the network. Nodes A/B/D/E are second layer nodes connected to node C.
2. Node C breaks down. After multiple failed attempts to reconnect, the second layer nodes begin the election process by broadcasting their router RSSIs. Node B has the strongest router RSSI.
3. Node B is elected as the root node and begins accepting downstream connections. The remaining second layer nodes A/D/E form upstream connections with node B thus the network is healed and can continue operating normally.
**Intermediate Parent Node Failure**

If an intermediate parent node breaks down, the disconnected child nodes will initially attempt to reconnect with the parent node. After multiple failed attempts to reconnect, each child node will begin to scan for potential parent nodes (see *Beacon Frames & RSSI Thresholding*).

If other potential parent nodes are available, each child node will individually select a new preferred parent node (see *Preferred Parent Node*) and form an upstream connection with it. If there are no other potential parent nodes for a particular child node, it will remain idle indefinitely.

The following diagram illustrates an example of self healing from an Intermediate Parent Node break down.

1. The following branch of the network consists of nodes A to G.
2. Node C breaks down. Nodes F/G detect the break down and attempt to reconnect with node C. After multiple failed attempts to reconnect, nodes F/G begin to select a new preferred parent node.
3. Node G is out of range from any other parent node hence remains idle for the time being. Node F is in range of nodes B/E, however node B is selected as it is the shallower node. Node F becomes an intermediate parent node after connecting with Node B thus node G can connect with node F. The network is healed, however the network routing as been affected and an extra layer has been added.

**Note:** If a child node has a designated parent node that breaks down, the child node will make no attempt to connect with a new parent node. The child node will remain idle indefinitely.

**Root Node Switching**

ESP-WIFI-MESH does not automatically switch the root node unless the root node breaks down. Even if the root node’s router RSSI degrades to the point of disconnection, the root node will remain unchanged. Root node switching is the act of explicitly starting a new election such that a node with a stronger router RSSI will be elected as the new root node. This can be a useful method of adapting to degrading root node performance.

To trigger a root node switch, the current root node must explicitly call `esp_mesh_waive_root()` to trigger a new election. The current root node will signal all nodes within the network to begin transmitting and scanning for beacon frames (see *Automatic Root Node Selection*) whilst remaining connected to the network (i.e., not idle). If
another node receives more votes than the current root node, a root node switch will be initiated. The root node will remain unchanged otherwise.

A newly elected root node sends a switch request to the current root node which in turn will respond with an acknowledgment signifying both nodes are ready to switch. Once the acknowledgment is received, the newly elected root node will disconnect from its parent and promptly form an upstream connection with the router thereby becoming the new root node of the network. The previous root node will disconnect from the router whilst maintaining all of its downstream connections and enter the idle state. The previous root node will then begin scanning for potential parent nodes and selecting a preferred parent.

The following diagram illustrates an example of a root node switch.

![Diagram of root node switch example](image)

1. Node C is the current root node but has degraded signal strength with the router (-85db). The node C triggers a new election and all nodes begin transmitting and scanning for beacon frames whilst still being connected.

2. After multiple rounds of transmission and scanning, node B is elected as the new root node. Node B sends node C a switch request and node C responds with an acknowledgment.

3. Node B disconnects from its parent and connects with the router becoming the network’s new root node. Node C disconnects from the router, enters the idle state, and begins scanning for and selecting a new preferred parent node. Node C maintains all its downstream connections throughout this process.

4. Node C selects node B as its preferred parent node, forms an upstream connection, and becomes a second layer node. The network layout is similar after the switch as node C still maintains the same subnetwork. However each node in node C’s subnetwork has been placed one layer deeper as a result of the switch. Parent Node Switching may adjust the network layout afterwards if any nodes have a new preferred parent node as a result of the root node switch.

**Note:** Root node switching must require an election hence is only supported when using a self-organized ESP-WIFI-MESH network. In other words, root node switching cannot occur if a designated root node is used.

**Parent Node Switching**

Parent Node Switching entails a child node switching its upstream connection to another parent node of a shallower layer. Parent Node Switching occurs autonomously meaning that a child node will change its upstream connection...
automatically if a potential parent node of a shallower layer becomes available (i.e., due to a *Asynchronous Power-on Reset*).

All potential parent nodes periodically transmit beacon frames (see *Beacon Frames & RSSI Thresholding*) allowing for a child node to scan for the availability of a shallower parent node. Due to parent node switching, a self-organized ESP-WIFI-MESH network can dynamically adjust its network layout to ensure each connection has a good RSSI and that the number of layers in the network is minimized.

### 4.14.6 Data Transmission

#### ESP-WIFI-MESH Packet

ESP-WIFI-MESH network data transmissions use ESP-WIFI-MESH packets. ESP-WIFI-MESH packets are *entirely contained within the frame body of a Wi-Fi data frame*. A multi-hop data transmission in an ESP-WIFI-MESH network will involve a single ESP-WIFI-MESH packet being carried over each wireless hop by a different Wi-Fi data frame.

The following diagram shows the structure of an ESP-WIFI-MESH packet and its relation with a Wi-Fi data frame.

![ESP-WIFI-MESH Packet](image)

**Fig. 39: ESP-WIFI-MESH Packet**

The **header** of an ESP-WIFI-MESH packet contains the MAC addresses of the source and destination nodes. The options field contains information pertaining to the special types of ESP-WIFI-MESH packets such as a group transmission or a packet originating from the external IP network (see *MESH_OPT_SEND_GROUP* and *MESH_OPT_RECV_DS_ADDR*).

The **payload** of an ESP-WIFI-MESH packet contains the actual application data. This data can be raw binary data, or encoded under an application layer protocol such as HTTP, MQTT, and JSON (see *mesh_proto_t*).

---

**Note:** When sending an ESP-WIFI-MESH packet to the external IP network, the destination address field of the header will contain the IP address and port of the target server rather than the MAC address of a node (see *mesh_addr_t*). Furthermore the root node will handle the formation of the outgoing TCP/IP packet.

---

#### Group Control & Multicasting

Multicasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to multiple nodes within the network. Multicasting in ESP-WIFI-MESH can be achieved by either specifying a list of target nodes, or specifying a preconfigured group of nodes. Both methods of multicasting are called via *esp_mesh_send()*.

To multicast by specifying a list of target nodes, users must first set the ESP-WIFI-MESH packet’s destination address to the **Multicast-Group Address** (*01:00:5E:xx:xx:xx*). This signifies that the ESP-WIFI-MESH packet is a multicast packet with a group of addresses, and that the address should be obtained from the header options. Users must then list the MAC addresses of the target nodes as options (see *mesh_opt_t* and *MESH_OPT_SEND_GROUP*). This method of multicasting requires no prior setup but can incur a large amount of overhead data as each target node’s MAC address must be listed in the options field of the header.
Chapter 4. API Guides

Multicasting by group allows an ESP-WIFI-MESH packet to be transmitted to a preconfigured group of nodes. Each grouping is identified by a unique ID, and a node can be placed into a group via `esp_mesh_set_group_id()`. Multicasting to a group involves setting the destination address of the ESP-WIFI-MESH packet to the target group ID. Furthermore, the `MESH_DATA_GROUP` flag must set. Using groups to multicast incurs less overhead, but requires nodes to previously added into groups.

**Note:** During a multicast, all nodes within the network still receive the ESP-WIFI-MESH packet on the MAC layer. However, nodes not included in the MAC address list or the target group will simply filter out the packet.

### Broadcasting

Broadcasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to all nodes within the network. Each node essentially forwards a broadcast packet to all of its upstream and downstream connections such that the packet propagates throughout the network as quickly as possible. However, ESP-WIFI-MESH utilizes the following methods to avoid wasting bandwidth during a broadcast.

1. When an intermediate parent node receives a broadcast packet from its parent, it will forward the packet to each of its child nodes whilst storing a copy of the packet for itself.
2. When an intermediate parent node is the source node of the broadcast, it will transmit the broadcast packet upstream to its parent node and downstream to each of its child nodes.
3. When an intermediate parent node receives a broadcast packet from one of its child nodes, it will forward the packet to its parent node and each of its remaining child nodes whilst storing a copy of the packet for itself.
4. When a leaf node is the source node of a broadcast, it will directly transmit the packet to its parent node.
5. When the root node is the source node of a broadcast, the root node will transmit the packet to all of its child nodes.
6. When the root node receives a broadcast packet from one of its child nodes, it will forward the packet to each of its remaining child nodes whilst storing a copy of the packet for itself.
7. When a node receives a broadcast packet with a source address matching its own MAC address, the node will discard the broadcast packet.
8. When an intermediate parent node receives a broadcast packet from its parent node which was originally transmitted from one of its child nodes, it will discard the broadcast packet.

### Upstream Flow Control

ESP-WIFI-MESH relies on parent nodes to control the upstream data flow of their immediate child nodes. To prevent a parent node’s message buffer from overflowing due to an overload of upstream transmissions, a parent node will allocate a quota for upstream transmissions known as a receiving window for each of its child nodes. Each child node must apply for a receiving window before it is permitted to transmit upstream. The size of a receiving window can be dynamically adjusted. An upstream transmission from a child node to the parent node consists of the following steps:

1. Before each transmission, the child node sends a window request to its parent node. The window request consists of a sequence number which corresponds to the child node’s data packet that is pending transmission.
2. The parent node receives the window request and compares the sequence number with the sequence number of the previous packet sent by the child node. The comparison is used to calculate the size of the receiving window which is transmitted back to the child node.
3. The child node transmits the data packet in accordance with the window size specified by the parent node. If the child node depletes its receiving window, it must obtain another receiving windows by sending a request before it is permitted to continue transmitting.
**Note:** ESP-WIFI-MESH does not support any downstream flow control.

**Warning:** Due to *Parent Node Switching*, packet loss may occur during upstream transmissions.

Due to the fact that the root node acts as the sole interface to an external IP network, it is critical that downstream nodes are aware of the root node’s connection status with the external IP network. Failing to do so can lead to nodes attempting to pass data upstream to the root node whilst it is disconnected from the IP network. This results in unnecessary transmissions and packet loss. ESP-WIFI-MESH address this issue by providing a mechanism to stabilize the throughput of outgoing data based on the connection status between the root node and the external IP network. The root node can broadcast its external IP network connection status to all other nodes by calling `esp_mesh_post_toDS_state()`.

**Bi-Directional Data Stream**

The following diagram illustrates the various network layers involved in an ESP-WIFI-MESH Bidirectional Data Stream.

![Bi-Directional Data Stream Diagram](image)

Fig. 40: ESP-WIFI-MESH Bidirectional Data Stream

Due to the use of *Routing Tables*, ESP-WIFI-MESH is able to handle pack forwarding entirely on the mesh layer. A TCP/IP layer is only required on the root node when it transmits/receives a packet to/from an external IP network.

### 4.14.7 Channel Switching

**Background**

In traditional Wi-Fi networks, *channels* are predetermined frequency ranges. In an infrastructure basic service set (BSS), the serving AP and its connected stations must be on the same operating channels (1 to 14) in which beacons are transmitted. Physically adjacent BSS (Basic Service Sets) operating on the same channel can lead to interference and degraded performance.

In order to allow a BSS adapt to changing physical layer conditions and maintain performance, Wi-Fi contains mechanisms for *network channel switching*. A network channel switch is an attempt to move a BSS to a new operating channel whilst minimizing disruption to the BSS during this process. However it should be recognized that a channel switch may be unsuccessful in moving all stations to the new operating channel.

In an infrastructure Wi-Fi network, network channel switches are triggered by the AP with the aim of having the AP and all connected stations synchronously switch to a new channel. Network channel switching is implemented...
by embedding a **Channel Switch Announcement (CSA)** element within the AP’s periodically transmitted beacon frames. The CSA element is used to advertise to all connected stations regarding an upcoming network channel switch and will be included in multiple beacon frames up until the switch occurs.

A CSA element contains information regarding the **New Channel Number** and a **Channel Switch Count** which indicates the number of beacon frame intervals (TBTTs) remaining until the network channel switch occurs. Therefore, the Channel Switch Count is decremented every beacon frame and allows connected stations to synchronize their channel switch with the AP.

### ESP-WIFI-MESH Network Channel Switching

ESP-WIFI-MESH Network Channel Switching also utilize beacon frames that contain a CSA element. However, being a multi-hop network makes the switching process in ESP-WIFI-MESH is more complex due to the fact that a beacon frame might not be able to reach all nodes within the network (i.e., in a single hop). Therefore, an ESP-WIFI-MESH network relies on nodes to forward the CSA element so that it is propagated throughout the network.

When an intermediate parent node with one or more child nodes receives a beacon frame containing a CSA, the node will forward the CSA element by including the element in its next transmitted beacon frame (i.e., with the same **New Channel Number** and **Channel Switch Count**). Given that all nodes within an ESP-WIFI-MESH network receive the same CSA, the nodes can synchronize their channel switches using the Channel Switch Count, albeit with a short delay due to CSA element forwarding.

An ESP-WIFI-MESH network channel switch can be triggered by either the router or the root node.

#### Root Node Triggered

A root node triggered channel switch can only occur when the ESP-WIFI-MESH network is **not connected to a router**. By calling `esp_mesh_switch_channel()`, the root node will set an initial Channel Switch Count value and begin including a CSA element in its beacon frames. Each CSA element is then received by second layer nodes, and forwarded downstream in their own beacon frames.

#### Router Triggered

When an ESP-WIFI-MESH network is connected to a router, the entire network must use the same channel as the router. Therefore, the **root node will not be permitted to trigger a channel switch when it is connected to a router**.

When the root node receives beacon frame containing a CSA element from the router, the **root node will set Channel Switch Count value in the CSA element to a custom value before forwarding it downstream via beacon frames**. It will also decrement the Channel Switch Count of subsequent CSA elements relative to the custom value. This custom value can be based on factors such as the number of network layers, the current number of nodes etc.

The setting the Channel Switch Count value to a custom value is due to the fact that the ESP-WIFI-MESH network and its router may have a different and varying beacon intervals. Therefore, the Channel Switch Count value provided by the router is irrelevant to an ESP-WIFI-MESH network. By using a custom value, nodes within the ESP-WIFI-MESH network are able to switch channels synchronously relative to the ESP-WIFI-MESH network’s beacon interval. However, this will also result in the ESP-WIFI-MESH network’s channel switch being unsynchronized with the channel switch of the router and its connected stations.

### Impact of Network Channel Switching

- Due to the ESP-WIFI-MESH network channel switch being unsynchronized with the router’s channel switch, there will be:
  - The ESP-WIFI-MESH network’s channel switch time is dependent on the ESP-WIFI-MESH network’s beacon interval and the root node’s custom Channel Switch Count value.
  - The channel discrepancy prevents any data exchange between the root node and the router during that ESP-WIFI-MESH network’s switch.
  - In the ESP-WIFI-MESH network, the root node and intermediate parent nodes will request their connected child nodes to stop transmissions until the channel switch takes place by setting the **Channel Switch Mode** field in the CSA element to 1.
Frequent router triggered network channel switches can degrade the ESP-WIFI-MESH network’s performance. Note that this can be caused by the ESP-WIFI-MESH network itself (e.g., due to wireless medium contention with ESP-WIFI-MESH network). If this is the case, users should disable the automatic channel switching on the router and use a specified channel instead.

- When there is a temporary channel discrepancy, the root node remains technically connected to the router.
  - Disconnection occurs after the root node fails to receive any beacon frames or probe responses from the router over a fixed number of router beacon intervals.
  - Upon disconnection, the root node will automatically re-scan all channels for the presence of a router.

- If the root node is unable to receive any of the router’s CSA beacon frames (e.g., due to short switch time given by the router):
  - After the router switches channels, the root node will no longer be able to receive the router’s beacon frames and probe responses and result in a disconnection after a fixed number of beacon intervals.
  - The root node will re-scan all channels for the router after disconnection.
  - The root node will maintain downstream connections throughout this process.

Note: Although ESP-WIFI-MESH network channel switching aims to move all nodes within the network to a new operating channel, it should be recognized that a channel switch might not successfully move all nodes (e.g., due to reasons such as node failures).

### Channel and Router Switching Configuration

ESP-WIFI-MESH allows for autonomous channel switching to be enabled/disabled via configuration. Likewise, autonomous router switching (i.e., when a root node autonomously connects to another router) can also be enabled/disabled by configuration. Autonomous channel switching and router switching is dependent on the following configuration parameters and run-time conditions.

- **Allow Channel Switch:** This parameter is set via the `allow_channel_switch` field of the `mesh_cfg_t` structure and permits an ESP-WIFI-MESH network to dynamically switch channels when set.
- **Preset Channel:** An ESP-WIFI-MESH network can have a preset channel by setting the `channel` field of the `mesh_cfg_t` structure to the desired channel number. If this field is unset, the `allow_channel_switch` parameter is overridden such that channel switches are always permitted.
- **Allow Router Switch:** This parameter is set via the `allow_router_switch` field of the `mesh_router_t` and permits an ESP-WIFI-MESH to dynamically switch to a different router when set.
- **Preset Router BSSID:** An ESP-WIFI-MESH network can have a preset router by setting the `bssid` field of the `mesh_router_t` structure to the BSSID of the desired router. If this field is unset, the `allow_router_switch` parameter is overridden such that router switches are always permitted.
- **Root Node Present:** The presence of a root node will can also affect whether or a channel or router switch is permitted.

The following table illustrates how the different combinations of parameters/conditions affect whether channel switching and/or router switching is permitted. Note that X represents a “do not care” for the parameter.
4.14.8 Performance

The performance of an ESP-WIFI-MESH network can be evaluated based on multiple metrics such as the following:

**Network Building Time:** The amount of time taken to build an ESP-WIFI-MESH network from scratch.

**Healing Time:** The amount of time taken for the network to detect a node break down and carry out appropriate actions to heal the network (such as generating a new root node or forming new connections).

**Per-hop latency:** The latency of data transmission over one wireless hop. In other words, the time taken to transmit a data packet from a parent node to a child node or vice versa.

**Network Node Capacity:** The total number of nodes the ESP-WIFI-MESH network can simultaneously support. This number is determined by the maximum number of downstream connections a node can accept and the maximum number of layers permissible in the network.

The following table lists the common performance figures of an ESP-WIFI-MESH network:

<table>
<thead>
<tr>
<th>Preset Channel Allow Channel Switch</th>
<th>Preset BSSID Allow Channel Switch</th>
<th>Root Present Node</th>
<th>Permitted Switches?</th>
</tr>
</thead>
<tbody>
<tr>
<td>N X N X X</td>
<td>Channel and Router</td>
<td></td>
<td></td>
</tr>
<tr>

<td></td>
<td></td>
</tr>
<tr>
<td>Y N Y Y Y</td>
<td>Channel and Router</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

*Note:* The following test conditions were used to generate the performance figures above.

- Number of test devices: **100**
- Maximum Downstream Connections to Accept: **6**
- Maximum Permissible Layers: **6**

*Note:* Throughput depends on packet error rate and hop count.

*Note:* The throughput of root node’s access to the external IP network is directly affected by the number of nodes in the ESP-WIFI-MESH network and the bandwidth of the router.
### 4.14.9 Further Notes

- Data transmission uses Wi-Fi WPA2-PSK encryption
- Mesh networking IE uses AES encryption

Note: The performance figures can vary greatly between installations based on network configuration and operating environment.

### 4.15 Support for External RAM

#### 4.15.1 Introduction

ESP32 has a few hundred kilobytes of internal RAM, residing on the same die as the rest of the chip components. It can be insufficient for some purposes, so ESP32 has the ability to use up to 4 MB of virtual addresses for external PSRAM (Psuedostatic RAM) memory. The external memory is incorporated in the memory map and, with certain restrictions, is usable in the same way as internal data RAM.

#### 4.15.2 Hardware

ESP32 supports PSRAM connected in parallel with the SPI flash chip. While ESP32 is capable of supporting several types of RAM chips, ESP-IDF currently only supports Espressif branded PSRAM chips (e.g., ESP-PSRAM32, ESP-PSRAM64, etc).

Note: Some PSRAM chips are 1.8 V devices and some are 3.3 V. The working voltage of the PSRAM chip must match the working voltage of the flash component. Consult the datasheet for your PSRAM chip and ESP32 device to find out the working voltages. For a 1.8 V PSRAM chip, make sure to either set the MTDI pin to a high signal level on bootup, or program ESP32 eFuses to always use the VDD_SIO level of 1.8 V. Not doing this can damage the PSRAM and/or flash chip.

Note: Espressif produces both modules and system-in-package chips that integrate compatible PSRAM and flash and are ready to mount on a product PCB. Consult the Espressif website for more information. If you are using a custom PSRAM chip, ESP-IDF SDK might not be compatible with it.

For specific details about connecting the SoC or module pins to an external PSRAM chip, consult the SoC or module datasheet.

#### 4.15.3 Configuring External RAM

ESP-IDF fully supports the use of external RAM in applications. Once the external RAM is initialized at startup, ESP-IDF can be configured to integrate the external RAM in several ways:

- Integrate RAM into the ESP32 Memory Map
- Add External RAM to the Capability Allocator
- Provide External RAM via malloc() (default)
Integrate RAM into the ESP32 Memory Map

Select this option by choosing Integrate RAM into memory map from \texttt{CONFIG_SPIRAM_USE}.

This is the most basic option for external RAM integration. Most likely, you will need another, more advanced option.

During the ESP-IDF startup, external RAM is mapped into the data virtual address space. The address space is dynamically allocated. The length will be the minimum length between the PSRAM size and the available data virtual address space size.

Applications can manually place data in external memory by creating pointers to this region. So if an application uses external memory, it is responsible for all management of the external RAM: coordinating buffer usage, preventing corruption, etc.

It is recommended to access the PSRAM by ESP-IDF heap memory allocator (see next chapter).

Add External RAM to the Capability Allocator

Select this option by choosing Make RAM allocatable using heap_caps_malloc(..., MALLOC_CAP_SPIRAM) from \texttt{CONFIG_SPIRAM_USE}.

When enabled, memory is mapped to data virtual address space and also added to the capabilities-based heap memory allocator using MALLOC_CAP_SPIRAM.

To allocate memory from external RAM, a program should call heap_caps_malloc(size, MALLOC_CAP_SPIRAM). After use, this memory can be freed by calling the normal \texttt{free()} function.

Provide External RAM via malloc()

Select this option by choosing Make RAM allocatable using malloc() as well from \texttt{CONFIG_SPIRAM_USE}. This is the default option.

In this case, memory is added to the capability allocator as described for the previous option. However, it is also added to the pool of RAM that can be returned by the standard malloc() function.

This allows any application to use the external RAM without having to rewrite the code to use heap_caps_malloc(..., MALLOC_CAP_SPIRAM).

An additional configuration item, \texttt{CONFIG_SPIRAM_MALLOC_ALWAYSINTERNAL}, can be used to set the size threshold when a single allocation should prefer external memory:

- When allocating a size less than the threshold, the allocator will try internal memory first.
- When allocating a size equal to or larger than the threshold, the allocator will try external memory first.

If a suitable block of preferred internal/external memory is not available, the allocator will try the other type of memory.

Because some buffers can only be allocated in internal memory, a second configuration item \texttt{CONFIG_SPIRAM_MALLOC_RESERVE_INTERNAL} defines a pool of internal memory which is reserved for only explicitly internal allocations (such as memory for DMA use). Regular malloc() will not allocate from this pool. The MALLOC_CAP_DMA and MALLOC_CAP_INTERNAL flags can be used to allocate memory from this pool.

Allow .bss Segment to Be Placed in External Memory

Enable this option by checking \texttt{CONFIG_SPIRAM_ALLOW_BSS_SEG_EXTERNAL_MEMORY}.

If enabled, the region of the data virtual address space where the PSRAM is mapped to will be used to store zero-initialized data (BSS segment) from the lwIP, net80211, libpp, and bluedroid ESP-IDF libraries.
Additional data can be moved from the internal BSS segment to external RAM by applying the macro `EXT_RAM_BSS_ATTR` to any static declaration (which is not initialized to a non-zero value).

It is also possible to place the BSS section of a component or a library to external RAM using linker fragment scheme `extram_bss`.

This option reduces the internal static memory used by the BSS segment.

Remaining external RAM can also be added to the capability heap allocator using the method shown above.

**Allow .noinit Segment to Be Placed in External Memory**

Enable this option by checking `CONFIG_SPIRAM_ALLOW_NOINIT_SEG_EXTERNAL_MEMORY`. If enabled, the region of the data virtual address space where the PSRAM is mapped to will be used to store non-initialized data. The values placed in this segment will not be initialized or modified even during startup or restart.

By applying the macro `EXT_RAM_NOINIT_ATTR`, data could be moved from the internal NOINIT segment to external RAM. Remaining external RAM can still be added to the capability heap allocator using the method shown above, *Add External RAM to the Capability Allocator*.

### 4.15.4 Restrictions

External RAM use has the following restrictions:

- When flash cache is disabled (for example, if the flash is being written to), the external RAM also becomes inaccessible. Any read operations from or write operations to it will lead to an illegal cache access exception. This is also the reason why ESP-IDF does not by default allocate any task stacks in external RAM (see below).
- External RAM uses the same cache region as the external flash. This means that frequently accessed variables in external RAM can be read and modified almost as quickly as in internal RAM. However, when accessing large chunks of data (> 32 KB), the cache can be insufficient, and speeds will fall back to the access speed of the external RAM. Moreover, accessing large chunks of data can “push out” cached flash, possibly making the execution of code slower afterwards.
- In general, external RAM will not be used as task stack memory. `xTaskCreate()` and similar functions will always allocate internal memory for stack and task TCBs.

The option `CONFIG_SPIRAM_ALLOW_STACK_EXTERNAL_MEMORY` can be used to allow placing task stacks into external memory. In these cases `xTaskCreateStatic()` must be used to specify a task stack buffer allocated from external memory, otherwise task stacks will still be allocated from internal memory.

### 4.15.5 Failure to Initialize

By default, failure to initialize external RAM will cause the ESP-IDF startup to abort. This can be disabled by enabling the config item `CONFIG_SPIRAM_IGNORE_NOTFOUND`.

If `CONFIG_SPIRAM_ALLOW_BSS_SEG_EXTERNAL_MEMORY` is enabled, the option to ignore failure is not available as the linker will have assigned symbols to external memory addresses at link time.

- Regarding stacks in PSRAM: For tasks that do not call ROM code in any way (directly or indirectly), the `CONFIG_SPIRAM_ALLOW_STACK_EXTERNAL_MEMORY` option will eliminate the check in `xTaskCreateStatic()`, allowing a task’s stack to be in external RAM. However, using this is not advised.
- When used at 80 MHz clock speed, external RAM must also occupy either the HSPI or VSPI bus. Select which SPI host will be used by `CONFIG_SPIRAM_OCCUPY_SPI_HOST`.
4.15.6 Chip Revisions

There are some issues with certain revisions of ESP32 that have repercussions for use with external RAM. The issues are documented in the ESP32 Series SoC Errata document. In particular, ESP-IDF handles the bugs mentioned in the following ways:

**ESP32 Rev v0.0**

ESP-IDF has no workaround for the bugs in this revision of silicon, and it cannot be used to map external PSRAM into ESP32’s main memory map.

**ESP32 Rev v1.0**

The bugs in this revision of silicon cause issues if certain sequences of machine instructions operate on external memory. (ESP32 Series SoC Errata 3.2). As a workaround, the `-mfix-esp32-psram-cache-issue` flag has been added to the ESP32 GCC compiler such that these sequences are filtered out. As a result, the compiler only outputs code that can safely be executed. The `CONFIG_SPIRAM_CACHE_WORKAROUND` option can be used to enable this workaround.

Aside from linking to a recompiled version of Newlib with the additional flag, ESP-IDF also does the following:

- Avoids using some ROM functions
- Allocates static memory for the Wi-Fi stack

**ESP32 Rev v3.0**

ESP32 rev v3.0 fixes the PSRAM cache issue found in rev v1.0. When `CONFIG_ESP32_REV_MIN` option is set to rev v3.0, compiler workarounds related to PSRAM will be disabled. For more information about ESP32 v3.0, see ESP32 Chip Revision v3.0 User Guide.

4.16 Fatal Errors

4.16.1 Overview

In certain situations, the execution of the program can not be continued in a well-defined way. In ESP-IDF, these situations include:

- CPU Exceptions: Illegal Instruction, Load/Store Alignment Error, Load/Store Prohibited error, Double Exception.
- System level checks and safeguards:
  - Interrupt watchdog timeout
  - Task watchdog timeout (only fatal if `CONFIG_ESP32_TASK_WDT_PANIC` is set)
  - Cache access error
  - Brownout detection event
  - Stack overflow
  - Stack smashing protection check
  - Heap integrity check
  - Undefined behavior sanitizer (UBSAN) checks
- Failed assertions, via `assert`, `configASSERT` and similar macros.

This guide explains the procedure used in ESP-IDF for handling these errors, and provides suggestions on troubleshooting the errors.
4.16.2 Panic Handler

Every error cause listed in the Overview will be handled by the panic handler.

The panic handler will start by printing the cause of the error to the console. For CPU exceptions, the message will be similar to

Guru Meditation Error: Core 0 panic'ed (IllegalInstruction). Exception was unhandled.

For some of the system level checks (interrupt watchdog, cache access error), the message will be similar to

Guru Meditation Error: Core 0 panic'ed (Cache disabled but cached memory region accessed). Exception was unhandled.

In all cases, the error cause will be printed in parentheses. See Guru Meditation Errors for a list of possible error causes.

Subsequent behavior of the panic handler can be set using CONFIG_ESP_SYSTEM_PANIC configuration choice. The available options are:

- **Print registers and reboot** (CONFIG_ESP_SYSTEM_PANIC_PRINT_REBOOT) — default option.
  - This will print register values at the point of the exception, print the backtrace, and restart the chip.
- **Print registers and halt** (CONFIG_ESP_SYSTEM_PANIC_PRINT_HALT)
  - Similar to the above option, but halt instead of rebooting. External reset is required to restart the program.
- **Silent reboot** (CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT)
  - Do not print registers or backtrace, restart the chip immediately.
- **Invoke GDB Stub** (CONFIG_ESP_SYSTEM_PANIC_GDBSTUB)
  - Start GDB server which can communicate with GDB over console UART port. This option will only provide read-only debugging or post-mortem debugging. See GDB Stub for more details.

The behavior of the panic handler is affected by three other configuration options.

- **If** CONFIG_ESP_DEBUG_OCDAWARE is enabled (which is the default), the panic handler will detect whether a JTAG debugger is connected. If it is, execution will be halted and control will be passed to the debugger. In this case, registers and backtrace are not dumped to the console, and GDBStub / Core Dump functions are not used.
- **If** the Core Dump feature is enabled, then the system state (task stacks and registers) will be dumped to either Flash or UART, for later analysis.
- **If** CONFIG_ESP_PANIC_HANDLER_IRAM is disabled (disabled by default), the panic handler code is placed in flash memory, not IRAM. This means that if ESP-IDF crashes while flash cache is disabled, the panic handler will automatically re-enable flash cache before running GDB Stub or Core Dump. This adds some minor risk, if the flash cache status is also corrupted during the crash.
  - If this option is enabled, the panic handler code (including required UART functions) is placed in IRAM, and hence will decrease the usable memory space in SRAM. But this may be necessary to debug some complex issues with crashes while flash cache is disabled (for example, when writing to SPI flash) or when flash cache is corrupted when an exception is triggered.
- **If** CONFIG_ESP_SYSTEM_PANIC_REBOOT_DELAY_SECONDS is enabled (disabled by default) and set to a number higher than 0, the panic handler will delay the reboot for that amount of time in seconds. This can help if the tool used to monitor serial output does not provide a possibility to stop and examine the serial output. In that case, delaying the reboot will allow users to examine and debug the panic handler output (backtrace, etc.) for the duration of the delay. After the delay, the device will reboot. The reset reason is preserved.

The following diagram illustrates the panic handler behavior:

4.16.3 Register Dump and Backtrace

Unless the CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT option is enabled, the panic handler prints some of the CPU registers, and the backtrace, to the console.
Fig. 41: Panic Handler Flowchart (click to enlarge)
Chapter 4. API Guides

The register values printed are the register values in the exception frame, i.e., values at the moment when the CPU exception or another fatal error has occurred.

A Register dump is not printed if the panic handler has been executed as a result of an `abort()` call.

In some cases, such as interrupt watchdog timeout, the panic handler may print additional CPU registers (EPC1-EPC4) and the registers/backtrace of the code running on the other CPU.

The backtrace line contains PC:SP pairs, where PC is the Program Counter and SP is Stack Pointer, for each stack frame of the current task. If a fatal error happens inside an ISR, the backtrace may include PC:SP pairs both from the task which was interrupted, and from the ISR.

If **IDF Monitor** is used, Program Counter values will be converted to code locations (function name, file name, and line number), and the output will be annotated with additional lines:

```
Core 0 register dump:

```

To find the location where a fatal error has happened, look at the lines which follow the “Backtrace” line. Fatal error location is the top line, and subsequent lines show the call stack.

### 4.16.4 GDB Stub

If the `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` option is enabled, the panic handler will not reset the chip when a fatal error happens. Instead, it will start a GDB remote protocol server, commonly referred to as GDB Stub. When this happens, a GDB instance running on the host computer can be instructed to connect to the ESP32 UART port.

Espressif Systems 2626
If *IDF Monitor* is used, GDB is started automatically when a GDB Stub prompt is detected on the UART. The output looks like this:

```
Entering gdb stub now.
$70b#e6GNU gdb (crosstool-NG crosstool-ng-1.22.0-80-gff1f415) 7.10
Copyright (C) 2015 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law. Type "show copying"
and "show warranty" for details.
This GDB was configured as "--host=x86_64-build_apple-darwin16.3.0 --target=xtensa-esp32-elf".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
Find the GDB manual and other documentation resources online at:
For help, type "help".
Type "apropos word" to search for commands related to "word"... Reading symbols from /Users/user/esp/example/build/example.elf...done.
0x400e1b41 in app_main ()
at /Users/user/esp/example/main/main.cpp:36
36 *((int*) 0) = 0;
(gdb)
```

The GDB prompt can be used to inspect CPU registers, local and static variables, and arbitrary locations in memory. It is not possible to set breakpoints, change the PC, or continue execution. To reset the program, exit GDB and perform an external reset: Ctrl-T Ctrl-R in IDF Monitor, or using the external reset button on the development board.

### 4.16.5 RTC Watchdog Timeout

The RTC watchdog is used in the startup code to keep track of execution time and it also helps to prevent a lock-up caused by an unstable power source. It is enabled by default (see `CONFIG_BOOTLOADER_WDT_ENABLE`). If the execution time is exceeded, the RTC watchdog will restart the system. In this case, the ROM bootloader will print a message with the RTC Watchdog Timeout reason for the reboot.

```
rst:0x10 (RTCWDT_RTC_RESET)
```

The RTC watchdog covers the execution time from the first stage bootloader (ROM bootloader) to application startup. It is initially set in the ROM bootloader, then configured in the bootloader with the `CONFIG_BOOTLOADER_WDT_TIME_MS` option (9000 ms by default). During the application initialization stage, it is reconfigured because the source of the slow clock may have changed, and finally disabled right before the `app_main()` call. There is an option `CONFIG_BOOTLOADER_WDT_DISABLE_IN_USER_CODE` which prevents the RTC watchdog from being disabled before `app_main`. Instead, the RTC watchdog remains active and must be fed periodically in your application’s code.

### 4.16.6 Guru Meditation Errors

This section explains the meaning of different error causes, printed in paren after the *Guru Meditation Error: Core panic'ed message*.

**Note:** See the [Guru Meditation Wikipedia article](https://en.wikipedia.org/wiki/Guru_Meditation) for historical origins of “Guru Meditation”. 

IllegalInstruction

This CPU exception indicates that the instruction which was executed was not a valid instruction. The most common reasons for this error include:

- FreeRTOS task function has returned. In FreeRTOS, if a task function needs to terminate, it should call `vTaskDelete()` and delete itself, instead of returning.
- Failure to read next instruction from SPI flash. This usually happens if:
  - Application has reconfigured the SPI flash pins as some other function (GPIO, UART, etc.). Consult the Hardware Design Guidelines and the datasheet for the chip or module for details about the SPI flash pins.
  - Some external device has accidentally been connected to the SPI flash pins, and has interfered with communication between ESP32 and SPI flash.
- In C++ code, exiting from a non-void function without returning a value is considered to be an undefined behavior. When optimizations are enabled, the compiler will often omit the epilogue in such functions. This most often results in an IllegalInstruction exception. By default, ESP-IDF build system enables `-Werror=return-type` which means that missing return statements are treated as compile time errors. However if the application project disables compiler warnings, this issue might go undetected and the IllegalInstruction exception will occur at run time.

InstrFetchProhibited

This CPU exception indicates that the CPU could not read an instruction because the address of the instruction does not belong to a valid region in instruction RAM or ROM.

Usually, this means an attempt to call a function pointer, which does not point to valid code. `PC` (Program Counter) register can be used as an indicator: it will be zero or will contain a garbage value (not 0x4xxxxxxx).

LoadProhibited, StoreProhibited

These CPU exceptions happen when an application attempts to read from or write to an invalid memory location. The address which has been written/read is found in the `EXCVADDR` register in the register dump. If this address is zero, it usually means that the application has attempted to dereference a NULL pointer. If this address is close to zero, it usually means that the application has attempted to access a member of a structure, but the pointer to the structure is NULL. If this address is something else (garbage value, not in 0x3fxxxxxx - 0x6xxxxxxx range), it likely means that the pointer used to access the data is either not initialized or has been corrupted.

IntegerDivideByZero

Application has attempted to do an integer division by zero.

LoadStoreAlignment

Application has attempted to read or write a memory location, and the address alignment does not match the load/store size. For example, a 32-bit read can only be done from a 4-byte aligned address, and a 16-bit write can only be done to a 2-byte aligned address.

LoadStoreError

This exception may happen in the following cases:

- If the application has attempted to do an 8- or 16- bit read to, or write from, a memory region which only supports 32-bit reads/writes. For example, dereferencing a `char*` pointer to instruction memory (IRAM, IROM) will result in such an error.
- If the application has attempted to write to a read-only memory region, such as IROM or DROM.
Unhandled Debug Exception

This CPU exception happens when the instruction `BREAK` is executed.

Interrupt Watchdog Timeout on CPU0/CPU1

Indicates that an interrupt watchdog timeout has occurred. See `Watchdogs` for more information.

Cache disabled but cached memory region accessed

In some situations, ESP-IDF will temporarily disable access to external SPI Flash and SPI RAM via caches. For example, this happens when `spi_flash` APIs are used to read/write/erase/mmap regions of SPI Flash. In these situations, tasks are suspended, and interrupt handlers not registered with `ESP_INTR_FLAG_IRAM` are disabled. Make sure that any interrupt handlers registered with this flag have all the code and data in IRAM/DRAM. Refer to the `SPI flash API documentation` for more details.

4.16.7 Other Fatal Errors

Brownout

ESP32 has a built-in brownout detector, which is enabled by default. The brownout detector can trigger a system reset if the supply voltage goes below a safe level. The brownout detector can be configured using `CONFIG_ESP_BROWNOUT_DET` and `CONFIG_ESP_BROWNOUT_DET_LVL_SEL` options.

When the brownout detector triggers, the following message is printed:

```
Brownout detector was triggered
```

The chip is reset after the message is printed.

Note that if the supply voltage is dropping at a fast rate, only part of the message may be seen on the console.

Corrupt Heap

ESP-IDF’s heap implementation contains a number of run-time checks of the heap structure. Additional checks (“Heap Poisoning”) can be enabled in menuconfig. If one of the checks fails, a message similar to the following will be printed:

```
CORRUPT HEAP: Bad tail at 0x3ffe270a. Expected 0xbaad5678 got 0xbaac5678
assertion "head != NULL" failed: file "/Users/user/esp/esp-idf/components/heap/
~multi_heap_poisoning.c", line 201, function: multi_heap_free
abort() was called at PC 0x400dca43 on core 0
```

Consult `Heap Memory Debugging` documentation for further information.

Stack overflow

FreeRTOS End of Stack Watchpoint

ESP-IDF provides a custom FreeRTOS stack overflow detecting mechanism based on watchpoints. Every time FreeRTOS switches task context, one of the watchpoints is set to watch the last 32 bytes of stack.

Generally, this may cause the watchpoint to be triggered up to 28 bytes earlier than expected. The value 32 is chosen because it is larger than the stack canary size in FreeRTOS (20 bytes). Adopting this approach ensures that the watchpoint triggers before the stack canary is corrupted, not after.
Chapter 4. API Guides

**Note:** Not every stack overflow is guaranteed to trigger the watchpoint. It is possible that the task writes to memory beyond the stack canary location, in which case the watchpoint will not be triggered.

If watchpoint triggers, the message will be similar to:

```
Debug exception reason: Stack canary watchpoint triggered (task_name)
```

This feature can be enabled by using the `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` option.

**FreeRTOS Stack Checks**  See `CONFIG_FREERTOS_CHECK_STACKOVERFLOW`

**Stack Smashing**

Stack smashing protection (based on GCC `-fstack-protector*` flags) can be enabled in ESP-IDF using `CONFIG_COMPILER_STACK_CHECK_MODE` option. If stack smashing is detected, message similar to the following will be printed:

```
Stack smashing protect failure!
abort() was called at PC 0x400d2138 on core 0
Backtrace: 0x4008e6c0:0x3ffc1780 0x4008e8b7:0x3fff1c17a0 0x400d2138:0x3fffc17c0...
  → 0x400e79d5:0x3fff1c17e0 0x400e79a7:0x3fff1c1840 0x400e79df:0x3ffe18a0...
  → 0x400e2235:0x3fff1c8c0 0x400e1916:0x3fff1c18f0 0x400e19cd:0x3ffe1910...
  → 0x400e1a11:0x3fff1930 0x400e1bb2:0x3fff1950 0x400d2c44:0x3fffc1a80
```

The backtrace should point to the function where stack smashing has occurred. Check the function code for unbounded access to local arrays.

**Undefined Behavior Sanitizer (UBSAN) Checks**

Undefined behavior sanitizer (UBSAN) is a compiler feature which adds run-time checks for potentially incorrect operations, such as:

- overflows (multiplication overflow, signed integer overflow)
- shift base or exponent errors (e.g., shift by more than 32 bits)
- integer conversion errors

See GCC documentation of `-fsanitize=undefined` option for the complete list of supported checks.

**Enabling UBSAN**  UBSAN is disabled by default. It can be enabled at file, component, or project level by adding the `-fsanitize=undefined` compiler option in the build system.

When enabling UBSAN for code which uses the SOC hardware register header files (`soc/xxx_reg.h`), it is recommended to disable shift-base sanitizer using `-fno-sanitize=shift-base` option. This is due to the fact that ESP-IDF register header files currently contain patterns which cause false positives for this specific sanitizer option.

To enable UBSAN at project level, add the following code at the end of the project’s `CMakeLists.txt` file:

```
idf_build_set_property(COMPILE_OPTIONS "-fsanitize=undefined" "-fno-sanitize=shift-base" APPEND)
```

Alternatively, pass these options through the `EXTRA_CFLAGS` and `EXTRA_CXXFLAGS` environment variables.
Enabling UBSAN results in significant increase of code and data size. Most applications, except for the trivial ones, will not fit into the available RAM of the microcontroller when UBSAN is enabled for the whole application. Therefore it is recommended that UBSAN is instead enabled for specific components under test.

To enable UBSAN for a specific component (component_name) from the project’s CMakeLists.txt file, add the following code at the end of the file:

```c
idf_component_get_property(lib component_name COMPONENT_LIB)
target_compile_options(${lib} PRIVATE "-fsanitize=undefined" "-fno-sanitize=shift-base")
```

**Note:** See the build system documentation for more information about build properties and component properties.

To enable UBSAN for a specific component (component_name) from CMakeLists.txt of the same component, add the following at the end of the file:

```c
target_compile_options(${COMPONENT_LIB} PRIVATE "-fsanitize=undefined" "-fno-sanitize=shift-base")
```

**UBSAN Output** When UBSAN detects an error, a message and the backtrace are printed, for example:

```
Undefined behavior of type out_of_bounds
Backtrace:
0x4008b383: panic_abort at /path/to/esp-idf/components/esp_system/panic.c:367
0x4008c791: esp_system_abort at /path/to/esp-idf/components/esp_system/system_api.c:106
0x4008c587: __ubsan_default_handler at /path/to/esp-idf/components/esp_system/ubsan.c:152
0x4008c6be: __ubsan_handle_out_of_bounds at /path/to/esp-idf/components/esp_system/ubsan.c:223
0x400db74f: test_ub at main.c:128
0x400db99c: app_main at main.c:56 (discriminator 1)
```

The types of errors reported by UBSAN can be as follows:
### Name | Meaning
--- | ---
`type_mismatch` | Incorrect pointer value: null, unaligned, not compatible with the given type.
`type_mismatch_v1` |  
`add_overflow`, `sub_overflow`, `mul_overflow`, `negate_overflow` | Integer overflow during addition, subtraction, multiplication, negation.
`divrem_overflow` | Integer division by 0 or INT_MIN.
`shift_out_of_bounds` | Overflow in left or right shift operators.
`out_of_bounds` | Access outside of bounds of an array.
`unreachable` | Unreachable code executed.
`missing_return` | Non-void function has reached its end without returning a value (C++ only).
`vla_bound_not_positive` | Size of variable length array is not positive.
`load_invalid_value` | Value of bool or enum (C++ only) variable is invalid (out of bounds).
`nonnull_arg` | Null argument passed to a function which is declared with a non-null attribute.
`nonnull_return` | Null value returned from a function which is declared with returnsnonnull attribute.
`builtin_unreachable` | `__builtin_unreachable` function called.
`pointer_overflow` | Overflow in pointer arithmetic.

## 4.17 Hardware Abstraction

ESP-IDF provides a group of APIs for hardware abstraction. These APIs allow you to control peripherals at different levels of abstraction, giving you more flexibility compared to using only the ESP-IDF drivers to interact with hardware. ESP-IDF Hardware abstraction is likely to be useful for writing high-performance bare-metal drivers, or for attempting to port an ESP chip to another platform.

This guide is split into the following sections:

1. **Architecture**
2. **LL (Low Level) Layer**
3. **HAL (Hardware Abstraction Layer)**

**Warning:** Hardware abstraction API (excluding the driver and xxx_types.h) should be considered an experimental feature, thus cannot be considered public API. The hardware abstraction API does not adhere to the API name changing restrictions of ESP-IDF’s versioning scheme. In other words, it is possible that Hardware Abstraction API may change in between non-major release versions.

**Note:** Although this document mainly focuses on hardware abstraction of peripherals, e.g., UART, SPI, I2C, certain layers of hardware abstraction extend to other aspects of hardware as well, e.g., some of the CPU’s features are partially abstracted.

### 4.17.1 Architecture

Hardware abstraction in ESP-IDF is comprised of the following layers, ordered from low level of abstraction that is closer to hardware, to high level of abstraction that is further away from hardware.

- Low Level (LL) Layer
- Hardware Abstraction Layer (HAL)
- Driver Layers
The LL Layer, and HAL are entirely contained within the hal component. Each layer is dependent on the layer below it, i.e., driver depends on HAL, HAL depends on LL, LL depends on the register header files.

For a particular peripheral xxx, its hardware abstraction generally consists of the header files described in the table below. Files that are Target Specific have a separate implementation for each target, i.e., a separate copy for each chip. However, the #include directive is still target-independent, i.e., is the same for different targets, as the build system automatically includes the correct version of the header and source files.

<table>
<thead>
<tr>
<th>Include Directive</th>
<th>Target Specific</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#include &quot;soc/xxx_caps.h&quot;</td>
<td>Y</td>
<td>This header contains a list of C macros specifying the various capabilities of the ESP32’s peripheral xxx. Hardware capabilities of a peripheral include things such as the number of channels, DMA support, hardware FIFO/buffer lengths, etc.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_struct.h&quot;</td>
<td>Y</td>
<td>The two headers contain a representation of a peripheral’s registers in C structure and C macro format respectively, allowing you to operate a peripheral at the register level via either of these two header files.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_reg.h&quot;</td>
<td>Y</td>
<td>If certain signals of a peripheral are mapped to a particular pin of the ESP32, their mappings are defined in this header as C macros.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_pins.h&quot;</td>
<td>Y</td>
<td>This header is mainly used as a convenience header file to automatically include xxx_caps.h, xxx_struct.h, and xxx_reg.h.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_periph.h&quot;</td>
<td>N</td>
<td>This header contains type definitions and macros that are shared among the LL, HAL, and driver layers. Moreover, it is considered public API thus can be included by the application level. The shared types and definitions usually related to non-implementation specific concepts such as the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Protocol-related types/macros such as frames, modes, common bus speeds, etc.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Features/characteristics of an xxx peripheral that are likely to be present on any implementation (implementation-independent) such as channels, operating modes, signal amplification or attenuation intensities, etc.</td>
</tr>
<tr>
<td>#include &quot;hal/xxx_types.h&quot;</td>

### 4.17.2 LL (Low Level) Layer

The primary purpose of the LL Layer is to abstract away register field access into more easily understandable functions. LL functions essentially translate various in/out arguments into the register fields of a peripheral in the form of get/set functions. All the necessary bit shifting, masking, offsetting, and endianness of the register fields should be handled by the LL functions.

```c
//Inside xxx_ll.h

static inline void xxx_ll_set_baud_rate(xxx_dev_t *hw,
```

(continues on next page)
xxx_ll_clk_src_t clock_source, 
uint32_t baud_rate) { 
    uint32_t src_clk_freq = (source_clk == XXX_SCLK_APB) ? APB_CLK_FREQ : REF_CLK_FREQ;
    uint32_t clock_divider = src_clk_freq / baud;
    // Set clock select field
    hw->clk_div_reg.divider = clock_divider >> 4;
    // Set clock divider field
    hw->config.clk_sel = (source_clk == XXX_SCLK_APB) ? 0 : 1;
}

static inline uint32_t xxx_ll_get_rx_byte_count(xxx_dev_t *hw) {
    return hw->status_reg.rx_cnt;
}

The code snippet above illustrates typical LL functions for a peripheral xxx. LL functions typically have the following characteristics:

- All LL functions are defined as static inline so that there is minimal overhead when calling these functions due to compiler optimization. These functions are not guaranteed to be inlined by the compiler, so any LL function that is called when the cache is disabled (e.g., from an IRAM ISR context) should be marked with __attribute__((always_inline)).
- The first argument should be a pointer to a xxx_dev_t type. The xxx_dev_t type is a structure representing the peripheral’s registers, thus the first argument is always a pointer to the starting address of the peripheral’s registers. Note that in some cases where the peripheral has multiple channels with identical register layouts, xxx_dev_t *hw may point to the registers of a particular channel instead.
- LL functions should be short, and in most cases are deterministic. In other words, in the worst case, runtime of the LL function can be determined at compile time. Thus, any loops in LL functions should be finite bounded; however, there are currently a few exceptions to this rule.
- LL functions are not thread-safe, it is the responsibility of the upper layers (driver layer) to ensure that registers or register fields are not accessed concurrently.

4.17.3 HAL (Hardware Abstraction Layer)

The HAL layer models the operational process of a peripheral as a set of general steps, where each step has an associated function. For each step, the details of a peripheral’s register implementation (i.e., which registers need to be set/read) are hidden (abstracted away) by the HAL. By modeling peripheral operation as a set of functional steps, any minor hardware implementation differences of the peripheral between different targets or chip versions can be abstracted away by the HAL (i.e., handled transparently). In other words, the HAL API for a particular peripheral remains mostly the same across multiple targets/chip versions.

The following HAL function examples are selected from the Watchdog Timer HAL as each function maps to one of the steps in a WDT’s operation life cycle, thus illustrating how a HAL abstracts a peripheral’s operation into functional steps.

// Initialize one of the WDTs
void wdt_hal_init(wdt_hal_context_t *hal, wdt_inst_t wdt_inst, uint32_t prescaler, _bool enable_intr);

// Configure a particular timeout stage of the WDT
void wdt_hal_config_stage(wdt_hal_context_t *hal, wdt_stage_t stage, uint32_t _timeout, wdt_stage_action_t behavior);

// Start the WDT
void wdt_hal_enable(wdt_hal_context_t *hal);

// Feed (i.e., reset) the WDT
void wdt_hal_feed(wdt_hal_context_t *hal);
HAL functions generally have the following characteristics:

- The first argument to a HAL function has the `xxx_hal_context_t *` type. The HAL context type is used to store information about a particular instance of the peripheral (i.e., the context instance). A HAL context is initialized by the `xxx_hal_init()` function and can store information such as the following:
  - The channel number of this instance
  - Pointer to the peripheral’s (or channel’s) registers (i.e., a `xxx_dev_t *` type)
  - Information about an ongoing transaction (e.g., pointer to DMA descriptor list in use)
  - Some configuration values for the instance (e.g., channel configurations)
  - Variables to maintain state information regarding the instance (e.g., a flag to indicate if the instance is waiting for transaction to complete)
- HAL functions should not contain any OS primitives such as queues, semaphores, mutexes, etc. All synchronization/concurrency should be handled at higher layers (e.g., the driver).
- Some peripherals may have steps that cannot be further abstracted by the HAL, thus end up being a direct wrapper (or macro) for an LL function.
- Some HAL functions may be placed in IRAM thus may carry an `IRAM_ATTR` or be placed in a separate `xxx_hal_iram.c` source file.

### 4.18 High Priority Interrupts

The Xtensa architecture supports 32 interrupts, divided over 7 priority levels from level 1 to 7, with level 7 being a non-maskable interrupt (NMI), plus an assortment of exceptions. On the ESP32, the Interrupt Allocation can route most interrupt sources to these interrupts via the interrupt mux. Normally, interrupts are written in C, but ESP-IDF allows high-priority interrupts to be written in assembly as well, resulting in very low interrupt latencies.

#### 4.18.1 Interrupt Priorities

<table>
<thead>
<tr>
<th>Priority Level</th>
<th>Symbol</th>
<th>Remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>N/A</td>
<td>Exception and low priority interrupts, handled by ESP-IDF.</td>
</tr>
<tr>
<td>2-3</td>
<td>N/A</td>
<td>Medium priority interrupts, handled by ESP-IDF.</td>
</tr>
<tr>
<td>4</td>
<td>xt_highint4</td>
<td>High priority interrupt, free to use.</td>
</tr>
<tr>
<td>5</td>
<td>xt_highint5</td>
<td>Normally used by ESP-IDF debug logic.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Non-maskable interrupt, free to use.</td>
</tr>
<tr>
<td>dbg</td>
<td>xt_debugexception</td>
<td>Debug exception. Called on e.g., a BREAK instruction.</td>
</tr>
</tbody>
</table>

Using these symbols is done by creating an assembly file with suffix `.S` and defining the named symbols, like this:

1. ESP-IDF debug logic can be configured to run on `xt_highint4` or `xt_highint5` in `CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL`. Bluetooth’s interrupt can be configured to run on priority level 4 by enabling `CONFIG_BTDM_CTRL_HLI`. If `CONFIG_BTDM_CTRL_HLI` is enabled, ESP-IDF debug logic must be running on priority level 5 interrupt.
2. If `CONFIG_BTDM_CTRL_HLI` is enabled, `xt_debugexception` is used to fix the live lock issue in ESP32 ECO3.
4.18.2 Notes

- Do not call C code from a high-priority interrupt; as these interrupts are run from a critical section, this can cause the target to crash. Note that although the panic handler interrupt does call normal C code, this exception is allowed due to the fact that this handler never returns (i.e., the application does not continue to run after the panic handler), so breaking C code execution flow is not a problem.

When `CONFIG_BTDM_CTRL_HLI` is enabled, C code is also called from a high-priority interrupt, this is possible thanks to some additional protection added to it.

- Make sure your assembly code gets linked in. Indeed, as the free-to-use symbols are declared as weak, the linker may discard the file containing the symbol. This happens if the only symbol defined, or used from the user file is the `xt_` free-to-use symbol. To avoid this, in the assembly file containing the `xt_` symbol, define another symbol, like:

```assembly
.global ld_include_my_isr_file
ld_include_my_isr_file:
```

Here it is called `ld_include_my_isr_file` but can have any name, as long as it is not defined anywhere else in the project.

Then, in the component `CMakeLists.txt`, add this name as an unresolved symbol to the ld command line arguments:

```bash
target_link_libraries(${COMPONENT_TARGET} "-u ld_include_my_isr_file")
```

This will ensure the linker to always includes the file defining `ld_include_my_isr_file`, so that the ISR is always linked.

- High-priority interrupts can be routed and handled using `esp_intr_alloc()` and associated functions. The handler and handler arguments to `esp_intr_alloc()` must be NULL, however.
- In theory, medium priority interrupts could also be handled in this way. ESP-IDF does not support this yet.
- To check Xtensa instruction set architecture (ISA), please refer to `Xtensa ISA Summary`.

4.19 JTAG Debugging

This document provides a guide to installing OpenOCD for ESP32 and debugging using GDB.

**Note:** You can also debug your ESP32 without needing to setup JTAG or OpenOCD by using `idf.py monitor`. See: `IDF Monitor` and `CONFIG_ESP_SYSTEM_GDBSTUB_Runtime`.

The document is structured as follows:

**Introduction**  Introduction to the purpose of this guide.
Chapter 4. API Guides

How it Works? Description how ESP32, JTAG interface, OpenOCD and GDB are interconnected and working together to enable debugging of ESP32.

Selecting JTAG Adapter What are the criteria and options to select JTAG adapter hardware.

Setup of OpenOCD Procedure to install OpenOCD and verify that it is installed.

Configuring ESP32 Target Configuration of OpenOCD software and setting up of JTAG adapter hardware, which together make up the debugging target.

Launching Debugger Steps to start up a debug session with GDB from Eclipse and from Command Line.

Debugging Examples If you are not familiar with GDB, check this section for debugging examples provided from Eclipse as well as from Command Line.

Building OpenOCD from Sources Procedure to build OpenOCD from sources for Windows, Linux and macOS operating systems.

Tips and Quirks This section provides collection of tips and quirks related to JTAG debugging of ESP32 with OpenOCD and GDB.

4.19.1 Introduction

The ESP32 has two powerful Xtensa cores, allowing for a great deal of variety of program architectures. The FreeRTOS OS that comes with ESP-IDF is capable of multi-core preemptive scheduling, allowing for an intuitive way of writing software.

The downside of the ease of programming is that debugging without the right tools is harder: figuring out a bug that is caused by two threads, running even simultaneously on two different CPU cores, can take a long time when all you have are printf() statements. A better (and in many cases quicker) way to debug such problems is by using a debugger, connected to the processors over a debug port.

Espressif has ported OpenOCD to support the ESP32 processor and the multi-core FreeRTOS (which is the foundation of most ESP32 apps). Additionally, some extra tools have been written to provide extra features that OpenOCD does not support natively.

This document provides a guide to installing OpenOCD for ESP32 and debugging using GDB under Linux, Windows and macOS. Except for OS specific installation procedures, the s/w user interface and use procedures are the same across all supported operating systems.

Note: Screenshots presented in this document have been made for Eclipse Neon 3 running on Ubuntu 16.04 LTS. There may be some small differences in what a particular user interface looks like, depending on whether you are using Windows, macOS or Linux and/or a different release of Eclipse.

4.19.2 How it Works?

The key software and hardware components that perform debugging of ESP32 with OpenOCD over JTAG (Joint Test Action Group) interface is presented in the diagram below under the “Debugging With JTAG” label. These components include xtensa-esp32-elf-gdb debugger, OpenOCD on chip debugger, and the JTAG adapter connected to ESP32 target.

Likewise, the “Application Loading and Monitoring” label indicates the key software and hardware components that allow an application to be compiled, built, and flashed to ESP32, as well as to provide means to monitor diagnostic messages from ESP32.

“Debugging With JTAG” and “Application Loading and Monitoring” is integrated under the Eclipse IDE in order to provide a quick and easy transition between writing/compiling/loading/debugging code. The Eclipse IDE (and the integrated debugging software) is available for Windows, Linux and macOS platforms. Depending on user preferences, both the debugger and idf.py build can also be used directly from terminal/command line, instead of Eclipse.

If the ESP-WROVER-KIT is used, then connection from PC to ESP32 is done effectively with a single USB cable. This is made possible by the FT2232H chip, which provides two USB channels, one for JTAG and the other for UART connection.
4.19.3 Selecting JTAG Adapter

The quickest and most convenient way to start with JTAG debugging is by using ESP-WROVER-KIT. Each version of this development board has JTAG interface already built in. No need for an external JTAG adapter and extra wiring/cable to connect JTAG to ESP32. ESP-WROVER-KIT is using FT2232H JTAG interface operating at 20 MHz clock speed, which is difficult to achieve with an external adapter.

If you decide to use separate JTAG adapter, look for one that is compatible with both the voltage levels on the ESP32 as well as with the OpenOCD software. The JTAG port on the ESP32 is an industry-standard JTAG port which lacks (and does not need) the TRST pin. The JTAG I/O pins all are powered from the VDD_3P3_RTC pin (which normally would be powered by a 3.3 V rail) so the JTAG adapter needs to be able to work with JTAG pins in that voltage range.

On the software side, OpenOCD supports a fair amount of JTAG adapters. See https://openocd.org/doc/html/Debug-Adapter-Hardware.html for an (unfortunately slightly incomplete) list of the adapters OpenOCD works with. This page lists SWD-compatible adapters as well; take note that the ESP32 does not support SWD. JTAG adapters that are hardcoded to a specific product line, e.g., ST-LINK debugging adapters for STM32 families, will not work.

The minimal signalling to get a working JTAG connection are TDI, TDO, TCK, TMS and GND. Some JTAG debuggers also need a connection from the ESP32 power line to a line called e.g., Vtar to set the working voltage. SRST can optionally be connected to the CH_PD of the ESP32, although for now, support in OpenOCD for that line is pretty minimal.

ESP-Prog is an example for using an external board for debugging by connecting it to the JTAG pins of ESP32.

4.19.4 Setup of OpenOCD

If you have already set up ESP-IDF with CMake build system according to the Getting Started Guide, then OpenOCD is already installed. After setting up the environment in your terminal, you should be able to run OpenOCD. Check this by executing the following command:

```
openocd --version
```

The output should be as follows (although the version may be more recent than listed here):
You may also verify that OpenOCD knows where its configuration scripts are located by printing the value of `OPENOCD_SCRIPTS` environment variable, by typing `echo $OPENOCD_SCRIPTS` (for Linux and macOS) or `echo %OPENOCD_SCRIPTS%` (for Windows). If a valid path is printed, then OpenOCD is set up correctly.

If any of these steps do not work, please go back to the setting up the tools section of the Getting Started Guide.

**Note:** It is also possible to build OpenOCD from source. Please refer to Building OpenOCD from Sources section for details.

### 4.19.5 Configuring ESP32 Target

Once OpenOCD is installed, you can proceed to configuring the ESP32 target (i.e. ESP32 board with JTAG interface). Configuring the target is split into the following three steps:

- **Configure and Connect JTAG Interface**
- **Run OpenOCD**
- **Upload Application for Debugging**

#### Configure and Connect JTAG Interface

This step depends on the JTAG and ESP32 board you are using (see the two cases described below).

#### Configure ESP-WROVER-KIT JTAG Interface

All versions of ESP-WROVER-KIT boards have built-in JTAG functionality. Putting it to work requires setting jumpers or DIP switches to enable JTAG functionality, and configuring USB drivers. Please refer to step by step instructions below.

#### Configure Hardware

- Enable on-board JTAG functionality by setting JP8 according to ESP-WROVER-KIT V4.1 Getting Started Guide, Section Setup Options.
- Verify if ESP32 pins used for JTAG communication are not connected to some other h/w that may disturb JTAG operation:

<table>
<thead>
<tr>
<th>ESP32 Pin</th>
<th>JTAG Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDO / GPIO15</td>
<td>TDO</td>
</tr>
<tr>
<td>MTDI / GPIO12</td>
<td>TDI</td>
</tr>
<tr>
<td>MTCK / GPIO13</td>
<td>TCK</td>
</tr>
<tr>
<td>MTMS / GPIO14</td>
<td>TMS</td>
</tr>
</tbody>
</table>

**Configure USB Drivers** Install and configure USB drivers, so OpenOCD is able to communicate with JTAG interface on ESP-WROVER-KIT board as well as with UART interface used to upload application for flash. Follow steps below specific to your operating system.

**Note:** ESP-WROVER-KIT uses an FT2232 adapter. The following instructions can also be used for other FT2232 based JTAG adapters.
**Windows**

2. Wait until USB ports of ESP-WROVER-KIT are recognized by Windows and drives are installed. If they do not install automatically, then download them from https://ftdichip.com/drivers/d2xx-drivers/ and install manually.
3. Download Zadig tool (Zadig_X.X.exe) from https://zadig.akeo.ie/ and run it.
4. In Zadig tool go to “Options” and check “List All Devices”.
5. Check the list of devices that should contain two ESP-WROVER-KIT specific USB entries: “Dual RS232-HS (Interface 0)” and “Dual RS232-HS (Interface 1)”. The driver name would be “FTDIBUS (vxxxx)” and USB ID: 0403 6010.

![Configuration of JTAG USB driver in Zadig tool](image)

6. The first device (Dual RS232-HS (Interface 0)) is connected to the JTAG port of the ESP32. Original “FTDIBUS (vxxxx)” driver of this device should be replaced with “WinUSB (v6xxxx)” . To do so, select “Dual RS232-HS (Interface 0) and reinstall attached driver to the “WinUSB (v6xxxx)” , see picture above.

**Note:** Do not change the second device “Dual RS232-HS (Interface 1)”. It is routed to ESP32’s serial port (UART) used for upload of application to ESP32’s flash.

Now ESP-WROVER-KIT’s JTAG interface should be available to the OpenOCD. To carry on with debugging environment setup, proceed to section *Run OpenOCD*.

**Linux**

2. Open a terminal, enter `ls -l /dev/ttyUSB*` command and check, if board’s USB ports are recognized by the OS. You are looking for similar result:
   ```bash
   user-name@computer-name:~/esp$ ls -l /dev/ttyUSB*
   crw-rw---- 1 root dialout 188, 0 Jul 10 19:04 /dev/ttyUSB0
   crw-rw---- 1 root dialout 188, 1 Jul 10 19:04 /dev/ttyUSB1
   ```
3. To set up access permissions to USB devices supported by OpenOCD, copy the udev rules file into the `/etc/udev/rules.d` directory.
4. Log off and login, then cycle the power to the board to make the changes effective. In terminal enter again `ls -l /dev/ttyUSB*` command to verify, if group-owner has changed from dialout to plugdev:
If you see similar result and you are a member of plugdev group, then the set up is complete.

The \( /dev/ttyUSBn \) interface with lower number is used for JTAG communication. The other interface is routed to ESP32’s serial port (UART) used for upload of application to ESP32’s flash.

Now ESP-WROVER-KIT’s JTAG interface should be available to the OpenOCD. To carry on with debugging environment setup, proceed to section Run OpenOCD.

**MacOS** On macOS, using FT2232 for JTAG and serial port at the same time needs some additional steps. When the OS loads FTDI serial port driver, it does so for both channels of FT2232 chip. However only one of these channels is used as a serial port, while the other is used as JTAG. If the OS has loaded FTDI serial port driver for the channel used for JTAG, OpenOCD will not be able to connect to the chip. There are two ways around this:

1. Manually unload the FTDI serial port driver before starting OpenOCD, start OpenOCD, then load the serial port driver.
2. Modify FTDI driver configuration so that it does not load itself for channel A of FT2232 chip, which is the channel used for JTAG on ESP-WROVER-KIT.

### Manually unloading the driver

1. Install FTDI driver from [https://ftdichip.com/drivers/vcp-drivers/](https://ftdichip.com/drivers/vcp-drivers/)
2. Connect USB cable to the ESP-WROVER-KIT.
3. Unload the serial port driver:

   ```bash
   sudo kextunload -b com.FTDI.driver.FTDIUSBSerialDriver
   ```

   In some cases you may need to unload Apple’s FTDI driver as well:
   
   - macOS < 10.15:
     ```bash
     sudo kextunload -b com.apple.driver.AppleUSBFTDI
     ```
   - macOS 10.15:
     ```bash
     sudo kextunload -b com.apple.DriverKit-AppleUSBFTDI
     ```

   **Warning:** Attempting to use serial over the wrong channel with the FTDI driver will cause a kernel panic. The ESP-WROVER-KIT uses channel A for JTAG and channel B for serial.

4. Run OpenOCD:

   ```bash
   openocd -f board/esp32-wrover-kit-3.3v.cfg
   ```

5. In another terminal window, load FTDI serial port driver again:

   ```bash
   sudo kextload -b com.FTDI.driver.FTDIUSBSerialDriver
   ```

**Note:** If you need to restart OpenOCD, there is no need to unload FTDI driver again — just stop OpenOCD and start it again. The driver only needs to be unloaded if ESP-WROVER-KIT was reconnected or power was toggled.

This procedure can be wrapped into a shell script, if desired.

### Modifying FTDI driver

In a nutshell, this approach requires modification to FTDI driver configuration file, which prevents the driver from being loaded for channel B of FT2232H.
Note: Other boards may use channel A for JTAG, so use this option with caution.

Warning: This approach also needs signature verification of drivers to be disabled, so may not be acceptable for all users.

1. Open FTDI driver configuration file using a text editor (note `sudo`):

   ```bash
   sudo nano /Library/Extensions/FTDIUSBSerialDriver.kext/Contents/Info.plist
   ```

2. Find and delete the following lines:

   ```xml
   <key>FT2232H_B</key>
   <dict>
     <key>CFBundleIdentifier</key>
     <string>com.FTDI.driver.FTDIUSBSerialDriver</string>
     <key>iOClass</key>
     <string>FTDIUSBSerialDriver</string>
     <key>iOProviderClass</key>
     <string>IOUSBInterface</string>
     <key>bConfigurationValue</key>
     <integer>1</integer>
     <key>bInterfaceNumber</key>
     <integer>1</integer>
     <key>bcdDevice</key>
     <integer>1792</integer>
     <key>idProduct</key>
     <integer>24592</integer>
     <key>idVendor</key>
     <integer>1027</integer>
   </dict>
   ```

3. Save and close the file

4. Disable driver signature verification:
   1. Open Apple logo menu, choose “Restart…”
   2. When you hear the chime after reboot, press CMD+R immediately
   3. Once Recovery mode starts up, open Terminal
   4. Run the command:

      ```bash
      csrutil enable --without kext
      ```
   5. Restart again

After these steps, serial port and JTAG can be used at the same time.

To carry on with debugging environment setup, proceed to section Run OpenOCD.

Configure Other JTAG Interfaces

For guidance about which JTAG interface to select when using OpenOCD with ESP32, refer to the section Selecting JTAG Adapter. Then follow the configuration steps below to get it working.

Configure Hardware

1. Identify all pins/signals on JTAG interface and ESP32 board that should be connected to establish communication.
### Table 25: ESP32 JTAG pins

<table>
<thead>
<tr>
<th>ESP32 Pin</th>
<th>JTAG Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDO / GPIO15</td>
<td>TDO</td>
</tr>
<tr>
<td>MTDI / GPIO12</td>
<td>TDI</td>
</tr>
<tr>
<td>MTCK / GPIO13</td>
<td>TCK</td>
</tr>
<tr>
<td>MTMS / GPIO14</td>
<td>TMS</td>
</tr>
</tbody>
</table>

2. Verify if ESP32 pins used for JTAG communication are not connected to some other hardware that may disturb JTAG operation.

3. Connect identified pin/signals of ESP32 and JTAG interface.

**Configure Drivers** You may need to install driver software to make JTAG work with computer. Refer to documentation of your JTAG adapter for related details.

On Linux, adding OpenOCD udev rules is required and is done by copying the udev rules file into the `/etc/udev/rules.d` directory.

**Connect** Connect JTAG interface to the computer. Power on ESP32 and JTAG interface boards. Check if the JTAG interface is visible on the computer.

To carry on with debugging environment setup, proceed to section *Run OpenOCD*.

**Run OpenOCD**

Once target is configured and connected to computer, you are ready to launch OpenOCD.

Open a terminal and set it up for using the ESP-IDF as described in the setting up the environment section of the Getting Started Guide. Then run OpenOCD (this command works on Windows, Linux, and macOS):

```
openocd -f board/esp32-wrover-kit-3.3v.cfg
```

**Note:** The files provided after `-f` above are specific for ESP-WROVER-KIT with ESP32-WROOM-32 module. You may need to provide different files depending on the hardware that is used. For guidance see Configuration of OpenOCD for Specific Target.

You should now see similar output (this log is for ESP-WROVER-KIT with ESP32-WROOM-32 module):

```
user-name@computer-name:~/esp/esp-idf$ openocd -f board/esp32-wrover-kit-3.3v.cfg
Open On-Chip Debugger v0.10.0-esp32-20190708 (2019-07-08-11:04)
Licensed under GNU GPL v2
For bug reports, read https://openocd.org/doc/doxygen/bugs.html
none separate

```

- If there is an error indicating permission problems, please see section on “Permissions delegation” in the OpenOCD README file located in the `~/esp/openocd-esp32` directory.
• In case there is an error in finding the configuration files, e.g., Can't find board/esp32-wrover-kit-3.3v.cfg, check if the OPENOCD_SCRIPTS environment variable is set correctly. This variable is used by OpenOCD to look for the files specified after the -f option. See Setup of OpenOCD section for details. Also check if the file is indeed under the provided path.

• If you see JTAG errors (e.g.,...all ones or...all zeroes), please check your JTAG connections, whether other signals are connected to JTAG besides ESP32’s pins, and see if everything is powered on correctly.

Upload Application for Debugging

Build and upload your application to ESP32 as usual, see Step 5. First Steps on ESP-IDF.

Another option is to write application image to flash using OpenOCD via JTAG with commands like this:

```
openocd -f board/esp32-wrover-kit-3.3v.cfg -c "program_esp filename.bin 0x10000..." verify exit"
```

OpenOCD flashing command program_esp has the following format:

```
program_esp <image_file> <offset> [verify] [reset] [exit] [compress] [encrypt]
```

- image_file - Path to program image file.
- offset - Offset in flash bank to write image.
- verify - Optional. Verify flash contents after writing.
- reset - Optional. Reset target after programming.
- exit - Optional. Finally exit OpenOCD.
- compress - Optional. Compress image file before programming.
- encrypt - Optional. Encrypt binary before writing to flash. Same functionality with idf.py encrypted-flash

You are now ready to start application debugging. Follow the steps described in the section below.

4.19.6 Launching Debugger

The toolchain for ESP32 features GNU Debugger, in short GDB. It is available with other toolchain programs under filename: xtensa-esp32-elf-gdb. GDB can be called and operated directly from command line in a terminal. Another option is to call it from within IDE (like Eclipse, Visual Studio Code, etc.) and operate indirectly with help of GUI instead of typing commands in a terminal.

The options of using debugger are discussed under links below.

- Eclipse
- Command Line
- Configuration for Visual Studio Code Debug

It is recommended to first check if debugger works from Command Line and then move to using Eclipse.

4.19.7 Debugging Examples

This section is intended for users not familiar with GDB. It presents example debugging session from Eclipse using simple application available under get-started/blink and covers the following debugging actions:

1. Navigating Through the Code, Call Stack and Threads
2. Setting and Clearing Breakpoints
3. Halting the Target Manually
4. Stepping Through the Code
5. Checking and Setting Memory
6. Watching and Setting Program Variables
7. Setting Conditional Breakpoints
Chapter 4. API Guides

Similar debugging actions are provided using GDB from *Command Line*.

**Note:** *Debugging FreeRTOS Objects* is currently only available for command line debugging.

Before proceeding to examples, set up your ESP32 target and load it with **get-started/blink**.

### 4.19.8 Building OpenOCD from Sources

Please refer to separate documents listed below, that describe build process.

**Building OpenOCD from Sources for Windows**

**Note:** This document outlines how to build a binary of OpenOCD from its source files instead of downloading the pre-built binary. For a quick setup, users can download a pre-built binary of OpenOCD from Espressif GitHub instead of compiling it themselves (see Setup of OpenOCD for more details).

**Note:** All code snippets in this document are assumed to be running in an MSYS2 shell with the MINGW32 subsystem.

**Install Dependencies** Install packages that are required to compile OpenOCD:

```
pacman --S --noconfirm --needed autoconf automake git make \
mingw-w64-i686-gcc \
mingw-w64-i686-toolchain \
mingw-w64-i686-libtool \
mingw-w64-i686-pkg-config \
mingw-w64-i686-cross-winpthreads-git \
p7zip
```

**Download Sources of OpenOCD** The sources for the ESP32-enabled variant of OpenOCD are available from Espressif’s GitHub under https://github.com/espressif/openocd-esp32. These source files can be pulled via Git using the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in ~/esp/openocd-esp32 directory.

**Downloading libusb** The libusb library is also required when building OpenOCD. The following commands will download a particular release of libusb and uncompress it to the current directory.

```
wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z
```

We now need to export the following variables such that the libusb library gets linked into the OpenOCD build.

```
export CPPFLAGS="$CPPFLAGS -I$PWD/libusb/include/libusb-1.0"
export LDFLAGS="$LDFLAGS -L$PWD/libusb/MinGW32/.libs/dll"
```
Chapter 4. API Guides

Build OpenOCD  The following commands will configure OpenOCD then build it.

```
cd ~/esp/openocd-esp32
export CPPFLAGS="-D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="-Wno-error"
./bootstrap
./configure --disable-doxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --
--build=i686-w64-mingw32 --host=i686-w64-mingw32
make
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src
cp /opt/i686-w64-mingw32/bin/libwinpthread-1.dll ./src
```

Once the build is completed, the OpenOCD binary will be placed in `~/esp/openocd-esp32/src/`. You can then optionally call `make install`. This will copy the OpenOCD binary to a user specified location.

- This location can be specified when OpenOCD is configured, or by setting `export DESTDIR="/custom/install/dir"` before calling `make install`.
- If you have an existing OpenOCD (from e.g., another development platform), you may want to skip this call as your existing OpenOCD may get overwritten.

Note:

- Should an error occur, resolve it and try again until the command `make` works.
- If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
- If the information of your device is not shown in the log, use `./configure` to enable it as described in `./openocd-esp32/doc/INSTALL.txt`.
- For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.Windows`.
- Don’t forget to copy `libusb-1.0.dll` and `libwinpthread-1.dll` into `OOCD_INSTALLDIR/bin` from `~/esp/openocd-esp32/src`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src` directory.

Full Listing  For greater convenience, all of commands called throughout the OpenOCD build process have been listed in the code snippet below. Users can copy this code snippet into a shell script then execute it:

```
pacman -S --noconfirm --needed autoconf automake git make mingw-w64-i686-gcc mingw-w64-i686-toolchain mingw-w64-i686-libtool mingw-w64-i686-pkg-config mingw-w64-
cross-winthreads-git p7zip

cd ~/esp

git clone --recursive https://github.com/espressif/openocd-esp32.git

wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z

export CPPFLAGS="-I$(PWD)/libusb/include/libusb-1.0"; export LDFLAGS="
-llibusb-1.0.22.7z/dll"

export CPPFLAGS="-D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="
-D__USE_MINGW_ANSI_STDIO=1 -Wno-error"
cd ~/esp/openocd-esp32
./bootstrap
./configure --disable-doxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --
--build=i686-w64-mingw32 --host=i686-w64-mingw32
make
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src
```

(continues on next page)
Next Steps  To carry on with debugging environment setup, proceed to section *Configuring ESP32 Target*.

Building OpenOCD from Sources for Linux

The following instructions are alternative to downloading binary OpenOCD from Espressif GitHub. To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section *Setup of OpenOCD*.

Download Sources of OpenOCD  The sources for the ESP32-enabled variant of OpenOCD are available from Espressif GitHub under [https://github.com/espressif/openocd-esp32](https://github.com/espressif/openocd-esp32). To download the sources, use the following commands:

```bash
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in `~/esp/openocd-esp32` directory.

Install Dependencies  Install packages that are required to compile OpenOCD.

**Note:** Install the following packages one by one, check if installation was successful and then proceed to the next package. Resolve reported problems before moving to the next step.

```bash
sudo apt-get install make
sudo apt-get install libtool
sudo apt-get install pkg-config
sudo apt-get install autoconf
sudo apt-get install automake
sudo apt-get install texinfo
sudo apt-get install libusb-1.0
```

**Note:**

- Version of pkg-config should be 0.2.3 or above.
- Version of autoconf should be 2.6.4 or above.
- Version of automake should be 1.9 or above.
- When using USB-Blaster, ASIX Presto, OpenJTAG and FT2232 as adapters, drivers libFTDI and FTD2XX need to be downloaded and installed.
- When using CMSIS-DAP, HIDAPI is needed.

Build OpenOCD  Proceed with configuring and building OpenOCD:
Chapter 4. API Guides

```bash
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g., another development platform), as it may get overwritten.

**Note:**

- Should an error occur, resolve it and try again until the command `make` works.
- If there is a submodule problem from OpenOCD, please cd to the openocd-esp32 directory and input `git submodule update --init`.
- If the ./configure is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
- If the information of your device is not shown in the log, use ./configure to enable it as described in ../openocd-esp32/doc/INSTALL.txt.
- For details concerning compiling OpenOCD, please refer to openocd-esp32/README.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in ~/openocd-esp32/bin directory.

**Next Steps** To carry on with debugging environment setup, proceed to section *Configuring ESP32 Target*.

### Building OpenOCD from Sources for MacOS

The following instructions are alternative to downloading binary OpenOCD from Espressif GitHub. To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section *Setup of OpenOCD*.

**Download Sources of OpenOCD** The sources for the ESP32-enabled variant of OpenOCD are available from Espressif GitHub under https://github.com/espressif/openocd-esp32. To download the sources, use the following commands:

```bash
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in ~/esp/openocd-esp32 directory.

**Install Dependencies** Install packages that are required to compile OpenOCD using Homebrew:

```bash
brew install automake libtool libusb wget gcc@4.9 pkg-config
```

**Build OpenOCD** Proceed with configuring and building OpenOCD:

```bash
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g., another development platform), as it may get overwritten.

**Note:**
• Should an error occur, resolve it and try again until the command `make` works.

• Error `Unknown command 'raggedright'` may indicate that the required version of `texinfo` was not installed on your computer or installed but was not linked to your PATH. To resolve this issue make sure `texinfo` is installed and PATH is adjusted prior to the `./bootstrap` by running:

```
brew install texinfo
export PATH=/usr/local/opt/texinfo/bin:$PATH
```

• If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.

• If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.

• If the information of your device is not shown in the log, use `./configure` to enable it as described in `./openocd-esp32/doc/INSTALL.txt`.

• For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.OSX`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src/openocd` directory.

### Next Steps
To carry on with debugging environment setup, proceed to section Configuring ESP32 Target.

The examples of invoking OpenOCD in this document assume using pre-built binary distribution described in section Setup of OpenOCD.

To use binaries build locally from sources, change the path to OpenOCD executable to `src/openocd` and set the `OPENOCD_SCRIPTS` environment variable so that OpenOCD can find the configuration files. For Linux and macOS:

```
cd ~/esp/openocd-esp32
export OPENOCD_SCRIPTS=$PWD/tcl
```

For Windows:

```
cd %USERPROFILE%\esp\openocd-esp32
set "OPENOCD_SCRIPTS=%CD%\tcl"
```

Example of invoking OpenOCD build locally from sources, for Linux and macOS:

```
src/openocd -f board/esp32-wrover-kit-3.3v.cfg
```

and Windows:

```
src\openocd -f board\esp32-wrover-kit-3.3v.cfg
```

### 4.19.9 Tips and Quirks

This section provides collection of links to all tips and quirks referred to from various parts of this guide.

#### Tips and Quirks

This section provides collection of all tips and quirks referred to from various parts of this guide.

**Breakpoints and Watchpoints Available** ESP32 debugger supports 2 hardware implemented breakpoints and 64 software ones. Hardware breakpoints are implemented by ESP32 chip’s logic and can be set anywhere in the code: either in flash or IRAM program’s regions. Additionally there are 2 types of software breakpoints implemented by OpenOCD: flash (up to 32) and IRAM (up to 32) breakpoints. Currently GDB can not
set software breakpoints in flash. So until this limitation is removed those breakpoints have to be emulated by OpenOCD as hardware ones (see below for details). ESP32 also supports 2 watchpoints, so 2 variables can be watched for change or read by the GDB command `watch myVariable`. Note that menuconfig option `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` uses the last watchpoint and will not provide expected results, if you also try to use it within OpenOCD/GDB. See menuconfig’s help for detailed description.

**What Else Should I Know About Breakpoints?** Emulating part of hardware breakpoints using software flash ones means that the GDB command `hb myFunction` which is invoked for function in flash will use pure hardware breakpoint if it is available otherwise one of the 32 software flash breakpoints is used. The same rule applies to `b myFunction`-like commands. In this case GDB will decide what type of breakpoint to set itself. If `myFunction` is resided in writable region (IRAM) software IRAM breakpoint will be used otherwise hardware or software flash breakpoint is used as it is done for `hb` command.

**Flash Mappings vs SW Flash Breakpoints** In order to set/clear software breakpoints in flash, OpenOCD needs to know their flash addresses. To accomplish conversion from the ESP32 address space to the flash one, OpenOCD uses mappings of program’s code regions resided in flash. Those mappings are kept in the image header which is prepended to program binary data (code and data segments) and is specific to every application image written to the flash. So to support software flash breakpoints OpenOCD should know where application image under debugging is resided in the flash. By default OpenOCD reads partition table at 0x8000 and uses mappings from the first found application image, but there can be the cases when it will not work, e.g., partition table is not at standard flash location or even there can be multiple images: one factory and two OTA and you may want to debug any of them. To cover all possible debugging scenarios OpenOCD supports special command which can be used to set arbitrary location of application image to debug. The command has the following format:

```bash
esp appimage_offset <offset>
```

Offset should be in hex format. To reset to the default behaviour you can specify `-1` as offset.

**Note:** Since GDB requests memory map from OpenOCD only once when connecting to it, this command should be specified in one of the TCL configuration files, or passed to OpenOCD via its command line. In the latter case command line should look like below:

```bash
openocd -f board/esp32-wrover-kit-3.3v.cfg -c "init; halt; esp appimage_offset_-0x210000"
```

Another option is to execute that command via OpenOCD telnet session and then connect GDB, but it seems to be less handy.

**Why Stepping with “next” Does Not Bypass Subroutine Calls?** When stepping through the code with `next` command, GDB is internally setting a breakpoint ahead in the code to bypass the subroutine calls. If all 2 breakpoints are already set, this functionality will not work. If this is the case, delete breakpoints to have one “spare”. With all breakpoints already used, stepping through the code with `next` command will work as like with `step` command and debugger will step inside subroutine calls.

**Support Options for OpenOCD at Compile Time** ESP-IDF has some support options for OpenOCD debugging which can be set at compile time:

- `CONFIG_ESP_DEBUG_OCD_AWARE` is enabled by default. If a panic or unhandled exception is thrown and a JTAG debugger is connected (ie OpenOCD is running), ESP-IDF will break into the debugger.
- `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` (disabled by default) sets watchpoint index 1 (the second of two) at the end of any task stack. This is the most accurate way to debug task stack overflows. Click the link for more details.

Please see the [project configuration menu](https://docs.espressif.com/espressif-idf/latest/zh/hardware-interfaces/remote-debugging/openocd-and-gdb.html) menu for more details on setting compile-time options.
Chapter 4. API Guides

FreeRTOS Support  OpenOCD has explicit support for the ESP-IDF FreeRTOS. GDB can see FreeRTOS tasks as threads. Viewing them all can be done using the GDB `i threads` command, changing to a certain task is done with `thread n`, with n being the number of the thread. FreeRTOS detection can be disabled in target’s configuration. For more details see Configuration of OpenOCD for Specific Target.

GDB has a Python extension for FreeRTOS support. ESP-IDF automatically loads this module into GDB with the `idf.py gdb` command when the system requirements are met. See more details in Debugging FreeRTOS Objects.

Why to Set SPI Flash Voltage in OpenOCD Configuration?  The MTDI pin of ESP32, being among four pins used for JTAG communication, is also one of ESP32’s bootstrapping pins. On power up ESP32 is sampling binary level on MTDI to set its internal voltage regulator used to supply power to external SPI flash chip. If binary level on MTDI pin on power up is low, the voltage regulator is set to deliver 3.3 V, if it is high, then the voltage is set to 1.8 V. The MTDI pin should have a pull-up or may rely on internal weak pull down resistor (see ESP32 Series Datasheet for details), depending on the type of SPI chip used. Once JTAG is connected, it overrides the pull-up or pull-down resistor that is supposed to do the bootstrapping.

To handle this issue OpenOCD’s board configuration file (e.g. board\esp32-wrover-kit-3.3v.cfg for ESP-WROVER-KIT board) provides `ESP32_FLASH_VOLTAGE` parameter to set the idle state of the TDO line to a specified binary level, therefore reducing the chance of a bad bootup of application due to incorrect flash voltage.

Check specification of ESP32 module connected to JTAG, what is the power supply voltage of SPI flash chip. Then set `ESP32_FLASH_VOLTAGE` accordingly. Most WROOM modules use 3.3 V flash. WROVER earlier than ESP32-WROVER-B use 1.8 V flash, while ESP32-WROVER-B and -E modules use 3.3 V flash.

Optimize JTAG Speed  In order to achieve higher data rates and minimize number of dropped packets it is recommended to optimize setting of JTAG clock frequency, so it is at maximum and still provides stable operation of JTAG. To do so use the following tips.

1. The upper limit of JTAG clock frequency is 20 MHz if CPU runs at 80 MHz, or 26 MHz if CPU runs at 160 MHz or 240 MHz.
2. Depending on particular JTAG adapter and the length of connecting cables, you may need to reduce JTAG frequency below 20 MHz or 26 MHz.
3. In particular reduce frequency, if you get DSR/DIR errors (and they do not relate to OpenOCD trying to read from a memory range without physical memory being present there).
4. ESP-WROVER-KIT operates stable at 20 MHz or 26 MHz.

What Is the Meaning of Debugger’s Startup Commands?  On startup, debugger is issuing sequence of commands to reset the chip and halt it at specific line of code. This sequence (shown below) is user defined to pick up at most convenient/appropriate line and start debugging.

- `set remote hardware-watchpoint-limit 2` — Restrict GDB to using available hardware watchpoints supported by the chip, 2 for ESP32. For more information see https://sourceware.org/gdb/onlinedocs/gdb/Remote-Configuration.html.
- `mon reset halt` — reset the chip and keep the CPUs halted
- `maintenance flush register-cache` — monitor (mon) command can not inform GDB that the target state has changed. GDB will assume that whatever stack the target had before `mon reset halt` will still be valid. In fact, after reset the target state will change, and executing `maintenance flush register-cache` is a way to force GDB to get new state from the target.
- `thb app_main` — Insert a temporary hardware breakpoint at app_main, put here another function name if required
- `c` — resume the program. It will then stop at breakpoint inserted at app_main.

Configuration of OpenOCD for Specific Target  There are several kinds of OpenOCD configuration files (*.cfg). All configuration files are located in subdirectories of `share/openocd/scripts` directory of OpenOCD distribution (`/tcl/scripts` directory of the source repository). For the purposes of this guide, the most important ones are `board`, `interface` and `target`.

Submit Document Feedback
• interface configuration files describe the JTAG adapter. Examples of JTAG adapters are ESP-Prog and J-Link.
• target configuration files describe specific chips, or in some cases, modules.
• board configuration files are provided for development boards with a built-in JTAG adapter. Such files include an interface configuration file to choose the adapter, and target configuration file to choose the chip/module.

The following configuration files are available for ESP32:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>board/esp32-wrover-kit-3.3v.cfg</td>
<td>Board configuration file for ESP-WROVER-KIT with a 3.3 V ESP32-WROOM-32 module or ESP32-WROVER-B / ESP32-WROVER-E module.</td>
</tr>
<tr>
<td>board/esp32-wrover-kit-1.8v.cfg</td>
<td>Board configuration file for ESP-WROVER-KIT with an 1.8 V ESP32-WROVER module.</td>
</tr>
<tr>
<td>board/esp32-ethernet-kit-3v.cfg</td>
<td>Board configuration file for ESP-Ethernet-KIT with a 3.3 V ESP32-WROVER-B / ESP32-WROVER-E module.</td>
</tr>
<tr>
<td>target/esp32.cfg</td>
<td>ESP32 target configuration file. Can be used together with one of the interface/configuration files.</td>
</tr>
<tr>
<td>target/esp32-solo-1.cfg</td>
<td>Target configuration file for ESP32-SOLO-1 module. Different from esp32.cfg in that it only configures one CPU.</td>
</tr>
<tr>
<td>interface/ftdi/esp32_devkitj_v1.cfg</td>
<td>JTAG adapter configuration file for ESP-WROVER-KIT and ESP-Prog boards.</td>
</tr>
</tbody>
</table>

If you are using one of the boards which have a pre-defined configuration file, you only need to pass one `-f` argument to OpenOCD, specifying that file.

If you are using a board not listed here, you need to specify both the interface configuration file and target configuration file.

**Custom Configuration Files** OpenOCD configuration files are written in TCL, and include a variety of choices for customization and scripting. This can be useful for non-standard debugging situations. Please refer to OpenOCD Manual for the TCL scripting reference.

**OpenOCD Configuration Variables** The following variables can be optionally set before including the ESP-specific target configuration file. This can be done either in a custom configuration file, or from the command line.

The syntax for setting a variable in TCL is:

```tcl
set VARIABLE_NAME value
```

To set a variable from the command line (replace the name of .cfg file with the correct file for your board):

```bash
openocd -c 'set VARIABLE_NAME value' -f board/esp-xxxxx-kit.cfg
```

It is important to set the variable before including the ESP-specific configuration file, otherwise the variable will not have effect. You can set multiple variables by repeating the `-c` option.
### Table 27: Common ESP-related OpenOCD variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP_RTOS</td>
<td>Set to <code>none</code> to disable RTOS support. In this case, thread list will not be available in GDB. Can be useful when debugging FreeRTOS itself, and stepping through the scheduler code.</td>
</tr>
<tr>
<td>ESP_FLASH_SIZE</td>
<td>Set to 0 to disable Flash breakpoints support.</td>
</tr>
<tr>
<td>ESP_SEMIHOST_BASED</td>
<td>Set to the path (on the host) which will be the default directory for semihosting functions.</td>
</tr>
</tbody>
</table>

### Table 28: ESP32-specific OpenOCD variables

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP32_FLASH_VOLTAGE</td>
<td>When using 1.8 V flash ESP32 based modules, set this variable to 1.8. Refer to <em>Why to Set SPI Flash Voltage in OpenOCD Configuration?</em>.</td>
</tr>
<tr>
<td>ESP32_ONLYCPU</td>
<td>For multi-core targets, can be set to 1 to only enable single core debugging.</td>
</tr>
</tbody>
</table>

### How Debugger Resets ESP32?

The board can be reset by entering `mon reset` or `mon reset halt` into GDB.

### Can JTAG Pins Be Used for Other Purposes?

Operation of JTAG may be disturbed, if some other hardware is connected to JTAG pins besides ESP32 module and JTAG adapter. ESP32 JTAG is using the following pins:

### Table 29: ESP32 JTAG pins

<table>
<thead>
<tr>
<th>ESP32 Pin</th>
<th>JTAG Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDO / GPIO15</td>
<td>TDO</td>
</tr>
<tr>
<td>MTDI / GPIO12</td>
<td>TDI</td>
</tr>
<tr>
<td>MTCK / GPIO13</td>
<td>TCK</td>
</tr>
<tr>
<td>MTMS / GPIO14</td>
<td>TMS</td>
</tr>
</tbody>
</table>

JTAG communication will likely fail, if configuration of JTAG pins is changed by a user application. If OpenOCD initializes correctly (detects all the CPU cores in the SOC), but loses sync and spews out a lot of DTR/DIR errors when the program is running, it is likely that the application reconfigures the JTAG pins to something else, or the user forgot to connect Vtart to a JTAG adapter that requires it.

Below is an excerpt from series of errors on the dual-core ESP32 reported by GDB after the application stepped into the code that reconfigured MTDO pin to be an input:

```
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates target still busy!
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
   → an exception!
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
   → an overrun!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates target still busy!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
   → an exception!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
   → an overrun!
```

### JTAG with Flash Encryption or Secure Boot

By default, enabling Flash Encryption and/or Secure Boot will disable JTAG debugging. On first boot, the bootloader will burn an eFuse bit to permanently disable JTAG at the same time it enables the other features.

The project configuration option `CONFIG_SECURE_BOOT_ALLOW_JTAG` will keep JTAG enabled at this time, removing all physical security but allowing debugging. (Although the name suggests Secure Boot, this option can be applied even when only Flash Encryption is enabled).
Chapter 4. API Guides

However, OpenOCD may attempt to automatically read and write the flash in order to set software breakpoints. This has two problems:

- Software breakpoints are incompatible with Flash Encryption, OpenOCD currently has no support for encrypting or decrypting flash contents.
- If Secure Boot is enabled, setting a software breakpoint will change the digest of a signed app and make the signature invalid. This means if a software breakpoint is set and then a reset occurs, the signature verification will fail on boot.

To disable software breakpoints while using JTAG, add an extra argument `-c 'set ESP_FLASH_SIZE 0'` to the start of the OpenOCD command line, see OpenOCD Configuration Variables.

Note: For the same reason, the ESP-IDF app may fail bootloader verification of app signatures, when this option is enabled and a software breakpoint is set.

JTAG and ESP32-WROOM-32 AT Firmware Compatibility Issue The ESP32-WROOM series of modules come pre-flashed with AT firmware. This firmware configures the pins GPIO12 to GPIO15 as SPI slave interface, which makes using JTAG impossible.

To make JTAG available, build new firmware that is not using pins GPIO12 to GPIO15 dedicated to JTAG communication. After that, flash the firmware onto your module. See also Can JTAG Pins Be Used for Other Purposes?

Reporting Issues with OpenOCD/GDB In case you encounter a problem with OpenOCD or GDB programs itself and do not find a solution searching available resources on the web, open an issue in the OpenOCD issue tracker under https://github.com/espressif/openocd-esp32/issues.

1. In issue report provide details of your configuration:
   a. JTAG adapter type, and the chip/module being debugged.
   b. Release of ESP-IDF used to compile and load application that is being debugged.
   c. Details of OS used for debugging.
   d. Is OS running natively on a PC or on a virtual machine?

2. Create a simple example that is representative to observed issue. Describe steps how to reproduce it. In such an example debugging should not be affected by non-deterministic behaviour introduced by the Wi-Fi stack, so problems will likely be easier to reproduce, if encountered once.

3. Prepare logs from debugging session by adding additional parameters to start up commands.
   OpenOCD:
   ```
   openocd -l openocd_log.txt -d3 -f board/esp32-wrover-kit-3.3v.cfg
   ```
   Logging to a file this way will prevent information displayed on the terminal. This may be a good thing taken amount of information provided, when increased debug level `-d3` is set. If you still like to see the log on the screen, then use another command instead:
   ```
   openocd -d3 -f board/esp32-wrover-kit-3.3v.cfg 2>&1 | tee openocd.log
   ```
   Debugger:
   ```
   xtensa-esp32-elf-gdb -ex "set remotelogfile gdb_log.txt" <all other options>
   ```
   Optionally add command remotelogfile gdb_log.txt to the gdbinit file.

4. Attach both openocd_log.txt and gdb_log.txt files to your issue report.

Using Debugger

This section covers the steps to configure and run a debugger using various methods, including:
Chapter 4. API Guides

- Eclipse
- Command Line
- `Idf.py` Debug Targets

For how to run a debugger from VS Code, see Configuration for Visual Studio Code Debug.

**Eclipse**

Note: It is recommended to first check if debugger works using `Idf.py` Debug Targets or from Command Line and then move to using Eclipse.

Eclipse is an integrated development environment (IDE) that provides a powerful set of tools for developing and debugging software applications. For ESP-IDF applications, IDF Eclipse plugin provides two ways of debugging:

1. ESP-IDF GDB OpenOCD Debugging
2. GDB Hardware Debugging

By default, Eclipse supports OpenOCD Debugging via the GDB Hardware Debugging plugin, which requires starting the OpenOCD server from the command line and configuring the GDB client from Eclipse to start with the debugging. This approach can be time-consuming and error-prone.

To make the debugging process easier, the IDF Eclipse plugin has a customized ESP-IDF GDB OpenOCD Debugging functionality. This functionality supports configuring the OpenOCD server and GDB client from within Eclipse. All the required configuration parameters will be pre-filled by the plugin, and you can start debugging with just a click of a button.

Therefore, it is recommended to use the ESP-IDF GDB OpenOCD Debugging via the IDF Eclipse plugin.

**GDB Hardware Debugging**

Note: This approach is recommended only if you are unable to debug using ESP-IDF GDB OpenOCD Debugging for some reason.

To install the GDB Hardware Debugging plugin, open Eclipse and select Help > Install New Software.

After installation is complete, follow these steps to configure the debugging session. Please note that some configuration parameters are generic, while others are project-specific. This will be shown below by configuring debugging for “blink” example project. If not done already, add this project to Eclipse workspace following Eclipse Plugin. The source of get-started/blink application is available in examples directory of ESP-IDF repository.

1. In Eclipse, go to Run > Debug Configuration. A new window will open. In the left pane of the window, double-click GDB Hardware Debugging (or select GDB Hardware Debugging and press the New button) to create a new configuration.
2. In a form that will show up on the right, enter the Name: of this configuration, e.g., “Blink checking”.
3. On the Main tab below, under Project: press the Browse button and select the blink project.
4. In the next line under C/C++ Application:, press the Browse button and select the blink.elf file. If blink.elf is not there, it is likely that this project has not been built yet. Refer to the Eclipse Plugin for instructions.
5. Finally, under Build (if required) before launching click Disable auto build. A sample window with settings entered in points 1 - 5 is shown below.
6. Click the Debugger tab. In field GDB Command, enter `xtensa-esp32-elf-gdb` to invoke the debugger.
7. Change the default configuration of the Remote host by entering 3333 under the Port number. Configuration entered in points 6 and 7 is shown on the following picture.
8. The last tab that requires changing the default configuration is Startup. Under Initialization Commands uncheck Reset and Delay (seconds) and Halt. Then, in the entry field below, enter the following lines:

   ```
   mon reset halt
   maintenance flush register-cache
   set remote hardware-watchpoint-limit 2
   ```
Fig. 44: Configuration of GDB Hardware Debugging - Main tab
Fig. 45: Configuration of GDB Hardware Debugging - Debugger tab
**Note:** To automatically update the image in the flash before starting a new debug session, add the following command lines to the beginning of the *Initialization Commands* textbox:

```
mon reset halt
mon program_esp ${workspace_loc:blink/build/blink.bin} 0x10000 verify
```

For description of `program_esp` command, see *Upload Application for Debugging*.

9. Uncheck the *Load image* option under *Load Image and Symbols*.

10. Further down on the same tab, establish an initial breakpoint to halt CPUs after they are reset by debugger. The plugin will set this breakpoint at the beginning of the function entered under *Set break point at*.

Checkout this option and enter `app_main` in provided field.

11. Check out *Resume* option. This will make the program to resume after `mon reset halt` is invoked per point 8. The program will then stop at breakpoint inserted at `app_main`.

Configuration described in points 8 - 11 is shown below.

![Fig. 46: Configuration of GDB Hardware Debugging - Startup tab](image)

If the Startup sequence looks convoluted and respective Initialization Commands are unclear, check *What Is the Meaning of Debugger’s Startup Commands?* for additional explanation.

12. If you have completed the Configuring ESP32 Target steps described above, so the target is running and ready to talk to debugger, go right to debugging by pressing *Debug* button. Otherwise press *Apply* to save changes, go back to Configuring ESP32 Target and return here to start debugging.

Once all configuration steps 1-12 are satisfied, the new Eclipse perspective called “Debug” will open, as shown in the example picture below.
Fig. 47: Debug Perspective in Eclipse
If you are not quite sure how to use GDB, check Eclipse example debugging session in section Debugging Examples.

**Command Line**

1. Begin by completing the steps described under Configuring ESP32 Target. This is prerequisite to start a debugging session.

2. Open a new terminal session and go to the directory that contains the project for debugging, e.g.,

   ```
   cd ~/esp/blink
   ```

3. When launching a debugger, you will need to provide a couple of configuration parameters and commands. Instead of entering them one by one in the command line, create a configuration file and name it `gdbinit`:

   ```
   target remote :3333
   set remote hardware-watchpoint-limit 2
   mon reset halt
   maintenance flush register-cache
   thb app_main
   c
   ```

   Save this file in the current directory.
   
   For more details on what is inside `gdbinit` file, see What Is the Meaning of Debugger’s Startup Commands?

4. Now you are ready to launch GDB. Type the following in terminal:

   ```
   xtensa-esp32-elf-gdb -x gdbinit build/blink.elf
   ```

5. If the previous steps have been done correctly, you will see a similar log concluded with the (gdb) prompt:

   ```
   user-name@computer-name:/esp/blink$ xtensa-esp32-elf-gdb -x gdbinit build/blink.elf
   GNU gdb (crosstool-NG crosstool-ng-1.22.0-61-gab8375a) 7.10

   Hardware assisted breakpoint 1 at 0x400db717: file /home/user-name/esp/blink/main/./blink.c, line 43.
   ```
   (continues on next page)
Note the third-to-last line, which shows debugger halting at breakpoint established in gdbinit file at function app_main(). Since the processor is halted, the LED should not be blinking. If this is what you see as well, you are ready to start debugging.

If you are not sure how to use GDB, check Command Line example debugging session in section Debugging Examples.

**Idf.py Debug Targets**  It is also possible to execute the described debugging tools conveniently from idf.py. These commands are supported:

1. `idf.py openocd`
   Runs OpenOCD in a console with configuration defined in the environment or via command line. It uses default script directory defined as OPENOCD_SCRIPTS environmental variable, which is automatically added from an Export script (export.sh or export.bat). It is possible to override the script location using command line argument --openocd-scripts.
   To configure the JTAG configuration for the current board, please use the environmental variable OPENOCD_COMMANDS or --openocd-commands command line argument. If none of the above is defined, OpenOCD is started with -f board/esp32-wrover-kit-3.3v.cfg board definition.

2. `idf.py gdb`
   Starts the GDB the same way as the Command Line, but generates the initial GDB scripts referring to the current project elf file.

3. `idf.py gdbtui`
   The same as 2, but starts the gdb with tui argument, allowing for a simple source code view.

4. `idf.py gdbgui`
   Starts gdbgui debugger frontend enabling out-of-the-box debugging in a browser window. To enable this option, run the install script with the “--enable-gdbgui” argument, e.g., install.sh --enable-gdbgui. You can combine these debugging actions on a single command line, allowing for convenient setup of blocking and non-blocking actions in one step. idf.py implements a simple logic to move the background actions (such as openocd) to the beginning and the interactive ones (such as gdb, monitor) to the end of the action list. An example of a very useful combination is:

```
idf.py openocd gdbgui monitor
```

The above command runs OpenOCD in the background, starts gdbgui to open a browser window with active debugger frontend and opens a serial monitor in the active console.

**Debugging Examples**

This section describes debugging with GDB from Eclipse as well as from Command Line.
**Eclipse** Verify if your target is ready and loaded with get-started/blink example. Configure and start debugger following steps in section *Eclipse*. Pick up where target was left by debugger, i.e., having the application halted at breakpoint established at `app_main()`.

![Debug Perspective in Eclipse](image)

**Fig. 48: Debug Perspective in Eclipse**

**Examples in This Section**

1. **Navigating Through the Code, Call Stack and Threads**
2. **Setting and Clearing Breakpoints**
3. **Halting the Target Manually**
4. **Stepping Through the Code**
5. **Checking and Setting Memory**
6. **Watching and Setting Program Variables**
7. **Setting Conditional Breakpoints**

**Navigating Through the Code, Call Stack and Threads** When the target is halted, debugger shows the list of threads in “Debug” window. The line of code where program halted is highlighted in another window below, as shown on the following picture. The LED stops blinking.

Specific thread where the program halted is expanded showing the call stack. It represents function calls that lead up to the highlighted line of code, where the target halted. The first line of call stack under Thread #1 contains the last called function `app_main()`, that in turn was called from function `main_task()` shown in a line below. Each line of the stack also contains the file name and line number where the function was called. By clicking/highlighting the stack entries, in window below, you will see contents of this file.

By expanding threads you can navigate throughout the application. Expand Thread #5 that contains much longer call stack. You will see there, besides function calls, numbers like `0x4000000c`. They represent addresses of binary code not provided in source form.
Fig. 49: Target halted during debugging
Fig. 50: Navigate through the call stack
In another window on right, you can see the disassembled machine code no matter if your project provides it in source or only the binary form.

Go back to the `app_main()` in Thread #1 to familiar code of `blink.c` file that will be examined in more details in the following examples. Debugger makes it easy to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

**Setting and Clearing Breakpoints**  
When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers/peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let’s establish two breakpoints when the state of LED changes. Basing on code listing above, this happens at lines 33 and 36. To do so, hold the “Control” on the keyboard and double clink on number 33 in file `blink.c` file. A dialog will open where you can confirm your selection by pressing “OK” button. If you do not like to see the dialog just double click the line number. Set another breakpoint in line 36.

![Setting a breakpoint](image)

**Fig. 51: Setting a breakpoint**

Information how many breakpoints are set and where is shown in window “Breakpoints” on top right. Click “Show Breakpoints Supported by Selected Target” to refresh this list. Besides the two just set breakpoints the list may contain temporary breakpoint at function `app_main()` established at debugger start. As maximum two breakpoints are allowed (see Breakpoints and Watchpoints Available), you need to delete it, or debugging will fail.

If you now click “Resume” (click `blink_task()` under “Tread #8”, if “Resume” button is grayed out), the processor will run and halt at a breakpoint. Clicking “Resume” another time will make it run again, halt on second breakpoint, and so on.

You will be also able to see that LED is changing the state after each click to “Resume” program execution.

Read more about breakpoints under Breakpoints and Watchpoints Available and What Else Should I Know About Breakpoints?
Fig. 52: Three breakpoints are set / maximum two are allowed
Halting the Target Manually  When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any break points defined. In such case, to go back to debugging mode, you can break program execution manually by pressing “Suspend” button.

To check it, delete all breakpoints and click “Resume”. Then click “Suspend”. Application will be halted at some random point and LED will stop blinking. Debugger will expand thread and highlight the line of code where application halted.

In particular case above, the application has been halted in line 52 of code in file freertos_hooks.c. Now you can resume it again by pressing “Resume” button or do some debugging as discussed below.

Stepping Through the Code  It is also possible to step through the code using “Step Into (F5)” and “Step Over (F6)” commands. The difference is that “Step Into (F5)” is entering inside subroutines calls, while “Step Over (F6)” steps over the call, treating it as a single source line.

Before being able to demonstrate this functionality, using information discussed in previous paragraph, make sure that you have only one breakpoint defined at line 36 of blink.c.

Resume program by entering pressing F8 and let it halt. Now press “Step Over (F6)”, one by one couple of times, to see how debugger is stepping one program line at a time.

If you press “Step Into (F5)” instead, then debugger will step inside subroutine calls.

In this particular case debugger stepped inside gpio_set_level(BLINK_GPIO, 0) and effectively moved to gpio.c driver code.

See Why Stepping with “next” Does Not Bypass Subroutine Calls? for potential limitation of using next command.

Checking and Setting Memory  To display or set contents of memory use “Memory” tab at the bottom of “Debug” perspective.
Chapter 4. API Guides

Fig. 54: Stepping through the code with “Step Over (F6)"
Fig. 55: Stepping through the code with “Step Into (F5)”
With the “Memory” tab, we will read from and write to the memory location 0x3FF44004 labeled as GPIO_OUT_REG used to set and clear individual GPIO’s.

For more information, see ESP32 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO_MUX) [PDF].

Being in the same blink.c project as before, set two breakpoints right after gpio_set_level instruction. Click “Memory” tab and then “Add Memory Monitor” button. Enter 0x3FF44004 in provided dialog.

Now resume program by pressing F8 and observe “Monitor” tab.

You should see one bit being flipped over at memory location 0x3FF44004 (and LED changing the state) each time F8 is pressed.

To set memory use the same “Monitor” tab and the same memory location. Type in alternate bit pattern as previously observed. Immediately after pressing enter you will see LED changing the state.

Watching and Setting Program Variables A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file blink.c by adding a declaration of a global variable int i above definition of function blink_task. Then add i++ inside while(1) of this function to get i incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter a breakpoint in the line where you put i++.
In next step, in the window with “Breakpoints”, click the “Expressions” tab. If this tab is not visible, then add it by going to the top menu Window > Show View > Expressions. Then click “Add new expression” and enter i. Resume program execution by pressing F8. Each time the program is halted you will see i value being incremented.

To modify i enter a new number in “Value” column. After pressing “Resume (F8)” the program will keep incrementing i starting from the new entered number.

**Setting Conditional Breakpoints**  Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Right click on the breakpoint to open a context menu and select “Breakpoint Properties”. Change the selection under “Type:” to “Hardware” and enter a “Condition:” like \( i == 2 \).

If current value of \( i \) is less than 2 (change it if required) and program is resumed, it will blink LED in a loop until condition \( i == 2 \) gets true and then finally halt.

**Command Line**  Verify if your target is ready and loaded with get-started/blink example. Configure and start debugger following steps in section **Command Line**. Pick up where target was left by debugger, i.e. having the application halted at breakpoint established at app_main():

```c
Temporary breakpoint i, app_main () at /home/user-name/esp/blink/main/.//blink.c:43
43 xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5, NULL);
```

**Examples in This Section**

1. **Navigating Through the Code, Call Stack and Threads**
Chapter 4. API Guides

Fig. 59: Setting a conditional breakpoint
Chapter 4. API Guides

2. Setting and Clearing Breakpoints
3. Halting and Resuming the Application
4. Stepping Through the Code
5. Checking and Setting Memory
6. Watching and Setting Program Variables
7. Setting Conditional Breakpoints
8. Debugging FreeRTOS Objects

Navigating Through the Code, Call Stack and Threads When you see the (gdb) prompt, the application is halted. LED should not be blinking.

To find out where exactly the code is halted, enter l or list, and debugger will show couple of lines of code around the halt point (line 43 of code in file blink.c)

```c
(gdb) l
38 }
39 }
40
41 void app_main()
42 {
43   xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5,
-> NULL);
44 }
```

Check how code listing works by entering, e.g., l 30, 40 to see particular range of lines of code.

You can use bt or backtrace to see what function calls lead up to this code:

```c
(gdb) bt
#0 app_main () at /home/user-name/esp/blink/main/./blink.c:43
#1 0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/esp32/./cpu_start.c:339
```

Line #0 of output provides the last function call before the application halted, i.e., app_main () we have listed previously. The app_main () was in turn called by function main_task from line 339 of code located in file cpu_start.c.

To get to the context of main_task in file cpu_start.c, enter frame N, where N = 1, because the main_task is listed under #1):

```c
(gdb) frame 1
#1 0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/esp32/./cpu_start.c:339
339   app_main();
```

Enter l and this will reveal the piece of code that called app_main() (in line 339):

```c
(gdb) l
334   }
335 #endif
336 //Enable allocation in region where the startup stacks were located.
337   heap_caps_enable_nonos_stack_heaps();
338   app_main();
339   vTaskDelete(NULL);
340 }
```

Espressif Systems 2673 Release v5.3-dev-277-gc8243465e4
Submit Document Feedback
By listing some lines before, you will see the function name `main_task` we have been looking for:

```c
(gdb) l 326, 341
326 static void main_task(void* args)
327 {
328   // Now that the application is about to start, disable boot watchdogs
329   REG_CLR_BIT(TIMG_WDTCONFIG0_REG(0), TIMG_WDT_FLASHBOOT_MOD_EN_S);
330   REG_CLR_BIT(RTC_CNTL_WDTCONFIG0_REG, RTC_CNTL_WDT_FLASHBOOT_MOD_EN);
331   #if !CONFIG_FREERTOS_UNICORE
332     // Wait for FreeRTOS initialization to finish on APP CPU, before replacing...
333     while (port_xSchedulerRunning[1] == 0) {
334       ;
335     }
336   #endif
337   //Enable allocation in region where the startup stacks were located.
338   heap_caps_enable_nonos_stack_heaps();
339   app_main();
340   vTaskDelete(NULL);
341 }
```

To see the other code, enter `i threads`. This will show the list of threads running on target:

```plaintext
(gdb) i threads
Id Target Id Frame
8 Thread 1073411336 (dport) 0x400d0848 in dport_access_init_core (arg=
   <--optimized out>) at /home/user-name/esp/esp-idf/components/esp32/.dport_access.c:170
7 Thread 1073408744 (ipc0) xQueueGenericReceive (xQueue=0x3ffae694,
   --pvBuffer=0x0, xTicksToWait=1644638200,
   xJustPeeking=0) at /home/user-name/esp/esp-idf/components/freertos/.queue.
   --c:1452
6 Thread 1073431096 (Tmr Svc) prvTimerTask (pvParameters=0x0) at /home/user-name/esp/esp-idf/components/freertos/.timers.c:445
5 Thread 1073410208 (ipc1 : Running) 0x4000bfea in ?? ()
4 Thread 1073432224 (dport) dport_access_init_core (arg=0x0) at /home/user-name/esp/esp-idf/components/esp32/.dport_access.c:150
3 Thread 1073415156 (IDLE) prvIdleTask (pvParameters=0x0) at /home/user-name/esp/esp-idf/components/freertos/.tasks.c:3282
2 Thread 1073415312 (IDLE) prvIdleTask (pvParameters=0x0) at /home/user-name/esp/esp-idf/components/freertos/.tasks.c:3282
* 1 Thread 1073411772 (main : Running) app_main () at /home/user-name/esp/blink/
   --main/.blink.c:43
```

The thread list shows the last function calls per each thread together with the name of C source file if available.

You can navigate to specific thread by entering `thread N`, where N is the thread Id. To see how it works go to thread thread 5:

```plaintext
(gdb) thread 5
[Switching to thread 5 (Thread 1073410208)]
#0 0x4000bfea in ?? ()
```

Then check the backtrace:

```plaintext
(gdb) bt
#0 0x4000bfea in ?? ()
#1 0x40083a85 in vPortCPUReleaseMutex (mux=<optimized out>) at /home/user-name/
   --esp-idf/components/freertos/.port.c:415
#2 0x40083fc8 in vTaskSwitchContext () at /home/user-name/esp-idf/components/
   --freertos/.tasks.c:1240
```

(continues on next page)
As you see, the backtrace may contain several entries. This will let you check what exact sequence of function calls lead to the code where the target halted. Question marks ?? instead of a function name indicate that application is available only in binary format, without any source file in C language. The value like 0x4000bfea is the memory address of the function call.

Using `bt`, `threads`, `thread N` and `list` commands we are now able to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

### Setting and Clearing Breakpoints

When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers/peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let’s establish two breakpoints when the state of LED changes. Basing on code listing above this happens at lines 33 and 36. Breakpoints may be established using command `break M` where M is the code line number:

```
(gdb) break 33
Breakpoint 2 at 0x400db6f6: file /home/user-name/esp/blink/main/./blink.c, line 33.
(gdb) break 36
Breakpoint 3 at 0x400db704: file /home/user-name/esp/blink/main/./blink.c, line 36.
```

If you new enter `c`, the processor will run and halt at a breakpoint. Entering `c` another time will make it run again, halt on second breakpoint, and so on:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F6 (active) APP_CPU: PC=0x400D10D8
Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./blink.c:33
    gpio_set_level(BLINK_GPIO, 0);
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F8 (active) APP_CPU: PC=0x400D10D8
Target halted. PRO_CPU: PC=0x400DB704 (active) APP_CPU: PC=0x400D10D8
Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./blink.c:36
    gpio_set_level(BLINK_GPIO, 1);
(gdb)
```

You will be also able to see that LED is changing the state only if you resume program execution by entering `c`.

To examine how many breakpoints are set and where, use command `info break`:

```
(gdb) info break
Num  Type        Disp Enb Address   What
2    breakpoint  keep y 0x400db6f6 in blink_task at /home/user-name/esp/blink/main/./blink.c:33
3    breakpoint  keep y 0x400db704 in blink_task at /home/user-name/esp/blink/main/./blink.c:36
```

(continues on next page)
Please note that breakpoint numbers (listed under **Num**) start with 2. This is because first breakpoint has been already established at function `app_main()` by running command `thb app_main` on debugger launch. As it was a temporary breakpoint, it has been automatically deleted and now is not listed anymore.

To remove breakpoints enter `delete N` command (in short `d N`), where `N` is the breakpoint number:

<table>
<thead>
<tr>
<th>(gdb) delete 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>No breakpoint number 1.</td>
</tr>
<tr>
<td>(gdb) delete 2</td>
</tr>
<tr>
<td>(gdb)</td>
</tr>
</tbody>
</table>

Read more about breakpoints under **Breakpoints and Watchpoints Available** and **What Else Should I Know About Breakpoints?**

**Halting and Resuming the Application** When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any breakpoints defined. In such case, to go back to debugging mode, you can break program execution manually by entering Ctrl+C.

To check it delete all breakpoints and enter `c` to resume application. Then enter Ctrl+C. Application will be halted at some random point and LED will stop blinking. Debugger will print the following:

<table>
<thead>
<tr>
<th>(gdb) c</th>
</tr>
</thead>
<tbody>
<tr>
<td>Continuing.</td>
</tr>
<tr>
<td>^CTarget halted. PRO_CPU: PC=0x400D0C00 APP_CPU: PC=0x400D0C00 (active)</td>
</tr>
<tr>
<td>[New Thread 1073433352]</td>
</tr>
<tr>
<td>Program received signal SIGINT, Interrupt.</td>
</tr>
<tr>
<td>[Switching to Thread 1073413512]</td>
</tr>
<tr>
<td>0x400d0c00 in esp_vApplicationIdleHook () at /home/user-name/esp/esp-idf/ →components/es32/.freertos_hooks.c:52</td>
</tr>
<tr>
<td>52 asm(&quot;waiti 0&quot;);</td>
</tr>
<tr>
<td>(gdb)</td>
</tr>
</tbody>
</table>

In particular case above, the application has been halted in line 52 of code in file `freertos_hooks.c`. Now you can resume it again by enter `c` or do some debugging as discussed below.

**Stepping Through the Code** It is also possible to step through the code using `step` and `next` commands (in short `s` and `n`). The difference is that `step` is entering inside subroutines calls, while `next` steps over the call, treating it as a single source line.

To demonstrate this functionality, using command `break` and `delete` discussed in previous paragraph, make sure that you have only one breakpoint defined at line 36 of `blink.c`:

<table>
<thead>
<tr>
<th>(gdb) info break</th>
</tr>
</thead>
<tbody>
<tr>
<td>Num</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>(gdb)</td>
</tr>
</tbody>
</table>

Resume program by entering `c` and let it halt:

<table>
<thead>
<tr>
<th>(gdb) c</th>
</tr>
</thead>
<tbody>
<tr>
<td>Continuing.</td>
</tr>
<tr>
<td>Target halted. PRO_CPU: PC=0x400DB754 (active) APP_CPU: PC=0x400D1128</td>
</tr>
</tbody>
</table>

(continues on next page)
### Chapter 4. API Guides

(continued from previous page)

```c
36  gpio_set_level(BLINK_GPIO, 1);
```

(gdb)

Then enter `n` couple of times to see how debugger is stepping one program line at a time:

```c
37  vTaskDelay(1000 / portTICK_PERIOD_MS);
```

(gdb)

```c
33  gpio_set_level(BLINK_GPIO, 0);
```

(gdb)

If you enter `s` instead, then debugger will step inside subroutine calls:

```c
33  gpio_set_level (gpio_num=GPIO_NUM_4, level=0) at /home/user-name/esp/esp-idf/components/esp_driver_gpio/src/gpio.c:183
```

(gdb)

In this particular case debugger stepped inside `gpio_set_level(BLINK_GPIO, 0)` and effectively moved to `gpio.c` driver code.

See **Why Stepping with “next” Does Not Bypass Subroutine Calls?** for potential limitation of using `next` command.

### Checking and Setting Memory

Displaying the contents of memory is done with command `x`. With additional parameters you may vary the format and count of memory locations displayed. Run `help x` to see more details. Companion command to `x` is set that let you write values to the memory.

We will demonstrate how `x` and set work by reading from and writing to the memory location 0x3FF44004 labeled as GPIO_OUT_REG used to set and clear individual GPIO's.

For more information, see **ESP32 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO_MUX) [PDF]**.

Being in the same `blink.c` project as before, set two breakpoints right after `gpio_set_level` instruction. Enter two times `c` to get to the break point followed by `x /1wx 0x3FF44004` to display contents of GPIO_OUT_REG memory location:

```c
34  vTaskDelay(1000 / portTICK_PERIOD_MS);
```

(gdb) c

Continuing.

```c
34  vTaskDelay(1000 / portTICK_PERIOD_MS);
```

(gdb) x /1wx 0x3FF44004

(continues on next page)
If your are blinking LED connected to GPIO4, then you should see fourth bit being flipped each time the LED changes the state:

```
0x3ff44004: 0x00000000
...
0x3ff44004: 0x00000010
```

Now, when the LED is off, that corresponds to 0x3ff44004: 0x00000000 being displayed, try using `set` command to set this bit by writing 0x00000010 to the same memory location:

```
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000000
(gdb) set {unsigned int}0x3FF44004=0x000010
```

You should see the LED to turn on immediately after entering `set {unsigned int}0x3FF44004=0x000010` command.

**Watching and Setting Program Variables**  
A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file `blink.c` by adding a declaration of a global variable `int i` above definition of function `blink_task`. Then add `i++` inside `while(1)` of this function to get `i` incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter the command `watch i`:

```
(gdb) watch i
Hardware watchpoint 2: i
(gdb)
```

This will insert so called “watchpoint” in each place of code where variable `i` is being modified. Now enter `continue` to resume the application and observe it being halted:

```
(gdb) c
Continuing.
```

Resume application couple more times so `i` gets incremented. Now you can enter `print i` (in short `p i`) to check the current value of `i`:
(gdb) p i
$1 = 3
(gdb)

To modify the value of i use set command as below (you can then print it out to check if it has been indeed changed):

(gdb) set var i = 0
(gdb) p i
$3 = 0
(gdb)

You may have up to two watchpoints, see Breakpoints and Watchpoints Available.

**Setting Conditional Breakpoints**  Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Delete existing breakpoints and try this:

(gdb) break blink.c:34 if (i == 2)
Breakpoint 3 at 0x400db753: file /home/user-name/esp/blink/main/.//blink.c, line 34.
(gdb)

Above command sets conditional breakpoint to halt program execution in line 34 of blink.c if i == 2.

If current value of i is less than 2 and program is resumed, it will blink LED in a loop until condition i == 2 gets true and then finally halt:

(gdb) set var i = 0
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB755 (active)  APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB755 (active)  APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB755 (active)  APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB755 (active)  APP_CPU: PC=0x400D112C
Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/.//blink.c:34
34 gpio_set_level(BLINK_GPIO, 0);
(gdb)

**Debugging FreeRTOS Objects**  This part might be interesting when you are debugging FreeRTOS tasks interactions.

Users that need to use the FreeRTOS task interactions can use the GDB freertos command. The freertos command is not native to GDB and comes from the freertos-gdb Python extension module. The freertos command contains a series of sub-commands as demonstrated in the code snippet:

(gdb) freertos
"freertos" must be followed by the name of a subcommand.
List of freertos subcommands:
freertos queue -- Generate a print out of the current queues info.
freertos semaphore -- Generate a print out of the current semaphores info.
freertos task -- Generate a print out of the current tasks and their states.
freertos timer -- Generate a print out of the current timers info.

For a more detailed description of this extension, please refer to https://pypi.org/project/freertos-gdb.

**Note:** The freertos-gdb Python module is included as a Python package requirement by ESP-IDF, thus should be automatically installed (see Step 3. Set up the Tools for more details).
Chapter 4. API Guides

The FreeRTOS extension automatically loads in case GDB is executed with command via `idf.py gdb`. Otherwise, the module could be enabled via the `python import freertos_gdb` command inside GDB. Users only need to have Python 3.6 (or above) that contains a Python shared library.

**Obtaining Help on Commands** Commands presented so far should provide are very basis and intended to let you quickly get started with JTAG debugging. Check help what are the other commands at your disposal. To obtain help on syntax and functionality of particular command, being at `(gdb)` prompt type `help` and command name:

```plaintext
(gdb) help next
Step program, proceeding through subroutine calls.
Usage: next [N]
Unlike "step", if the current source line calls a subroutine,
this command does not enter the subroutine, but instead steps over
the call, in effect treating it as a single source line.
(gdb)
```

By typing just `help`, you will get top level list of command classes, to aid you drilling down to more details. Optionally refer to available GDB cheat sheets, for instance [https://darkdust.net/files/GDB%20Cheat%20Sheet.pdf](https://darkdust.net/files/GDB%20Cheat%20Sheet.pdf). Good to have as a reference (even if not all commands are applicable in an embedded environment).

**Ending Debugger Session** To quit debugger enter `q`:

```plaintext
(gdb) q
A debugging session is active.
Inferior 1 [Remote target] will be detached.
Quit anyway? (y or n) y
Detaching from program: /home/user-name/esp/blink/build/blink.elf, Remote target
Ending remote debugging.
user-name@computer-name:~/esp/blink$
```

## 4.20 Linker Script Generation

### 4.20.1 Overview

There are several *memory regions* where code and data can be placed. Code and read-only data are placed by default in flash, writable data in RAM, etc. However, it is sometimes necessary to change these default placements.

For example, it may be necessary to place:

- critical code in RAM for performance reasons.
- executable code in IRAM so that it can be ran while cache is disabled.
- code in RTC memory for use in a wake stub.
- code in RTC memory for use by the ULP coprocessor.
With the linker script generation mechanism, it is possible to specify these placements at the component level within ESP-IDF. The component presents information on how it would like to place its symbols, objects or the entire archive. During build, the information presented by the components are collected, parsed and processed; and the placement rules generated is used to link the app.

### 4.20.2 Quick Start

This section presents a guide for quickly placing code/data to RAM and RTC memory - placements ESP-IDF provides out-of-the-box.

For this guide, suppose we have the following:

```plaintext
components
    └── my_component
        ├── CMakeLists.txt
        ├── Kconfig
        │    └── my_src1.c
        │    └── my_src2.c
        │    └── my_src3.c
        └── my_linker_fragment_file.lf
```

- a component named `my_component` that is archived as library `libmy_component.a` during build
- three source files archived under the library, `my_src1.c`, `my_src2.c`, and `my_src3.c` which are compiled as `my_src1.o`, `my_src2.o` and `my_src3.o`, respectively
- under `my_src1.o`, the function `my_function1` is defined; under `my_src2.o`, the function `my_function2` is defined
- there is bool-type config `PERFORMANCE_MODE` (y/n) and int type config `PERFORMANCE_LEVEL` (with range 0-3) in `my_component`’s Kconfig

#### Creating and Specifying a Linker Fragment File

Before anything else, a linker fragment file needs to be created. A linker fragment file is simply a text file with a `.lf` extension upon which the desired placements will be written. After creating the file, it is then necessary to present it to the build system. The instructions for the build systems supported by ESP-IDF are as follows:

In the component’s `CMakeLists.txt` file, specify argument `LDFFRAGMENTS` in the `idf_component_register` call. The value of `LDFFRAGMENTS` can either be an absolute path or a relative path from the component directory to the created linker fragment file.

```plaintext
# file paths relative to CMakeLists.txt
idf_component_register(...
    LDFFRAGMENTS "path/to/linker_fragment_file.lf" "path/to/
    → another_linker_fragment_file.lf"
    ...
)
```

#### Specifying Placements

It is possible to specify placements at the following levels of granularity:

- object file (.obj or .o files)
- symbol (function/variable)
- archive (.a files)
**Placing Object Files**  Suppose the entirety of `my_src1.o` is performance-critical, so it is desirable to place it in RAM. On the other hand, the entirety of `my_src2.o` contains symbols needed coming out of deep sleep, so it needs to be put under RTC memory.

In the linker fragment file, we can write:

```makefile
[mapping:my_component]
archive: libmy_component.a
entries:
  my_src1 (noflash) # places all my_src1 code/read-only data under IRAM/DRAM
  my_src2 (rtc)    # places all my_src2 code/ data and read-only data under...
→ RTC fast memory/RTC slow memory
```

What happens to `my_src3.o`? Since it is not specified, default placements are used for `my_src3.o`. More on default placements [here](#).

**Placing Symbols**  Continuing our example, suppose that among functions defined under `object1.o`, only `my_function1` is performance-critical; and under `object2.o`, only `my_function2` needs to execute after the chip comes out of deep sleep. This could be accomplished by writing:

```makefile
[mapping:my_component]
archive: libmy_component.a
entries:
  my_src1:my_function1 (noflash)
  my_src2:my_function2 (rtc)
```

The default placements are used for the rest of the functions in `my_src1.o` and `my_src2.o` and the entire `object3.o`. Something similar can be achieved for placing data by writing the variable name instead of the function name, like so:

```makefile
my_src1:my_variable (noflash)
```

**Warning:** There are [limitations](#) in placing code/data at symbol granularity. In order to ensure proper placements, an alternative would be to group relevant code and data into source files, and use [object-granularity placements](#).

**Placing Entire Archive**  In this example, suppose that the entire component archive needs to be placed in RAM. This can be written as:

```makefile
[mapping:my_component]
archive: libmy_component.a
entries:
  * (noflash)
```

Similarly, this places the entire component in RTC memory:

```makefile
[mapping:my_component]
archive: libmy_component.a
entries:
  * (rtc)
```

**Configuration-Dependent Placements**  Suppose that the entire component library should only have special placement when a certain condition is true; for example, when `CONFIG_PERFORMANCE_MODE == y`. This could be written as:

```makefile
[mapping:my_component]
archive: libmy_component.a
```
entries:

if PERFORMANCE_MODE = y:
  * (noflash)
else:
  * (default)

For a more complex config-dependent placement, suppose the following requirements: when CONFIG_PERFORMANCE_LEVEL == 1, only object1.o is put in RAM; when CONFIG_PERFORMANCE_LEVEL == 2, object1.o and object2.o; and when CONFIG_PERFORMANCE_LEVEL == 3 all object files under the archive are to be put into RAM. When these three are false however, put entire library in RTC memory. This scenario is a bit contrived, but, it can be written as:

[mapping:my_component]
archive: libmy_component.a
entries:

if PERFORMANCE_LEVEL = 1:
  my_src1 (noflash)
elif PERFORMANCE_LEVEL = 2:
  my_src1 (noflash)
  my_src2 (noflash)
elif PERFORMANCE_LEVEL = 3:
  my_src1 (noflash)
  my_src2 (noflash)
  my_src3 (noflash)
else:
  * (rtc)

Nesting condition-checking is also possible. The following is equivalent to the snippet above:

[mapping:my_component]
archive: libmy_component.a
entries:

if PERFORMANCE_LEVEL <= 3 && PERFORMANCE_LEVEL > 0:
  if PERFORMANCE_LEVEL >= 1:
    object1 (noflash)
  if PERFORMANCE_LEVEL >= 2:
    object2 (noflash)
  if PERFORMANCE_LEVEL >= 3:
    object2 (noflash)
else:
  * (rtc)

The ‘default’ Placements

Up until this point, the term ‘default placements’ has been mentioned as fallback placements when the placement rules rtc and noflash are not specified. It is important to note that the tokens noflash or rtc are not merely keywords, but are actually entities called fragments, specifically schemes.

In the same manner as rtc and noflash are schemes, there exists a default scheme which defines what the default placement rules should be. As the name suggests, it is where code and data are usually placed, i.e., code/constants is placed in flash, variables placed in RAM, etc. More on the default scheme here.

---

Note: For an example of an ESP-IDF component using the linker script generation mechanism, see freertos/CMakeLists.txt. freertos uses this to place its object files to the instruction RAM for performance reasons.

This marks the end of the quick start guide. The following text discusses the internals of the mechanism in a little bit more detail. The following sections should be helpful in creating custom placements or modifying default behavior.
4.20.3 Linker Script Generation Internals

Linking is the last step in the process of turning C/C++ source files into an executable. It is performed by the toolchain’s linker, and accepts linker scripts which specify code/data placements, among other things. With the linker script generation mechanism, this process is no different, except that the linker script passed to the linker is dynamically generated from: (1) the collected linker fragment files and (2) linker script template.

Note: The tool that implements the linker script generation mechanism lives under tools/ldgen.

Linker Fragment Files

As mentioned in the quick start guide, fragment files are simple text files with the .lf extension containing the desired placements. This is a simplified description of what fragment files actually contain are ‘fragments’. Fragments are entities which contain pieces of information which, when put together, form placement rules that tell where to place sections of object files in the output binary. There are three types of fragments: sections, scheme and mapping.

Grammar The three fragment types share a common grammar:

```
[type:name]
key: value
dump value
value
value
...
```

- type: Corresponds to the fragment type, can either be sections, scheme or mapping.
- name: The name of the fragment, should be unique for the specified fragment type.
- key, value: Contents of the fragment; each fragment type may support different keys and different grammars for the key values.
  - For sections and scheme, the only supported key is entries
  - For mappings, both archive and entries are supported.

Note: In cases where multiple fragments of the same type and name are encountered, an exception is thrown.

Note: The only valid characters for fragment names and keys are alphanumeric characters and underscore.

Condition Checking

Condition checking enable the linker script generation to be configuration-aware. Depending on whether expressions involving configuration values are true or not, a particular set of values for a key can be used. The evaluation uses eval_string from kconfiglib package and adheres to its required syntax and limitations. Supported operators are as follows:

- comparison
  - LessThan <
  - LessThanOrEqualTo <=
  - MoreThan >
  - MoreThanOrEqualTo >=
  - Equal =
  - NotEqual !=
- logical
  - Or ||
– And &&
– Negation !

• grouping
  – Parenthesis ()

Condition checking behaves as you would expect an if...elseif/elif...else block in other languages. Condition-checking is possible for both key values and entire fragments. The two sample fragments below are equivalent:

```plaintext
# Value for keys is dependent on config
[type:name]
key_1:
  if CONDITION = y:
    value_1
  else:
    value_2
key_2:
  if CONDITION = y:
    value_a
  else:
    value_b

# Entire fragment definition is dependent on config
if CONDITION = y:
  [type:name]
  key_1:
    value_1
  key_2:
    value_a
else:
  [type:name]
  key_1:
    value_2
  key_2:
    value_b
```

Comments

Comment in linker fragment files begin with #. Like in other languages, comment are used to provide helpful descriptions and documentation and are ignored during processing.

Types  Sections

Sections fragments defines a list of object file sections that the GCC compiler emits. It may be a default section (e.g., .text, .data) or it may be user defined section through the __attribute__ keyword.

The use of an optional ‘+’ indicates the inclusion of the section in the list, as well as sections that start with it. This is the preferred method over listing both explicitly.

```plaintext
[sections:name]
entries:
  .section+
  .section
  ...
```

Example:

```plaintext
# Non-preferred
[sections:text]
entries:
  .text
  .text.*
```

(continues on next page)
Scheme

Scheme fragments define what target a sections fragment is assigned to.

```
[scheme:name]
entries:
  sections -> target
  sections -> target
  ...
```

Example:

```
[scheme:noflash]
entries:
  text -> iram0_text  # the entries under the sections fragment named...
  --text will go to iram0_text
  rodata -> dram0_data  # the entries under the sections fragment named...
  --rodata will go to dram0_data
```

The default scheme

There exists a special scheme with the name default. This scheme is special because catch-all placement rules are generated from its entries. This means that, if one of its entries is `text -> flash_text`, the placement rule will be generated for the target `flash_text`.

```
*(.literal .literal.* .text .text.*)
```

These catch-all rules then effectively serve as fallback rules for those whose mappings were not specified.

The default scheme is defined in `esp_system/app.lf`. The noflash and rtc scheme fragments which are built-in schemes referenced in the quickstart guide are also defined in this file.

Mapping

Mapping fragments define what scheme fragment to use for mappable entities, i.e., object files, function names, variable names, archives.

```
[mapping:name]
archive: archive  # output archive file name, as built (i.e., libxxx.
  --a)
entries:
  object:symbol {scheme}  # symbol granularity
  object {scheme}  # object granularity
  * {scheme}  # archive granularity
```

There are three levels of placement granularity:

- symbol: The object file name and symbol name are specified. The symbol name can be a function name or a variable name.
- object: Only the object file name is specified.
- archive: * is specified, which is a short-hand for all the object files under the archive.

To know what an entry means, let us expand a sample object-granularity placement:
Then expanding the scheme fragment from its entries definitions, we have:

```plaintext
object (scheme)
```

Expanding the sections fragment with its entries definition:

```plaintext
object (.section, # given this object file
 .section, # put its sections listed here at this
 ... -> target, # target
   .section,
   .section, # same should be done for these sections
 ... -> target,
 ...
 ...) # and so on
```

Example:

```plaintext
[mapping:map]
archive: libfreertos.a
entries:
  * (noflash)
```

Aside from the entity and scheme, flags can also be specified in an entry. The following flags are supported (note: <> = argument name, [] = optional):

1. **ALIGN(<alignment>[, pre, post])**
   - Align the placement by the amount specified in alignment. Generates

2. **SORT([<sort_by_first>,<sort_by_second>])**
   - Emits SORT_BY_NAME, SORT_BY_ALIGNMENT, SORT_BY_INIT_PRIORITY or SORT in the input section description.
   - Possible values for sort_by_first and sort_by_second are: name, alignment, init_priority.
   - If both sort_by_first and sort_by_second are not specified, the input sections are sorted by name. If both are specified, then the nested sorting follows the same rules discussed in [https://sourceware.org/binutils/docs/ld/Input-Section-Wildcards.html](https://sourceware.org/binutils/docs/ld/Input-Section-Wildcards.html).

3. **KEEP()**
   - Prevent the linker from discarding the placement by surrounding the input section description with KEEP command. See [https://sourceware.org/binutils/docs/ld/Input-Section-Keep.html](https://sourceware.org/binutils/docs/ld/Input-Section-Keep.html) for more details.

4. **SURROUND(<name>)**
   - Generate symbols before and after the placement. The generated symbols follow the naming _<name>_start and _<name>_end. For example, if name == sym1,

When adding flags, the specific section -> target in the scheme needs to be specified. For multiple section -> target, use a comma as a separator. For example,

```plaintext
# Notes:
# A. semicolon after entity-scheme
# B. comma before section2 -> target2
# C. section1 -> target1 and section2 -> target2 should be defined in entries of _
  \-scheme1
entity1 (scheme1);
    section1 -> target1 KEEP() ALIGN(4, pre, post),
    section2 -> target2 SURROUND(sym) ALIGN(4, post) SORT()
```
Putting it all together, the following mapping fragment, for example,

```
[mapping:name]
archive: lib1.a
entries:
  obj1 (noflash);
    rodata -> dram0_data KEEP() SORT() ALIGN(8) SURROUND(my_sym)
```

generates an output on the linker script:

```
. = ALIGN(8)
_my_sym_start = ABSOLUTE(.)
KEEP(lib1.a:obj1.*{ SORT(.rodata) SORT(.rodata.*) })
_my_sym_end = ABSOLUTE(.)
```

Note that ALIGN and SURROUND, as mentioned in the flag descriptions, are order sensitive. Therefore, if for the same mapping fragment these two are switched, the following is generated instead:

```
_my_sym_start = ABSOLUTE(.)
. = ALIGN(8)
KEEP(lib1.a:obj1.*{ SORT(.rodata) SORT(.rodata.*) })
_my_sym_end = ABSOLUTE(.)
```

On Symbol-Granularity Placements  Symbol granularity placements is possible due to compiler flags `-ffunction-sections` and `-fdata-sections`. ESP-IDF compiles with these flags by default. If the user opts to remove these flags, then the symbol-granularity placements will not work. Furthermore, even with the presence of these flags, there are still other limitations to keep in mind due to the dependence on the compiler’s emitted output sections.

For example, with `-ffunction-sections`, separate sections are emitted for each function; with section names predictably constructed i.e., `.text.{func_name}` and `.literal.{func_name}`. This is not the case for string literals within the function, as they go to pooled or generated section names.

With `-fdata-sections`, for global scope data the compiler predictably emits either `.data.{var_name}`, `.rodata.{var_name}` or `.bss.{var_name}`; and so Type I mapping entry works for these. However, this is not the case for static data declared in function scope, as the generated section name is a result of mangling the variable name with some other information.

Linker Script Template

The linker script template is the skeleton in which the generated placement rules are put into. It is an otherwise ordinary linker script, with a specific marker syntax that indicates where the generated placement rules are placed.

To reference the placement rules collected under a `target` token, the following syntax is used:

```
mapping[target]
```

Example:

The example below is an excerpt from a possible linker script template. It defines an output section `.iram0.text`, and inside is a marker referencing the target `iram0_text`.

```
.iram0.text :
{
  /* Code marked as running out of IRAM */
  _iram_text_start = ABSOLUTE(.);

  /* Marker referencing iram0_text */
  mapping[iram0_text]
```

(continues on next page)
Suppose the generator collected the fragment definitions below:

```plaintext
[sections:text]
 .text+
 .literal+
[sections:iram]
 .iram1+
[scheme:default]
 entries:
  text -> flash_text
  iram -> iram0_text
[scheme:noflash]
 entries:
  text -> iram0_text
[mapping:freertos]
 archive: libfreertos.a
 entries:
  * (noflash)
```

Then the corresponding excerpt from the generated linker script will be as follows:

```plaintext
.iram0.text :
{
  /* Code marked as running out of IRAM */
  _iram_text_start = ABSOLUTE(.);

  /* Placement rules generated from the processed fragments, placed where the-
   -marker was in the template */
  "libfreertos.a:(.literal .text .literal.* .text.*)"
  _iram_text_end = ABSOLUTE(.);
} > iram0_0_seg

*libfreertos.a:(.literal .text .literal.* .text.*)

  Rule generated from the entry * (noflash) of the freertos mapping fragment. All text sections
  of all object files under the archive libfreertos.a will be collected under the target iram0_text
  (as per the noflash scheme) and placed wherever in the template iram0_text is referenced by a
  marker.

*.(iram1 .iram1.*)

  Rule generated from the default scheme entry iram -> iram0_text. Since the default scheme
  specifies an iram -> iram0_text entry, it too is placed wherever iram0_text is referenced
  by a marker. Since it is a rule generated from the default scheme, it comes first among all
  other rules collected under the same target name.

The linker script template currently used is esp_system/ld/esp32/sections.ld.in; the generated output
script sections.ld is put under its build directory.
Chapter 4. API Guides

Migrate to ESP-IDF v5.0 Linker Script Fragment Files Grammar

The old grammar supported in ESP-IDF v3.x would be dropped in ESP-IDF v5.0. Here are a few notes on how to migrate properly:

1. Now indentation is enforced and improperly indented fragment files would generate a runtime parse exception. This was not enforced in the old version but previous documentation and examples demonstrate properly indented grammar.
2. Migrate the old condition entry to the `if...elif...else` structure for conditionals. You can refer to the earlier chapter for detailed grammar.
3. Mapping fragments now requires a name like other fragment types.

4.21 lwIP

ESP-IDF uses the open source lwIP lightweight TCP/IP stack. The ESP-IDF version of lwIP (esp-lwip) has some modifications and additions compared to the upstream project.

4.21.1 Supported APIs

ESP-IDF supports the following lwIP TCP/IP stack functions:

- **BSD Sockets API**
- **Netconn API** is enabled but not officially supported for ESP-IDF applications

Adapted APIs

**Warning:** When using any lwIP API other than the **BSD Sockets API**, please make sure that the API is thread-safe. To check if a given API call is thread-safe, enable the `CONFIG_LWIP_CHECK_THREAD_SAFETY` configuration option and run the application. This enables lwIP to assert the correct access of the TCP/IP core functionality. If the API is not accessed or locked properly from the appropriate lwIP FreeRTOS Task, the execution will be aborted. The general recommendation is to use the **ESP-NETIF** component to interact with lwIP.

Some common lwIP app APIs are supported indirectly by ESP-IDF:

- Dynamic Host Configuration Protocol (DHCP) Server & Client are supported indirectly via the **ESP-NETIF** functionality.
- Simple Network Time Protocol (SNTP) is also supported via the **ESP-NETIF**, or directly via the `lwip/include/apps/esp_snntp.h` functions, which also provide thread-safe API to `lwip/lwip/src/include/lwip/apps/snntp.h` functions, see also **SNTP Time Synchronization**.
- ICMP Ping is supported using a variation on the lwIP ping API, see **ICMP Echo**.
- ICMPv6 Ping, supported by lwIP's ICMPv6 Echo API, is used to test IPv6 network connectivity. For more information, see **protocols/sockets/lwip/icmpv6.h**.
- NetBIOS lookup is available using the standard lwIP API, `protocols/http_server/restful_server.h` has the option to demonstrate using NetBIOS to look up a host on the LAN.
- mDNS uses a different implementation to the lwIP default mDNS, see **mDNS Service**. But lwIP can look up mDNS hosts using standard APIs such as `gethostbyname()` and the convention `hostname.local`, provided the `CONFIG_LWIP_DNS_SUPPORT_MDNS_QUERIES` setting is enabled.
- The PPP implementation in lwIP can be used to create PPPoS (PPP over serial) interface in ESP-IDF. Please refer to the documentation of the **ESP-NETIF** component to create and configure a PPP network interface, by means of the `ESP_NETIF_DEFAULT_PPP()` macro defined in `esp_netif/include/esp_netif_ppp.h`. Additional runtime settings are provided via `esp_netif/include/esp_netif_ppp.h`. PPPoS interfaces are typically
used to interact with NBloT/GSM/LTE modems. More application-level friendly API is supported by the esp_modem library, which uses this PPP lwIP module behind the scenes.

### 4.21.2 BSD Sockets API

The BSD Sockets API is a common cross-platform TCP/IP sockets API that originated in the Berkeley Standard Distribution of UNIX but is now standardized in a section of the POSIX specification. BSD Sockets are sometimes called POSIX Sockets or Berkeley Sockets.

As implemented in ESP-IDF, lwIP supports all of the common usages of the BSD Sockets API.

**References**

A wide range of BSD Sockets reference materials are available, including:

- Single UNIX Specification - BSD Sockets page
- Berkeley Sockets - Wikipedia page

**Examples**

A number of ESP-IDF examples show how to use the BSD Sockets APIs:

- protocols/sockets/tcp_server
- protocols/sockets/tcp_client
- protocols/sockets/udp_server
- protocols/sockets/udp_client
- protocols/sockets/udp_multicast
- protocols/http_request: this simplified example uses a TCP socket to send an HTTP request, but ESP HTTP Client is a much better option for sending HTTP requests

**Supported Functions**

The following BSD socket API functions are supported. For full details, see lwip/lwip/src/include/lwip/sockets.h.

- socket()
- bind()
- accept()
- shutdown()
- getpeername()
- getsockopt() & setsockopt(): see Socket Options
- close(): via Virtual Filesystem Component
- read(), readv(), write(), writev(): via Virtual Filesystem Component
- recv(), recvmsg(), recvfrom()
- send(), sendmsg(), sendto()
- select(): via Virtual Filesystem Component
- poll(): on ESP-IDF, poll() is implemented by calling select() internally, so using select() directly is recommended, if a choice of methods is available
- fcntl(): see fcntl()

**Non-standard functions:**

- ioctl(): see ioctl()

**Note:** Some lwIP application sample code uses prefixed versions of BSD APIs, e.g., lwip_socket(), instead of the standard socket(). Both forms can be used with ESP-IDF, but using standard names is recommended.
Socket Error Handling

BSD Socket error handling code is very important for robust socket applications. Normally, socket error handling involves the following aspects:

- Detecting the error
- Getting the error reason code
- Handling the error according to the reason code

In lwIP, we have two different scenarios for handling socket errors:

- Socket API returns an error. For more information, see Socket API Errors.
- `select(int maxfdp1, fd_set *readset, fd_set *writeset, fd_set *exceptset, struct timeval *timeout)` has an exception descriptor indicating that the socket has an error. For more information, see select() Errors.

**Socket API Errors**  Error detection

- We can know that the socket API fails according to its return value.

**Get the error reason code**

- When socket API fails, the return value does not contain the failure reason and the application can get the error reason code by accessing `errno`. Different values indicate different meanings. For more information, see Socket Error Reason Code.

**Example:**

```c
int err;
int sockfd;

if (sockfd = socket(AF_INET, SOCK_STREAM, 0) < 0) {
    // the error code is obtained from errno
    err = errno;
    return err;
}
```

**select() Errors**  Error detection

- Socket error when `select()` has exception descriptor.

**Get the error reason code**

- If the `select()` indicates that the socket fails, we cannot get the error reason code by accessing `errno`, instead we should call `getsockopt()` to get the failure reason code. Since `select()` has exception descriptor, the error code is not given to `errno`.

**Note:** The `getsockopt()` function has the following prototype: `int getsockopt(int s, int level, int optname, void *optval, socklen_t *optlen)`. Its purpose is to get the current value of the option of any type, any state socket, and store the result in `optval`. For example, when you get the error code on a socket, you can get it by `getsockopt(sockfd, SOL_SOCKET, SO_ERROR, &err, &optlen).

**Example:**

```c
int err;

if (select(sockfd + 1, NULL, NULL, &exfds, &tval) <= 0) {
    err = errno;
    return err;
} else {
    if (FD_ISSET(sockfd, &exfds)) {
        // (continues on next page)
    }
```
Socket Error Reason Code  Below is a list of common error codes. For a more detailed list of standard POSIX/C error codes, please see newlib_errno.h and the platform-specific extensions newlib/platform_include/errno.h.

<table>
<thead>
<tr>
<th>Error code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECONNREFUSED</td>
<td>Connection refused</td>
</tr>
<tr>
<td>EADDRINUSE</td>
<td>Address already in use</td>
</tr>
<tr>
<td>ECONNABORTED</td>
<td>Software caused connection abort</td>
</tr>
<tr>
<td>ENETUNREACH</td>
<td>Network is unreachable</td>
</tr>
<tr>
<td>ENETDOWN</td>
<td>Network interface is not configured</td>
</tr>
<tr>
<td>ETIMEDOUT</td>
<td>Connection timed out</td>
</tr>
<tr>
<td>EHOSTDOWN</td>
<td>Host is down</td>
</tr>
<tr>
<td>EHOSTUNREACH</td>
<td>Host is unreachable</td>
</tr>
<tr>
<td>EINPROGRESS</td>
<td>Connection already in progress</td>
</tr>
<tr>
<td>EALREADY</td>
<td>Socket already connected</td>
</tr>
<tr>
<td>EDESTADDRREQ</td>
<td>Destination address required</td>
</tr>
<tr>
<td>EPROTONOSUPPORT</td>
<td>Unknown protocol</td>
</tr>
</tbody>
</table>

Socket Options

The getsockopt() and setsockopt() functions allow getting and setting per-socket options respectively. Not all standard socket options are supported by lwIP in ESP-IDF. The following socket options are supported:

Common Options  Used with level argument SOL_SOCKET.

- **SO_REUSEADDR**: available if `CONFIG_LWIP_SO_REUSE` is set, whose behavior can be customized by setting `CONFIG_LWIP_SO_REUSE_RXTOALL`
- **SO_KEEPALIVE**
- **SO_BROADCAST**
- **SO_ACCEPTCONN**
- **SO_RCVBUF**: available if `CONFIG_LWIP_SO_RCVBUF` is set
- **SO_SNDTIMEO / SO_RCVTIMEO**
- **SO_ERROR**: only used with select(), see Socket Error Handling
- **SO_TYPE**
- **SO_NO_CHECK**: for UDP sockets only

IP Options  Used with level argument IPPROTO_IP.

- **IP_TOS**
- **IP_TTL**
- **IP_PKTINFO**: available if `CONFIG_LWIP_NETBUF_RECVINFO` is set

For multicast UDP sockets:

- **IP_MULTICAST_IF**
- **IP_MULTICAST_LOOP**
- **IP_MULTICAST_TTL**
- **IP_ADD_MEMBERSHIP**
- **IP_DROP_MEMBERSHIP**
Chapter 4. API Guides

TCP Options  TCP sockets only. Used with level argument IPPROTO_TCP.
  - TCP_NODELAY

Options relating to TCP keepalive probes:
  - TCP_KEEPALIVE: int value, TCP keepalive period in milliseconds
  - TCP_KEEPIF: same as TCP_KEEPALIVE, but the value is in seconds
  - TCP_KEEPINCS: int value, the interval between keepalive probes in seconds
  - TCP_KEEPCNET: int value, number of keepalive probes before timing out

IPv6 Options  IPv6 sockets only. Used with level argument IPPROTO_IPV6.
  - IPV6_CHECKSUM
  - IPV6_V6ONLY

For multicast IPv6 UDP sockets:
  - IPV6_JOIN_GROUP/IPV6_ADD_MEMBERSHIP
  - IPV6_LEAVE_GROUP/IPV6_DROP_MEMBERSHIP
  - IPV6_MULTICAST_IF
  - IPV6_MULTICAST_HOPS
  - IPV6_MULTICAST_LOOP

fcntl()

The fcntl() function is a standard API for manipulating options related to a file descriptor. In ESP-IDF, the Virtual Filesystem Component layer is used to implement this function.

When the file descriptor is a socket, only the following fcntl() values are supported:
  - O_NONBLOCK to set or clear non-blocking I/O mode. Also supports O_NDELAY, which is identical to O_NONBLOCK.
  - O_RDONLY, O_WRONLY, O_RDWR flags for different read or write modes. These flags can only be read using F_GETFL, and cannot be set using F_SETFL. A TCP socket returns a different mode depending on whether the connection has been closed at either end or is still open at both ends. UDP sockets always return O_RDWR.

ioctl()

The ioctl() function provides a semi-standard way to access some internal features of the TCP/IP stack. In ESP-IDF, the Virtual Filesystem Component layer is used to implement this function.

When the file descriptor is a socket, only the following ioctl() values are supported:
  - FIONREAD returns the number of bytes of the pending data already received in the socket’s network buffer.
  - FIONBIO is an alternative way to set/clear non-blocking I/O status for a socket, equivalent to fcntl(fd, F_GETFL, O_NONBLOCK, ...).

4.21.3 Netconn API

lwIP supports two lower-level APIs as well as the BSD Sockets API: the Netconn API and the Raw API.

The lwIP Raw API is designed for single-threaded devices and is not supported in ESP-IDF.

The Netconn API is used to implement the BSD Sockets API inside lwIP, and it can also be called directly from ESP-IDF apps. This API has lower resource usage than the BSD Sockets API. In particular, it can send and receive data without firstly copying it into internal lwIP buffers.

Important:  Espressif does not test the Netconn API in ESP-IDF. As such, this functionality is enabled but not supported. Some functionality may only work correctly when used from the BSD Sockets API.
For more information about the Netconn API, consult lwip/lwip/src/include/lwip/api.h and part of the **unofficial** lwIP Application Developers Manual.

### 4.21.4 lwIP FreeRTOS Task

lwIP creates a dedicated TCP/IP FreeRTOS task to handle socket API requests from other tasks.

A number of configuration items are available to modify the task and the queues (mailboxes) used to send data to/from the TCP/IP task:

- `CONFIG_LWIP_TCPIP_RECVMBOX_SIZE`
- `CONFIG_LWIP_TCPIP_TASK_STACK_SIZE`
- `CONFIG_LWIP_TCPIP_TASK_AFFINITY`

### 4.21.5 IPv6 Support

Both IPv4 and IPv6 are supported in a dual-stack configuration and are enabled by default. Both IPv6 and IPv4 may be disabled separately if they are not needed, see Minimum RAM Usage.

IPv6 support is limited to **Stateless Autoconfiguration** only. **Stateful configuration** is not supported in ESP-IDF, nor in upstream lwIP.

IPv6 Address configuration is defined by means of these protocols or services:

- **SLAAC** IPv6 Stateless Address Autoconfiguration (RFC-2462)
- **DHCPv6** Dynamic Host Configuration Protocol for IPv6 (RFC-8415)

None of these two types of address configuration is enabled by default, so the device uses only Link Local addresses or statically-defined addresses.

#### Stateless Autoconfiguration Process

To enable address autoconfiguration using the Router Advertisement protocol, please enable:

- `CONFIG_LWIP_IPV6_AUTOCONFIG`

This configuration option enables IPv6 autoconfiguration for all network interfaces, which differs from the upstream lwIP behavior, where the autoconfiguration needs to be explicitly enabled for each `netif` with `netif->ip6_autoconfig_enabled=1`.

#### DHCPv6

DHCPv6 in lwIP is very simple and supports only stateless configuration. It could be enabled using:

- `CONFIG_LWIP_IPV6_DHCP6`

Since the DHCPv6 works only in its stateless configuration, the **Stateless Autoconfiguration Process** has to be enabled as well via `CONFIG_LWIP_IPV6_AUTOCONFIG`.

Moreover, the DHCPv6 needs to be explicitly enabled from the application code using:

```c
dhcp6_enable_stateless(netif);
```

#### DNS Servers in IPv6 Autoconfiguration

In order to autoconfigure DNS server(s), especially in IPv6-only networks, we have these two options:
• Recursive Domain Name System (DNS): this belongs to the Neighbor Discovery Protocol (NDP) and uses Stateless Autoconfiguration Process. The number of servers must be set `CONFIG_LWIP_RDNSS_MAX_DNS_SERVERS`, this option is disabled by default, i.e., set to 0.
• DHCPv6 stateless configuration, uses DHCPv6 to configure DNS servers. Note that this configuration assumes IPv6 Router Advertisement Flags (RFC-5175) to be set to
  – Managed Address Configuration Flag = 0
  – Other Configuration Flag = 1

4.21.6 ESP-lwIP Custom Modifications

Additions

The following code is added, which is not present in the upstream lwIP release:

Thread-Safe Sockets It is possible to close() a socket from a different thread than the one that created it. The close() call blocks, until any function calls currently using that socket from other tasks have returned.

It is, however, not possible to delete a task while it is actively waiting on select() or poll() APIs. It is always necessary that these APIs exit before destroying the task, as this might corrupt internal structures and cause subsequent crashes of the lwIP. These APIs allocate globally referenced callback pointers on the stack so that when the task gets destroyed before unrolling the stack, the lwIP could still hold pointers to the deleted stack.

On-Demand Timers lwIP IGMP and MLD6 feature both initialize a timer in order to trigger timeout events at certain times.

The default lwIP implementation is to have these timers enabled all the time, even if no timeout events are active. This increases CPU usage and power consumption when using automatic Light-sleep mode. ESP-lwIP default behavior is to set each timer on demand, so it is only enabled when an event is pending.

To return to the default lwIP behavior, which is always-on timers, disable `CONFIG_LWIP_TIMERS_ONDEMAND`.

lwIP Timers API When not using Wi-Fi, the lwIP timer can be turned off via the API to reduce power consumption.

The following API functions are supported. For full details, see lwip/lwip/src/include/lwip/timeouts.h.

• sys_timeouts_init()
• sys_timeouts_deinit()

Additional Socket Options

• Some standard IPV4 and IPV6 multicast socket options are implemented, see Socket Options.
• Possible to set IPV6-only UDP and TCP sockets with IPV6_V6ONLY socket option, while normal lwIP is TCP-only.

IP Layer Features

• IPV4-source-based routing implementation is different
• IPV4-mapped IPV6 addresses are supported

Customized lwIP Hooks The original lwIP supports implementing custom compile-time modifications via LWIP_HOOK_FILENAME. This file is already used by the ESP-IDF port layer, but ESP-IDF users could still include and implement any custom additions via a header file defined by the macro ESP_IDF_LWIP_HOOK_FILENAME. Here is an example of adding a custom hook file to the build process, and the hook is called my_hook.h, located in the project’s main folder:
### Limitations

Calling `send()` or `sendto()` repeatedly on a UDP socket may eventually fail with `errno` equal to `ENOMEM`. This failure occurs due to the limitations of buffer sizes in the lower-layer network interface drivers. If all driver transmit buffers are full, the UDP transmission will fail. For applications that transmit a high volume of UDP datagrams and aim to avoid any dropped datagrams by the sender, it is advisable to implement error code checking and employ a retransmission mechanism with a short delay.

Increasing the number of TX buffers in the Wi-Fi or Ethernet project configuration as applicable may also help.

### 4.21.7 Performance Optimization

TCP/IP performance is a complex subject, and performance can be optimized toward multiple goals. The default settings of ESP-IDF are tuned for a compromise between throughput, latency, and moderate memory usage.

#### Maximum Throughput

Espressif tests ESP-IDF TCP/IP throughput using the `wifi/ipperf` example in an RF-sealed enclosure.

The `wifi/ipperf/sdkconfig.defaults` file for the ipperf example contains settings known to maximize TCP/IP throughput, usually at the expense of higher RAM usage. To get maximum TCP/IP throughput in an application at the expense of other factors, it is suggested to apply settings from this file into the project `sdkconfig`.

**Important:** Suggest applying changes a few at a time and checking the performance each time with a particular application workload.

- If a lot of tasks are competing for CPU time on the system, consider that the lwIP task has configurable CPU affinity (`CONFIG_LWIP_TCPIP_TASK_AFFINITY`) and runs at fixed priority (18, `ESP_TASK_TCPIP_PRIO`). To optimize CPU utilization, consider assigning competing tasks to different cores or adjusting their priorities to lower values. For additional details on built-in task priorities, please refer to [Built-in Task Priorities](#).
- If using `select()` function with socket arguments only, disabling `CONFIG_VFS_SUPPORT_SELECT` will make `select()` calls faster.
- If there is enough free IRAM, select `CONFIG_LWIP_IRAM_OPTIMIZATION` and `CONFIG_LWIP_EXTRA_IRAM_OPTIMIZATION` to improve TX/RX throughput.

If using a Wi-Fi network interface, please also refer to [Wi-Fi Buffer Usage](#).

#### Minimum Latency

Except for increasing buffer sizes, most changes that increase throughput also decrease latency by reducing the amount of CPU time spent in lwIP functions.

- For TCP sockets, lwIP supports setting the standard `TCP_NODELAY` flag to disable Nagle’s algorithm.

#### Minimum RAM Usage

Most lwIP RAM usage is on-demand, as RAM is allocated from the heap as needed. Therefore, changing lwIP settings to reduce RAM usage may not change RAM usage at idle, but can change it at peak.
• Reducing `CONFIG_LWIP_MAX_SOCKETS` reduces the maximum number of sockets in the system. This also causes TCP sockets in the **WAIT_CLOSE** state to be closed and recycled more rapidly when needed to open a new socket, further reducing RAM usage.

• Reducing `CONFIG_LWIP_TCP_IP_RECVMBOX_SIZE`, `CONFIG_LWIP_TCP_RECVMBOX_SIZE` and `CONFIG_LWIP_UDP_RECVMBOX_SIZE` reduce RAM usage at the expense of throughput, depending on usage.

• Reducing `CONFIG_LWIP_TCP_MSL` and `CONFIG_LWIP_TCP_FIN_WAIT_TIMEOUT` reduces the maximum segment lifetime in the system. This also causes TCP sockets in the **TIME_WAIT** and **FIN_WAIT_2** states to be closed and recycled more rapidly.

• Disabling `CONFIG_LWIP_IPV6` can save about 39 KB for firmware size and 2 KB RAM when the system is powered up and 7 KB RAM when the TCP/IP stack is running. If there is no requirement for supporting IPV6, it can be disabled to save flash and RAM footprint.

• Disabling `CONFIG_LWIP_IPV4` can save about 26 KB of firmware size and 600 B RAM on power up and 6 KB RAM when the TCP/IP stack is running. If the local network supports IPv6-only configuration, IPv4 can be disabled to save flash and RAM footprint.

If using Wi-Fi, please also refer to [Wi-Fi Buffer Usage](#).

### Peak Buffer Usage

The peak heap memory that lwIP consumes is the **theoretically-maximum memory** that the lwIP driver consumes. Generally, the peak heap memory that lwIP consumes depends on:

- the memory required to create a UDP connection: `lwip_udp_conn`
- the memory required to create a TCP connection: `lwip_tcp_conn`
- the number of UDP connections that the application has: `lwip_udp_con_num`
- the number of TCP connections that the application has: `lwip_tcp_con_num`
- the TCP TX window size: `lwip_tcp_tx_win_size`
- the TCP RX window size: `lwip_tcp_rx_win_size`

So, the peak heap memory that the lwIP consumes can be calculated with the following formula:

\[
\text{lwp_dynamic_peak_memory} = (\text{lwp_udp_con_num} \times \text{lwp_udp_conn}) + (\text{lwp_tcp_con_num} \times (\text{lwp_tcp_tx_win_size} + \text{lwp_tcp_rx_win_size} + \text{lwp_tcp_conn}))
\]

Some TCP-based applications need only one TCP connection. However, they may choose to close this TCP connection and create a new one when an error occurs (e.g., a sending failure). This may result in multiple TCP connections existing in the system simultaneously, because it may take a long time for a TCP connection to close, according to the TCP state machine, refer to RFC793.

### 4.22 Memory Types

ESP32 chip has multiple memory types and flexible memory mapping features. This section describes how ESP-IDF uses these features by default.

ESP-IDF distinguishes between instruction memory bus (IRAM, IROM, RTC FAST memory) and data memory bus (DRAM, DROM). Instruction memory is executable, and can only be read or written via 4-byte aligned words. Data memory is not executable and can be accessed via individual byte operations. For more information about the different memory buses consult the [ESP32 Technical Reference Manual](#) > System and Memory.

#### 4.22.1 DRAM (Data RAM)

Non-constant static data (.data) and zero-initialized data (.bss) is placed by the linker into Internal SRAM as data memory. The remaining space in this region is used for the runtime heap.

By applying the `EXT_RAM_BSS_ATTR` macro, zero-initialized data can also be placed into external RAM. To use this macro, the `CONFIG_SPIRAM_ALLOW_BSS_SEG_EXTERNAL_MEMORY` needs to be enabled. See [Allow .bss Segment to Be Placed in External Memory](#).

The available size of the internal DRAM region is reduced by 64 KB (by shifting start address to `0x3FFC0000`) if Bluetooth stack is used. Length of this region is also reduced by 16 KB or 32 KB if trace memory is used. Due
to some memory fragmentation issues caused by ROM, it is also not possible to use all available DRAM for static allocations - however the remaining DRAM is still available as heap at runtime.

**Note:** There is 520 KB of available SRAM (320 KB of DRAM and 200 KB of IRAM) on the ESP32. However, due to a technical limitation, the maximum statically allocated DRAM usage is 160 KB. The remaining 160 KB (for a total of 320 KB of DRAM) can only be allocated at runtime as heap.

Constant data may also be placed into DRAM, for example if it is used in an non-flash-safe ISR (see explanation under *How to Place Code in IRAM*).

**“noinit” DRAM**

The macro `__NOINIT_ATTR` can be used as attribute to place data into `.noinit` section. The values placed into this section will not be initialized at startup and should keep its value after software restart.

By applying the `EXT_RAM_NOINIT_ATTR` macro, non-initialized value could also be placed in external RAM. To do this, the `CONFIG_SPIRAM_ALLOW_NOINIT_SEG_EXTERNAL_MEMORY` needs to be enabled. See *Allow .noinit Segment to Be Placed in External Memory*. If the `CONFIG_SPIRAM_ALLOW_NOINIT_SEG_EXTERNAL_MEMORY` is not enabled, `EXT_RAM_NOINIT_ATTR` will behave just as `__NOINIT_ATTR`, it will make data to be placed into `.noinit` segment in internal RAM.

Example:

```c
__NOINIT_ATTR uint32_t noinit_data;
```

### 4.22.2 IRAM (Instruction RAM)

ESP-IDF allocates part of the Internal SRAM0 region for instruction RAM. The region is defined in *ESP32 Technical Reference Manual > System and Memory > Embedded Memory* [PDF]. Except for the first 64 KB block which is used for PRO and APP MMU caches, the rest of this memory range (i.e., from 0x40080000 to 0x400A0000) is used to store parts of the application which need to run from RAM.

**When to Place Code in IRAM**

Cases when parts of the application should be placed into IRAM:

- Interrupt handlers must be placed into IRAM if `ESP_INTR_FLAG_IRAM` is used when registering the interrupt handler. For more information, see *IRAM-Safe Interrupt Handlers*.
- Some timing critical code may be placed into IRAM to reduce the penalty associated with loading the code from flash. ESP32 reads code and data from flash via the MMU cache. In some cases, placing a function into IRAM may reduce delays caused by a cache miss and significantly improve that function’s performance.

**How to Place Code in IRAM**

Some code is automatically placed into the IRAM region using the linker script.

If some specific application code needs to be placed into IRAM, it can be done by using the *Linker Script Generation* feature and adding a linker script fragment file to your component that targets at the entire source files or functions with the `noflash` placement. See the *Linker Script Generation* docs for more information.

Alternatively, it is possible to specify IRAM placement in the source code using the `IRAM_ATTR` macro:

```c
#include "esp_attr.h"

t void IRAM_ATTR gpio_isr_handler(void* arg)
{
    
(continues on next page)
There are some possible issues with placement in IRAM, that may cause problems with IRAM-safe interrupt handlers:

- Strings or constants inside an IRAM_ATTR function may not be placed in RAM automatically. It is possible to use DRAM_ATTR attributes to mark these, or using the linker script method will cause these to be automatically placed correctly.

```c
void IRAM_ATTR gpio_isr_handler(void* arg)
{
    const static DRAM_ATTR uint8_t INDEX_DATA[] = { 45, 33, 12, 0 };
    const static char *MSG = DRAM_STR("I am a string stored in RAM");
}
```

Note that knowing which data should be marked with DRAM_ATTR can be hard, the compiler will sometimes recognize that a variable or expression is constant (even if it is not marked const) and optimize it into flash, unless it is marked with DRAM_ATTR.

- GCC optimizations that automatically generate jump tables or switch/case lookup tables place these tables in flash. IDF by default builds all files with -fno-jump-tables -fno-tree-switch-conversion flagsto avoid this.

Jump table optimizations can be re-enabled for individual source files that do not need to be placed in IRAM. For instructions on how to add the -fno-jump-tables -fno-tree-switch-conversion options when compiling individual source files, see Controlling Component Compilation.

### 4.22.3 IROM (Code Executed from flash)

If a function is not explicitly placed into IRAM (Instruction RAM) or RTC memory, it is placed into flash. As IRAM is limited, most of an application’s binary code must be placed into IROM instead.

The mechanism by which Flash MMU is used to allow code execution from flash is described in ESP32 Technical Reference Manual > Memory Management and Protection Units (MMU, MPU) [PDF].

During Application Startup Flow, the bootloader (which runs from IRAM)configures the MMU flash cache to map the app’s instruction code region to the instruction space. Flash accessed via the MMU is cached using some internal SRAM and accessing cached flash data is as fast as accessing other types of internal memory.

### 4.22.4 DROM (Data Stored in flash)

By default, constant data is placed by the linker into a region mapped to the MMU flash cache. This is the same as the IROM (Code Executed from flash) section, but is for read-only data not executable code.

The only constant data not placed into this memory type by default are literal constants which are embedded by the compiler into application code. These are placed as the surrounding function’s executable instructions.

The DRAM_ATTR attribute can be used to force constants from DROM into the DRAM (Data RAM) section (see above).

### 4.22.5 RTC Slow Memory

Global and static variables used by code which runs from RTC memory must be placed into RTC Slow memory. For example deep sleep variables can be placed here instead of RTC FAST memory, or code and variables accessed by the ULP Coprocessor Programming.

The attribute macro named RTC_NOINIT_ATTR can be used to place data into this type of memory. The values placed into this section keep their value after waking from deep sleep.
Example:

```c
RTC_NOINIT_ATTR uint32_t rtc_noinit_data;
```

### 4.22.6 RTC FAST Memory

The same region of RTC FAST memory can be accessed as both instruction and data memory. Code which has to run after wake-up from deep sleep mode has to be placed into RTC memory. Please check detailed description in deep sleep documentation.

In single core mode (CONFIG_FREERTOS_UNICORE), remaining RTC FAST memory is added to the heap, unless the option `CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP` is disabled. This memory can be used interchangeably with `DRAM (Data RAM)`, but is slightly slower to access and not DMA-capable.

This option is not available in dual core mode, because on ESP32, RTC FAST memory can only be accessed by the PRO CPU.

### 4.22.7 DMA-Capable Requirement

Most peripheral DMA controllers (e.g., SPI, sdmmc, etc.) have requirements that sending/receiving buffers should be placed in DRAM and word-aligned. We suggest to place DMA buffers in static variables rather than in the stack. Use macro `DMA_ATTR` to declare global/local static variables like:

```c
dma_attr uint8_t buffer[] = "I want to send something";

void app_main()
{
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

Or:

```c
void app_main()
{
    dma_attr static uint8_t buffer[] = "I want to send something";
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

It is also possible to allocate DMA-capable memory buffers dynamically by using the `MALLOC_CAP_DMA` capabilities flag.

### 4.22.8 DMA Buffer in the Stack

Placing DMA buffers in the stack is possible but discouraged. If doing so, pay attention to the following:
• Placing DRAM buffers on the stack is not recommended if the stack may be in PSRAM. If the stack of a task is placed in the PSRAM, several steps have to be taken as described in Support for External RAM.
• Use macro `WORD_ALIGNED_ATTR` in functions before variables to place them in proper positions like:

```c
void app_main()
{
    uint8_t stuff;
    WORD_ALIGNED_ATTR uint8_t buffer[] = "I want to send something";  // or...
    // the buffer will be placed right after stuff.
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

### 4.23 OpenThread

OpenThread is an IP stack running on the 802.15.4 MAC layer which features mesh network and low power consumption.

#### 4.23.1 Modes of the OpenThread Stack

OpenThread can run under the following modes on Espressif chips:

**Standalone Node**

The full OpenThread stack and the application layer run on the same chip. This mode is available on chips with 15.4 radio such as ESP32-H2 and ESP32-C6.

**Radio Co-Processor (RCP)**

The chip is connected to another host running the OpenThread IP stack. It sends and receives 15.4 packets on behalf of the host. This mode is available on chips with 15.4 radio such as ESP32-H2 and ESP32-C6. The underlying transport between the chip and the host can be SPI or UART. For the sake of latency, we recommend using SPI as the underlying transport.

**OpenThread Host**

For chips without a 15.4 radio, it can be connected to an RCP and run OpenThread under host mode. This mode enables OpenThread on Wi-Fi chips such as ESP32, ESP32-S2, ESP32-S3, and ESP32-C3. The following diagram shows how devices work under different modes:

#### 4.23.2 How to Write an OpenThread Application

The OpenThread `openthread/ot_cli` example is a good place to start at. It demonstrates basic OpenThread initialization and simple socket-based server and client.
Chapter 4. API Guides

Before OpenThread Initialization

- s1.1: The main task calls `esp_vfs_eventfd_register()` to initialize the eventfd virtual file system. The eventfd file system is used for task notification in the OpenThread driver.
- s1.2: The main task calls `nvs_flash_init()` to initialize the NVS where the Thread network data is stored.
- s1.3: Optional. The main task calls `esp_netif_init()` only when it wants to create the network interface for Thread.
- s1.4: The main task calls `esp_event_loop_create()` to create the system Event task and initialize an application event’s callback function.

OpenThread Stack Initialization

- s2.1: Call `esp_openthread_init()` to initialize the OpenThread stack.

OpenThread Network Interface Initialization

The whole stage is optional and only required if the application wants to create the network interface for Thread.

- s3.1: Call `esp_netif_new()` with `ESP_NETIF_DEFAULT_OPENTHREAD` to create the interface.
- s3.2: Call `esp_openthread_netif_glue_init()` to create the OpenThread interface handlers.
- s3.3: Call `esp_netif_attach()` to attach the handlers to the interface.

The OpenThread Main Loop

- s4.3: Call `esp_openthread_launch_mainloop()` to launch the OpenThread main loop. Note that this is a busy loop and does not return until the OpenThread stack is terminated.

Calling OpenThread APIs

The OpenThread APIs are not thread-safe. When calling OpenThread APIs from other tasks, make sure to hold the lock with `esp_openthread_lock_acquire()` and release the lock with `esp_openthread_lock_release()` afterwards.
Deinitialization

The following steps are required to deinitialize the OpenThread stack:

- Call `esp_netif_destroy()` and `esp_openthread_netif_glue_deinit()` to deinitialize the OpenThread network interface if you have created one.
- Call `esp_openthread_deinit()` to deinitialize the OpenThread stack.

4.23.3 The OpenThread Border Router

The OpenThread border router connects the Thread network with other IP networks. It provides IPv6 connectivity, service registration, and commission functionality.

To launch an OpenThread border router on an ESP chip, you need to connect an RCP to a Wi-Fi capable chip such as ESP32.

Calling `esp_openthread_border_router_init()` during the initialization launches all the border routing functionalities.

You may refer to the `openthread/ot_br` example and the README for further border router details.

4.24 Partition Tables

4.24.1 Overview

A single ESP32’s flash can contain multiple apps, as well as many different kinds of data (calibration data, filesystems, parameter storage, etc). For this reason a partition table is flashed to (default offset) 0x8000 in the flash.

The partition table length is 0xC00 bytes, as we allow a maximum of 95 entries. An MD5 checksum, used for checking the integrity of the partition table at runtime, is appended after the table data. Thus, the partition table occupies an entire flash sector, which size is 0x1000 (4 KB). As a result, any partition following it must be at least located at (default offset) + 0x1000.

Each entry in the partition table has a name (label), type (app, data, or something else), subtype and the offset in flash where the partition is loaded.

The simplest way to use the partition table is to open the project configuration menu (`idf.py menuconfig`) and choose one of the simple predefined partition tables under `CONFIG_PARTITION_TABLE_TYPE`:

- “Single factory app, no OTA”
- “Factory app, two OTA definitions”

In both cases the factory app is flashed at offset 0x10000. If you execute `idf.py partition-table` then it will print a summary of the partition table.

4.24.2 Built-in Partition Tables

Here is the summary printed for the “Single factory app, no OTA” configuration:

```
# ESP-IDF Partition Table
# Name,  Type, SubType, Offset, Size, Flags
nvs,    data, nvs, 0x9000, 0x6000,
phy_init, data, phy, 0xf000, 0x1000,
factory, app, factory, 0x10000, 1M,
```

- At a 0x10000 (64 KB) offset in the flash is the app labelled “factory”. The bootloader will run this app by default.
• There are also two data regions defined in the partition table for storing NVS library partition and PHY init data.

Here is the summary printed for the “Factory app, two OTA definitions” configuration:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>SubType</th>
<th>Offset</th>
<th>Size</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvs</td>
<td>data</td>
<td>nvs</td>
<td>0x9000</td>
<td>0x4000</td>
<td></td>
</tr>
<tr>
<td>otdata</td>
<td>data</td>
<td>ota</td>
<td>0xd000</td>
<td>0x2000</td>
<td></td>
</tr>
<tr>
<td>phy_init</td>
<td>data</td>
<td>phy</td>
<td>0xf000</td>
<td>0x1000</td>
<td></td>
</tr>
<tr>
<td>factory</td>
<td>app</td>
<td>factory</td>
<td>0x10000</td>
<td>1M</td>
<td></td>
</tr>
<tr>
<td>ota_0</td>
<td>app</td>
<td>ota_0</td>
<td>0x110000</td>
<td>1M</td>
<td></td>
</tr>
<tr>
<td>ota_1</td>
<td>app</td>
<td>ota_1</td>
<td>0x210000</td>
<td>1M</td>
<td></td>
</tr>
</tbody>
</table>

• There are now three app partition definitions. The type of the factory app (at 0x10000) and the next two “OTA” apps are all set to “app”, but their subtypes are different.

• There is also a new “otadata” slot, which holds the data for OTA updates. The bootloader consults this data in order to know which app to execute. If “ota data” is empty, it will execute the factory app.

4.24.3 Creating Custom Tables

If you choose “Custom partition table CSV” in menuconfig then you can also enter the name of a CSV file (in the project directory) to use for your partition table. The CSV file can describe any number of definitions for the table you need.

The CSV format is the same format as printed in the summaries shown above. However, not all fields are required in the CSV. For example, here is the “input” CSV for the OTA partition table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>SubType</th>
<th>Offset</th>
<th>Size</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvs</td>
<td>data</td>
<td>nvs</td>
<td>0x9000</td>
<td>0x4000</td>
<td></td>
</tr>
<tr>
<td>otdata</td>
<td>data</td>
<td>ota</td>
<td>0xd000</td>
<td>0x2000</td>
<td></td>
</tr>
<tr>
<td>phy_init</td>
<td>data</td>
<td>phy</td>
<td>0xf000</td>
<td>0x1000</td>
<td></td>
</tr>
<tr>
<td>factory</td>
<td>app</td>
<td>factory</td>
<td>0x10000</td>
<td>1M</td>
<td></td>
</tr>
<tr>
<td>ota_0</td>
<td>app</td>
<td>ota_0</td>
<td>,</td>
<td>,</td>
<td>1M</td>
</tr>
<tr>
<td>ota_1</td>
<td>app</td>
<td>ota_1</td>
<td>,</td>
<td>,</td>
<td>1M</td>
</tr>
<tr>
<td>nvs_key</td>
<td>data</td>
<td>nvs_keys</td>
<td>,</td>
<td>0x1000</td>
<td></td>
</tr>
</tbody>
</table>

• Whitespace between fields is ignored, and so is any line starting with # (comments).

• Each non-comment line in the CSV file is a partition definition.

• The “Offset” field for each partition is empty. The gen_esp32part.py tool fills in each blank offset, starting after the partition table and making sure each partition is aligned correctly.

Name Field

Name field can be any meaningful name. It is not significant to the ESP32. The maximum length of names is 16 bytes, including one null terminator. Names longer than the maximum length will be truncated.

Type Field

Partition type field can be specified as app (0x00) or data (0x01). Or it can be a number 0-254 (or as hex 0x00-0xFE). Types 0x00-0x3F are reserved for ESP-IDF core functions.

If your app needs to store data in a format not already supported by ESP-IDF, then please add a custom partition type value in the range 0x40-0xFE.

See esp_partition_type_t for the enum definitions for app and data partitions.

If writing in C++ then specifying a application-defined partition type requires casting an integer to esp_partition_type_t in order to use it with the partition API. For example:
The ESP-IDF bootloader ignores any partition types other than app (0x00) and data (0x01).

SubType

The 8-bit SubType field is specific to a given partition type. ESP-IDF currently only specifies the meaning of the subtype field for app and data partition types.

See enum `esp_partition_subtype_t` for the full list of subtypes defined by ESP-IDF, including the following:

- **factory (0x00)** is the default app partition. The bootloader will execute the factory app unless there it sees a partition of type data/ota, in which case it reads this partition to determine which OTA image to boot.
  - OTA never updates the factory partition.
  - If you want to conserve flash usage in an OTA project, you can remove the factory partition and use `ota_0` instead.
- **ota_0 (0x10) … ota_15 (0x1F)** are the OTA app slots. When OTA is in use, the OTA data partition configures which app slot the bootloader should boot. When using OTA, an application should have at least two OTA application slots (`ota_0 & ota_1`). Refer to the OTA documentation for more details.
- **test (0x20)** is a reserved subtype for factory test procedures. It will be used as the fallback boot partition if no other valid app partition is found. It is also possible to configure the bootloader to read a GPIO input during each boot, and boot this partition if the GPIO is held low, see *Boot from Test Firmware*.

- **ota (0)** is the OTA data partition which stores information about the currently selected OTA app slot. This partition should be 0x2000 bytes in size. Refer to the OTA documentation for more details.
- **phy (1)** is for storing PHY initialisation data. This allows PHY to be configured per-device, instead of in firmware.
  - In the default configuration, the phy partition is not used and PHY initialisation data is compiled into the app itself. As such, this partition can be removed from the partition table to save space.
  - To load PHY data from this partition, open the project configuration menu (`idf.py menuconfig`) and enable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION` option. You will also need to flash your devices with phy init data as the esp-idf build system does not do this automatically.
- **nvs (2)** is for the Non-Volatile Storage (NVS) API.
  - NVS is used to store per-device PHY calibration data (different to initialisation data).
  - NVS is used to store Wi-Fi data if the `esp_wifi_set_storage(WIFI_STORAGE_FLASH)` initialization function is used.
  - The NVS API can also be used for other application data.
  - It is strongly recommended that you include an NVS partition of at least 0x3000 bytes in your project.
  - If using NVS API to store a lot of data, increase the NVS partition size from the default 0x6000 bytes.
- **nvs_keys (4)** is for the NVS key partition. See Non-Volatile Storage (NVS) API for more details.
  - It is used to store NVS encryption keys when NVS Encryption feature is enabled.
  - The size of this partition should be 4096 bytes (minimum partition size).
- **coredump (0x03)** is for storing core dumps while using a custom partition table CSV file. See Core Dump for more details.
- **efuse (0x05)** is for emulating eFuse bits using Virtual eFuses.
- **undefined (0x06)** is implicitly used for data partitions with unspecified (empty) subtype, but it is possible to explicitly mark them as undefined as well.
- **fat (0x81)** is for FAT Filesystem Support.
- **spiffs (0x82)** is for SPIFFS Filesystem.
- **littlefs (0x83)** is for LittleFS filesystem. See storage/littlefs example for more details.
• If the partition type is any application-defined value (range 0x40-0xFE), then subtype field can be any value chosen by the application (range 0x00-0xFE). Note that when writing in C++, an application-defined subtype value requires casting to type `esp_partition_subtype_t` in order to use it with the `partition API`.

**Extra Partition SubTypes**

A component can define a new partition subtype by setting the `EXTRA_PARTITION_SUBTYPES` property. This property is a CMake list, each entry of which is a comma separated string with `<type>, <subtype>, <value>` format. The build system uses this property to add extra subtypes and creates fields named `ESP_PARTITION_SUBTYPE_<type>_<subtype>` in `esp_partition_subtype_t`. The project can use this subtype to define partitions in the partitions table CSV file and use the new fields in `esp_partition_subtype_t`.

**Offset & Size**

The offset represents the partition address in the SPI flash, which sector size is 0x1000 (4 KB). Thus, the offset must be a multiple of 4 KB.

Partitions with blank offsets in the CSV file will start after the previous partition, or after the partition table in the case of the first partition.

Partitions of type `app` have to be placed at offsets aligned to 0x10000 (64 K). If you leave the offset field blank, `gen_esp32part.py` will automatically align the partition. If you specify an unaligned offset for an app partition, the tool will return an error.

Sizes and offsets can be specified as decimal numbers, hex numbers with the prefix 0x, or size multipliers K or M (1024 and 1024*1024 bytes).

If you want the partitions in the partition table to work relative to any placement (`CONFIG_PARTITION_TABLE_OFFSET`) of the table itself, leave the offset field (in CSV file) for all partitions blank. Similarly, if changing the partition table offset then be aware that all blank partition offsets may change to match, and that any fixed offsets may now collide with the partition table (causing an error).

**Flags**

Two flags are currently supported, `encrypted` and `readonly`:

• If `encrypted` flag is set, the partition will be encrypted if `Flash Encryption` is enabled.

**Note**: app type partitions will always be encrypted, regardless of whether this flag is set or not.

• If `readonly` flag is set, the partition will be read-only. This flag is only supported for data type partitions except `ota` and `coredump` subtypes. This flag can help to protect against accidental writes to a partition that contains critical device-specific configuration data, e.g., factory data partition.

**Note**: Using C file I/O API to open a file (fopen`) in any write mode (w, w+, a, a+, r+) will fail and return NULL. Using open with any other flag than `O_RDONLY` will fail and return -1 while `errno` global variable will be set to `EROFS`. This is also true for any other POSIX syscall function performing write or erase operations. Opening a handle in read-write mode for NVS on a read-only partition will fail and return `ESP_ERR_NOT_ALLOWED` error code. Using a lower level API like `esp_partition`, `spi_flash`, etc. to write to a read-only partition will result in `ESP_ERR_NOT_ALLOWED` error code.

You can specify multiple flags by separating them with a colon. For example, `encrypted:readonly`.
4.24.4 Generating Binary Partition Table

The partition table which is flashed to the ESP32 is in a binary format, not CSV. The tool partition_table/gen_esp32part.py is used to convert between CSV and binary formats.

If you configure the partition table CSV name in the project configuration (idf.py menuconfig) and then build the project or run idf.py partition-table, this conversion is done as part of the build process.

To convert CSV to Binary manually:
```
python gen_esp32part.py input_partitions.csv binary_partitions.bin
```

To convert binary format back to CSV manually:
```
python gen_esp32part.py binary_partitions.bin input_partitions.csv
```

To display the contents of a binary partition table on stdout (this is how the summaries displayed when running idf.py partition-table are generated):
```
python gen_esp32part.py binary_partitions.bin
```

4.24.5 Partition Size Checks

The ESP-IDF build system will automatically check if generated binaries fit in the available partition space, and will fail with an error if a binary is too large.

Currently these checks are performed for the following binaries:

- Bootloader binary must fit in space before partition table (see Bootloader Size).
- App binary should fit in at least one partition of type app. If the app binary does not fit in any app partition, the build will fail. If it only fits in some of the app partitions, a warning is printed about this.

**Note:** Although the build process will fail if the size check returns an error, the binary files are still generated and can be flashed (although they may not work if they are too large for the available space.)

**MD5 Checksum**

The binary format of the partition table contains an MD5 checksum computed based on the partition table. This checksum is used for checking the integrity of the partition table during the boot.

The MD5 checksum generation can be disabled by the --disable-md5sum option of gen_esp32part.py or by the CONFIG_PARTITION_TABLE_MD5 option. This is useful for example when one uses a bootloader from ESP-IDF before v3.1 which cannot process MD5 checksums and the boot fails with the error message invalid magic number 0xebeb.

4.24.6 Flashing the Partition Table

- idf.py partition-table-flash: will flash the partition table with esptool.py.
- idf.py flash: Will flash everything including the partition table.

A manual flashing command is also printed as part of idf.py partition-table output.

**Note:** Note that updating the partition table does not erase data that may have been stored according to the old partition table. You can use idf.py erase-flash (or esptool.py erase_flash) to erase the entire flash contents.
4.24.7 Partition Tool (parttool.py)

The component partition_table provides a tool parttool.py for performing partition-related operations on a target device. The following operations can be performed using the tool:

- reading a partition and saving the contents to a file (read_partition)
- writing the contents of a file to a partition (write_partition)
- erasing a partition (erase_partition)
- retrieving info such as name, offset, size and flag ("encrypted") of a given partition (get_partition_info)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool’s Python API and command-line interface, respectively.

Python API

Before anything else, make sure that the partool module is imported.

```python
import sys
import os

idf_path = os.environ["IDF_PATH"]  # get value of IDF_PATH from environment
parttool_dir = os.path.join(idf_path, "components", "partition_table")  # partool.py lives in $IDF_PATH/components/partition_table
sys.path.append(parttool_dir)  # this enables Python to find partool module

# import all names inside partool module
from partool import *
```

The starting point for using the tool’s Python API to do is create a PartoolTarget object:

```python
# Create a partool.py target device connected on serial port /dev/ttyUSB1
target = PartoolTarget("/dev/ttyUSB1")
```

The created object can now be used to perform operations on the target device:

```python
# Erase partition with name 'storage'
target.erase_partition(PartitionName("storage"))

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin'
target.read_partition(PartitionType("data", "spiffs"), "spiffs.bin")

# Write to partition 'factory' the contents of a file named 'factory.bin'
target.write_partition(PartitionName("factory"), "factory.bin")

# Print the size of default boot partition
storage = target.get_partition_info(PARTITION_BOOT_DEFAULT)
print(storage.size)
```

The partition to operate on is specified using PartitionName or PartitionType or PARTITION_BOOT_DEFAULT. As the name implies, these can be used to refer to partitions of a particular name, type-subtype combination, or the default boot partition.

More information on the Python API is available in the docstrings for the tool.

Command-line Interface

The command-line interface of parttool.py has the following structure:
4.25 Performance

ESP-IDF ships with default settings that are designed for a trade-off between performance, resource usage, and available functionality.

These guides describe how to optimize a firmware application for a particular aspect of performance. Usually this involves some trade-off in terms of limiting available functions, or swapping one aspect of performance (such as execution speed) for another (such as RAM usage).

4.25.1 How to Optimize Performance

1. Decide the performance-critical aspects of your application, such as achieving a particular response time for a certain network operation, meeting a particular startup time limit, or maintaining a certain level of peripheral data throughput.
2. Find a way to measure this performance (some methods are outlined in the guides below).
3. Modify the code and project configuration and compare the new measurement to the old measurement.
4. Repeat step 3 until the performance meets the requirements set out in step 1.

4.25.2 Guides

Speed Optimization
Overview  Optimizing execution speed is a key element of software performance. Code that executes faster can also have other positive effects, e.g., reducing overall power consumption. However, improving execution speed may have trade-offs with other aspects of performance such as Minimizing Binary Size.

Choose What to Optimize  If a function in the application firmware is executed once per week in the background, it may not matter if that function takes 10 ms or 100 ms to execute. If a function is executed constantly at 10 Hz, it matters greatly if it takes 10 ms or 100 ms to execute.

Most kinds of application firmware only have a small set of functions that require optimal performance. Perhaps those functions are executed very often, or have to meet some application requirements for latency or throughput. Optimization efforts should be targeted at these particular functions.

Measuring Performance  The first step to improving something is to measure it.

Basic Performance Measurements  You may be able to measure directly the performance relative to an external interaction with the world, e.g., see the examples wifi/iperf and ethernet/iperf for measuring general network performance. Or you can use an oscilloscope or logic analyzer to measure the timing of an interaction with a device peripheral.

Otherwise, one way to measure performance is to augment the code to take timing measurements:

```c
#include "esp_timer.h"

void measure_important_function(void) {
    const unsigned MEASUREMENTS = 5000;
    uint64_t start = esp_timer_get_time();
    for (int retries = 0; retries < MEASUREMENTS; retries++) {
        important_function(); // This is the thing you need to measure
    }
    uint64_t end = esp_timer_get_time();
    printf("%u iterations took %llu milliseconds (%llu microseconds per invocation)\n", MEASUREMENTS, (end - start)/1000, (end - start)/MEASUREMENTS);
}
```

Executing the target multiple times can help average out factors, e.g., RTOS context switches, overhead of measurements, etc.

- Using `esp_timer_get_time()` generates “wall clock” timestamps with microsecond precision, but has moderate overhead each time the timing functions are called.
- It is also possible to use the standard Unix `gettimeofday()` and `utime()` functions, although the overhead is slightly higher.
- Otherwise, including `hal/cpu_hal.h` and calling the HAL function `cpu_hal_get_cycle_count()` returns the number of CPU cycles executed. This function has lower overhead than the others, which is good for measuring very short execution times with high precision.
  The CPU cycles are counted per-core, so only use this method from an interrupt handler, or a task that is pinned to a single core.
- While performing “microbenchmarks” (i.e., benchmarking only a very small routine of code that runs in less than 1-2 milliseconds), the flash cache performance can sometimes cause big variations in timing measurements depending on the binary. This happens because binary layout can cause different patterns of cache misses in a particular sequence of execution. If the test code is larger, then this effect usually averages out. Executing a small function multiple times when benchmarking can help reduce the impact of flash cache misses. Alternatively, move this code to IRAM (see Targeted Optimizations).

External Tracing  The Application Level Tracing Library allows measuring code execution with minimal impact on the code itself.
Tasks  If the option `CONFIG_FREERTOS_GENERATE_RUN_TIME_STATS` is enabled, then the FreeRTOS API `vTaskGetRunTimeStats()` can be used to retrieve runtime information about the processor time used by each FreeRTOS task.

SEGGER SystemView is an excellent tool for visualizing task execution and looking for performance issues or improvements in the system as a whole.

**Improving Overall Speed**  The following optimizations improve the execution of nearly all code, including boot times, throughput, latency, etc:

- Set `CONFIG_ESPTOOLPY_FLASHFREQ` to 80 MHz. This is double the 40 MHz default value and doubles the speed at which code is loaded or executed from flash. You should verify that the board or module that connects the ESP32 to the flash chip is rated for 80 MHz operation at the relevant temperature ranges before changing this setting. This information is contained in the hardware datasheet(s).
- Set `CONFIG_ESPTOOLPY_FLASHMODE` to QIO or QOUT mode (Quad I/O). Both almost double the speed at which code is loaded or executed from flash compared to the default DIO mode. QIO is slightly faster than QOUT if both are supported. Note that both the flash chip model, and the electrical connections between the ESP32 and the flash chip must support quad I/O modes or the SoC will not work correctly.
- Set `CONFIG_COMPILER_OPTIMIZATION` to `Optimize for performance (-O2)` . This may slightly increase binary size compared to the default setting, but almost certainly increases the performance of some code. Note that if your code contains C or C++ Undefined Behavior, then increasing the compiler optimization level may expose bugs that otherwise are not seen.
- If the application uses PSRAM and is based on ESP32 rev. 3 (ECO3), setting `CONFIG_ESP32_REV_MIN` to 3 disables PSRAM bug workarounds, reducing the code size and improving overall performance.
- Avoid using floating point arithmetic `float`. Even though ESP32 has a single precision hardware floating point unit, floating point calculations are always slower than integer calculations. If possible then use fixed point representations, a different method of integer representation, or convert part of the calculation to be integer only before switching to floating point.
- Avoid using double precision floating point arithmetic `double`. These calculations are emulated in software and are very slow. If possible then use an integer-based representation, or single-precision floating point.

**Reduce Logging Overhead**  Although standard output is buffered, it is possible for an application to be limited by the rate at which it can print data to log output once buffers are full. This is particularly relevant for startup time if a lot of output is logged, but such problem can happen at other times as well. There are multiple ways to solve this problem:

- Reduce the volume of log output by lowering the app `CONFIG_LOG_DEFAULT_LEVEL` (the equivalent bootloader setting is `CONFIG_BOOTLOADER_LOG_LEVEL`). This also reduces the binary size, and saves some CPU time spent on string formatting.
- Increase the speed of logging output by increasing the `CONFIG_ESP_CONSOLE_UART_BAUDRATE`.

**Not Recommended**  The following options also increase execution speed, but are not recommended as they also reduce the debuggability of the firmware application and may increase the severity of any bugs.

- Set `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL` to disabled. This also reduces firmware binary size by a small amount. However, it may increase the severity of bugs in the firmware including security-related bugs. If it is necessary to do this to optimize a particular function, consider adding `#define NDEBUG` at the top of that single source file instead.

**Targeted Optimizations**  The following changes increase the speed of a chosen part of the firmware application:
chapter 4. API Guides

- Move frequently executed code to IRAM. By default, all code in the app is executed from flash cache. This means that it is possible for the CPU to have to wait on a “cache miss” while the next instructions are loaded from flash. Functions which are copied into IRAM are loaded once at boot time, and then always execute at full speed.

IRAM is a limited resource, and using more IRAM may reduce available DRAM, so a strategic approach is needed when moving code to IRAM. See IRAM (Instruction RAM) for more information.
- Jump table optimizations can be re-enabled for individual source files that do not need to be placed in IRAM. For hot paths in large switch cases, this improves performance. For instructions on how to add the -fjump-tables and -ftree-switch-conversion options when compiling individual source files, see Controlling Component Compilation

Improving Startup Time    In addition to the overall performance improvements shown above, the following options can be tweaked to specifically reduce startup time:

- Minimizing the CONFIG_LOG_DEFAULT_LEVEL and CONFIG_BOOTLOADER_LOG_LEVEL has a large impact on startup time. To enable more logging after the app starts up, set the CONFIG_LOG_MAXIMUM_LEVEL as well, and then call esp_log_level_set() to restore higher level logs. The system/startup_time main function shows how to do this.
- If using Deep-sleep mode, setting CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP allows a faster wake from sleep. Note that if using Secure Boot, this represents a security compromise, as Secure Boot validation are not be performed on wake.
- Setting CONFIG_BOOTLOADER_SKIP_VALIDATE_ON_POWER_ON skips verifying the binary on every boot from the power-on reset. How much time this saves depends on the binary size and the flash settings. Note that this setting carries some risk if the flash becomes corrupt unexpectedly. Read the help text of the config item for an explanation and recommendations if using this option.
- It is possible to save a small amount of time during boot by disabling RTC slow clock calibration. To do so, set CONFIG_RTC_CLK_CAL_CYCLES to 0. Any part of the firmware that uses RTC slow clock as a timing source will be less accurate as a result.

The example project system/startup_time is pre-configured to optimize startup time. The file system/startup_time/sdkconfig.defaults contain all of these settings. You can append these to the end of your project’s own sdkconfig file to merge the settings, but please read the documentation for each setting first.

Task Priorities    As ESP-IDF FreeRTOS is a real-time operating system, it is necessary to ensure that high-throughput or low-latency tasks are granted a high priority in order to run immediately. Priority is set when calling xTaskCreate() or xTaskCreatePinnedToCore() and can be changed at runtime by calling vTaskPrioritySet().

It is also necessary to ensure that tasks yield CPU (by calling vTaskDelay(), sleep(), or by blocking on semaphores, queues, task notifications, etc) in order to not starve lower-priority tasks and cause problems for the overall system. The Task Watchdog Timer (TWDT) provides a mechanism to automatically detect if task starvation happens. However, note that a TWDT timeout does not always indicate a problem, because sometimes the correct operation of the firmware requires some long-running computation. In these cases, tweaking the TWDT timeout or even disabling the TWDT may be necessary.

Built-in Task Priorities    ESP-IDF starts a number of system tasks at fixed priority levels. Some are automatically started during the boot process, while some are started only if the application firmware initializes a particular feature. To optimize performance, structure the task priorities of your application properly to ensure the tasks are not delayed by the system tasks, while also not starving system tasks and impacting other functions of the system.

This may require splitting up a particular task. For example, perform a time-critical operation in a high-priority task or an interrupt handler and do the non-time-critical part in a lower-priority task.

Header components/esp_system/include/esp_task.h contains macros for the priority levels used for built-in ESP-IDF tasks system. See Background Tasks for more details about the system tasks.

Common priorities are:
Chapter 4. API Guides

- **Running the Main Task** that executes app_main function has minimum priority (1). This task is pinned to Core 0 by default (configurable).

- **High Resolution Timer (ESP Timer)** system task to manage high precision timer events and execute callbacks has high priority (22, ESP_TASK_TIMER_PRIO). This task is pinned to Core 0.

- FreeRTOS Timer Task to handle FreeRTOS timer callbacks is created when the scheduler initializes and has minimum task priority (1, configurable). This task is pinned to Core 0.

- **Event Loop Library** system task to manage the default system event loop and execute callbacks has high priority (20, ESP_TASK_EVENT_PRIO) and it is pinned to Core 0. This configuration is only used if the application calls `esp_event_loop_create_default()`, it is possible to call `esp_event_loop_create()` with a custom task configuration instead.

- **lwIP** TCP/IP task has high priority (18, ESP_TASK_TCPIP_PRIO) and is not pinned to any core (configurable).

- **Wi-Fi Driver** task has high priority (23) and is pinned to Core 0 by default (configurable).

- Wi-Fi wpapsupplicant component may create dedicated tasks while the Wi-Fi Protected Setup (WPS), WPA2 EAP-TLS, Device Provisioning Protocol (DPP) or BSS Transition Management (BTM) features are in use. These tasks all have low priority (2) and are not pinned to any core.

- **Controller & VHCI** task has high priority (23, ESP_TASK_BT_CONTROLLER_PRIO) and is pinned to Core 0 by default (configurable). The Bluetooth Controller needs to respond to requests with low latency, so it should always be among the highest priority task assigned to a single CPU.

- **NimBLE-based Host APIs** task has high priority (21) and is pinned to Core 0 by default (configurable).

- **Bluetooth® API** creates multiple tasks when used:
  - Stack event callback task (BTC) has high priority (19).
  - Stack BTU layer task has high priority (20).
  - Host HCI host task has high priority (22).

  All Bluedroid Tasks are pinned to the same core, which is Core 0 by default (configurable).

  - The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the priority is medium-high (15) and the task is not pinned to any core. These settings can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
  
  - If using the ESP-MQTT component, it creates a task with default priority 5 (configurable, depending on `CONFIG_MQTT_USE_CUSTOM_CONFIG`) and not pinned to any core (configurable).
  
  - To see what is the task priority for mDNS service, please check Performance Optimization.

**Choosing Task Priorities of the Application**

With a few exceptions, most importantly the lwIP TCP/IP task, in the default configuration most built-in tasks are pinned to Core 0. This makes it quite easy for the application to place high priority tasks on Core 1. Using priority 19 or higher guarantees that an application task can run on Core 1 without being preempted by any built-in task. To further isolate the tasks running on each CPU, configure the lwIP task to only run on Core 0 instead of either core, which may reduce total TCP/IP throughput depending on what other tasks are running.

In general, it is not recommended to set task priorities on Core 0 higher than the built-in Wi-Fi/Bluetooth operations as starving them of CPU may make the system unstable. Choosing priority 19 and Core 0 allows lower-layer Wi-Fi/Bluetooth functionality to run without delays, but still pre-empt the lwIP TCP/IP stack and other less time-critical internal functionality. This is an option for time-critical tasks that do not perform network operations. Any task that does TCP/IP network operations should run at lower priority than the lwIP TCP/IP task (18) to avoid priority-inversion issues.

**Note:** Setting a task to always run in preference to built-in ESP-IDF tasks does not require pinning the task to Core 1. Instead, the task can be left unpinned and assigned a priority of 17 or lower. This allows the task to optionally run on Core 0 if there are no higher-priority built-in tasks running on that core. Using unpinned tasks can improve the overall CPU utilization, however it makes reasoning about task scheduling more complex.

**Note:** Task execution is always completely suspended when writing to the built-in SPI flash chip. Only IRAM-Safe

Espressif Systems

Submit Document Feedback
Interrupt Handlers continues executing.

**Improving Interrupt Performance** ESP-IDF supports dynamic Interrupt Allocation with interrupt preemption. Each interrupt in the system has a priority, and higher-priority interrupts preempt lower priority ones.

Interrupt handlers execute in preference to any task, provided the task is not inside a critical section. For this reason, it is important to minimize the amount of time spent in executing an interrupt handler.

To obtain the best performance for a particular interrupt handler:

- Assign more important interrupts a higher priority using a flag such as `ESP_INTR_FLAG_LEVEL2` or `ESP_INTR_FLAG_LEVEL3` when calling `esp_intr_alloc()`.
- Assign the interrupt on a CPU where built-in Wi-Fi/Bluetooth tasks are not configured to run, which means assigning the interrupt on Core 1 by default, see *Built-in Task Priorities*. Interrupts are assigned on the same CPU where the `esp_intr_alloc()` function call is made.
- If you are sure the entire interrupt handler can run from IRAM (see *IRAM-Safe Interrupt Handlers*) then set the `ESP_INTR_FLAG_IRAM` flag when calling `esp_intr_alloc()` to assign the interrupt. This prevents it being temporarily disabled if the application firmware writes to the internal SPI flash.
- Even if the interrupt handler is not IRAM-safe, if it is going to be executed frequently then consider moving the handler function to IRAM anyhow. This minimizes the chance of a flash cache miss when the interrupt code is executed (see *Targeted Optimizations*). It is possible to do this without adding the `ESP_INTR_FLAG_IRAM` flag to mark the interrupt as IRAM-safe, if only part of the handler is guaranteed to be in IRAM.

**Improving Network Speed**

- For Wi-Fi, see *How to Improve Wi-Fi Performance* and *Wi-Fi Buffer Usage*
- For lwIP TCP/IP (Wi-Fi and Ethernet), see *Performance Optimization*
- The `wifi/perf` example contains a configuration that is heavily optimized for Wi-Fi TCP/IP throughput. Append the contents of the files `wifi/perf/sdkconfig.defaults`, `wifi/perf/sdkconfig.defaults.esp32` and `wifi/perf/sdkconfig.ci.99` to the `sdkconfig` file in your project in order to add all of these options. Note that some of these options may have trade-offs in terms of reduced debuggability, increased firmware size, increased memory usage, or reduced performance of other features. To get the best result, read the documentation pages linked above and use related information to determine exactly which options are best suited for your app.
- The `ethernet/perf` example contains a configuration that is heavily optimized for Ethernet TCP/IP throughput. Examine `ethernet/perf/sdkconfig.defaults` for more details. Note that some of these options may have trade-offs in terms of reduced debuggability, increased firmware size, increased memory usage, or reduced performance of other features. To get the best result, read the documentation pages linked above and use related information to determine exactly which options are best suited for your app.

**Improving I/O Performance** Using standard C library functions like `fread` and `fwrite` instead of platform specific unbuffered syscalls such as `read` and `write` can be slow. These functions are designed to be portable, so they are not necessarily optimized for speed, have a certain overhead and are buffered.

*FAT Filesystem Support* specific information and tips:

- Maximum size of the R/W request = FatFS cluster size (allocation unit size).
- Use `read` and `write` instead of `fread` and `fwrite`.
- To increase speed of buffered reading functions like `fread` and `fgets`, you can increase a size of the file buffer (Newlib’s default is 128 bytes) to a higher number like 4096, 8192 or 16384. This can be done locally via the `setvbuf` function used on a certain file pointer or globally applied to all files via modifying `CONFIG_FATFS_VFS_FSTAT_BLKSIZE`.

**Note:** Setting a bigger buffer size also increases the heap memory usage.
Minimizing Binary Size

The ESP-IDF build system compiles all source files in the project and ESP-IDF, but only functions and variables that are actually referenced by the program are linked into the final binary. In some cases, it is necessary to reduce the total size of the firmware binary, e.g., in order to fit it into the available flash partition size.

The first step to reducing the total firmware binary size is measuring what is causing the size to increase.

Measuring Static Sizes

To optimize both the firmware binary size and the memory usage, it is necessary to measure statically-allocated RAM (.data, .bss), code (.text), and read-only data (.rodata) in your project.

Using the `idf.py` sub-commands size, size-components, and size-files provides a summary of memory used by the project:

Note: It is possible to add `-DOUTPUT_FORMAT=csv` or `-DOUTPUT_FORMAT=json` to get the output in CSV or JSON format.

Size Summary `idf.py size`

```
$ idf.py size
[...]
Total sizes:
  Used static DRAM: 10608 bytes (170128 remain, 5.9% used)
    .data size: 8464 bytes
    .bss size: 2144 bytes
  Used static IRAM: 48834 bytes (82238 remain, 37.3% used)
    .text size: 47807 bytes
    .vectors size: 1027 bytes
  Used Flash size: 117391 bytes
    .text: 80103 bytes
    .rodata: 37032 bytes
Total image size: 174689 bytes (.bin may be padded larger)
```

This output breaks down the size of all static memory regions in the firmware binary:

```
$ idf.py size
[...]
Total sizes:
  Used static DRAM: 10608 bytes (170128 remain, 5.9% used)
    .data size: 8464 bytes
    .bss size: 2144 bytes
  Used static IRAM: 48834 bytes (82238 remain, 37.3% used)
    .text size: 47807 bytes
    .vectors size: 1027 bytes
  Used Flash size: 117391 bytes
    .text: 80103 bytes
    .rodata: 37032 bytes
Total image size: 174689 bytes (.bin may be padded larger)
```

- **Used static DRAM**: Total amount of DRAM allocated at compile time. `remain` indicates the amount of DRAM left to be used as heap memory at runtime. Note that due to meta data overhead, implementation constraints, and startup heap allocations, the actual size of the DRAM heap is smaller.
  - `.data size`: Amount of DRAM allocated at compile time for the `.data` (i.e., all statically allocated variables that are initialized to non-zero values). `.data` also consumes space in the binary image to store the non-zero initialization values.
  - `.bss size`: Amount of DRAM allocated at compile time for `.bss` (i.e., all statically allocated variables that are initialized to zero). `.bss` does not consume extra space in flash.
Chapter 4. API Guides

- **Used static IRAM**: Total amount of IRAM allocated at compile time. `remain` indicates the amount of IRAM left to be used as heap memory at runtime. Note that due to meta data overhead, implementation constraints, and startup heap allocations, the actual size of the IRAM heap is smaller.
  - `.text` size: Amount of IRAM used for `.text` (i.e., all code that is executed from IRAM). `.text` also consumes space in the binary image as the code is initially stored there and is then copied over to IRAM on startup.
- **Used Flash size**: Total amount of flash used (excluding usage by DRAM and IRAM)
  - `.text`: Amount of flash used for `.text` (i.e., all code that is executed via the flash cache, see IROM).
  - `.rodata`: Amount of flash used for `.rodata` (i.e., read-only data that is loaded via the flash cache, see DROM).
- **Total image size** is the estimated total size of the binary file.

**Component Usage Summary `idf.py size-components`** The summary output provided by `idf.py size` does not give enough details to find the main contributor to excessive binary size. To analyze in detail, use `idf.py size-components`.

```bash
$ idf.py size-components
[...]
Total sizes:
  DRAM .data size: 14956 bytes
  DRAM .bss size: 15808 bytes
Used static DRAM: 30764 bytes (149972 available, 17.0% used)
Used static IRAM: 83918 bytes (47154 available, 64.0% used)
  Flash code: 559943 bytes
  Flash rodata: 176736 bytes
Total image size: ~835553 bytes (bin may be padded larger)
Per-archive contributions to ELF file:

    (exe) 0 0 0 3 0 3
```

(continues on next page)
The first lines of the output from `idf.py size-components` are the same as that from `idf.py size`. After this, a table is printed as `Per-archive contributions to ELF file`. This means how much each static library archive has contributed to the final binary size.

Generally, one static library archive is built per component, although some are binary libraries included by a particular component, for example, `libnet80211.a` is included by `esp_wifi` component. There are also toolchain libraries such as `libc.a` and `libgcc.a` listed here, these provide Standard C/C++ Library and toolchain built-in functionality.

If your project is simple and only has a main component, then all of the project’s code will be shown under `libmain.a`. If your project includes its own components (see Build System), then they will each be shown on a separate line.

The table is sorted in descending order of the total contribution of the static archive to the binary size.

The columns are as follows:

- **DRAM .data & .bss & other** - .data and .bss are the same as for the totals shown above. Both are static variables and reduce the total available RAM at runtime, but .bss does not contribute to the binary file size. other is a column for any custom section types that also contribute to RAM size. Usually, the value is 0.
- **IRAM** - is the same as for the totals shown above. It refers to code linked to execute from IRAM, which uses space in the binary file and also reduces IRAM that can be dynamically allocated at runtime using `HEAP_CAP_32BIT`.
- **D/IRAM** - shows IRAM space which, due to occupying D/IRAM space, is also reducing available DRAM available as heap at runtime.
- **Flash code & rodata** - these are the same as the totals above, IROM and DROM space accessed from the flash cache that contribute to the binary size.

**Source File Usage Summary `idf.py size-files`** For even more details, run `idf.py size-files` to get a summary of the contribution each object file has made to the final binary size. Each object file corresponds to a single source file.

$$ idf.py size-files $$

```

</table>
| [... additional lines removed ...]
For example, we can see that the file `x509_crt_bundle.S.o` contributed 64,212 bytes to the total firmware size, all as `.rodata` in flash. Therefore we can guess that this application is using the ESP x509 Certificate Bundle feature and not using this feature would save at last this many bytes from the firmware size.

Some of the object files are linked from binary libraries and therefore you will not find a corresponding source file. To locate which component a source file belongs to, it is generally possible to search in the ESP-IDF source tree or look in the Linker Map File for the full path.

**Comparing Two Binaries**  If making some changes that affect binary size, it is possible to use an ESP-IDF tool to break down the exact differences in size. This operation is not part of `idf.py`, it is necessary to run the `esp_idf_size` Python tool directly.

To do so, first, locate the linker map file with the name `PROJECTNAME.map` in the build directory. The `esp_idf_size` tool performs its analysis based on the output of the linker map file.

To compare with another binary, you also need its corresponding `.map` file saved from the build directory.

For example, to compare two builds, one of which with the default `CONFIG_COMPILER_OPTIMIZATION` setting Debug `(-Og)` configuration while another with Optimize for size `(-Os)`:

```
$ python -m esp_idf_size --diff build_Og/https_request.map build_Os/https_request.map
```

We can see from the Difference column that changing this one setting caused the whole binary to be over 60 KB smaller and over 5 KB more RAM is available.

It is also possible to use the `diff` mode to output a table of component-level (static library archive) differences:

```
python -m esp_idf_size --archives --diff build_Og/https_request.map build_Os/https_request.map
```

Also at the individual source file level:

```
python -m esp_idf_size --files --diff build_Og/https_request.map build_Os/https_request.map
```

Other options, like writing the output to a file, are available, pass `--help` to see the full list.
Chapter 4. API Guides

**Showing Size When Linker Fails**  If too much static memory is allocated, the linker will fail with an error such as DRAM segment data does not fit. region `iram0_0_seg' overflowed by 44 bytes, or similar.

In these cases, idf.py size will not succeed either. However, it is possible to run esp_idf_size manually to view the partial static memory usage. The memory usage will miss the variables that could not be linked, so there still appears to be some free space.

The map file argument is `<projectname>.map` in the build directory.

```python
python -m esp_idf_size build/project_name.map
```

It is also possible to view the equivalent of `size-components` or `size-files` output:

```python
python -m esp_idf_size --archives build/project_name.map
python -m esp_idf_size --files build/project_name.map
```

**Linker Map File**

**Note:** This is an advanced analysis method, but it can be very useful. Feel free to skip ahead to *Reducing Overall Size* and possibly come back to this later.

The idf.py size analysis tools all work by parsing the GNU binutils linker map file, which is a summary of everything the linker did when it created (i.e., linked) the final firmware binary file.

Linker map files themselves are plain text files, so it is possible to read them and find out exactly what the linker did. However, they are also very complex and long, often exceeding 100,000 lines.

The map file itself is broken into parts and each part has a heading. The parts are:

- **Archive member included to satisfy reference by file (symbol)**
  - This shows you: for each object file included in the link, what symbol (function or variable) was the linker searching for when it included that object file.
  - If you are wondering why some object file in particular was included in the binary, this part may give a clue. This part can be used in conjunction with the Cross Reference Table at the end of the file.

**Note:** Not every object file shown in this list ends up included in the final binary, some end up in the Discarded input sections list instead.

- **Allocating common symbols**
  - This is a list of some global variables along with their sizes. Common symbols have a particular meaning in ELF binary files, but ESP-IDF does not make much use of them.

- **Discarded input sections**
  - These sections were read by the linker as part of an object file to be linked into the final binary, but then nothing else referred to them, so they were discarded from the final binary.
  - For ESP-IDF, this list can be very long, as we compile each function and static variable to a unique section in order to minimize the final binary size. Specifically, ESP-IDF uses compiler options `-ffunction-sections -fdata-sections` and linker option `--gc-sections`.
  - Items mentioned in this list do not contribute to the final binary.

- **Memory Configuration, Linker script and memory map**
  - These two parts go together. Some of the output comes directly from the linker command line and the Linker Script, both provided by Build System. The linker script is partially generated from the ESP-IDF project using the Linker Script Generation feature.
  - As the output of the `Linker script and memory map` part of the map unfolds, you can see each symbol (function or static variable) linked into the final binary along with its address (as a 16 digit hex number), its length (also in hex), and the library and object file it was linked from (which can be used to determine the component and the source file).
  - Following all of the output sections that take up space in the final .bin file, the memory map also includes some sections in the ELF file that are only used for debugging, e.g., ELF sections `.debug_*`,
etc. These do not contribute to the final binary size. You can notice the address of these symbols is a very small number, starting from 0x0000000000000000 and counting up.

• Cross Reference Table
  – This table shows the symbol (function or static variable) that the list of object file(s) refers to.
  If you are wondering why a particular thing is included in the binary, this will help determine what included it.

Note: Unfortunately, the Cross Reference Table does not only include symbols that made it into the final binary. It also includes symbols in discarded sections. Therefore, just because something is shown here does not mean that it was included in the final binary - this needs to be checked separately.

Note: Linker map files are generated by the GNU binutils linker ld, not ESP-IDF. You can find additional information online about the linker map file format. This quick summary is written from the perspective of ESP-IDF build system in particular.

Reducing Overall Size  The following configuration options reduces the final binary size of almost any ESP-IDF project:

• Set CONFIG_COMPILER_OPTIMIZATION to Optimize for size (−Os). In some cases, Optimize for performance (−O2) will also reduce the binary size compared to the default. Note that if your code contains C or C++ Undefined Behavior then increasing the compiler optimization level may expose bugs that otherwise do not happen.

• Reduce the compiled-in log output by lowering the app CONFIG_LOG_DEFAULT_LEVEL. If the CONFIG_LOG_MAXIMUM_LEVEL is changed from the default then this setting controls the binary size instead. Reducing compiled-in logging reduces the number of strings in the binary, and also the code size of the calls to logging functions.

• Set the CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL to Silent. This avoids compiling in a dedicated assertion string and source file name for each assert that may fail. It is still possible to find the failed assertion in the code by looking at the memory address where the assertion failed.

• Besides the CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL, you can disable or silent the assertion for the HAL component separately by setting CONFIG_HAL_DEFAULT_ASSERTION_LEVEL. It is to notice that ESP-IDF lowers the HAL assertion level in bootloader to be silent even if CONFIG_HAL_DEFAULT_ASSERTION_LEVEL is set to full-assertion level. This is to reduce the bootloader size.

• Setting CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT removes specific error messages for particular internal ESP-IDF error check macros. This may make it harder to debug some error conditions by reading the log output.

• If the binary needs to run on only certain revision(s) of ESP32, increasing CONFIG_ESP32_REV_MIN to match can result in a reduced binary size. This will make a large difference if setting ESP32 minimum revision 3, and PSRAM is enabled.

• Do not enable CONFIG_COMPILER_CXX_EXCEPTIONS, CONFIG_COMPILER_CXX_RTTI, or set the CONFIG_COMPILER_STACK_CHECK_MODE to Overall. All of these options are already disabled by default, but they have a large impact on binary size.

• Disabling CONFIG_ESP_ERR_TO_NAME_LOOKUP removes the lookup table to translate user-friendly names for error values (see Error Handling) in error logs, etc. This saves some binary size, but error values will be printed as integers only.

• Setting CONFIG_ESP_SYSTEM_PANIC to Silent reboot saves a small amount of binary size, however this is only recommended if no one will use UART output to debug the device.

• If the application binary uses only one of the security versions of the protocomm component, then the support for others can be disabled to save some code size. The support can be disabled through CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_0, CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_1 or CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_2 respectively.
Note: In addition to the many configuration items shown here, there are a number of configuration options where changing the option from the default increases binary size. These are not noted here. Where the increase is significant is usually noted in the configuration item help text.

Targeted Optimizations  The following binary size optimizations apply to a particular component or a function:

Wi-Fi

• Disabling `CONFIG_ESP_WIFI_ENABLE_WPA3_SAE` will save some Wi-Fi binary size if WPA3 support is not needed. Note that WPA3 is mandatory for new Wi-Fi device certifications.
• Disabling `CONFIG_ESP_WIFI_SOFTAP_SUPPORT` will save some Wi-Fi binary size if soft-AP support is not needed.
• Disabling `CONFIG_ESP_WIFI_ENTERPRISE_SUPPORT` will save some Wi-Fi binary size if enterprise support is not needed.

ADC

• Disabling ADC calibration features `CONFIG_ADC_CAL_EFUSE_TP_ENABLE`, `CONFIG_ADC_CAL_EFUSE_VREF_ENABLE`, `CONFIG_ADC_CAL_LUT_ENABLE` will save a small amount of binary size if ADC driver is used, at expense of accuracy.

Bluetooth NimBLE  If using NimBLE-based Host APIs then the following modifications can reduce binary size:

• Set `CONFIG_BTDM_CTRL_BLE_MAX_CONN` to 1 if only one Bluetooth LE connection is needed.
• Set `CONFIG_BT_NIMBLE_MAX_CONNECTIONS` to 1 if only one Bluetooth LE connection is needed.
• Disable either `CONFIG_BT_NIMBLE_ROLE_CENTRAL` or `CONFIG_BT_NIMBLE_ROLE_OBSERVER` if these roles are not needed.
• Reducing `CONFIG_BT_NIMBLE_LOG_LEVEL` can reduce binary size. Note that if the overall log level has been reduced as described above in Reducing Overall Size then this also reduces the NimBLE log level.

lwIP IPv6

• Setting `CONFIG_LWIP_IPV6` to `false` will reduce the size of the lwIP TCP/IP stack, at the cost of only supporting IPv4.

Note: IPv6 is required by some components such as `coap` and `ASIO Port`. These components will not be available if IPv6 is disabled.

lwIP IPv4

• If IPv4 connectivity is not required, setting `CONFIG_LWIP_IPV4` to `false` will reduce the size of the lwIP, supporting IPv6-only TCP/IP stack.

Note: Before disabling IPv4 support, please note that IPv6 only network environments are not ubiquitous and must be supported in the local network, e.g., by your internet service provider or using constrained local network settings.
Newlib Nano Formatting  By default, ESP-IDF uses Newlib “full” formatting for I/O functions (printf(), scanf(), etc.)

Enabling the config option CONFIG_NEWLIB_NANO_FORMAT will switch Newlib to the “Nano” formatting mode. This is smaller in code size, and a large part of the implementation is compiled into the ESP32 ROM, so it does not need to be included in the binary at all.

The exact difference in binary size depends on which features the firmware uses, but 25 KB ~ 50 KB is typical.

Enabling “Nano” formatting reduces the stack usage of each function that calls printf() or another string formatting function, see Reducing Stack Sizes.

“Nano” formatting does not support 64-bit integers, or C99 formatting features. For a full list of restrictions, search for --enable-newlib-nano-formatted-io in the Newlib README file.

MbedTLS Features  Under Component Config > mbedTLS, there are multiple mbedTLS features enabled default, some of which can be disabled if not needed to save code size.

These include:

- CONFIG_MBEDTLS_HAVE_TIME
- CONFIG_MBEDTLS_ECDSA_DETERMINISTIC
- CONFIG_MBEDTLS_SHA512_C
- CONFIG_MBEDTLS_CLIENT_SSL_SESSION_TICKETS
- CONFIG_MBEDTLS_SERVER_SSL_SESSION_TICKETS
- CONFIG_MBEDTLS_SSL_CONTEXT.Serialization
- CONFIG_MBEDTLS_SSL_ALPN
- CONFIG_MBEDTLS_SSL_RENEGOTIATION
- CONFIG_MBEDTLS_CCM_C
- CONFIG_MBEDTLS_GCM_C
- CONFIG_MBEDTLS_ECP_C (Alternatively: Leave this option enabled but disable some of the elliptic curves listed in the sub-menu.)
- CONFIG_MBEDTLS_ECP_NIST_OPTIM
- CONFIG_MBEDTLS_ECP_FIXED_POINT_OPTIM
- Change CONFIG_MBEDTLS_TLS_MODE if both server & client functionalities are not needed
- Consider disabling some cipher suites listed in the TLS Key Exchange Methods sub-menu (i.e., CONFIG_MBEDTLS_KEY_EXCHANGE_RSA)

The help text for each option has some more information for reference.

Important:  It is strongly not recommended to disable all these mbedTLS options. Only disable options of which you understand the functionality and are certain that it is not needed in the application. In particular:

- Ensure that any TLS server(s) the device connects to can still be used. If the server is controlled by a third party or a cloud service, it is recommended to ensure that the firmware supports at least two of the supported cipher suites in case one is disabled in a future update.
- Ensure that any TLS client(s) that connect to the device can still connect with supported/recommended cipher suites. Note that future versions of client operating systems may remove support for some features, so it is recommended to enable multiple supported cipher suites, or algorithms for redundancy.

If depending on third party clients or servers, always pay attention to announcements about future changes to supported TLS features. If not, the ESP32 device may become inaccessible if support changes.

Note:  Not every combination of mbedTLS compile-time config is tested in ESP-IDF. If you find a combination that fails to compile or function as expected, please report the details on GitHub.

VFS  Virtual Filesystem Component feature in ESP-IDF allows multiple filesystem drivers and file-like peripheral drivers to be accessed using standard I/O functions (open, read, write, etc.) and C library functions (fopen,
fread, fwrite, etc.). When filesystem or file-like peripheral driver functionality is not used in the application, this feature can be fully or partially disabled. VFS component provides the following configuration options:

- **CONFIG_VFS_SUPPORT_TERMIOS** — can be disabled if the application does not use `termios` family of functions. Currently, these functions are implemented only for UART VFS driver. Most applications can disable this option. Disabling this option reduces the code size by about 1.8 KB.
- **CONFIG_VFS_SUPPORT_SELECT** — can be disabled if the application does not use the `select` function with file descriptors. Currently, only the UART and eventfd VFS drivers implement `select` support. Note that when this option is disabled, `select` can still be used for socket file descriptors. Disabling this option reduces the code size by about 2.7 KB.
- **CONFIG_VFS_SUPPORT_DIR** — can be disabled if the application does not use directory-related functions, such as `readdir` (see the description of this option for the complete list). Applications that only open, read and write specific files and do not need to enumerate or create directories can disable this option, reducing the code size by 0.5 KB or more, depending on the filesystem drivers in use.
- **CONFIG_VFS_SUPPORT_IO** — can be disabled if the application does not use filesystems or file-like peripheral drivers. This disables all VFS functionality, including the three options mentioned above. When this option is disabled, `Console` can not be used. Note that the application can still use standard I/O functions with socket file descriptors when this option is disabled. Compared to the default configuration, disabling this option reduces code size by about 9.4 KB.

**Bootloader Size**

This document deals with the size of an ESP-IDF app binary only, and not the ESP-IDF Second Stage Bootloader.

For a discussion of ESP-IDF bootloader binary size, see *Bootloader Size*.

**IRAM Binary Size**

If the IRAM section of a binary is too large, this issue can be resolved by reducing IRAM memory usage. See *Optimizing IRAM Usage*.

**Minimizing RAM Usage**

In some cases, a firmware application’s available RAM may run low or run out entirely. In these cases, it is necessary to tune the memory usage of the firmware application.

In general, firmware should aim to leave some headroom of free internal RAM to deal with extraordinary situations or changes in RAM usage in future updates.

**Background**

Before optimizing ESP-IDF RAM usage, it is necessary to understand the basics of ESP32 memory types, the difference between static and dynamic memory usage in C, and the way ESP-IDF uses stack and heap. This information can all be found in *Heap Memory Allocation*.

**Measuring Static Memory Usage**

The `idf.py` tool can be used to generate reports about the static memory usage of an application, see *Measuring Static Sizes*.

**Measuring Dynamic Memory Usage**

ESP-IDF contains a range of heap APIs for measuring free heap at runtime, see *Heap Memory Debugging*.

**Note:** In embedded systems, heap fragmentation can be a significant issue alongside total RAM usage. The heap measurement APIs provide ways to measure the largest free block. Monitoring this value along with the total number of free bytes can give a quick indication of whether heap fragmentation is becoming an issue.
Reducing Static Memory Usage

- Reducing the static memory usage of the application increases the amount of RAM available for heap runtime, and vice versa.
- Generally speaking, minimizing static memory usage requires monitoring the .data and .bss sizes. For tools to do this, see Measuring Static Sizes.
- Internal ESP-IDF functions do not make heavy use of static RAM in C. In many instances (such as Wi-Fi library, Bluetooth controller), static buffers are still allocated from the heap. However, the allocation is performed only once during feature initialization and will be freed if the feature is deinitialized. This approach is adopted to optimize the availability of free memory at various stages of the application’s life cycle.

To minimize static memory use:

- Constant data can be stored in flash memory instead of RAM, thus it is recommended to declare structures, buffers, or other variables as const. This approach may require modifying firmware functions to accept const * arguments instead of mutable pointer arguments. These changes can also help reduce the stack usage of certain functions.
- If using Bluedroid, setting the option CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY will cause Bluedroid to allocate memory on initialization and free it on deinitialization. This does not necessarily reduce the peak memory usage, but changes it from static memory usage to runtime memory usage.
- If using OpenThread, enabling the option CONFIG_OPENTHREAD_PLATFORM_MSGPOOL_MANAGEMENT will cause OpenThread to allocate message pool buffers from PSRAM, which will reduce static memory use.

Reducing Stack Sizes

In FreeRTOS, task stacks are usually allocated from the heap. The stack size for each task is fixed and passed as an argument to xTaskCreate(). Each task can use up to its allocated stack size, but using more than this will cause an otherwise valid program to crash, with a stack overflow or heap corruption.

Therefore, determining the optimum sizes of each task stack, minimizing the required size of each task stack, and minimizing the number of task stacks as whole, can all substantially reduce RAM usage.

To determine the optimum size for a particular task stack, users can consider the following methods:

- At runtime, call the function uxTaskGetStackHighWaterMark() with the handle of any task where you think there is unused stack memory. This function returns the minimum lifetime free stack memory in bytes.
  - The easiest time to call uxTaskGetStackHighWaterMark() is from the task itself: call uxTaskGetStackHighWaterMark(NULL) to get the current task’s high water mark after the time that the task has achieved its peak stack usage, i.e., if there is a main loop, execute the main loop a number of times with all possible states, and then call uxTaskGetStackHighWaterMark().
  - Often, it is possible to subtract almost the entire value returned here from the total stack size of a task, but allow some safety margin to account for unexpected small increases in stack usage at runtime.
- Call uxTaskGetSystemState() at runtime to get a summary of all tasks in the system. This includes their individual stack high watermark values.
- When debugger watchpoints are not being used, users can set the CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK option. This will cause one of the watchpoints to watch the last word of the task’s stack. If that word is overwritten (such as in a stack overflow), a panic is triggered immediately. This is slightly more reliable than the default CONFIG_FREERTOS_CHECK_STACKOVERFLOW option of Check using canary bytes, because the panic happens immediately, rather than on the next RTOS context switch. Neither option is perfect. In some cases, it is possible that the stack pointer skips the watchpoint or canary bytes and corrupts another region of RAM instead.

To reduce the required size of a particular task stack, users can consider the following methods:

- Avoid stack heavy functions. String formatting functions like printf() are particularly heavy users of the stack, so any task which does not ever call these can usually have its stack size reduced.
  - Enabling Newlib Nano Formatting reduces the stack usage of any task that calls printf() or other C string formatting functions.
- Avoid allocating large variables on the stack. In C, any large structures or arrays allocated as an automatic variable (i.e., default scope of a C declaration) uses space on the stack. To minimize the sizes of these, allocate
them statically and/or see if you can save memory by dynamically allocating them from the heap only when they are needed.

- Avoid deep recursive function calls. Individual recursive function calls do not always add a lot of stack usage each time they are called, but if each function includes large stack-based variables then the overhead can get quite high.

To reduce the total number of tasks, users can consider the following method:

- Combine tasks. If a particular task is never created, the task’s stack is never allocated, thus reducing RAM usage significantly. Unnecessary tasks can typically be removed if those tasks can be combined with another task. In an application, tasks can typically be combined or removed if:
  - The work done by the tasks can be structured into multiple functions that are called sequentially.
  - The work done by the tasks can be structured into smaller jobs that are serialized (via a FreeRTOS queue or similar) for execution by a worker task.

Internal Task Stack Sizes ESP-IDF allocates a number of internal tasks for housekeeping purposes or operating system functions. Some are created during the startup process, and some are created at runtime when particular features are initialized.

The default stack sizes for these tasks are usually set conservatively high to allow all common usage patterns. Many of the stack sizes are configurable, and it may be possible to reduce them to match the real runtime stack usage of the task.

**Important:** If internal task stack sizes are set too small, ESP-IDF will crash unpredictably. Even if the root cause is task stack overflow, this is not always clear when debugging. It is recommended that internal stack sizes are only reduced carefully (if at all), with close attention to high water mark free space under load. If reporting an issue that occurs when internal task stack sizes have been reduced, please always include the following information and the specific configuration that is being used.

- **Running the Main Task** has stack size `CONFIG_ESP_MAIN_TASK_STACK_SIZE`.
- **High Resolution Timer (ESP Timer)** system task which executes callbacks has stack size `CONFIG_ESP_TIMER_TASK_STACK_SIZE`.
- FreeRTOS Timer Task to handle FreeRTOS timer callbacks has stack size `CONFIG_FREERTOS_TIMER_TASK_STACK_DEPTH`.
- **Event Loop Library** system task to execute callbacks for the default system event loop has stack size `CONFIG_ESP_SYSTEM_EVENT_TASK_STACK_SIZE`.
- **lwIP TCP/IP task** has stack size `CONFIG_LWIP_TCPIP_TASK_STACK_SIZE`.
- **Bluetooth® API** have task stack size `CONFIG_BT_BT_TASK_STACK_SIZE`, `CONFIG_BT_BTU_TASK_STACK_SIZE`.
- **NimBLE-based Host APIs** has task stack size `CONFIG_BT_NIMBLE_HOST_TASK_STACK_SIZE`.
- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the task stack size is 4 KB. This setting can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
- FreeRTOS idle task stack size is configured by `CONFIG_FREERTOS_IDLE_TASK_STACKSIZE`.
- If using the **ESP-MQTT** component, it creates a task with stack size configured by `CONFIG_MQTT_TASK_STACK_SIZE`. MQTT stack size can also be configured using `task_stack` field of `esp_mqtt_client_config_t`.
- To see how to optimize RAM usage when using mDNS, please check **Minimizing RAM Usage**.

**Note:** Aside from built-in system features such as ESP-timer, if an ESP-IDF feature is not initialized by the firmware, then no associated task is created. In those cases, the stack usage is zero, and the stack-size configuration for the task is not relevant.

Reducing Heap Usage For functions that assist in analyzing heap usage at runtime, see **Heap Memory Debugging**.
Normally, optimizing heap usage consists of analyzing the usage and removing calls to `malloc()` that are not being used, reducing the corresponding sizes, or freeing previously allocated buffers earlier.

There are some ESP-IDF configuration options that can reduce heap usage at runtime:

- lwIP documentation has a section to configure Minimum RAM Usage.
- Wi-Fi Buffer Usage describes options to either reduce the number of static buffers or reduce the maximum number of dynamic buffers in use, so as to minimize memory usage at a possible cost of performance. Note that static Wi-Fi buffers are still allocated from the heap when Wi-Fi is initialized, and will be freed if Wi-Fi is deinitialized.
- The Ethernet driver allocates DMA buffers for the internal Ethernet MAC when it is initialized - configuration options are `CONFIG_ETH_DMA_BUFFER_SIZE`, `CONFIG_ETH_DMA_RX_BUFFER_NUM`, `CONFIG_ETH_DMA_TX_BUFFER_NUM`.
- Several Mbed TLS configuration options can be used to reduce heap memory usage. See the Reducing Heap Usage docs for details.
- In single-core mode only, it is possible to use IRAM as byte-accessible memory added to the regular heap by enabling `CONFIG_ESP32_IRAM_AS_8BIT_ACCESSIBLE_MEMORY`. Note that this option carries a performance penalty, and the risk of security issues caused by executable data. If this option is enabled, then it is possible to set other options to prefer certain buffers allocated from this memory: `CONFIG_MBEDTLS_MEM_ALLOC_MODE`, NimBLE.
- Reduce `CONFIG_BTDM_CTRL_BLE_MAX_CONN` if using Bluetooth LE.
- Reduce `CONFIG_BTDM_CTRL_BR_EDR_MAX_ACL_CONN` if using Bluetooth Classic.

**Note:** There are other configuration options that increase heap usage at runtime if changed from the defaults. These options are not listed above, but the help text for the configuration item will mention if there is some memory impact.

**Optimizing IRAM Usage** If the app allocates more static IRAM than available, then the app will fail to build, and linker errors such as section `.iram0.text` will not fit in region `iram0_0_seg`, IRAM0 segment data does not fit, and region `iram0_0_seg` overflown by 84-bytes will be seen. If this happens, it is necessary to find ways to reduce static IRAM usage in order to link the application.

To analyze the IRAM usage in the firmware binary, use Measuring Static Sizes. If the firmware failed to link, steps to analyze are shown at Showing Size When Linker Fails.

The following options will reduce IRAM usage of some ESP-IDF features:

- Enable `CONFIG_FREERTOS_PLACE_FUNCTIONS_INTO_FLASH`. Provided these functions are not incorrectly used from ISRs, this option is safe to enable in all configurations.
- Enable `CONFIG_RINGBUF_PLACE_FUNCTIONS_INTO_FLASH`. Provided these functions are not incorrectly used from ISRs, this option is safe to enable in all configurations.
- Enable `CONFIG_RINGBUF_PLACE_ISR_FUNCTIONS_INTO_FLASH`. This option is not safe to use if the ISR ringbuf functions are used from an IRAM interrupt context, e.g., if `CONFIG_UART_ISR_IN_IRAM` is enabled. For the ESP-IDF drivers where this is the case, you can get an error at run-time when installing the driver in question.
- Disabling Wi-Fi options `CONFIG_ESP_WIFI_IRAM_OPT` and/or `CONFIG_ESP_WIFI_RX_IRAM_OPT` options frees available IRAM at the cost of Wi-Fi performance.
- Disabling `CONFIG_SPI_FLASH_ROM_DRIVER_PATCH` frees some IRAM but is only available in some flash configurations, see the configuration item help text.
- If the application uses PSRAM and is based on ESP32 rev. 3 (ECO3), setting `CONFIG_ESP32_REV_MIN` to 3 disables PSRAM bug workarounds, saving 10 KB or more of IRAM.
- Disabling `CONFIG_ESP_EVENT_POST_FROM_IRAM_ISR` prevents posting `esp_event` events from IRAM-Safe Interrupt Handlers but saves some IRAM.
- Disabling `CONFIG_SPI_MASTER_ISR_IN_IRAM` prevents `spi_master` interrupts from being serviced while writing to flash, and may otherwise reduce `spi_master` performance, but saves some IRAM.
Disabling `CONFIG_SPI_SLAVE_ISR_IN_IRAM` prevents spi_slave interrupts from being serviced while writing to flash, which saves some IRAM.

Setting `CONFIG_HAL_DEFAULT_ASSERTION_LEVEL` to disable assertion for HAL component saves some IRAM, especially for HAL code which calls HAL_ASSERT a lot and resides in IRAM.

Refer to the sdkconfig menu Auto-detect Flash chips, and you can disable flash drivers which you do not need to save some IRAM.

Enable `CONFIG_HEAP_PLACE_FUNCTION_INTO_FLASH`. Provided that `CONFIG_SPI_MASTER_ISR_IN_IRAM` is not enabled and the heap functions are not incorrectly used from ISRs, this option is safe to enable in all configurations.

**Using SRAM1 for IRAM** The SRAM1 memory area is normally used for DRAM, but it is possible to use parts of it for IRAM with `CONFIG_ESP_SYSTEM_ESP32_SRAM1_REGION_AS_IRAM`. This memory would previously be reserved for DRAM data usage (e.g., .bss) by the software bootloader and later added to the heap. After this option was introduced, the bootloader DRAM size was reduced to a value closer to what it normally actually needs.

To use this option, ESP-IDF should be able to recognize that the new SRAM1 area is also a valid load address for an image segment. If the software bootloader was compiled before this option existed, then the bootloader will not be able to load the app that has code placed in this new extended IRAM area. This would typically happen if you are doing an OTA update, where only the app would be updated.

If the IRAM section were to be placed in an invalid area, then this would be detected during the bootup process, and result in a failed boot:

```
E (204) esp_image: Segment 5 0x400845f8-0x400a126c invalid: bad load address range
```

**Warning:** Apps compiled with `CONFIG_ESP_SYSTEM_ESP32_SRAM1_REGION_AS_IRAM` may fail to boot, if used together with a software bootloader that was compiled before this config option was introduced. If you are using an older bootloader and updating over OTA, please test carefully before pushing any updates.

Any memory that ends up unused for static IRAM will be added to the heap.

**Putting C Library in Flash** When compiling for ESP32 revisions older than ECO3 (`CONFIG_ESP32_REV_MIN`), the PSRAM Cache bug workaround (`CONFIG_SPIRAM_CACHE_WORKAROUND`) option is enabled, and the C library functions normally located in ROM are recompiled with the workaround and placed into IRAM instead. For most applications, it is safe to move many of the C library functions into flash, reclaiming some IRAM. Corresponding options include:

- `CONFIG_SPIRAM_CACHE_LIBJMP_IN_IRAM`: affects the functions `longjmp` and `setjump`.
- `CONFIG_SPIRAM_CACHE_LIBMATH_IN_IRAM`: affects the functions `abs`, `div`, `labs`, `ldiv`, `quorem`, `fpclassify` and `nan`.
- `CONFIG_SPIRAM_CACHE_LIBNUMPARSER_IN_IRAM`: affects the functions `utoa`, `itoa`, `atol`, `strtol`, and `strtoul`.
- `CONFIG_SPIRAM_CACHE_LIBIO_IN_IRAM`: affects the functions `wcrtomb`, `fwrite`, `wbuf`, `wsetups`, `fputwc`, `wctomb_r`, `ungetc`, `makebuf`, `fflush`, `refill`, and `sccl`.
- `CONFIG_SPIRAM_CACHE_LIBTIME_IN_IRAM`: affects the functions `asctime`, `asctime_r`, `ctime`, `ctime_r`, `lcltime`, `lcltime_r`, `gmtime`, `gmtime_r`, `strftime`, `mktime`, `mktzinfo`, `systimes`, `month_lengths`, `timelocal`, `tzvart`, `tzlock`, `tzcalc_limits`, and `strptime`.
- `CONFIG_SPIRAM_CACHE_LIBCHAR_IN_IRAM`: affects the functions `ctype_`, `toupper`, `tolower`, `toascii`, `strupr`, `bzero`, `isalnum`, `isalpha`, `isascii`, `isblank`, `isalnum`, `iscntrl`, `isdigit`, `isgraph`, `islower`, `isprint`, `ispunct`, `ispasm`, and `isupper`.
- `CONFIG_SPIRAM_CACHE_LIBMEM_IN_IRAM`: affects the functions `memcpy`, `memchr`, `memmove`, and `memchr`.
- `CONFIG_SPIRAM_CACHE_LIBSTR_IN_IRAM`: affects the functions `strcasecmp`, `strcasecmp`, `strcat`, `strcoll`, `strcp`, `strcspn`, `strdup`, `strdup_r`, `strlen`, `strlcpy`, `strlcn`, `strcmp`, `strchr`, `strchr_r`, `strcmp`, `strchr`, `strcoll`, `strcp`, `strcspn`, `strdup`, `strdup_r`, `strlen`, `strlcpy`, `strlcn`, `memcmp`, `memmove`, and `memchr`.
Chapter 4. API Guides

strlwr, strncasecmp, strcat, strcmp, strncpy, strndup, strndup_r, strrchr, strsep, strspn, strstr, strtok_r, and `strupr.

• CONFIG_SPIRAM_CACHE_LIBRAND_IN_IRAM: affects the functions srand, rand, and rand_r.
• CONFIG_SPIRAM_CACHE_LIBENV_IN_IRAM: affects the functions environ, envlock, and getenv_r.
• CONFIG_SPIRAM_CACHE_LIBFILE_IN_IRAM: affects the functions lock, isatty, fclose, open, close, creat, read, rshift, sbrk, stdio, syscalls, sysclose, sysopen, creat, symlink, impure, fwalk, and findfp.
• CONFIG_SPIRAM_CACHE_LIBMISC_IN_IRAM: affects the functions raise and system.

The exact amount of IRAM saved will depend on how much C library code is actually used by the application. In addition, the following options may be used to move more of the C library code into flash, however note that this may result in reduced performance. Be careful not to use the C library function allocated with ESP_INTR_FLAG_IRAM flag from interrupts when cache is disabled, refer to IRAM-Safe Interrupt Handlers for more details. For these reasons, the functions itoa, memcmp, memcpy, memset, strcat, strcmp, and strlen are always put in IRAM.

Note: Moving frequently-called functions from IRAM to flash may increase their execution time.

Note: Other configuration options exist that will increase IRAM usage by moving some functionality into IRAM, usually for performance, but the default option is not to do this. These are not listed here. The IRAM size impact of enabling these options is usually noted in the configuration item help text.

4.26 Reproducible Builds

4.26.1 Introduction

ESP-IDF build system has support for reproducible builds.

When reproducible builds are enabled, the application built with ESP-IDF does not depend on the build environment. Both the .elf file and .bin files of the application remains exactly the same, even if the following variables change:

• Directory where the project is located
• Directory where ESP-IDF is located (IDF_PATH)
• Build time

4.26.2 Reasons for Non-Reproducible Builds

There are several reasons why an application may depend on the build environment, even when the same source code and tools versions are used.

• In C code, __FILE__ preprocessor macro is expanded to the full path of the source file.
• __DATE__ and __TIME__ preprocessor macros are expanded to compilation date and time.
• When the compiler generates object files, it adds sections with debug information. These sections help debuggers, like GDB, to locate the source code which corresponds to a particular location in the machine code. These sections typically contain paths of relevant source files. These paths may be absolute, and will include the path to ESP-IDF or to the project.

There are also other possible reasons, such as unstable order of inputs and non-determinism in the build system.

4.26.3 Enabling Reproducible Builds in ESP-IDF

Reproducible builds can be enabled in ESP-IDF using CONFIG_APP_REPRODUCIBLE_BUILD option.

This option is disabled by default. It can be enabled in menuconfig.
The option may also be added into `sdkconfig.defaults`. If adding the option into `sdkconfig.defaults`, delete the `sdkconfig` file and run the build again. See *Custom Sdkconfig Defaults* for more information.

### 4.26.4 How Reproducible Builds Are Achieved

ESP-IDF achieves reproducible builds using the following measures:

- In ESP-IDF source code, `__DATE__` and `__TIME__` macros are not used when reproducible builds are enabled. Note, if the application source code uses these macros, the build will not be reproducible.
- ESP-IDF build system passes a set of `-fmacro-prefix-map` and `-fdebug-prefix-map` flags to replace base paths with placeholders:
  - Path to ESP-IDF is replaced with `/IDF`
  - Path to the project is replaced with `/IDF_PROJECT`
  - Path to the build directory is replaced with `/IDF_BUILD`
  - Paths to components are replaced with `/COMPONENT_NAME_DIR` (where `NAME` is the name of the component)
- Build date and time are not included into the application metadata structure and bootloader metadata structure if `CONFIG_APP_REPRODUCIBLE_BUILD` is enabled.
- ESP-IDF build system ensures that source file lists, component lists and other sequences are sorted before passing them to CMake. Various other parts of the build system, such as the linker script generator also perform sorting to ensure that same output is produced regardless of the environment.

### 4.26.5 Reproducible Builds and Debugging

When reproducible builds are enabled, file names included in debug information sections are altered as shown in the previous section. Due to this fact, the debugger (GDB) is not able to locate the source files for the given code location.

This issue can be solved using GDB `set substitute-path` command. For example, by adding the following command to GDB init script, the altered paths can be reverted to the original ones:

```bash
set substitute-path /COMPONENT_FREERTOS_DIR /home/user/esp/esp-idf/components/
  freertos
```

ESP-IDF build system generates a file with the list of such `set substitute-path` commands automatically during the build process. The file is called `prefix_map_gdbinit` and is located in the project `build` directory.

When `idf.py gdb` is used to start debugging, this additional gdbinit file is automatically passed to GDB. When launching GDB manually or from and IDE, please pass this additional gdbinit script to GDB using `-x build/prefix_map_gdbinit` argument.

### 4.26.6 Factors Which Still Affect Reproducible Builds

Note that the built application still depends on:

- ESP-IDF version
- Versions of the build tools (CMake, Ninja) and the cross-compiler

*IDF Docker Image* can be used to ensure that these factors do not affect the build.

### 4.27 RF Calibration

ESP32 supports three RF calibration methods during RF initialization:

1. Partial calibration
2. Full calibration
3. No calibration
### 4.27.1 Partial Calibration

During RF initialization, the partial calibration method is used by default for RF calibration. It is done based on the full calibration data which is stored in the NVS. To use this method, please go to menuconfig and enable `CONFIG_ESP_PHY_CALIBRATION_AND_DATA_STORAGE`.

### 4.27.2 Full Calibration

Full calibration is triggered in the following conditions:

1. NVS does not exist.
2. The NVS partition to store calibration data has been erased.
3. Hardware MAC address has changed.
4. PHY library version has changed.
5. The RF calibration data loaded from the NVS partition is broken.

Full calibration takes 100 ms longer than the partial calibration method. If boot duration is not of critical importance to the application, the full calibration method is recommended. To switch to the full calibration method, go to menuconfig and disable `CONFIG_ESP_PHY_CALIBRATION_AND_DATA_STORAGE`. If you use the default method of RF calibration, there are two ways to add the function of triggering full calibration as a last-resort remedy.

1. Erase the NVS partition if you do not mind all of the data stored in the NVS partition is erased. That is indeed the easiest way.
2. Call API `esp_phy_erase_cal_data_in_nvs()` before initializing Wi-Fi and Bluetooth®/Bluetooth Low Energy based on some conditions (e.g., an option provided in some diagnostic mode). In this case, only the PHY namespace of the NVS partition is erased.

### 4.27.3 No Calibration

The no calibration method is only used when the device wakes up from Deep-sleep mode.

### 4.27.4 PHY Initialization Data

The PHY initialization data is used for RF calibration. There are two ways to get the PHY initialization data.

One is to use the default initialization data which is located in the header file `components/esp_phy esp32/include/phy_init_data.h`. It is embedded into the application binary after compiling and then stored into read-only memory (DROM). To use the default initialization data, please go to menuconfig and disable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION`.

An alternative is to store the initialization data in a PHY data partition. A PHY data partition is included in the default partition table. However, when using a custom partition table, please ensure that a PHY data partition (type: data, subtype: phy) is included in the custom partition table. Whether you are using a custom partition table or the default partition table, if initialization data is stored in a partition, it has to be flashed there, otherwise a runtime error occurs. If you want to use initialization data stored in a partition, go to menuconfig and enable the option `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION`.

### 4.27.5 API Reference

#### Header File

- `components/esp_phy/include/esp_phy_init.h`
- This header file can be included with:

  ```c
  #include "esp_phy_init.h"
  ```
- This header file is a part of the API provided by the `esp_phy` component. To declare that your component depends on `esp_phy`, add the following to your CMakeLists.txt:
REQUIRES esp_phy
or
PRIV_REQUIRES esp_phy

## Functions

### const esp_phy_init_data_t *esp_phy_get_init_data (void)

Get PHY init data.

If “Use a partition to store PHY init data” option is set in menuconfig, this function will load PHY init data from a partition. Otherwise, PHY init data will be compiled into the application itself, and this function will return a pointer to PHY init data located in read-only memory (DROM).

If “Use a partition to store PHY init data” option is enabled, this function may return NULL if the data loaded from flash is not valid.

**Note:** Call esp_phy_release_init_data to release the pointer obtained using this function after the call to esp_wifi_init.

**Returns** pointer to PHY init data structure

### void esp_phy_release_init_data (const esp_phy_init_data_t *data)

Release PHY init data.

**Parameters** data – pointer to PHY init data structure obtained from esp_phy_get_init_data function

### esp_err_t esp_phy_load_cal_data_from_nvs (esp_phy_calibration_data_t *out_cal_data)

Function called by esp_phy_load_cal_and_init to load PHY calibration data.

This is a convenience function which can be used to load PHY calibration data from NVS. Data can be stored to NVS using esp_phy_store_cal_data_to_nvs function.

If calibration data is not present in the NVS, or data is not valid (was obtained for a chip with a different MAC address, or obtained for a different version of software), this function will return an error.

**Parameters** out_cal_data – pointer to calibration data structure to be filled with loaded data.

**Returns** ESP_OK on success

### esp_err_t esp_phy_store_cal_data_to_nvs (const esp_phy_calibration_data_t *cal_data)

Function called by esp_phy_load_cal_and_init to store PHY calibration data.

This is a convenience function which can be used to store PHY calibration data to the NVS. Calibration data is returned by esp_phy_load_cal_and_init function. Data saved using this function to the NVS can later be loaded using esp_phy_store_cal_data_to_nvs function.

**Parameters** cal_data – pointer to calibration data which has to be saved.

**Returns** ESP_OK on success

### esp_err_t esp_phy_erase_cal_data_in_nvs (void)

Erase PHY calibration data which is stored in the NVS.

This is a function which can be used to trigger full calibration as a last-resort remedy if partial calibration is used. It can be called in the application based on some conditions (e.g. an option provided in some diagnostic mode).

**Returns** ESP_OK on success

**Returns** others on fail. Please refer to NVS API return value error number.
void esp_phy_enable (esp_phy_modem_t modem)  
Enable PHY and RF module.

PHY and RF module should be enabled in order to use WiFi or BT. Now PHY and RF enabling job is done automatically when start WiFi or BT. Users should not call this API in their application.

Parameters modem – the modem to call the phy enable.

void esp_phy_disable (esp_phy_modem_t modem)  
Disable PHY and RF module.

PHY module should be disabled in order to shutdown WiFi or BT. Now PHY and RF disabling job is done automatically when stop WiFi or BT. Users should not call this API in their application.

Parameters modem – the modem to call the phy disable.

void esp_btbb_enable (void)  
Enable BTBB module.

BTBB module should be enabled in order to use IEEE802154 or BT. Now BTBB enabling job is done automatically when start IEEE802154 or BT. Users should not call this API in their application.

void esp_btbb_disable (void)  
Disable BTBB module.

Disable BTBB module, used by IEEE802154 or Bluetooth. Users should not call this API in their application.

void esp_phy_load_cal_and_init (void)  
Load calibration data from NVS and initialize PHY and RF module.

void esp_phy_modem_init (void)  
Initialize backup memory for Phy power up/down.

void esp_phy_modem_deinit (void)  
Deinitialize backup memory for Phy power up/down Set phy_init_flag if all modems deinit on ESP32C3.

void esp_phy_common_clock_enable (void)  
Enable WiFi/BT common clock.

void esp_phy_common_clock_disable (void)  
Disable WiFi/BT common clock.

int64_t esp_phy_rf_get_on_ts (void)  
Get the time stamp when PHY/RF was switched on.

Returns return 0 if PHY/RF is never switched on. Otherwise return time in microsecond since boot when phy/rf was last switched on

esp_err_t esp_phy_update_country_info (const char *country)  
Update the corresponding PHY init type according to the country code of Wi-Fi.

Parameters country – country code

Returns ESP_OK on success.

Returns esp_err_t code describing the error on fail

char *get_phy_version_str (void)  
Get PHY lib version.

Returns PHY lib version.

void phy_init_param_set (uint8_t param)  
Set PHY init parameters.

Parameters param – is 1 means combo module
void phy_wifi_enable_set (uint8_t enable)

Wi-Fi RX enable.

**Parameters**
- `enable` - True for enable wifi receiving mode as default, false for closing wifi receiving mode as default.

**Structures**

struct esp_phy_init_data_t

Structure holding PHY init parameters.

**Public Members**

- `uint8_t params[128]`

  opaque PHY initialization parameters

struct esp_phy_calibration_data_t

Opaque PHY calibration data.

**Public Members**

- `uint8_t version[4]`

  PHY version

- `uint8_t mac[6]`

  The MAC address of the station

- `uint8_t opaque[1894]`

  calibration data

**Enumerations**

enum esp_phy_modem_t

PHY enable or disable modem.

**Values:**

- enumerator PHY_MODEM_WIFI

  PHY modem WIFI

- enumerator PHY_MODEM_BT

  PHY modem BT

- enumerator PHY_MODEM_IEEE802154

  PHY modem IEEE802154
Chapter 4. API Guides

```c
enum esp_phy_calibration_mode_t
{
    PHYRF_CAL_PARTIAL,  // Do part of RF calibration. This should be used after power-on reset.
    PHYRF_CAL_NONE,     // Don’t do any RF calibration. This mode is only suggested to be used after deep sleep reset.
    PHYRF_CAL_FULL,     // Do full RF calibration. Produces best results, but also consumes a lot of time and current. Suggested to be used once.
};
```

**Header File**

- components/esp_phy/include/esp_phy_cert_test.h
- This header file can be included with:

```c
#include "esp_phy_cert_test.h"
```
- This header file is a part of the API provided by the esp Phy component. To declare that your component depends on esp Phy, add the following to your CMakeLists.txt:

```cmake
REQUIRES esp_phy
```

or

```cmake
PRIV_REQUIRES esp_phy
```

**Functions**

- `void esp_wifi_power_domain_on (void)`
  
  Wifi power domain power on.

- `void esp_wifi_power_domain_off (void)`
  
  Wifi power domain power off.

- `void esp_phy_rftest_config (uint8_t conf)`
  
  Environment variable configuration.

  **Parameters**
  
  - `conf` – Set to 1 to enter RF test mode.

- `void esp_phy_rftest_init (void)`
  
  RF initialization configuration.

- `void esp_phy_tx_contin_en (bool contin_en)`
  
  TX Continuous mode.

  **Parameters**
  
  - `contin_en` – Set to true for continuous packet sending, which can be used for certification testing; Set to false to cancel continuous mode, which is the default mode and can be used for WLAN tester.

- `void esp_phy_cbw40m_en (bool en)`
  
  HT40/HT20 mode selection.

  **Parameters**
  
  - `en` – Set to false to enter 11n HT20 mode; Set to true to enter 11n HT40 mode;
void esp_phy_wifi_tx (uint32_t chan, esp_phy_wifi_rate_t rate, int8_t backoff, uint32_t length_byte, uint32_t packet_delay, uint32_t packet_num)

Wi-Fi TX command.

**Parameters**
- **chan** - channel setting, 1~14;
- **rate** - rate setting;
- **backoff** - Transmit power attenuation, unit is 0.25dB. For example, 4 means that the power is attenuated by 1dB;
- **length_byte** - TX packet length configuration, indicating PSDU Length, unit is byte;
- **packet_delay** - TX packet interval configuration, unit is us;
- **packet_num** - The number of packets sent, 0 means sending packets continuously, other values represent the number of packets to send.

void esp_phy_test_start_stop (uint8_t value)

Test start/stop command, used to stop transmitting or reciving state.

**Parameters**
- **value** - Value should be set to 3 before TX/RX. Set value to 0 to end TX/RX state.

void esp_phy_wifi_rx (uint32_t chan, esp_phy_wifi_rate_t rate)

Wi-Fi RX command.

**Parameters**
- **chan** - channel setting, 1~14;
- **rate** - rate setting;

void esp_phy_wifi_tx_tone (uint32_t start, uint32_t chan, uint32_t backoff)

Wi-Fi Carrier Wave(CW) TX command.

**Parameters**
- **start** - enable CW, 1 means transmit, 0 means stop transmitting;
- **chan** - CW channel setting, 1~14;
- **backoff** - CW power attenuation parameter, unit is 0.25dB. 4 indicates the power is attenuated by 1dB.

void esp_phy_ble_tx (uint32_t txpwr, uint32_t chan, uint32_t len, esp_phy_ble_type_t data_type, uint32_t syncw, esp_phy_ble_rate_t rate, uint32_t tx_num_in)

BLE TX command.

**Parameters**
- **txpwr** - Transmit power level. Tx power is about (level-8)*3 dBm, step is 3dB. Level 8 is around 0 dBm;
- **chan** - channel setting, range is 0~39, corresponding frequency = 2402+chan*2;
- **len** - Payload length setting, range is 0-255, unit is byte, 37 bytes is employed generally;
- **data_type** - Data type setting;
- **syncw** - Packet identification (need to be provided by the packet generator or instrument manufacturer), 0x71764129 is employed generally;
- **rate** - rate setting;
- **tx_num_in** - The number of packets sent, 0 means sending packets continuously, other values represent the number of packets to send.

void esp_phy_ble_rx (uint32_t chan, uint32_t syncw, esp_phy_ble_rate_t rate)

BLE RX command.

**Parameters**
- **chan** - channel selection, range is 0-39; Channels 0, 1, 2~10 correspond to 2404MHz, 2406MHz, 2408MHz~2424MHz respectively; Channels 11, 12, 13~36 correspond to 2428MHz, 2430MHz, 2432MHz~2478MHz respectively; Channel 37: 2402MHz, Channel 38: 2426MHz, Channel 39: 2480MHz;
- **syncw** - Packet identification (need to be provided by the packet generator or instrument manufacturer), 0x71764129 is employed generally;
- **rate** - rate setting;
void esp_phy_bt_tx_tone(uint32_t start, uint32_t chan, uint32_t power)
BLE Carrier Wave(CW) TX command.

Parameters
• start – enable CW, 1 means transmit, 0 means stop transmitting;
• chan – Single carrier transmission channel selection, range is 0~39, corresponding frequency freq = 2402 + chan*2;
• power – CW power attenuation parameter, unit is 0.25dB. 4 indicates the power is attenuated by 1dB.

void esp_phy_get_rx_result(esp_phy_rx_result_t *rx_result)
Get some RX information.

Parameters rx_result – This struct for storing RX information;

Structures

struct esp_phy_rx_result_t
Structure holding PHY RX result.

Public Members

uint32_t phy_rx_correct_count
The number of desired packets received

int phy_rx_rssi
Average RSSI of desired packets

uint32_t phy_rx_total_count
The number of total packets received

uint32_t phy_rx_result_flag
0 means no RX info; 1 means the lastest Wi-Fi RX info; 2 means the lastest BLE RX info.

Enumerations

enum esp_phy_wifi_rate_t
Values:

enumerator PHY_RATE_1M
enumerator PHY_RATE_2M
enumerator PHY_RATE_5M5
enumerator PHY_RATE_11M
enumerator PHY_RATE_6M

    enumerator PHY_BLE_TYPE_1010
    enumerator PHY_BLE_TYPE_00001111
    enumerator PHY_BLE_TYPE_prbs9
    enumerator PHY_BLE_TYPE_00111100
    enumerator PHY_BLE_TYPE_MAX
}
```

4.28 Thread Local Storage

4.28.1 Overview

Thread-local storage (TLS) is a mechanism by which variables are allocated such that there is one instance of the variable per extant thread. ESP-IDF provides three ways to make use of such variables:

- **FreeRTOS Native APIs**: ESP-IDF FreeRTOS native APIs.
- **Pthread APIs**: ESP-IDF pthread APIs.
- **C11 Standard**: C11 standard introduces special keywords to declare variables as thread local.

4.28.2 FreeRTOS Native APIs

The ESP-IDF FreeRTOS provides the following APIs to manage thread local variables:

- `vTaskSetThreadLocalStoragePointer()`
- `pvTaskGetThreadLocalStoragePointer()`
- `vTaskSetThreadLocalStoragePointerAndDelCallback()`

In this case, the maximum number of variables that can be allocated is limited by `CONFIG_FREERTOS_THREAD_LOCAL_STORAGE_POINTERS`. Variables are kept in the task control block (TCB) and accessed by their index. Note that index 0 is reserved for ESP-IDF internal uses.

Using the APIs above, you can allocate thread local variables of an arbitrary size, and assign them to any number of tasks. Different tasks can have different sets of TLS variables.

If size of the variable is more than 4 bytes, then you need to allocate/deallocate memory for it. Variable’s deallocation is initiated by FreeRTOS when task is deleted, but user must provide callback function to do proper cleanup.

4.28.3 Pthread APIs

The ESP-IDF provides the following **POSIX Threads Support** to manage thread local variables:

- `pthread_key_create()`
- `pthread_key_delete()`
- `pthread_getspecific()`
- `pthread_setspecific()`
These APIs have all benefits of the ones above, but eliminates some their limits. The number of variables is limited only by size of available memory on the heap. Due to the dynamic nature, this API introduces additional performance overhead compared to the native one.

### 4.28.4 C11 Standard

The ESP-IDF FreeRTOS supports thread local variables according to C11 standard, ones specified with `__thread` keyword. For details on this feature, please refer to the [GCC documentation](https://gcc.gnu.org/). Storage for that kind of variables is allocated on the task stack. Note that area for all such variables in the program is allocated on the stack of every task in the system even if that task does not use such variables at all. For example, ESP-IDF system tasks (e.g., `ipc`, `timer` tasks etc.) will also have that extra stack space allocated. Thus feature should be used with care.

Using C11 thread local variables comes at a trade-off. On one hand, they are quite handy to use in programming and can be accessed using minimal CPU instructions. However, this benefit comes at the cost of additional stack usage for all tasks in the system. Due to static nature of variables allocation, all tasks in the system have the same sets of C11 thread local variables.

### 4.29 Tools

#### 4.29.1 IDF Frontend - idf.py

The `idf.py` command-line tool provides a front-end for easily managing your project builds, deployment and debugging, and more. It manages several tools, for example:

- `CMake`, which configures the project to be built.
- `Ninja`, which builds the project.
- `esptool.py`, which flashes the target.

**Important:** `idf.py` should be run in an ESP-IDF project directory, i.e., a directory containing a `CMakeLists.txt` file. Older style projects that contain a `Makefile` will not work with `idf.py`.

### Commands

**Start a New Project:** `create-project`

```
idf.py create-project <project name>
```

This command creates a new ESP-IDF project. Additionally, the folder where the project will be created in can be specified by the `--path` option.

**Create a New Component:** `create-component`

```
idf.py create-component <component name>
```

This command creates a new component, which will have a minimum set of files necessary for building. The `-C` option can be used to specify the directory the component will be created in. For more information about components see the [Component CMakeLists Files](https://docs.espressif.com/projects/esp-idf/en/latest/development-tools.html#components).
Select the Target Chip: `set-target` ESP-IDF supports multiple targets (chips). A full list of supported targets in your version of ESP-IDF can be seen by running `idf.py --list-targets`.

```
idf.py set-target <target>
```

This command sets the current project target.

**Important:** `idf.py set-target` will clear the build directory and re-generate the `sdkconfig` file from scratch. The old `sdkconfig` file will be saved as `sdkconfig.old`.

**Note:** The behavior of the `idf.py set-target` command is equivalent to:

1. clearing the build directory (`idf.py fullclean`)
2. removing the `sdkconfig` file (`mv sdkconfig sdkconfig.old`)
3. configuring the project with the new target (`idf.py -DIDF_TARGET=esp32 reconfigure`)

It is also possible to pass the desired `IDF_TARGET` as an environment variable (e.g., `export IDF_TARGET=esp32s2`) or as a CMake variable (e.g., `--IDF_TARGET=esp32s2` argument to CMake or `idf.py`). Setting the environment variable is a convenient method if you mostly work with one type of the chip.

To specify the default value of `IDF_TARGET` for a given project, please add the `CONFIG_IDF_TARGET` option to the project’s `sdkconfig.defaults` file, e.g., `CONFIG_IDF_TARGET="esp32s2"`. This value of the option will be used if `IDF_TARGET` is not specified by other methods, such as using an environment variable, a CMake variable, or the `idf.py set-target` command.

If the target has not been set by any of these methods, the build system will default to `esp32` target.

**Start the Graphical Configuration Tool:** `menuconfig`

```
idf.py menuconfig
```

**Build the Project:** `build`

```
idf.py build
```

This command builds the project found in the current directory. This can involve multiple steps:

- Create the build directory if needed. The sub-directory `build` is used to hold build output, although this can be changed with the `-B` option.
- Run CMake as necessary to configure the project and generate build files for the main build tool.
- Run the main build tool (Ninja or GNU Make). By default, the build tool is automatically detected but it can be explicitly set by passing the `-G` option to `idf.py`.

Building is incremental, so if no source files or configuration has changed since the last build, nothing will be done. Additionally, the command can be run with `app`, `bootloader` and `partition-table` arguments to build only the app, bootloader or partition table as applicable.

**Remove the Build Output:** `clean`

```
idf.py clean
```

This command removes the project build output files from the build directory, and the project will be fully rebuilt on next build. Using this command does not remove the CMake configuration output inside the build folder.

**Delete the Entire Build Contents:** `fullclean`
This command deletes the entire “build” directory contents, which includes all CMake configuration output. The next time the project is built, CMake will configure it from scratch. Note that this option recursively deletes all files in the build directory, so use with care. Project configuration is not deleted.

**Flash the Project: flash**

This command automatically builds the project if necessary, and then flash it to the target. You can use `-p` and `-b` options to set serial port name and flasher baud rate, respectively.

**Note:** The environment variables `ESPPORT` and `ESPBAUD` can be used to set default values for the `-p` and `-b` options, respectively. Providing these options on the command line overrides the default.

Similarly to the `build` command, the command can be run with `app`, `bootloader` and `partition-table` arguments to flash only the app, bootloader or partition table as applicable.

**Hints on How to Resolve Errors**

`idf.py` will try to suggest hints on how to resolve errors. It works with a database of hints stored in `tools/idf_py_actions/hints.yml` and the hints will be printed if a match is found for the given error. The menuconfig target is not supported at the moment by automatic hints on resolving errors.

The `--no-hints` argument of `idf.py` can be used to turn the hints off in case they are not desired.

**Important Notes**

Multiple `idf.py` commands can be combined into one. For example, `idf.py -p COM4 clean flash monitor` will clean the source tree, then build the project and flash it to the target before running the serial monitor.

The order of multiple `idf.py` commands on the same invocation is not important, as they will automatically be executed in the correct order for everything to take effect (e.g., building before flashing, erasing before flashing).

For commands that are not known to `idf.py`, an attempt to execute them as a build system target will be made.

The command `idf.py` supports `shell autocompletion` for bash, zsh and fish shells.

In order to make `shell autocompletion` supported, please make sure you have at least Python 3.5 and `click 7.1` or newer (`Software`).

To enable autocompletion for `idf.py`, use the `export` command (`Step 4. Set up the environment variables`). Autocompletion is initiated by pressing the TAB key. Type `idf.py` - and press the TAB key to autocomplete options.

The autocomplete support for PowerShell is planned in the future.

**Advanced Commands**

**Open the Documentation: docs**

This command opens the documentation for the projects target and ESP-IDF version in the browser.
Show Size: `size`

```
idf.py size
```

This command prints app size information including the occupied RAM and flash and section (i.e., .bss) sizes.

```
idf.py size-components
```

Similarly, this command prints the same information for each component used in the project.

```
idf.py size-files
```

This command prints size information per source file in the project.

**Options**

- `--format` specifies the output format with available options: `text`, `csv`, `json`, default being `text`.
- `--output-file` optionally specifies the name of the file to print the command output to instead of the standard output.

Reconfigure the Project: `reconfigure`

```
idf.py reconfigure
```

This command forces CMake to be rerun regardless of whether it is necessary. It is unnecessary during normal usage, but can be useful after adding/removing files from the source tree, or when modifying CMake cache variables. For example, `idf.py --DNAME='VALUE' reconfigure` can be used to set variable `NAME` in CMake cache to value `VALUE`.

Clean the Python Byte Code: `python-clean`

```
idf.py python-clean
```

This command deletes generated python byte code from the ESP-IDF directory. The byte code may cause issues when switching between ESP-IDF and Python versions. It is advised to run this target after switching versions of Python.

Generate a UF2 Binary: `uf2`

```
idf.py uf2
```

This command generates a UF2 (USB Flashing Format) binary `uf2.bin` in the build directory. This file includes all the necessary binaries (bootloader, app, and partition table) for flashing the target.

This UF2 file can be copied to a USB mass storage device exposed by another ESP running the ESP USB Bridge project. The bridge MCU will use it to flash the target MCU. This is as simple as copying (or “drag-and-dropping”) the file to the exposed disk accessed by a file explorer in your machine.

To generate a UF2 binary for the application only (not including the bootloader and partition table), use the `uf2-app` command.

```
idf.py uf2-app
```

**Global Options**

To list all available root level options, run `idf.py --help`. To list options that are specific for a subcommand, run `idf.py <command> --help`, e.g., `idf.py monitor --help`. Here is a list of some useful options:

- `--C <dir>` allows overriding the project directory from the default current working directory.
- `--B <dir>` allows overriding the build directory from the default build subdirectory of the project directory.
--ccache enables CCache when compiling source files if the CCache tool is installed. This can dramatically reduce the build time.

**Important:** Note that some older versions of CCache may exhibit bugs on some platforms, so if files are not rebuilt as expected, try disabling CCache and rebuilding the project. To enable CCache by default, set the IDF_CCACHE_ENABLE environment variable to a non-zero value.

• --v flag causes both idf.py and the build system to produce verbose build output. This can be useful for debugging build problems.
• --cmake-warn-uninitialized (or -w) causes CMake to print uninitialized variable warnings found in the project directory only. This only controls CMake variable warnings inside CMake itself, not other types of build warnings. This option can also be set permanently by setting the IDF_CMAKE_WARN_UNINITIALIZED environment variable to a non-zero value.
• --no-hints flag disables hints on resolving errors and disable capturing output.

## 4.29.2 IDF Docker Image

IDF Docker image (espressif/idf) is intended for building applications and libraries with specific versions of ESP-IDF when doing automated builds.

The image contains:

• Common utilities such as git, wget, curl, and zip.
• Python 3.8 or newer.
• A copy of a specific version of ESP-IDF. See below for information about versions. IDF_PATH environment variable is set and points to the ESP-IDF location in the container.
• All the build tools required for the specific version of ESP-IDF: CMake, Ninja, cross-compiler toolchains, etc.
• All Python packages required by ESP-IDF are installed in a virtual environment.

The image ENTRYPOINT sets up the PATH environment variable to point to the correct version of tools, and activates the Python virtual environment. As a result, the environment is ready to use the ESP-IDF build system.

The image can also be used as a base for custom images, if additional utilities are required.

### Tags

Multiple tags of this image are maintained:

• latest: tracks master branch of ESP-IDF
• vX.Y: corresponds to ESP-IDF release vX.Y
• release-vX.Y: tracks release/vX.Y branch of ESP-IDF

**Note:** Versions of ESP-IDF released before this feature was introduced do not have corresponding Docker image versions. You can check the up-to-date list of available tags at https://hub.docker.com/r/espressif/idf/tags.

### Usage

**Setting up Docker** Before using the espressif/idf Docker image locally, make sure you have Docker installed. Follow the instructions at https://docs.docker.com/install/, if it is not installed yet.

If using the image in a CI environment, consult the documentation of your CI service on how to specify the image used for the build process.
Building a Project with CMake   In the project directory, run:

```
docker run --rm -v $PWD:/project -w /project -u $UID -e HOME=/tmp espressif/idf-
,idf.py build
```

The above command explained:

- `docker run`: runs a Docker image. It is a shorter form of the command `docker container run`.
- `--rm`: removes the container when the build is finished.
- `-v $PWD:/project`: mounts the current directory on the host ($PWD) as /project directory in the container.
- `-w /project`: makes /project the working directory for the command.
- `-u $UID`: makes the command run with your user ID so that files are created as you (instead of root).
- `-e HOME=/tmp`: gives the user a home directory for storing temporary files created by idf.py in ~/.cache.
- `espressif/idf`: uses Docker image espressif/idf with tag latest. The latest tag is implicitly added by Docker when no tag is specified.
- `idf.py build`: runs this command inside the container.

To build with a specific Docker image tag, specify it as `espressif/idf:TAG`, for example:

```
docker run --rm -v $PWD:/project -w /project -u $UID -e HOME=/tmp espressif/idf-
release-v4.4 idf.py build
```

You can check the up-to-date list of available tags at [https://hub.docker.com/r/espressif/idf/tags](https://hub.docker.com/r/espressif/idf/tags).

Using the Image Interactively   It is also possible to do builds interactively, to debug build issues or test the automated build scripts. Start the container with `-i -t` flags:

```
docker run --rm -v $PWD:/project -w /project -u $UID -e HOME=/tmp -it espressif/idf
```

Then inside the container, use `idf.py` as usual:

```
idf.py menuconfig
idf.py build
```

**Note:** Commands which communicate with the development board, such as `idf.py flash` and `idf.py monitor` does not work in the container, unless the serial port is passed through into the container. This can be done with Docker for Linux with the `device` option. However, currently, this is not possible with Docker for Windows ([https://github.com/docker/for-win/issues/1018](https://github.com/docker/for-win/issues/1018)) and Docker for Mac ([https://github.com/docker/for-mac/issues/900](https://github.com/docker/for-mac/issues/900)). This limitation may be overcome by using remote serial ports. An example of how to do this can be found in the following `using remote serial port` section.

Using Remote Serial Port   The RFC2217 (Telnet) protocol can be used to remotely connect to a serial port. For more information please see the [remote serial ports](https://github.com/esp-idf/esp-idf) documentation in the ESP tool project. This method can also be used to access the serial port inside a Docker container if it cannot be accessed directly. Following is an example of how to use the Flash command from within a Docker container.

On host install and start `esp_rfc2217_server`:

- On Windows, the package is available as a one-file bundled executable created by `pyinstaller` and it can be downloaded from the `esptool releases` page in a ZIP archive along with other ESP tool utilities:

```
esp_rfc2217_server -v -p 4000 COM3
```

- On Linux or macOS, the package is available as part of `esptool`, which can be found in the ESP-IDF environment or by installing using `pip`:
pip install esptool

And then starting the server by executing:

```
esp_rfc2217_server.py -v -p 4000 /dev/ttyUSB0
```

Now the device attached to the host can be flashed from inside a Docker container by using:

```
docker run --rm -v <host_path>:<container_path> -w /<container_path> espressif/idf
   idf.py --port 'rfc2217://host.docker.internal:4000?ign_set_control' flash
```

Please make sure that `<host_path>` is properly set to your project path on the host, and `<container_path>` is set as a working directory inside the container with the `-w` option. The `host.docker.internal` is a special Docker DNS name to access the host. This can be replaced with a host IP if necessary.

**Building Custom Images**

The Docker file in ESP-IDF repository provides several build arguments which can be used to customize the Docker image:

- **IDF_CLONE_URL**: URL of the repository to clone ESP-IDF from. Can be set to a custom URL when working with a fork of ESP-IDF. The default is https://github.com/espressif/esp-idf.git.
- **IDF_CLONE_BRANCH_OR_TAG**: Name of a git branch or tag used when cloning ESP-IDF. This value is passed to the `git clone` command using the `--branch` argument. The default is `master`.
- **IDF_CHECKOUT_REF**: If this argument is set to a non-empty value, `git checkout $IDF_CHECKOUT_REF` command performs after cloning. This argument can be set to the SHA of the specific commit to check out, for example, if some specific commit on a release branch is desired.
- **IDF_CLONE_SHALLOW**: If this argument is set to a non-empty value, `--depth=1 --shallow-submodules` arguments are be used when performing `git clone`. This significantly reduces the amount of data downloaded and the size of the resulting Docker image. However, if switching to a different branch in such a “shallow” repository is necessary, an additional `git fetch origin <branch>` command must be executed first.
- **IDF_INSTALL_TARGETS**: Comma-separated list of ESP-IDF targets to install toolchains for, or all to install toolchains for all targets. Selecting specific targets reduces the amount of data downloaded and the size of the resulting Docker image. The default is all.

To use these arguments, pass them via the `--build-arg` command line option. For example, the following command builds a Docker image with a shallow clone of ESP-IDF v4.4.1 and tools for ESP32-C3 only:

```
docker build -t idf-custom:v4.4.1-esp32c3 \
   --build-arg IDF_CLONE_BRANCH_OR_TAG=v4.4.1 \
   --build-arg IDF_CLONE_SHALLOW=1 \
   --build-arg IDF_INSTALL_TARGETS=esp32c3 \
   tools/docker
```

### 4.29.3 IDF Windows Installer

**Command-Line Parameters**

Windows Installer esp-idf-tools-setup provides the following command-line parameters:

- `/CONFIG=[PATH]` - Path to ini configuration file to override default configuration of the installer. Default: `config.ini`.
• /GITRECURSIVE={yes|no} - Clone recursively all Git repository submodules. Default: yes.
• /GITREPO={URL|PATH} - URL of repository to clone ESP-IDF. Default: https://github.com/espressif/esp-idf.git.
• /GITRESET={yes|no} - Enable/Disable git reset of repository during installation. Default: yes.
• /HELP - Display command line options provided by Inno Setup installer.
• /IDFDIR={PATH} - Path to directory where it is installed. Default: {userdesktop}\esp-idf.
• /IDFVERSION={v4.3|v4.1|master} - Use specific ESP-IDF version. E.g., v4.1, v4.2, master. Default: empty, pick the first version in the list.
• /LOG={PATH} - Store installation log file in specific directory. Default: empty.
• /OFFLINE={yes|no} - Execute installation of Python packages by pip in offline mode. The same result can be achieved by setting the environment variable PIP_NO_INDEX. Default: no.
• /USEEMBEDDEDPYTHON={yes|no} - Use Embedded Python version for the installation. Set to no to allow the Python selection screen in the installer. Default: yes.
• /PYTHONNOUSERSITE={yes|no} - Set PYTHONNOUSERSITE variable before launching any Python command to avoid loading Python packages from AppDataRoaming. Default: yes.
• /PYTHONWHEELSURL={URL} - Specify URLs to PyPi repositories for resolving binary Python Wheel dependencies. The same result can be achieved by setting the environment variable PIP_EXTRA_INDEX_URL. Default: https://dl.espressif.com/pypi.
• /SKIPSYSTEMCHECK={yes|no} - Skip System Check page. Default: no.
• /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL - Perform silent installation.

Unattended Installation

The unattended installation of ESP-IDF can be achieved by following command-line parameters:

```bash
esp-idf-tools-setup-x.x.exe /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL
```

When running the installer from the command line, it detaches its process from the command line and starts a separate process in the background to perform the installation without blocking the use of the command line. The following PowerShell script allows you to wait for the installer to complete:

```powershell
$InstallerProcess = Get-Process esp-idf-tools-setup
Wait-Process -Id $InstallerProcess.id
```

Custom Python and Custom Location of Python Wheels

The IDF installer is using by default embedded Python with reference to the Python Wheel mirror.

The following parameters allow to select custom Python and custom location of Python wheels:

```bash
esp-idf-tools-setup-x.x.exe /USEEMBEDDEDPYTHON=no /PYTHONWHEELSURL=https://pypi.org/simple/
```

4.29.4 IDF Component Manager

The IDF Component Manager is a tool that downloads dependencies for any ESP-IDF CMake project. The download happens automatically during a run of CMake. It can source components either from the component registry or from a Git repository.

A list of components can be found on https://components.espressif.com/.

For detailed information about the IDF Component Manager, see the IDF Component Manager and ESP Component Registry Documentation.
## Using with a Project

Dependencies for each component in the project are defined in a separate manifest file named `idf_component.yml` placed in the root of the component. The manifest file template can be created by running `idf.py create-manifest`. By default, a manifest file is created for the main component. You can explicitly either specify the directory where the manifest should be created using the `--path` option or specify the component in your components folder using `--component=my_component`. The `create-manifest` command can be run in the following ways:

- `idf.py create-manifest` creates a manifest file for the main component
- `idf.py create-manifest --component=my_component` creates a manifest file for the component `my_component` in the components directory
- `idf.py create-manifest --path="../..//my_component"` creates a manifest file for the component `my_component` in the `my_component` directory

When a new manifest is added to one of the components in the project, it is necessary to reconfigure the project manually by running `idf.py reconfigure`. The build will then track changes in `idf_component.yml` manifests and automatically trigger CMake when necessary.

To add a dependency to a component (e.g., `my_component`) in your ESP-IDF project, you can run the command `idf.py add-dependency`. The `DEPENDENCY` argument represents an additional component managed by the IDF Component Manager that `my_component` depends on. It is defined in the format `namespace/name=1.0.0`, where `namespace/name` is the name of the component and `=1.0.0` is a version range of the component, see the Versioning Documentation. By default, dependencies are added to the main component. You can either explicitly specify a directory where the manifest is located using the `--path` option, or specify the component in your components folder using `--component=my_component`. The `add-dependency` command can be run in the following ways:

- `idf.py add-dependency example/cmp` adds a dependency on the most recent version of `example/cmp` to the main component
- `idf.py add-dependency --component=my_component example/cmp<=3.3.3` adds a dependency on the version `<=3.3.3` of `example/cmp` to the component `my_component` in the components directory
- `idf.py add-dependency --path="../..//my_component" example/cmp^3.3.3` adds a dependency on the version `^3.3.3` of `example/cmp` to the component `my_component` in the `my_component` directory

**Note:** The command `add-dependency` adds dependencies to your project explicitly from the Espressif Component Registry.

To update dependencies of the ESP-IDF project, you can run the command `idf.py update-dependencies`. You can also specify the path to the project directory using `--project-dir PATH`.

There is an example application `build_system/cmake/component_manager` that uses components installed by the component manager.

It is not necessary to have a manifest for components that do not need any managed dependencies.

When CMake configures the project (e.g., `idf.py reconfigure`) component manager does a few things:

- Processes `idf_component.yml` manifests for every component in the project and recursively solves dependencies.
- Creates a `dependencies.lock` file in the root of the project with a full list of dependencies.
- Downloads all dependencies to the `managed_components` directory.

The lock file `dependencies.lock` and the content of the `managed_components` directory are not supposed to be modified by a user. When the component manager runs, it always makes sure they are up to date. If these files were accidentally modified, it is possible to re-run the component manager by triggering CMake with `idf.py reconfigure`.

You may set the build property `DEPENDENCIES_LOCK` to specify the lock-file path in the top-level CMakeLists.txt. For example, adding `idf_build_set_property(DEPENDENCIES_LOCK dependencies.lock)` dependencies.
lock.$\{$IDF_TARGET\}$ before project\(\text{PROJECT\_NAME}\) could help generate different lock files for different targets.

### Creating a Project From an Example

Some components on the registry contain example projects. To create a new project from an example you can run the command \texttt{idf.py create-project-from-example EXAMPLE}. The \texttt{EXAMPLE} argument should be in the format \texttt{namespace/name=1.0.0:example} where \texttt{namespace/name} is the name of the component, \texttt{=1.0.0} is a version range of the component (see the Versioning Documentation) and \texttt{example} is the example’s name. You can find the list of examples for every component and the command to start a project for it in the Espressif Component Registry.

### Defining Dependencies in the Manifest

You can easily define dependencies in the manifest file \texttt{idf_component.yml} by editing it directly in the text editor. Below are some basic examples that demonstrate how to define dependencies.

You can define a dependency from the registry by specifying the component name and the version range:

```
dependencies:
  # Define a dependency from the registry (https://components.espressif.com/
  # component/example/cmp)
  example/cmp: ">=1.0.0"
```

To define a dependency from a Git repository, provide the path to the component within the repository and the repository’s URL:

```
dependencies:
  # Define a dependency from a Git repository
  test_component:
    path: test_component
    git: ssh://git@gitlab.com/user/components.git
```

During the development of components, you can use components from a local directory by specifying either a relative or an absolute path:

```
dependencies:
  # Define local dependency with relative path
  some_local_component:
    path: ../../projects/component
```

For detailed information about the manifest file format, see Manifest File Format Documentation.

### Disabling the Component Manager

The component manager can be explicitly disabled by setting the \texttt{IDF\_COMPONENT\_MANAGER} environment variable to 0.

### 4.29.5 IDF Clang-Tidy

The IDF Clang Tidy is a tool that uses \texttt{clang-tidy} to run static analysis on your current app.
**Warning:** This functionality and the toolchain it relies on are still under development. There may be breaking changes before a final release.

Only clang based toolchain is currently supported. It has to be activated by setting IDF_TOOLCHAIN=clang in the environment or in CMake cache before configuring the project.

---

**Prerequisites**

If you have never run this tool before, take the following steps to get this tool prepared.

1. Run `idf_tools.py install esp-clang` to install the clang-tidy required binaries

   **Note:** This toolchain is still under development. After the final release, you do not have to install them manually.

2. Run the export scripts (export.sh / export.bat / ...) again to refresh the environment variables.

---

**Extra Commands**

**clang-check** Run `idf.py clang-check` to re-generate the compilation database and run clang-tidy under your current project folder. The output would be written to `<project_dir>/warnings.txt`. Run `idf.py clang-check --help` to see the full documentation.

**clang-html-report**

1. Run `pip install codereport` to install the additional dependency.
2. Run `idf.py clang-html-report` to generate an HTML report in folder `<project_dir>/html_report` according to the warnings.txt. Please open the `<project_dir>/html_report/index.html` in your browser to check the report.

---

**Bug Report**

This tool is hosted in `espressif/clang-tidy-runner`. If you were to face any bugs or have any feature request, please report them via Github issues

---

**4.29.6 Downloadable IDF Tools**

The ESP-IDF build process relies on a number of tools: cross-compiler toolchains, CMake build system, and others.

Installing the tools using an OS-specific package manager (e.g., apt, yum, brew, etc.) is the preferred method, when the required version of the tool is available. This recommendation is reflected in the Get Started. For example, on Linux and macOS, it is recommended to install CMake using an OS package manager.

However, some of the tools are specific to ESP-IDF and are not available in OS package repositories. Furthermore, different ESP-IDF versions require different tool versions for proper operation. To solve these two problems, ESP-IDF provides a set of scripts that can download and install the correct tool versions and set up the environment accordingly.

The rest of the document refers to these downloadable tools simply as “tools”. Other kinds of tools used in ESP-IDF are:

- Python scripts bundled with ESP-IDF such as `idf.py`
- Python packages installed from PyPI
The following sections explain the installation method and provide the list of tools installed on each platform.

**Note:** This document is provided for advanced users who need to customize their installation, users who wish to understand the installation process, and ESP-IDF developers.

If you are looking for instructions on how to install the tools, see *Get Started*.

### Tools Metadata File

The list of tools and tool versions required for each platform is located in `tools/tools.json`. The schema of this file is defined by `tools/tools_schema.json`.

This file is used by the `tools/idf_tools.py` script when installing the tools or setting up the environment variables.

### Tools Installation Directory

The `IDF_TOOLS_PATH` environment variable specifies the location where the tools are to be downloaded and installed. If not set, the default location will be `HOME/.espressif` on Linux and macOS, and `%USER_PROFILE%\AppData\Roaming\espressif` on Windows.

Inside the `IDF_TOOLS_PATH` directory, the tools installation scripts create the following directories and files:

- **dist** — where the archives of the tools are downloaded.
- **tools** — where the tools are extracted. The tools are extracted into subdirectories: `tools/TOOL_NAME/VERSION/`. This arrangement allows different versions of tools to be installed side by side.
- **idf-env.json** — user install options, such as targets and features, are stored in this file. Targets are selected chip targets for which tools are installed and kept up-to-date. Features determine the Python package set which should be installed. These options will be discussed later.
- **python_env** — not related to the tools; virtual Python environments are installed in the sub-directories. Note that the Python environment directory can be placed elsewhere by setting the `IDF_PYTHON_ENV_PATH` environment variable.
- **espidf.constraints.*.txt** — one constraint file for each ESP-IDF release containing Python package version requirements.

### GitHub Assets Mirror

Most of the tools downloaded by the tools installer are GitHub Release Assets, which are files attached to a software release on GitHub.

If GitHub downloads are inaccessible or slow to access, a GitHub assets mirror can be configured.

To use Espressif’s download server, set the environment variable `IDF_GITHUB_ASSETS` to `dl.espressif.com/github_assets`, or `dl.espressif.cn/github_assets` for faster download in China. When the install process is downloading a tool from `github.com`, the URL will be rewritten to use this server instead.

Any mirror server can be used provided the URL matches the `github.com` download URL format. For any GitHub asset URL that the install process downloads, it will replace `https://github.com` with `https://${IDF_GITHUB_ASSETS}`.

**Note:** The Espressif download server currently does not mirror everything from GitHub, but only files attached as Assets to some releases, as well as source archives for some releases.

### idf_tools.py Script

The `tools/idf_tools.py` script bundled with ESP-IDF performs several functions:
• install: Download the tool into the `${IDF_TOOLS_PATH}/dist` directory and extract it into `${IDF_TOOLS_PATH}/tools/TOOL_NAME/VERSION`. The install command accepts the list of tools to install in the TOOL_NAME or TOOL_NAME@VERSION format. If all is given, all the tools, including required and optional ones, are installed. If no argument or required is given, only the required tools are installed.

• download: Similar to install but doesn’t extract the tools. An optional --platform argument may be used to download the tools for the specific platform.

• export: Lists the environment variables that need to be set to use the installed tools. For most of the tools, setting the PATH environment variable is sufficient, but some tools require extra environment variables. The environment variables can be listed in either shell or key-value formats, which can be set using the --format parameter:
  - export optional parameters:
    * --unset: Creates a statement that unsets specific global variables and restores the environment to its state before calling export.{sh/fish}.
    * --add_paths_extras: Adds extra ESP-IDF-related paths of $PATH to ${IDF_TOOLS_PATH}/esp-idf.json, which is used to remove global variables when the active ESP-IDF environment is deactivated. For example, while processing the export.{sh/fish} script, if new paths are added to the global variable $PATH, this option saves these new paths to the ${IDF_TOOLS_PATH}/esp-idf.json file.
  - shell: Produces output suitable for evaluation in the shell. For example, produce the following output on Linux and macOS:

    ```shell
    export PATH="/home/user/.espressif/tools/tool/v1.0.0/bin:$PATH"
    ```

    Produce the following output on Windows:

    ```shell
    set "PATH=C:\Users\user\.espressif\tools\v1.0.0\bin;%PATH%"
    ```

    Note: Exporting environment variables in Powershell format is not supported at the moment. key-value format may be used instead.

    The output of this command may be used to update the environment variables if the shell supports it. For example

    ```shell
    eval $(IDF_PATH/tools/idf_tools.py export)
    ```

    - key-value: Produces output in the VARIABLE=VALUE format that is suitable for parsing by other scripts

    ```shell
    PATH=/home/user/.espressif/tools/tool/v1.0.0:$PATH
    ```

    Note that the script consuming this output has to perform expansion of $VAR or %VAR% patterns found in the output.

• list: Lists the known versions of the tools, and indicates which ones are installed. The following option is available to customize the output.
  - --outdated: Lists only outdated versions of tools installed in IDF_TOOLS_PATH.

• check: For each tool, checks whether the tool is available in the system path and in IDF_TOOLS_PATH.

• install-python-env: Creates a Python virtual environment in the `${IDF_TOOLS_PATH}/python_env` directory or directly in the directory set by the IDF_PYTHON_ENV_PATH environment variable, and install the required Python packages there.
  - An optional --features argument allows one to specify a comma-separated list of features to be added or removed.
    1. A feature that begins with -- will be removed, and features with + or without any sign will be added.
       Example syntax for removing feature XY is --features=--XY, and for adding feature XY is --features=+XY or --features=XY. If both removing and adding options are provided with the same feature, no operation is performed.
    2. For each feature, a requirements file must exist. For example, feature XY is a valid feature if $(IDF_PATH)/tools/requirements/requirements.XY.txt is an existing file with a list of Python packages to be installed.
    3. There is one mandatory core feature ensuring the core functionality of ESP-IDF, e.g., build, flash,
monitor, debug in console. There can be an arbitrary number of optional features.

4. The selected list of features is stored in `idf-env.json`.

5. The requirement files contain a list of the desired Python packages to be installed and the `espidf.constraints.*.txt` file downloaded from https://dl.espressif.com and stored in `${IDF_TOOLS_PATH}`, which contains the package version requirements for a given ESP-IDF version.

**Note:** Although it is not recommended, the download and use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to no.

- `check-python-dependencies`: Checks if all required Python packages are installed. Packages from `${IDF_PATH}/tools/requirements/requirements.*.txt` files selected by the feature list of `idf-env.json` are checked with the package versions specified in the `espidf.constraints.*.txt` file.

**Note:** The constraint file is downloaded with the `install-python-env` command. Similar to the `install-python-env` command, the use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to no.

- `uninstall`: Prints and removes tools that are currently not used by the active ESP-IDF version.
  - `--dry-run`: Prints installed unused tools.
  - `--remove-archives`: Additionally removes all older versions of previously downloaded installation packages.

### Install Scripts

Shell-specific user-facing installation scripts are provided in the root directory of ESP-IDF repository to facilitate tools installation. These are:

- `install.bat` for Windows Command Prompt
- `install.ps1` for Powershell
- `install.sh` for Bash
- `install.fish` for Fish

Apart from downloading and installing the tools in `IDF_TOOLS_PATH`, these scripts prepare a Python virtual environment, and install the required packages into that environment.

These scripts accept optionally a comma-separated list of chip targets and `--enable-` arguments for enabling features. These arguments are passed to the `idf_tools.py` script which stores them in `idf-env.json`. Therefore, chip targets and features can be enabled incrementally.

To install tools for all chip targets, run the scripts without any optional arguments using `idf_tools.py install --targets=all`. Similarly, to install Python packages for core ESP-IDF functionality, run `idf_tools.py install-python-env --features=core`.

It is also possible to install tools for specific chip targets. For example, `install.sh esp32` installs tools only for ESP32. See Step 3. Set up the Tools for more examples.

`install.sh --enable-XY` enables feature XY (by running `idf_tools.py install-python-env --features=core,XY`).

### Export Scripts

Since the installed tools are not permanently added to the user or system `PATH` environment variable, an extra step is required to use them in the command line. The following scripts modify the environment variables in the current shell to make the correct versions of the tools available:

- `export.bat` for Windows Command Prompt
- `export.ps1` for Powershell
Chapter 4. API Guides

- `export.sh` for Bash
- `export.fish` for Fish

**Note:** To modify the shell environment in Bash, `export.sh` must be “sourced” by using the `. ./export.sh` command. Please ensure to include the leading dot and space.

`export.sh` may be used with shells other than Bash (such as zsh). However, in this case, it is required to set the `IDF_PATH` environment variable before running the script. When used in Bash, the script guesses the `IDF_PATH` value from its own location.

In addition to calling `idf_tools.py`, these scripts list the directories that have been added to the `PATH`.

**Other Installation Methods**

Depending on the environment, more user-friendly wrappers for `idf_tools.py` are provided:

- **ESP-IDF Tools Installer** can download and install the tools. Internally the installer uses `idf_tools.py`.
- **ESP-IDF Eclipse Plugin** includes a menu item to set up the tools. Internally the plugin calls `idf_tools.py`.
- **VSCode ESP-IDF Extension** includes an onboarding flow. This flow helps set up the tools. Although the extension does not rely on `idf_tools.py`, the same installation method is used.

**Custom Installation**

Although the methods above are recommended for ESP-IDF users, they are not a must for building ESP-IDF applications. ESP-IDF build system expects that all the necessary tools are installed somewhere, and made available in the `PATH`.

**Uninstall ESP-IDF**

Uninstalling ESP-IDF requires removing both the tools and the environment variables that have been configured during the installation.

- Windows users using the **Windows ESP-IDF Tools Installer** can simply run the uninstall wizard to remove ESP-IDF.
- To remove an installation performed by running the supported `install scripts`, simply delete the `tools installation directory` including the downloaded and installed tools. Any environment variables set by the `export scripts` are not permanent and will not be present after opening a new environment.
- When dealing with a custom installation, in addition to deleting the tools as mentioned above, you may also need to manually revert any changes to environment variables or system paths that were made to accommodate the ESP-IDF tools (e.g., `IDF_PYTHON_ENV_PATH` or `IDF_TOOLS_PATH`). If you manually copied any tools, you would need to track and delete those files manually.
- If you installed any plugins like the **ESP-IDF Eclipse Plugin** or **VSCode ESP-IDF Extension**, you should follow the specific uninstallation instructions described in the documentation of those components.

**Note:** Uninstalling the ESP-IDF tools does not remove any project files or your code. Be mindful of what you are deleting to avoid losing any work. If you are unsure about a step, refer back to the installation instructions.

These instructions assume that the tools were installed following the procedures in this provided document. If you’ve used a custom installation method, you might need to adapt these instructions accordingly.

## 4.30 Unit Testing in ESP32

ESP-IDF provides the following methods to test software.

- Target based tests using a central unit test application which runs on the esp32. These tests use the Unity unit test framework. They can be integrated into an ESP-IDF component by placing them in the component’s test subdirectory. This document mainly introduces this target based tests.
- Linux-host based unit tests in which part of the hardware can be abstracted via mocks. Currently, Linux-host based tests are still under development and only a small fraction of IDF components support them. More information on running IDF applications on the host can be found here: [Running Applications on the Host Machine](https://github.com/espressif/esp-toolchain-docs/blob/main/qemu/esp32/README.md).
4.30.1 Normal Test Cases

Unit tests are located in the test subdirectory of a component. Tests are written in C, and a single C source file can contain multiple test cases. Test files start with the word “test”.

Each test file should include the unity.h header and the header for the C module to be tested.

Tests are added in a function in the C file as follows:

```c
TEST_CASE("test name", "[module name]")
{
    // Add test here
}
```

- The first argument is a descriptive name for the test.
- The second argument is an identifier in square brackets. Identifiers are used to group related test, or tests with specific properties.

**Note:** There is no need to add a main function with UNITY_BEGIN() and UNITY_END() in each test case. unity_platform.c will run UNITY_BEGIN() autonomously, and run the test cases, then call UNITY_END().

The test subdirectory should contain a component CMakeLists.txt, since they are themselves components (i.e., a test component). ESP-IDF uses the Unity test framework located in the unity component. Thus, each test component should specify the unity component as a component requirement using the REQUIRES argument. Normally, components should list their sources manually; for component tests however, this requirement is relaxed and the use of the SRC_DIRS argument in idf_component_register is advised.

Overall, the minimal test subdirectory CMakeLists.txt file should contain the following:

```cmake
idf_component_register(SRC_DIRS "."
    INCLUDE_DIRS "."
    REQUIRES unity)
```

See [http://www.throwtheswitch.org/unity](http://www.throwtheswitch.org/unity) for more information about writing tests in Unity.

4.30.2 Multi-device Test Cases

The normal test cases will be executed on one DUT (Device Under Test). However, components that require some form of communication (e.g., GPIO, SPI) require another device to communicate with, thus cannot be tested through normal test cases. Multi-device test cases involve writing multiple test functions, and running them on multiple DUTs.

The following is an example of a multi-device test case:

```c
void gpio_master_test()
{
    gpio_config_t slave_config = {
        .pin_bit_mask = 1 << MASTER_GPIO_PIN,
        .mode = GPIO_MODE_INPUT,
    };
    gpio_config(&slave_config);
    unity_wait_for_signal("output high level");
    TEST_ASSERT(gpio_get_level(MASTER_GPIO_PIN) == 1);
}

void gpio_slave_test()
{
    gpio_config_t master_config = {
        .pin_bit_mask = 1 << SLAVE_GPIO_PIN,
        .mode = GPIO_MODE_OUTPUT,
    };
    (continues on next page)```

Submit Document Feedback

Espressif Systems 2764 Release v5.3-dev-277-gc8243465e4
The macro TEST_CASE_MULTIPLE_DEVICES is used to declare a multi-device test case.

- The first argument is test case name.
- The second argument is test case description.
- From the third argument, up to 5 test functions can be defined, each function will be the entry point of tests running on each DUT.

Running test cases from different DUTs could require synchronizing between DUTs. We provide unity_wait_for_signal and unity_send_signal to support synchronizing with UART. As the scenario in the above example, the slave should get GPIO level after master set level. DUT UART console will prompt and user interaction is required:

DUT1 (master) console:

```
Waiting for signal: [output high level]!
Please press "Enter" key to once any board send this signal.
```

DUT2 (slave) console:

```
Send signal: [output high level]!
```

Once the signal is sent from DUT2, you need to press “Enter” on DUT1, then DUT1 unblocks from unity_wait_for_signal and starts to change GPIO level.

### 4.30.3 Multi-stage Test Cases

The normal test cases are expected to finish without reset (or only need to check if reset happens). Sometimes we expect to run some specific tests after certain kinds of reset. For example, we want to test if the reset reason is correct after a wake up from deep sleep. We need to create a deep-sleep reset first and then check the reset reason. To support this, we can define multi-stage test cases, to group a set of test functions:

```c
static void trigger_deepsleep(void)
{
    esp_sleep_enable_timer_wakeup(2000);
    esp_deep_sleep_start();
}

void check_deepsleep_reset_reason()
{
    soc_reset_reason_t reason = esp_rom_get_reset_reason(0);
    TEST_ASSERT(reason == RESET_REASON_CORE_DEEP_SLEEP);
}

TEST_CASE_MULTIPLE_STAGES("reset reason check for deepsleep", 
                         
```

Multi-stage test cases present a group of test functions to users. It needs user interactions (select cases and select different stages) to run the case.
4.30.4 Tests For Different Targets

Some tests (especially those related to hardware) cannot run on all targets. Below is a guide how to make your unit tests run on only specified targets.

1. Wrap your test code by !(TEMPORARY_)DISABLED_FOR_TARGETS() macros and place them either in the original test file, or separate the code into files grouped by functions, but make sure all these files will be processed by the compiler. E.g.:

```c
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
TEST_CASE("a test that is not ready for esp32 and esp8266 yet", "[]")
{
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
```

Once you need one of the tests to be compiled on a specified target, just modify the targets in the disabled list. It’s more encouraged to use some general conception that can be described in soc_caps.h to control the disabling of tests. If this is done but some of the tests are not ready yet, use both of them (and remove !(TEMPORARY_)DISABLED_FOR_TARGETS()) later. E.g.:

```c
#if SOC_SDIO_SLAVE_SUPPORTED
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
TEST_CASE("a sdio slave tests that is not ready for esp64 yet", "[sdio_slave]")
{
    //available for esp32 now, and will be available for esp64 in the future
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
#endif //SOC_SDIO_SLAVE_SUPPORTED
```

2. For test code that you are 100% for sure that will not be supported (e.g., no peripheral at all), use DISABLED_FOR_TARGETS; for test code that should be disabled temporarily, or due to lack of runners, etc., use TEMPORARY_DISABLED_FOR_TARGETS.

Some old ways of disabling unit tests for targets, that have obvious disadvantages, are deprecated:

- DON’T put the test code under test/target folder and use CMakeLists.txt to choose one of the target folder. This is prevented because test code is more likely to be reused than the implementations. If you put something into test/esp32 just to avoid building it on esp32s2, it’s hard to make the code tidy if you want to enable the test again on esp32s3.
- DON’T use CONFIG_IDF_TARGET_xxx macros to disable the test items any more. This makes it harder to track disabled tests and enable them again. Also, a black-list style #if !disabled is preferred to white-list style #if CONFIG_IDF_TARGET_xxx, since you will not silently disable cases when new targets are added in the future. But for test implementations, it’s allowed to use #if CONFIG_IDF_TARGET_xxx to pick one of the implementation code.
  - Test item: some items that will be performed on some targets, but skipped on other targets. E.g. There are three test items SD 1-bit, SD 4-bit and SDSPI. For ESP32-S2, which doesn’t have SD host, among the tests only SDSPI is enabled on ESP32-S2.
  - Test implementation: some code will always happen, but in different ways. E.g. There is no SDIO PKT_LEN register on ESP8266. If you want to get the length from the slave as a step in the test process, you can have different implementation code protected by #if CONFIG_IDF_TARGET_reading in different ways. But please avoid using #else macro. When new target is added, the test case will fail at building stage, so that the maintainer will be aware of this, and choose one of the implementations explicitly.

4.30.5 Building Unit Test App

Follow the setup instructions in the top-level esp-idf README. Make sure that IDF_PATH environment variable is set to point to the path of esp-idf top-level directory.

Change into tools/unit-test-app directory to configure and build it:
Chapter 4. API Guides

- `idf.py menuconfig` - configure unit test app.
- `idf.py -T all build` - build unit test app with tests for each component having tests in the test subdirectory.
- `idf.py -T "xxx yyy" build` - build unit test app with tests for some space-separated specific components (For instance: `idf.py -T heap build` - build unit tests only for heap component directory).
- `idf.py -T all -E "xxx yyy" build` - build unit test app with all unit tests, except for unit tests of some components (For instance: `idf.py -T all -E "ulp mbedtls" build` - build all unit tests excludes ulp and mbedtls components).

**Note:** Due to inherent limitations of Windows command prompt, following syntax has to be used in order to build unit-test-app with multiple components: `idf.py -T xxx -T yyy build` or with escaped quotes: `idf.py -T \"xxx yyy\" build` in PowerShell or `idf.py -T \"ssd1306 hts221\" build` in Windows command prompt.

When the build finishes, it will print instructions for flashing the chip. You can simply run `idf.py flash` to flash all build output.

You can also run `idf.py -T all flash` or `idf.py -T xxx flash` to build and flash. Everything needed will be rebuilt automatically before flashing.

Use menuconfig to set the serial port for flashing. For more information, see tools/unit-test-app/README.md.

### 4.30.6 Running Unit Tests

After flashing reset the ESP32 and it will boot the unit test app.

When unit test app is idle, press “Enter” will make it print test menu with all available tests:

```
Here's the test menu, pick your combo:
(1) "esp_ota_begin() verifies arguments" [ota]
(2) "esp_ota_get_next_update_partition logic" [ota]
(3) "Verify bootloader image in flash" [bootloader_support]
(4) "Verify unit test app image" [bootloader_support]
(5) "can use new and delete" [cxx]
(6) "can call virtual functions" [cxx]
(7) "can use static initializers for non-POD types" [cxx]
(8) "can use std::vector" [cxx]
(9) "static initialization guards work as expected" [cxx]
(10) "global initializers run in the correct order" [cxx]
(11) "before scheduler has started, static initializers work correctly" [cxx]
(12) "adc2 work with wifi" [adc]
(13) "gpio master/slave test example" [ignore][misc][test_env=UT_T2_1][multi_→device]
  (1) "gpio_master_test"
  (2) "gpio_slave_test"
(14) "SPI Master clockdiv calculation routines" [spi]
(15) "SPI Master test" [spi][ignore]
(16) "SPI Master test, interaction of multiple devs" [spi][ignore]
(17) "SPI Master no response when switch from host1 (SPI2) to host2 (SPI3)"_→[spi]
(18) "SPI Master DMA test, TX and RX in different regions" [spi]
(19) "SPI Master DMA test: length, start, not aligned" [spi]
(20) "reset reason check for deepsleep" [esp32][test_env=UT_T2_1][multi_stage]
  (1) "trigger_deepsleep"
  (2) "check_deepsleep_reset_reason"
```

The normal case will print the case name and description. Master-slave cases will also print the sub-menu (the registered test function names).

Test cases can be run by inputting one of the following:
• Test case name in quotation marks to run a single test case
• Test case index to run a single test case
• Module name in square brackets to run all test cases for a specific module
• An asterisk to run all test cases

[multi_device] and [multi_stage] tags tell the test runner whether a test case is a multiple devices or multiple stages of test case. These tags are automatically added by `TEST_CASE_MULTIPLE_STAGES and TEST_CASE_MULTIPLE_DEVICES macros.

After you select a multi-device test case, it will print sub-menu:

Running gpio master/slave test example...
gpio master/slave test example
(1)  "gpio_master_test"
(2)  "gpio_slave_test"

You need to input a number to select the test running on the DUT.

Similar to multi-device test cases, multi-stage test cases will also print sub-menu:

Running reset reason check for deepsleep...
reset reason check for deepsleep
(1)  "trigger_deepsleep"
(2)  "check_deepsleep_reset_reason"

First time you execute this case, input 1 to run first stage (trigger deepsleep). After DUT is rebooted and able to run test cases, select this case again and input 2 to run the second stage. The case only passes if the last stage passes and all previous stages trigger reset.

4.30.7 Timing Code with Cache Compensated Timer

Instructions and data stored in external memory (e.g., SPI Flash and SPI RAM) are accessed through the CPU’s unified instruction and data cache. When code or data is in cache, access is very fast (i.e., a cache hit). However, if the instruction or data is not in cache, it needs to be fetched from external memory (i.e., a cache miss). Access to external memory is significantly slower, as the CPU must execute stall cycles whilst waiting for the instruction or data to be retrieved from external memory. This can cause the overall code execution speed to vary depending on the number of cache hits or misses.

Code and data placements can vary between builds, and some arrangements may be more favorable with regards to cache access (i.e., minimizing cache misses). This can technically affect execution speed, however these factors are usually irrelevant as their effect ‘average out’ over the device’s operation.

The effect of the cache on execution speed, however, can be relevant in benchmarking scenarios (especially micro benchmarks). There might be some variability in measured time between runs and between different builds. A technique for eliminating for some of the variability is to place code and data in instruction or data RAM (IRAM/DRAM), respectively. The CPU can access IRAM and DRAM directly, eliminating the cache out of the equation. However, this might not always be viable as the size of IRAM and DRAM is limited.

The cache compensated timer is an alternative to placing the code/data to be benchmarked in IRAM/DRAM. This timer uses the processor’s internal event counters in order to determine the amount of time spent on waiting for code/data in case of a cache miss, then subtract that from the recorded wall time.

```c
// Start the timer
ccomp_timer_start();

// Function to time
func_code_to_time();

// Stop the timer, and return the elapsed time in microseconds relative to
// ccomp_timer_start
int64_t t = ccomp_timer_stop();
```
One limitation of the cache compensated timer is that the task that benchmarked functions should be pinned to a
core. This is due to each core having its own event counters that are independent of each other. For example, if
`ccomp_timer_start` gets called on one core, put to sleep by the scheduler, wakes up, and gets rescheduled on
the other core, then the corresponding `ccomp_timer_stop` will be invalid.

4.30.8 Mocks

**Note:** Currently, mocking is only possible with some selected components when running on the Linux host. In the
future, we plan to make essential components in IDF mock-able. This will also include mocking when running on
the ESP32.

One of the biggest problems regarding unit testing on embedded systems are the strong hardware dependencies. Running unit tests directly on the ESP32 can be especially difficult for higher layer components for the following reasons:

- Decreased test reliability due to lower layer components and/or hardware setup.
- Increased difficulty in testing edge cases due to limitations of lower layer components and/or hardware setup.
- Increased difficulty in identifying the root cause due to the large number of dependencies influencing the
  behavior.

When testing a particular component, (i.e., the component under test), mocking allows the dependencies of the
component under test to be substituted (i.e., mocked) entirely in software. Through mocking, hardware details are
emulated and specified at run time, but only if necessary. To allow mocking, ESP-IDF integrates the CMock mocking
framework as a component. With the addition of some CMake functions in the ESP-IDF build system, it is possible
to conveniently mock the entirety (or a part) of an IDF component.

Ideally, all components that the component under test is dependent on should be mocked, thus allowing the test
environment complete control over all interactions with the component under test. However, if mocking all dependent
components becomes too complex or too tedious (e.g., because you need to mock too many function calls) you have
the following options:

- Include more “real” IDF code in the tests. This may work but increases the dependency on the “real” code’s
  behavior. Furthermore, once a test fails, you may not know if the failure is in your actual code under test or
  the “real” IDF code.
- Re-evaluate the design of the code under test and attempt to reduce its dependencies by dividing the code
  under test into more manageable components. This may seem burdensome but it is quite common that unit
tests expose software design weaknesses. Fixing design weaknesses will not only help with unit testing in the
short term, but will help future code maintenance as well.

Refer to `cmock/CMock/docs/CMock_Summary.md` for more details on how CMock works and how to create and
use mocks.

**Requirements**

Mocking with CMock requires **Ruby** on the host machine. Furthermore, since mocking currently only works on the
Linux target, the requirements of the latter also need to be fulfilled:

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX sim-
ululator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the `CMakeLists.txt` of
the application’s root directory:
This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

### Mock a Component

If a mocked component, called a component mock, is already available in ESP-IDF, then it can be used right away as long as it satisfies the required functionality. Refer to Component Linux/Mock Support Overview to see which components are mocked already. Then refer to Adjustments in Unit Test in order to use the component mock.

It is necessary to create component mocks if they are not yet provided in ESP-IDF. To create a component mock, the component needs to be overwritten in a particular way. Overriding a component entails creating a component with the exact same name as the original component, then letting the build system discover it later than the original component (see Multiple components with the same name for more details).

In the component mock, the following parts are specified:

- The headers providing the functions to generate mocks for
- Include paths of the aforementioned headers
- Dependencies of the mock component (this is necessary e.g. if the headers include files from other components)

All these parts have to be specified using the IDF build system function `idf_component_mock`. You can use the IDF build system function `idf_component_get_property` with the tag `COMPONENT_OVERRIDEN_DIR` to access the component directory of the original component and then register the mock component parts using `idf_component_mock`:

```bash
idf_component_get_property(original_component_dir <original-component-name>.
  COMPONENT_OVERRIDEN_DIR)
...
idf_component_mock(INCLUDE_DIRS "${original_component_dir}/include"
  REQUIRES freertos
  MOCK_HEADER_FILES ${original_component_dir}/include/header_containing_
  <functions_to_mock.h>)
```

The component mock also requires a separate mock directory containing a mock_config.yaml file that configures CMock. A simple `mock_config.yaml` could look like this:

```yaml
:cmock:
  :plugins:
    - expect
    - expect_any_args
```

For more details about the CMock configuration yaml file, have a look at `cmock/CMock/docs/CMock_Summary.md`.

Note that the component mock does not have to mock the original component in its entirety. As long as the test project’s dependencies and dependencies of other code to the original components are satisfied by the component mock, partial mocking is adequate. In fact, most of the component mocks in IDF in `tools/mocks` are only partially mocking the original component.

Examples of component mocks can be found under `tools/mocks` in the IDF directory. General information on how to override an IDF component can be found in Multiple components with the same name. There are several examples for testing code while mocking dependencies with CMock (non-exhaustive list):

- unit test for the NVS Page class
- unit test for esp_event
- unit test for mqtt
Adjustments in Unit Test

The unit test needs to inform the cmake build system to mock dependent components (i.e., it needs to override the
original component with the mock component). This is done by either placing the component mock into the project’s
components directory or adding the mock component’s directory using the following line in the project’s root
CMakeLists.txt:

```
list(APPEND EXTRA_COMPONENT_DIRS "<mock_component_dir>")
```

Both methods will override existing components in ESP-IDF with the component mock. The latter is particularly
convenient if you use component mocks that are already supplied by IDF.

Users can refer to the esp_event host-based unittest and its esp_event/host_test/esp_event_unit_test/CMakeLists.txt
as an example of a component mock.

4.31 Running ESP-IDF Applications on Host

**Note:** Running ESP-IDF applications on host is currently still an experimental feature, thus there is no guarantee for
API stability. However, user feedback via the ESP-IDF GitHub repository or the ESP32 forum is highly welcome,
and may help influence the future of design of the ESP-IDF host-based applications.

This document provides an overview of the methods to run ESP-IDF applications on Linux, and what type of ESP-
IDF applications can typically be run on Linux.

4.31.1 Introduction

Typically, an ESP-IDF application is built (cross-compiled) on a host machine, uploaded (i.e., flashed) to an ESP
chip for execution, and monitored by the host machine via a UART/USB port. However, execution of an ESP-IDF
application on an ESP chip can be limiting in various development/usage/testing scenarios.

Therefore, it is possible for an ESP-IDF application to be built and executed entirely within the same Linux host
machine (henceforth referred to as “running on host”). Running ESP-IDF applications on host has several advantages:

- No need to upload to a target.
- Faster execution on a host machine, compared to running on an ESP chip.
- No requirements for any specific hardware, except the host machine itself.
- Easier automation and setup for software testing.
- Large number of tools for code and runtime analysis, e.g., Valgrind.

A large number of ESP-IDF components depend on chip-specific hardware. These hardware dependencies must
be mocked or simulated when running on host. ESP-IDF currently supports the following mocking and simulation
approaches:

1. Using the FreeRTOS POSIX/Linux simulator that simulates FreeRTOS scheduling. On top of this simulation,
other APIs are also simulated or implemented when running on host.
2. Using CMock to mock all dependencies and run the code in complete isolation.

In principle, it is possible to mix both approaches (POSIX/Linux simulator and mocking using CMock), but this has
not been done yet in ESP-IDF. Note that despite the name, the FreeRTOS POSIX/Linux simulator currently also
works on macOS. Running ESP-IDF applications on host machines is often used for testing. However, simulating the
environment and mocking dependencies does not fully represent the target device. Thus, testing on the target device
is still necessary, though with a different focus that usually puts more weight on integration and system testing.
Note: Another possibility to run applications on the host is to use the QEMU simulator. However, QEMU development for ESP-IDF applications is still a work in progress and has not been documented yet.

CMock-Based Approach

This approach uses the CMock framework to solve the problem of missing hardware and software dependencies. CMock-based applications running on the host machine have the added advantage that they usually only compile the necessary code, i.e., the (mostly mocked) dependencies instead of the entire system. For a general introduction toMocks and how to configure and use them in ESP-IDF, please refer to Mocks.

POSIX/Linux Simulator Approach

The FreeRTOS POSIX/Linux simulator is available on ESP-IDF as a preview target already. This simulator allows ESP-IDF components to be implemented on the host, making them accessible to ESP-IDF applications when running on host. Currently, only a limited number of components are ready to be built on Linux. Furthermore, the functionality of each component ported to Linux may also be limited or different compared to the functionality when building that component for a chip target. For more information about whether the desired components are supported on Linux, please refer to Component Linux/Mock Support Overview.

Note: The FreeRTOS POSIX/Linux simulator allows configuring the Amazon SMP FreeRTOS version. However, the simulation still runs in single-core mode. The main reason allowing Amazon SMP FreeRTOS is to provide API compatibility with ESP-IDF applications written for Amazon SMP FreeRTOS.

4.31.2 Requirements for Using Mocks

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (libbsd, libbsd-dev)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the COMPONENTS variable to main in the CMakeLists.txt of the application’s root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

If any mocks are used, then Ruby is required, too.

4.31.3 Build and Run

To build the application on Linux, the target has to be set to linux and then it can be built and run:

```
idf.py --preview set-target linux
idf.py build
idf.py monitor
```
4.31.4 Component Linux/Mock Support Overview

Note that any “Yes” here does not necessarily mean a full implementation or mocking. It can also mean a partial implementation or mocking of functionality. Usually, the implementation or mocking is done to a point where enough functionality is provided to build and run a test application.

4.32 Wi-Fi Driver

4.32.1 ESP32 Wi-Fi Feature List

The following features are supported:

- 4 virtual Wi-Fi interfaces, which are STA, AP, Sniffer and reserved.
- Station-only mode, AP-only mode, station/AP-coexistence mode
- IEEE 802.11b, IEEE 802.11g, IEEE 802.11n, and APIs to configure the protocol mode
Chapter 4. API Guides

- WPA/WPA2/WPA3/WPA2-Enterprise/WPA3-Enterprise/WAPI/WPS and DPP
- AMSDU, AMPDU, HT40, QoS, and other key features
- Modem-sleep
- The Espressif-specific ESP-NOW protocol and Long Range mode, which supports up to 1 km of data traffic
- Up to 20 MBit/s TCP throughput and 30 MBit/s UDP throughput over the air
- Sniffer
- Both fast scan and all-channel scan
- Multiple antennas
- Channel state information
- Wi-Fi Aware (NAN)

4.32.2 How To Write a Wi-Fi Application

Preparation

Generally, the most effective way to begin your own Wi-Fi application is to select an example which is similar to your own application, and port the useful part into your project. It is not a MUST, but it is strongly recommended that you take some time to read this article first, especially if you want to program a robust Wi-Fi application.

This article is supplementary to the Wi-Fi APIs/Examples. It describes the principles of using the Wi-Fi APIs, the limitations of the current Wi-Fi API implementation, and the most common pitfalls in using Wi-Fi. This article also reveals some design details of the Wi-Fi driver. We recommend you to select an example.

Setting Wi-Fi Compile-time Options

Refer to Wi-Fi Menuconfig.

Init Wi-Fi

Refer to ESP32 Wi-Fi station General Scenario and ESP32 Wi-Fi AP General Scenario.

Start/Connect Wi-Fi

Refer to ESP32 Wi-Fi station General Scenario and ESP32 Wi-Fi AP General Scenario.

Event-Handling

Generally, it is easy to write code in “sunny-day” scenarios, such as WIFI_EVENT_STA_START and WIFI_EVENT_STA_CONNECTED. The hard part is to write routines in “rainy-day” scenarios, such as WIFI_EVENT_STA_DISCONNECTED. Good handling of “rainy-day” scenarios is fundamental to robust Wi-Fi applications. Refer to ESP32 Wi-Fi Event Description, ESP32 Wi-Fi station General Scenario, and ESP32 Wi-Fi AP General Scenario. See also the overview of the Event Loop Library in ESP-IDF.

Write Error-Recovery Routines Correctly at All Times

Just like the handling of “rainy-day” scenarios, a good error-recovery routine is also fundamental to robust Wi-Fi applications. Refer to ESP32 Wi-Fi API Error Code.
4.32.3 ESP32 Wi-Fi API Error Code

All of the ESP32 Wi-Fi APIs have well-defined return values, namely, the error code. The error code can be categorized into:

- No errors, e.g., `ESP_OK` means that the API returns successfully.
- Recoverable errors, such as `ESP_ERR_NO_MEM`.
- Non-recoverable, non-critical errors.
- Non-recoverable, critical errors.

Whether the error is critical or not depends on the API and the application scenario, and it is defined by the API user.

The primary principle to write a robust application with Wi-Fi API is to always check the error code and write the error-handling code. Generally, the error-handling code can be used:

- For recoverable errors, in which case you can write a recoverable-error code. For example, when `esp_wifi_start()` returns `ESP_ERR_NO_MEM`, the recoverable-error code `vTaskDelay` can be called in order to get a microseconds’ delay for another try.
- For non-recoverable, yet non-critical errors, in which case printing the error code is a good method for error handling.
- For non-recoverable and also critical errors, in which case “assert” may be a good method for error handling. For example, if `esp_wifi_set_mode()` returns `ESP_ERR_WIFI_NOT_INIT`, it means that the Wi-Fi driver is not initialized by `esp_wifi_init()` successfully. You can detect this kind of error very quickly in the application development phase.

In `esp_common/include/esp_err.h`, `ESP_ERROR_CHECK` checks the return values. It is a rather commonplace error-handling code and can be used as the default error-handling code in the application development phase. However, it is strongly recommended that API users write their own error-handling code.

4.32.4 ESP32 Wi-Fi API Parameter Initialization

When initializing struct parameters for the API, one of two approaches should be followed:

- Explicitly set all fields of the parameter.
- Use get API to get current configuration first, then set application specific fields.

Initializing or getting the entire structure is very important, because most of the time the value 0 indicates that the default value is used. More fields may be added to the struct in the future and initializing these to zero ensures the application will still work correctly after ESP-IDF is updated to a new release.

4.32.5 ESP32 Wi-Fi Programming Model

The ESP32 Wi-Fi programming model is depicted as follows:

The Wi-Fi driver can be considered a black box that knows nothing about high-layer code, such as the TCP/IP stack, application task, and event task. The application task (code) generally calls Wi-Fi driver APIs to initialize Wi-Fi and handles Wi-Fi events when necessary. Wi-Fi driver receives API calls, handles them, and posts events to the application.

Wi-Fi event handling is based on the `esp_event library`. Events are sent by the Wi-Fi driver to the `default event loop`. Application may handle these events in callbacks registered using `esp_event_handler_register()`. Wi-Fi events are also handled by `esp_netif component` to provide a set of default behaviors. For example, when Wi-Fi station connects to an AP, `esp_netif` will automatically start the DHCP client by default.

4.32.6 ESP32 Wi-Fi Event Description

WIFI_EVENT_WIFI_READY

The Wi-Fi driver will never generate this event, which, as a result, can be ignored by the application event callback. This event may be removed in future releases.
WIFI_EVENT_SCAN_DONE

The scan-done event is triggered by `esp_wifi_scan_start()` and will arise in the following scenarios:

- The scan is completed, e.g., the target AP is found successfully, or all channels have been scanned.
- The scan is stopped by `esp_wifi_scan_stop()`.
- The `esp_wifi_scan_start()` is called before the scan is completed. A new scan will override the current scan and a scan-done event will be generated.

The scan-done event will not arise in the following scenarios:

- It is a blocked scan.
- The scan is caused by `esp_wifi_connect()`.

Upon receiving this event, the event task does nothing. The application event callback needs to call `esp_wifi_scan_get_ap_num()` and `esp_wifi_scan_get_ap_records()` to fetch the scanned AP list and trigger the Wi-Fi driver to free the internal memory which is allocated during the scan (do not forget to do this!). Refer to *ESP32 Wi-Fi Scan* for a more detailed description.

WIFI_EVENT_STA_START

If `esp_wifi_start()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will initialize the LwIP network interface (netif). Generally, the application event callback needs to call `esp_wifi_connect()` to connect to the configured AP.

WIFI_EVENT_STA_STOP

If `esp_wifi_stop()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will release the station’s IP address, stop the DHCP client, remove TCP/UDP-related connections, and clear the LwIP station netif, etc. The application event callback generally does not need to do anything.

WIFI_EVENT_STA_CONNECTED

If `esp_wifi_connect()` returns `ESP_OK` and the station successfully connects to the target AP, the connection event will arise. Upon receiving this event, the event task starts the DHCP client and begins the DHCP process of getting the IP address. Then, the Wi-Fi driver is ready for sending and receiving data. This moment is good for beginning the application work, provided that the application does not depend on LwIP, namely the IP address. However, if the application is LwIP-based, then you need to wait until the got ip event comes in.
WIFI_EVENT_STA_DISCONNECTED

This event can be generated in the following scenarios:

- When `esp_wifi_disconnect()` or `esp_wifi_stop()` is called and the station is already connected to the AP.
- When `esp_wifi_connect()` is called, but the Wi-Fi driver fails to set up a connection with the AP due to certain reasons, e.g., the scan fails to find the target AP or the authentication times out. If there are more than one AP with the same SSID, the disconnected event will be raised after the station fails to connect all of the found APs.
- When the Wi-Fi connection is disrupted because of specific reasons, e.g., the station continuously loses N beacons, the AP kicks off the station, or the AP’s authentication mode is changed.

Upon receiving this event, the default behaviors of the event task are:

- Shutting down the station’s LwIP netif.
- Notifying the LwIP task to clear the UDP/TCP connections which cause the wrong status to all sockets. For socket-based applications, the application callback can choose to close all sockets and re-create them, if necessary, upon receiving this event.

The most common event handle code for this event in application is to call `esp_wifi_connect()` to reconnect the Wi-Fi. However, if the event is raised because `esp_wifi_disconnect()` is called, the application should not call `esp_wifi_connect()` to reconnect. It is the application’s responsibility to distinguish whether the event is caused by `esp_wifi_disconnect()` or other reasons. Sometimes a better reconnection strategy is required. Refer to Wi-Fi Reconnect and Scan When Wi-Fi Is Connecting.

Another thing that deserves attention is that the default behavior of LwIP is to abort all TCP socket connections on receiving the disconnect. In most cases, it is not a problem. However, for some special applications, this may not be what they want. Consider the following scenarios:

- The application creates a TCP connection to maintain the application-level keep-alive data that is sent out every 60 seconds.
- Due to certain reasons, the Wi-Fi connection is cut off, and the WIFI_EVENT_STA_DISCONNECTED is raised. According to the current implementation, all TCP connections will be removed and the keep-alive socket will be in a wrong status. However, since the application designer believes that the network layer should ignore this error at the Wi-Fi layer, the application does not close the socket.
- Five seconds later, the Wi-Fi connection is restored because `esp_wifi_connect()` is called in the application event callback function. Moreover, the station connects to the same AP and gets the same IPV4 address as before.
- Sixty seconds later, when the application sends out data with the keep-alive socket, the socket returns an error and the application closes the socket and re-creates it when necessary.

In above scenarios, ideally, the application sockets and the network layer should not be affected, since the Wi-Fi connection only fails temporarily and recovers very quickly. The application can enable “Keep TCP connections when IP changed” via LwIP menuconfig.

IP_EVENT_STA_GOT_IP

This event arises when the DHCP client successfully gets the IPV4 address from the DHCP server, or when the IPV4 address is changed. The event means that everything is ready and the application can begin its tasks (e.g., creating sockets).

The IPV4 may be changed because of the following reasons:

- The DHCP client fails to renew/rebind the IPV4 address, and the station’s IPV4 is reset to 0.
- The DHCP client rebinds to a different address.
- The static-configured IPV4 address is changed.

Whether the IPV4 address is changed or not is indicated by the field `ip_change` of `ip_event_got_ip_t`. The socket is based on the IPV4 address, which means that, if the IPV4 changes, all sockets relating to this IPV4 will become abnormal. Upon receiving this event, the application needs to close all sockets and recreate the application when the IPV4 changes to a valid one.
**IP_EVENT_GOT_IP6**

This event arises when the IPV6 SLAAC support auto-configures an address for the ESP32, or when this address changes. The event means that everything is ready and the application can begin its tasks, e.g., creating sockets.

**IP_EVENT_STA_LOST_IP**

This event arises when the IPV4 address becomes invalid. IP_EVENT_STA_LOST_IP does not arise immediately after the Wi-Fi disconnects. Instead, it starts an IPV4 address lost timer. If the IPV4 address is got before ip lost timer expires, IP_EVENT_STA_LOST_IP does not happen. Otherwise, the event arises when the IPV4 address lost timer expires.

Generally, the application can ignore this event, because it is just a debug event to inform that the IPV4 address is lost.

**WIFI_EVENT_AP_START**

Similar to **WIFI_EVENT_STA_START**.

**WIFI_EVENT_AP_STOP**

Similar to **WIFI_EVENT_STA_STOP**.

**WIFI_EVENT_AP_STACONNECTED**

Every time a station is connected to ESP32 AP, the **WIFI_EVENT_AP_STACONNECTED** will arise. Upon receiving this event, the event task will do nothing, and the application callback can also ignore it. However, you may want to do something, for example, to get the info of the connected STA.

**WIFI_EVENT_AP_STADISCONNECTED**

This event can happen in the following scenarios:

- The application calls `esp_wifi_disconnect()`, or `esp_wifi_deauth_sta()`, to manually disconnect the station.
- The Wi-Fi driver kicks off the station, e.g., because the AP has not received any packets in the past five minutes. The time can be modified by `esp_wifi_set_inactive_time()`.
- The station kicks off the AP.

When this event happens, the event task will do nothing, but the application event callback needs to do something, e.g., close the socket which is related to this station.

**WIFI_EVENT_AP_PROBEREQRECVD**

This event is disabled by default. The application can enable it via API `esp_wifi_set_event_mask()`. When this event is enabled, it will be raised each time the AP receives a probe request.

**WIFI_EVENT_STA_BEACON_TIMEOUT**

If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens, the **WIFI_EVENT_STA_BEACON_TIMEOUT** will arise. The application can set inactive time via API `esp_wifi_set_inactive_time()`.
The `WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START` will arise at the start of connectionless module `Interval`. See `connectionless module power save`.

### 4.32.7 ESP32 Wi-Fi Station General Scenario

Below is a “big scenario” which describes some small scenarios in station mode:

1. **Wi-Fi/LwIP Init Phase**
   - s1.1: The main task calls `esp_netif_init()` to create an LwIP core task and initialize LwIP-related work.
   - s1.2: The main task calls `esp_event_loop_create()` to create a system Event task and initialize an application event’s callback function. In the scenario above, the application event’s callback function does nothing but relaying the event to the application task.
   - s1.3: The main task calls `esp_netif_create_default_wifi_ap()` or `esp_netif_create_default_wifi_sta()` to create default network interface instance binding station or AP with TCP/IP stack.
   - s1.4: The main task calls `esp_wifi_init()` to create the Wi-Fi driver task and initialize the Wi-Fi driver.
   - s1.5: The main task calls OS API to create the application task.

Step 1.1 ~ 1.5 is a recommended sequence that initializes a Wi-Fi-/LwIP-based application. However, it is **NOT** a must-follow sequence, which means that you can create the application task in step 1.1 and put all other initialization in the application task. Moreover, you may not want to create the application task in the initialization phase if the application task depends on the sockets. Rather, you can defer the task creation until the IP is obtained.

2. **Wi-Fi Configuration Phase**

Once the Wi-Fi driver is initialized, you can start configuring the Wi-Fi driver. In this scenario, the mode is station, so you may need to call `esp_wifi_set_mode()` (WIFI_MODE_STA) to configure the Wi-Fi mode as station. You can call other `esp_wifi_set_xxx` APIs to configure more settings, such as the protocol mode, the country code, and the bandwidth. Refer to `ESP32 Wi-Fi Configuration`.

Generally, the Wi-Fi driver should be configured before the Wi-Fi connection is set up. But this is **NOT** mandatory, which means that you can configure the Wi-Fi connection anytime, provided that the Wi-Fi driver is initialized successfully. However, if the configuration does not need to change after the Wi-Fi connection is set up, you should configure the Wi-Fi driver at this stage, because the configuration APIs (such as `esp_wifi_set_protocol()`) will cause the Wi-Fi to reconnect, which may not be desirable.

If the Wi-Fi NVS flash is enabled by menuconfig, all Wi-Fi configuration in this phase, or later phases, will be stored into flash. When the board powers on/reboots, you do not need to configure the Wi-Fi driver from scratch. You only need to call `esp_wifi_get_xxx` APIs to fetch the configuration stored in flash previously. You can also configure the Wi-Fi driver if the previous configuration is not what you want.

3. **Wi-Fi Start Phase**

   - s3.1: Call `esp_wifi_start()` to start the Wi-Fi driver.
   - s3.2: The Wi-Fi driver posts `WIFI_EVENT_STA_START` to the event task; then, the event task will do some common things and will call the application event callback function.
   - s3.3: The application event callback function relays the `WIFI_EVENT_STA_START` to the application task. We recommend that you call `esp_wifi_connect()`. However, you can also call `esp_wifi_connect()` in other phrases after the `WIFI_EVENT_STA_START` arises.
Chapter 4. API Guides

Submit Document Feedback
4. Wi-Fi Connect Phase

- s4.1: Once `esp_wifi_connect()` is called, the Wi-Fi driver will start the internal scan/connection process.
- s4.2: If the internal scan/connection process is successful, the `WIFI_EVENT_STA_CONNECTED` will be generated. In the event task, it starts the DHCP client, which will finally trigger the DHCP process.
- s4.3: In the above-mentioned scenario, the application event callback will relay the event to the application task. Generally, the application needs to do nothing, and you can do whatever you want, e.g., print a log.

In step 4.2, the Wi-Fi connection may fail because, for example, the password is wrong, or the AP is not found. In a case like this, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason for such a failure will be provided. For handling events that disrupt Wi-Fi connection, please refer to phase 6.

5. Wi-Fi ‘Got IP’ Phase

- s5.1: Once the DHCP client is initialized in step 4.2, the `got IP` phase will begin.
- s5.2: If the IP address is successfully received from the DHCP server, then `IP_EVENT_STA_GOT_IP` will arise and the event task will perform common handling.
- s5.3: In the application event callback, `IP_EVENT_STA_GOT_IP` is relayed to the application task. For LwIP-based applications, this event is very special and means that everything is ready for the application to begin its tasks, e.g., creating the TCP/UDP socket. A very common mistake is to initialize the socket before `IP_EVENT_STA_GOT_IP` is received. **DO NOT start the socket-related work before the IP is received.**

6. Wi-Fi Disconnect Phase

- s6.1: When the Wi-Fi connection is disrupted, e.g., the AP is powered off or the RSSI is poor, `WIFI_EVENT_STA_DISCONNECTED` will arise. This event may also arise in phase 3. Here, the event task will notify the LwIP task to clear/remove all UDP/TCP connections. Then, all application sockets will be in a wrong status. In other words, no socket can work properly when this event happens.
- s6.2: In the scenario described above, the application event callback function relays `WIFI_EVENT_STA_DISCONNECTED` to the application task. The recommended actions are: 1) call `esp_wifi_connect()` to reconnect the Wi-Fi, 2) close all sockets, and 3) re-create them if necessary. For details, please refer to `WIFI_EVENT_STA_DISCONNECTED`.

7. Wi-Fi IP Change Phase

- s7.1: If the IP address is changed, the `IP_EVENT_STA_GOT_IP` will arise with “ip_change” set to true.
- s7.2: This event is important to the application. When it occurs, the timing is good for closing all created sockets and recreating them.

8. Wi-Fi Deinit Phase

- s8.1: Call `esp_wifi_disconnect()` to disconnect the Wi-Fi connectivity.
- s8.2: Call `esp_wifi_stop()` to stop the Wi-Fi driver.
- s8.3: Call `esp_wifi_deinit()` to unload the Wi-Fi driver.

4.3.28 ESP32 Wi-Fi AP General Scenario

Below is a “big scenario” which describes some small scenarios in AP mode:
Fig. 63: Sample Wi-Fi Event Scenarios in AP Mode
4.32.9 ESP32 Wi-Fi Scan

Currently, the `esp_wifi_scan_start()` API is supported only in station or station/AP mode.

**Scan Type**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Scan</td>
<td>Scan by sending a probe request. The default scan is an active scan.</td>
</tr>
<tr>
<td>Passive Scan</td>
<td>No probe request is sent out. Just switch to the specific channel and wait for a beacon. Application can enable it via the scan_type field of <code>wifi_scan_config_t</code>.</td>
</tr>
<tr>
<td>Foreground Scan</td>
<td>This scan is applicable when there is no Wi-Fi connection in station mode. Foreground or background scanning is controlled by the Wi-Fi driver and cannot be configured by the application.</td>
</tr>
<tr>
<td>All-Channel Scan</td>
<td>It scans all of the channels. If the channel field of <code>wifi_scan_config_t</code> is set to 0, it is an all-channel scan.</td>
</tr>
<tr>
<td>Specific Channel Scan</td>
<td>It scans specific channels only. If the channel field of <code>wifi_scan_config_t</code> set to 1-14, it is a specific-channel scan.</td>
</tr>
</tbody>
</table>

The scan modes in above table can be combined arbitrarily, so there are in total 8 different scans:

- All-Channel Background Active Scan
- All-Channel Background Passive Scan
- All-Channel Foreground Active Scan
- All-Channel Foreground Passive Scan
- Specific-Channel Background Active Scan
- Specific-Channel Background Passive Scan
- Specific-Channel Foreground Active Scan
- Specific-Channel Foreground Passive Scan

**Scan Configuration**

The scan type and other per-scan attributes are configured by `esp_wifi_scan_start()`. The table below provides a detailed description of `wifi_scan_config_t`.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssid</td>
<td>If the SSID is not NULL, it is only the AP with the same SSID that can be scanned.</td>
</tr>
<tr>
<td>bssid</td>
<td>If the BSSID is not NULL, it is only the AP with the same BSSID that can be scanned.</td>
</tr>
<tr>
<td>channel</td>
<td>If “channel” is 0, there will be an all-channel scan; otherwise, there will be a specific-channel scan.</td>
</tr>
<tr>
<td>show_hidden</td>
<td>If “show_hidden” is 0, the scan ignores the AP with a hidden SSID; otherwise, the scan considers the hidden AP a normal one.</td>
</tr>
<tr>
<td>scan_type</td>
<td>If “scan_type” is WIFI_SCAN_TYPE_ACTIVE, the scan is “active”; otherwise, it is a “passive” one.</td>
</tr>
<tr>
<td>scan_time</td>
<td>This field is used to control how long the scan dwells on each channel. For passive scans, scan_time.passive designates the dwell time for each channel. For active scans, dwell times for each channel are listed in the table below. Here, min is short for scan_time.active.min and max is short for scan_time.active.max.</td>
</tr>
<tr>
<td></td>
<td>• min=0, max=0: scan dwells on each channel for 120 ms.</td>
</tr>
<tr>
<td></td>
<td>• min&gt;0, max=0: scan dwells on each channel for 120 ms.</td>
</tr>
<tr>
<td></td>
<td>• min=0, max&gt;0: scan dwells on each channel for max ms.</td>
</tr>
<tr>
<td></td>
<td>• min&gt;0, max&gt;0: the minimum time the scan dwells on each channel is min ms. If no AP is found during this time frame, the scan switches to the next channel. Otherwise, the scan dwells on the channel for max ms.</td>
</tr>
</tbody>
</table>

If you want to improve the performance of the scan, you can try to modify these two parameters.

There are also some global scan attributes which are configured by API `esp_wifi_set_config()`, refer to Station Basic Configuration.

### Scan All APs on All Channels (Foreground)

**Scenario:**

The scenario above describes an all-channel, foreground scan. The foreground scan can only occur in station mode where the station does not connect to any AP. Whether it is a foreground or background scan is totally determined by the Wi-Fi driver, and cannot be configured by the application.

Detailed scenario description:

**Scan Configuration Phase**

- s1.1: Call `esp_wifi_set_country()` to set the country info if the default country info is not what you want. Refer to Wi-Fi Country Code.
- s1.2: Call `esp_wifi_scan_start()` to configure the scan. To do so, you can refer to Scan Configuration. Since this is an all-channel scan, just set the SSID/BSSID/channel to 0.

**Wi-Fi Driver’s Internal Scan Phase**

- s2.1: The Wi-Fi driver switches to channel 1. In this case, the scan type is WIFI_SCAN_TYPE_ACTIVE, and a probe request is broadcasted. Otherwise, the Wi-Fi will wait for a beacon from the APs. The Wi-Fi driver will stay in channel 1 for some time. The dwell time is configured in min/max time, with the default value being 120 ms.
- s2.2: The Wi-Fi driver switches to channel 2 and performs the same operation as in step 2.1.
- s2.3: The Wi-Fi driver scans the last channel N, where N is determined by the country code which is configured in step 1.1.

**Scan-Done Event Handling Phase**

- s3.1: When all channels are scanned, WIFI_EVENT_SCAN_DONE will arise.
Fig. 64: Foreground Scan of all Wi-Fi Channels
• s3.2: The application’s event callback function notifies the application task that WIFI_EVENT_SCAN_DONE is received. esp_wifi_scan_get_ap_num() is called to get the number of APs that have been found in this scan. Then, it allocates enough entries and calls esp_wifi_scan_get_ap_records() to get the AP records. Please note that the AP records in the Wi-Fi driver will be freed once esp_wifi_scan_get_ap_records() is called. Do not call esp_wifi_scan_get_ap_records() twice for a single scan-done event. If esp_wifi_scan_get_ap_records() is not called when the scan-done event occurs, the AP records allocated by the Wi-Fi driver will not be freed. So, make sure you call esp_wifi_scan_get_ap_records(), yet only once.

Scan All APs on All Channels (Background)

Scenario:
The scenario above is an all-channel background scan. Compared to Scan All APs on All Channels (Foreground), the difference in the all-channel background scan is that the Wi-Fi driver will scan the back-to-home channel for 30 ms before it switches to the next channel to give the Wi-Fi connection a chance to transmit/receive data.

Scan for Specific AP on All Channels

Scenario:
This scan is similar to Scan All APs on All Channels (Foreground). The differences are:

• s1.1: In step 1.2, the target AP will be configured to SSID/BSSID.
• s2.1~s2.N: Each time the Wi-Fi driver scans an AP, it will check whether it is a target AP or not. If the scan is WIFI_FAST_SCAN scan and the target AP is found, then the scan-done event will arise and scanning will end; otherwise, the scan will continue. Please note that the first scanned channel may not be channel 1, because the Wi-Fi driver optimizes the scanning sequence.

It is a possible situation that there are multiple APs that match the target AP info, e.g., two APs with the SSID of “ap” are scanned. In this case, if the scan is WIFI_FAST_SCAN, then only the first scanned “ap” will be found. If the scan is WIFI_ALL_CHANNEL_SCAN, both “ap” will be found and the station will connect the “ap” according to the configured strategy. Refer to Station Basic Configuration.

You can scan a specific AP, or all of them, in any given channel. These two scenarios are very similar.

Scan in Wi-Fi Connect

When esp_wifi_connect() is called, the Wi-Fi driver will try to scan the configured AP first. The scan in “Wi-Fi Connect” is the same as Scan for Specific AP On All Channels, except that no scan-done event will be generated when the scan is completed. If the target AP is found, the Wi-Fi driver will start the Wi-Fi connection; otherwise, WIFI_EVENT_STA_DISCONNECTED will be generated. Refer to Scan for Specific AP On All Channels.

Scan in Blocked Mode

If the block parameter of esp_wifi_scan_start() is true, then the scan is a blocked one, and the application task will be blocked until the scan is done. The blocked scan is similar to an unblocked one, except that no scan-done event will arise when the blocked scan is completed.

Parallel Scan

Two application tasks may call esp_wifi_scan_start() at the same time, or the same application task calls esp_wifi_scan_start() before it gets a scan-done event. Both scenarios can happen. However, the Wi-Fi driver does not support multiple concurrent scans adequately. As a result, concurrent scans should be avoided. Support for concurrent scan will be enhanced in future releases, as the ESP32’s Wi-Fi functionality improves continuously.
Fig. 65: Background Scan of all Wi-Fi Channels
Fig. 66: Scan of specific Wi-Fi Channels
Scan When Wi-Fi Is Connecting

The `esp_wifi_scan_start()` fails immediately if the Wi-Fi is connecting, because the connecting has higher priority than the scan. If scan fails because of connecting, the recommended strategy is to delay for some time and retry scan again. The scan will succeed once the connecting is completed.

However, the retry/delay strategy may not work all the time. Considering the following scenarios:

- The station is connecting a non-existing AP or it connects the existing AP with a wrong password, it always raises the event `WIFI_EVENT_STA_DISCONNECTED`.
- The application calls `esp_wifi_connect()` to reconnect on receiving the disconnect event.
- Another application task, e.g., the console task, calls `esp_wifi_scan_start()` to do scan, the scan always fails immediately because the station keeps connecting.
- When scan fails, the application simply delays for some time and retries the scan.

In the above scenarios, the scan will never succeed because the connecting is in process. So if the application supports similar scenario, it needs to implement a better reconnection strategy. For example:

- The application can choose to define a maximum continuous reconnection counter and stop reconnecting once the counter reaches the maximum.
- The application can choose to reconnect immediately in the first N continuous reconnection, then give a delay sometime and reconnect again.

The application can define its own reconnection strategy to avoid the scan starve to death. Refer to `<Wi-Fi Reconnect>`.

4.32.10 ESP32 Wi-Fi Station Connecting Scenario

This scenario depicts the case if only one target AP is found in the scan phase. For scenarios where more than one AP with the same SSID is found, refer to `ESP32 Wi-Fi Station Connecting When Multiple APs Are Found`.

Generally, the application can ignore the connecting process. Below is a brief introduction to the process for those who are really interested.

Scenario:

**Scan Phase**

- s1.1: The Wi-Fi driver begins scanning in “Wi-Fi Connect”. Refer to `Scan in Wi-Fi Connect` for more details.
- s1.2: If the scan fails to find the target AP, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_NO_AP_FOUND`. Refer to `Wi-Fi Reason Code`.

**Auth Phase**

- s2.1: The authentication request packet is sent and the auth timer is enabled.
- s2.2: If the authentication response packet is not received before the authentication timer times out, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_AUTH_EXPIRE`. Refer to `Wi-Fi Reason Code`.
- s2.3: The auth-response packet is received and the auth-timer is stopped.
- s2.4: The AP rejects authentication in the response and `WIFI_EVENT_STA_DISCONNECTED` arises, while the reason code is `WIFI_REASON_AUTH_FAIL` or the reasons specified by the AP. Refer to `Wi-Fi Reason Code`.

**Association Phase**

- s3.1: The association request is sent and the association timer is enabled.
- s3.2: If the association response is not received before the association timer times out, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_ASSOC_EXPIRE`. Refer to `Wi-Fi Reason Code`. 
Fig. 67. Wi-Fi Station Connecting Process

1. Scan Phase

1.1 > Scan

1.2 > WiFi_EVENT_STA_DISCONNECTED

2. Auth Phase

2.1 > Auth request

2.2 > WiFi_EVENT_STA_DISCONNECTED

2.3 > Auth response

2.4 > WiFi_EVENT_STA_DISCONNECTED

3. Assoc Phase

3.1 > Assoc request

3.2 > WiFi_EVENT_STA_DISCONNECTED

3.3 > Assoc response

3.4 > WiFi_EVENT_STA_DISCONNECTED

4. 4-way Handshake Phase

4.1 > WiFi_EVENT_STA_DISCONNECTED

4.2 > 1/4 EAPOL

4.3 > 2/4 EAPOL

4.4 > WiFi_EVENT_STA_DISCONNECTED

4.5 > 3/4 EAPOL

4.6 > 4/4 EAPOL

4.7 > WiFi_EVENT_STA_CONNECTED
• s3.3: The association response is received and the association timer is stopped.
• s3.4: The AP rejects the association in the response and \texttt{WIFI\_EVENT\_STA\_DISCONNECTED}
arises, while the reason code is the one specified in the association response. Refer to \textit{Wi-Fi Reason Code}.

\textbf{Four-way Handshake Phase}

• s4.1: The handshake timer is enabled, and the 1/4 EAPOL is not received before the handshake timer expires. \texttt{WIFI\_EVENT\_STA\_DISCONNECTED} will arise and the reason code will be \texttt{WIFI\_REASON\_HANDSHAKE\_TIMEOUT}. Refer to \textit{Wi-Fi Reason Code}.
• s4.2: The 1/4 EAPOL is received.
• s4.3: The station replies 2/4 EAPOL.
• s4.4: If the 3/4 EAPOL is not received before the handshake timer expires, \texttt{WIFI\_EVENT\_STA\_DISCONNECTED} will arise and the reason code will be \texttt{WIFI\_REASON\_HANDSHAKE\_TIMEOUT}. Refer to \textit{Wi-Fi Reason Code}.
• s4.5: The 3/4 EAPOL is received.
• s4.6: The station replies 4/4 EAPOL.
• s4.7: The station raises \texttt{WIFI\_EVENT\_STA\_CONNECTED}.

\textbf{Wi-Fi Reason Code}

The table below shows the reason-code defined in ESP32. The first column is the macro name defined in \texttt{esp\_wifi/include/esp\_wifi\_types.h}. The common prefix \texttt{WIFI\_REASON} is removed, which means that \texttt{UNSPECIFIED} actually stands for \texttt{WIFI\_REASON\_UNSPECIFIED} and so on. The second column is the value of the reason. The third column is the standard value to which this reason is mapped in section 9.4.1.7 of IEEE 802.11-2020. (For more information, refer to the standard mentioned above.) The last column describes the reason.

### Wi-Fi Reason code related to low RSSI

The table below shows the Wi-Fi reason-code may related to low RSSI.
4.32.11 ESP32 Wi-Fi Station Connecting When Multiple APs Are Found

This scenario is similar as ESP32 Wi-Fi Station Connecting Scenario. The difference is that the station will not raise the event WIFI_EVENT_STA_DISCONNECTED unless it fails to connect all of the found APs.

4.32.12 Wi-Fi Reconnect

The station may disconnect due to many reasons, e.g., the connected AP is restarted. It is the application’s responsibility to reconnect. The recommended reconnection strategy is to call esp_wifi_connect() on receiving event WIFI_EVENT_STA_DISCONNECTED.

Sometimes the application needs more complex reconnection strategy:

- If the disconnect event is raised because the esp_wifi_disconnect() is called, the application may not want to do the reconnection.
- If the esp_wifi_scan_start() may be called at anytime, a better reconnection strategy is necessary. Refer to Scan When Wi-Fi Is Connecting.

Another thing that need to be considered is that the reconnection may not connect the same AP if there are more than one APs with the same SSID. The reconnection always select current best APs to connect.

4.32.13 Wi-Fi Beacon Timeout

The beacon timeout mechanism is used by ESP32 station to detect whether the AP is alive or not. If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens. The application can set inactive time via API esp_wifi_set_inactive_time().

After the beacon times out, the station sends 5 probe requests to the AP. If still no probe response or beacon is received from AP, the station disconnects from the AP and raises the event WIFI_EVENT_STA_DISCONNECTED.

It should be considered that the timer used for beacon timeout will be reset during the scanning process. It means that the scan process will affect the triggering of the event WIFI_EVENT_STA_BEACON_TIMEOUT.

4.32.14 ESP32 Wi-Fi Configuration

All configurations will be stored into flash when the Wi-Fi NVS is enabled; otherwise, refer to Wi-Fi NVS Flash.

Wi-Fi Mode

Call esp_wifi_set_mode() to set the Wi-Fi mode.
### Mode Description

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIFI_MODE_NULL</td>
<td>NULL mode: in this mode, the internal data struct is not allocated to the station and the AP, while both the station and AP interfaces are not initialized for RX/TX Wi-Fi data. Generally, this mode is used for Sniffer, or when you only want to stop both the station and the AP without calling <code>esp_wifi_deinit()</code> to unload the whole Wi-Fi driver.</td>
</tr>
<tr>
<td>WIFI_MODE_STA</td>
<td>Station mode: in this mode, <code>esp_wifi_start()</code> will init the internal station data, while the station’s interface is ready for the RX and TX Wi-Fi data. After <code>esp_wifi_connect()</code>, the station will connect to the target AP.</td>
</tr>
<tr>
<td>WIFI_MODE_AP</td>
<td>AP mode: in this mode, <code>esp_wifi_start()</code> will init the internal AP data, while the AP’s interface is ready for RX/TX Wi-Fi data. Then, the Wi-Fi driver starts broad-casting beacons, and the AP is ready to get connected to other stations.</td>
</tr>
<tr>
<td>WIFI_MODE_APSTA</td>
<td>Station/AP coexistence mode: in this mode, <code>esp_wifi_start()</code> will simultaneously initialize both the station and the AP. This is done in station mode and AP mode. Please note that the channel of the external AP, which the ESP station is connected to, has higher priority over the ESP AP channel.</td>
</tr>
</tbody>
</table>

### Station Basic Configuration

API `esp_wifi_set_config()` can be used to configure the station. And the configuration will be stored in NVS. The table below describes the fields in detail.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssid</td>
<td>This is the SSID of the target AP, to which the station wants to connect.</td>
</tr>
<tr>
<td>password</td>
<td>Password of the target AP.</td>
</tr>
<tr>
<td>scan_method</td>
<td>For WIFI_FAST_SCAN scan, the scan ends when the first matched AP is found. For WIFI_ALL_CHANNEL_SCAN, the scan finds all matched APs on all channels. The default scan is WIFI_FAST_SCAN.</td>
</tr>
<tr>
<td>bssid_set</td>
<td>If bssid_set is 0, the station connects to the AP whose SSID is the same as the field “ssid”, while the field “bssid” is ignored. In all other cases, the station connects to the AP whose SSID is the same as the “ssid” field, while its BSSID is the same the “bssid” field.</td>
</tr>
<tr>
<td>bssid</td>
<td>This is valid only when bssid_set is 1; see field “bssid_set”.</td>
</tr>
<tr>
<td>channel</td>
<td>If the channel is 0, the station scans the channel 1 ~ N to search for the target AP; otherwise, the station starts by scanning the channel whose value is the same as that of the “channel” field, and then scans the channel 1 ~ N but skip the specific channel to find the target AP. For example, if the channel is 3, the scan order will be 3, 1, 2, 4, …, N. If you do not know which channel the target AP is running on, set it to 0.</td>
</tr>
<tr>
<td>sort_method</td>
<td>This field is only for WIFI_ALL_CHANNEL_SCAN. If the sort_method is WIFI_CONNECT_AP_BY_SIGNAL, all matched APs are sorted by signal, and the AP with the best signal will be connected firstly. For example, the station wants to connect an AP whose SSID is “apxx”. If the scan finds two APs whose SSID equals to “apxx”, and the first AP’s signal is -90 dBm while the second AP’s signal is -30 dBm, the station connects the second AP firstly, and it would not connect the first one unless it fails to connect the second one.</td>
</tr>
<tr>
<td>threshold</td>
<td>The threshold is used to filter the found AP. If the RSSI or security mode is less than the configured threshold, the AP will be discarded. If the RSSI is set to 0, it means the default threshold and the default RSSI threshold are -127 dBm. If the authmode threshold is set to 0, it means the default threshold and the default authmode threshold are open.</td>
</tr>
</tbody>
</table>
Attention: WEP/WPA security modes are deprecated in IEEE 802.11-2016 specifications and are recommended not to be used. These modes can be rejected using authmode threshold by setting threshold as WPA2 by threshold.authmode as WIFI_AUTH_WPA2_PSK.

AP Basic Configuration

API `esp_wifi_set_config()` can be used to configure the AP. And the configuration will be stored in NVS. The table below describes the fields in detail.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssid</td>
<td>SSID of AP; if the ssid[0] is 0xFF and ssid[1] is 0xFF, the AP defaults the SSID to ESP_aabbcc, where “aabbcc” is the last three bytes of the AP MAC.</td>
</tr>
<tr>
<td>password</td>
<td>Password of AP; if the auth mode is WIFI_AUTH_OPEN, this field will be ignored.</td>
</tr>
<tr>
<td>ssid_len</td>
<td>Length of SSID; if ssid_len is 0, check the SSID until there is a termination character. If ssid_len &gt; 32, change it to 32; otherwise, set the SSID length according to ssid_len.</td>
</tr>
<tr>
<td>channel</td>
<td>Channel of AP; if the channel is out of range, the Wi-Fi driver defaults to channel 1. So, please make sure the channel is within the required range. For more details, refer to Wi-Fi Country Code.</td>
</tr>
<tr>
<td>authmode</td>
<td>Auth mode of ESP AP; currently, ESP AP does not support AUTH_WEP. If the authmode is an invalid value, AP defaults the value to WIFI_AUTH_OPEN.</td>
</tr>
<tr>
<td>ssid_hidden</td>
<td>If ssid_hidden is 1, AP does not broadcast the SSID; otherwise, it does broadcast the SSID.</td>
</tr>
<tr>
<td>max_connection</td>
<td>The max number of stations allowed to connect in, the default value is 10. ESP Wi-Fi supports up to 15 (ESP_WIFI_MAX_CONN_NUM) Wi-Fi connections. Please note that ESP AP and ESP-NOW share the same encryption hardware keys, so the max_connection parameter will be affected by the CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM. The total number of encryption hardware keys is 17, if CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM &lt;= 2, the max_connection can be set up to 15, otherwise the max_connection can be set up to (17 - CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM).</td>
</tr>
<tr>
<td>beacon_interval</td>
<td>Beacon interval; the value is 100 ~ 60000 ms, with default value being 100 ms. If the value is out of range, AP defaults it to 100 ms.</td>
</tr>
</tbody>
</table>

Wi-Fi Protocol Mode

Currently, the ESP-IDF supports the following protocol modes:
## Protocol Mode

### Protocol Mode | Description
--- | ---
802.11b | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B)` to set the station/AP to 802.11b-only mode.
802.11bg | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G)` to set the station/AP to 802.11bg mode.
802.11g | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G)` and `esp_wifi_config_11b_rate(ifx, true)` to set the station/AP to 802.11g mode.
802.11bgn | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N)` to set the station/AP to BGN mode.
802.11gn | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N)` and `esp_wifi_config_11b_rate(ifx, true)` to set the station/AP to 802.11gn mode.
802.11 BGNLR | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N|WIFI_PROTOCOL_LR)` to set the station/AP to BGN and the LR mode.
802.11 LR | Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_LR)` to set the station/AP only to the LR mode. This mode is an Espressif-patented mode which can achieve a one-kilometer line of sight range. Please make sure both the station and the AP are connected to an ESP device.

### Long Range (LR)

Long Range (LR) mode is an Espressif-patented Wi-Fi mode which can achieve a one-kilometer line of sight range. Compared to the traditional 802.11b mode, it has better reception sensitivity, stronger anti-interference ability, and longer transmission distance.

#### LR Compatibility

Since LR is Espressif-unique Wi-Fi mode, only ESP32 chip series devices (except ESP32-C2) can transmit and receive the LR data. In other words, the ESP32 chip series devices (except ESP32-C2) should not transmit the data in LR data rate if the connected device does not support LR. The application can achieve this by configuring a suitable Wi-Fi mode. If the negotiated mode supports LR, the ESP32 chip series devices (except ESP32-C2) may transmit data in LR rate. Otherwise, ESP32 chip series devices (except ESP32-C2) will transmit all data in the traditional Wi-Fi data rate.

The following table depicts the Wi-Fi mode negotiation:

<table>
<thead>
<tr>
<th>APSTA</th>
<th>BGN</th>
<th>BG</th>
<th>B</th>
<th>BGNLR</th>
<th>BGLR</th>
<th>BLR</th>
<th>LR</th>
</tr>
</thead>
<tbody>
<tr>

<td>LR</td>
</tr>
<tr>
<td>LR</td>
<td>*</td>
<td>*</td>
<td>*</td>
<td>LR</td>
<td>LR</td>
<td>LR</td>
<td>LR</td>
</tr>
</tbody>
</table>
In the above table, the row is the Wi-Fi mode of AP and the column is the Wi-Fi mode of station. The "-" indicates Wi-Fi mode of the AP and station are not compatible.

According to the table, the following conclusions can be drawn:

- For LR-enabled AP of ESP32, it is incompatible with traditional 802.11 mode, because the beacon is sent in LR mode.
- For LR-enabled station of ESP32 whose mode is NOT LR-only mode, it is compatible with traditional 802.11 mode.
- If both station and AP are ESP32 series chips devices (except ESP32-C2) and both of them have enabled LR mode, the negotiated mode supports LR.

If the negotiated Wi-Fi mode supports both traditional 802.11 mode and LR mode, it is the Wi-Fi driver’s responsibility to automatically select the best data rate in different Wi-Fi modes and the application can ignore it.

**LR Impacts to Traditional Wi-Fi Device**  
The data transmission in LR rate has no impacts on the traditional Wi-Fi device because:

- The CCA and backoff process in LR mode are consistent with 802.11 specification.
- The traditional Wi-Fi device can detect the LR signal via CCA and do backoff.

In other words, the transmission impact in LR mode is similar to that in 802.11b mode.

**LR Transmission Distance**  
The reception sensitivity gain of LR is about 4 dB larger than that of the traditional 802.11b mode. Theoretically, the transmission distance is about 2 to 2.5 times the distance of 11B.

**LR Throughput**  
The LR rate has very limited throughput, because the raw PHY data rate LR is 1/2 Mbps and 1/4 Mbps.

**When to Use LR**  
The general conditions for using LR are:

- Both the AP and station are Espressif devices.
- Long distance Wi-Fi connection and data transmission is required.
- Data throughput requirements are very small, such as remote device control.

**Wi-Fi Country Code**

Call `esp_wifi_set_country()` to set the country info. The table below describes the fields in detail. Please consult local 2.4 GHz RF operating regulations before configuring these fields.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| cc[3]  | Country code string. This attribute identifies the country or noncountry entity in which the station/AP is operating. If it is a country, the first two octets of this string is the two-character country info as described in the document ISO/IEC3166-1. The third octet is one of the following:  
  • an ASCII space character, which means the regulations under which the station/AP is operating encompass all environments for the current frequency band in the country.  
  • an ASCII ‘O’ character, which means the regulations under which the station/AP is operating are for an outdoor environment only.  
  • an ASCII ‘I’ character, which means the regulations under which the station/AP is operating are for an indoor environment only.  
  • an ASCII ‘X’ character, which means the station/AP is operating under a non-country entity. The first two octets of the noncountry entity is two ASCII ‘XX’ characters.  
  • the binary representation of the Operating Class table number currently in use. Refer to Annex E of IEEE Std 802.11-2020. |
| schan  | Start channel. It is the minimum channel number of the regulations under which the station/AP can operate. |
| nchan  | Total number of channels as per the regulations. For example, if the schan=1, nchan=13, then the station/AP can send data from channel 1 to 13. |
| policy | Country policy. This field controls which country info will be used if the configured country info is in conflict with the connected AP’s. For more details on related policies, see the following section. |

The default country info is:

```c
wifi_country_t config = {
 .cc = "01",
 .schan = 1,
 .nchan = 11,
 .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

If the Wi-Fi Mode is station/AP coexist mode, they share the same configured country info. Sometimes, the country info of AP, to which the station is connected, is different from the country info of configured. For example, the configured station has country info:

```c
wifi_country_t config = {
 .cc = "JP",
 .schan = 1,
 .nchan = 14,
 .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

but the connected AP has country info:

```c
wifi_country_t config = {
 .cc = "CN",
 .schan = 1,
 .nchan = 13,
};
```

then country info of connected AP’s is used.

The following table depicts which country info is used in different Wi-Fi modes and different country policies, and it also describes the impact on active scan.
### Wi-Fi Mode

<table>
<thead>
<tr>
<th>Wi-Fi Mode</th>
<th>Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Station</td>
<td>WIFI_COUNTRY_POLICY_manual</td>
<td>If the connected AP has country IE in its beacon, the country info equals to the country info in beacon. Otherwise, use the default country info.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For scan: Use active scan from 1 to 11 and use passive scan from 12 to 14. Always keep in mind that if an AP with hidden SSID and station is set to a passive scan channel, the passive scan will not find it. In other words, if the application hopes to find the AP with hidden SSID in every channel, the policy of country info should be configured to WIFI_COUNTRY_POLICY_MANUAL.</td>
</tr>
<tr>
<td>Station</td>
<td>WIFI_COUNTRY_POLICY_manual</td>
<td>Always use the configured country info. For scan: Use active scan from schan to schan+nchan-1.</td>
</tr>
<tr>
<td>AP</td>
<td>WIFI_COUNTRY_POLICY_manual</td>
<td>Always use the configured country info. For scan: Use active scan from schan to schan+nchan-1.</td>
</tr>
<tr>
<td>Station/AP-coexistence</td>
<td>WIFI_COUNTRY_POLICY_manual</td>
<td>Same as station mode with policy WIFI_COUNTRY_POLICY_MANUAL. AP: If the station does not connect to any external AP, the AP uses the configured country info. If the station connects to an external AP, the AP has the same country info as the station.</td>
</tr>
<tr>
<td>Station/AP-coexistence</td>
<td>WIFI_COUNTRY_POLICY_manual</td>
<td>Same as station mode with policy WIFI_COUNTRY_POLICY_MANUAL. AP: Same as AP mode with policy WIFI_COUNTRY_POLICY_MANUAL.</td>
</tr>
</tbody>
</table>

**Home Channel**  
In AP mode, the home channel is defined as the AP channel. In station mode, home channel is defined as the channel of AP which the station is connected to. In station/AP-coexistence mode, the home channel of AP and station must be the same, and if they are different, the station’s home channel is always in priority. For example, assume that the AP is on channel 6, and the station connects to an AP whose channel is 9. Since the station’s home channel has higher priority, the AP needs to switch its channel from 6 to 9 to make sure that it has the same home channel as the station. While switching channel, the ESP32 in AP mode will notify the connected stations about the channel migration using a Channel Switch Announcement (CSA). Station that supports channel switching will transit without disconnecting and reconnecting to the AP.

**Wi-Fi Vendor IE Configuration**

By default, all Wi-Fi management frames are processed by the Wi-Fi driver, and the application can ignore them. However, some applications may have to handle the beacon, probe request, probe response, and other management frames. For example, if you insert some vendor-specific IE into the management frames, it is only the management frames which contain this vendor-specific IE that will be processed. In ESP32, `esp_wifi_set_vendor_ie()` and `esp_wifi_set_vendor_ie_cb()` are responsible for this kind of tasks.

### 4.32.15 Wi-Fi Easy Connect™ (DPP)

Wi-Fi Easy Connect™ (or Device Provisioning Protocol) is a secure and standardized provisioning protocol for configuring Wi-Fi devices. More information can be found in `esp_dpp`. 
**WPA2-Enterprise**

WPA2-Enterprise is the secure authentication mechanism for enterprise wireless networks. It uses RADIUS server for authentication of network users before connecting to the Access Point. The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, and PEAP. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both. When ESP32 in station mode tries to connect an AP in enterprise mode, it sends authentication request to AP which is sent to RADIUS server by AP for authenticating the station. Based on different EAP methods, the parameters can be set in configuration which can be opened using `idf.py menuconfig`. WPA2_Enterprise is supported by ESP32 only in station mode.

For establishing a secure connection, AP and station negotiate and agree on the best possible cipher suite to be used. ESP32 supports 802.1X/EAP (WPA) method of AKM and Advanced encryption standard with Counter Mode Cipher Block Chaining Message Authentication protocol (AES-CCM) cipher suite. It also supports the cipher suites supported by mbedts if `USE_MBEDTLS_CRYPTO` flag is set.

**ESP32 currently supports the following EAP methods:**

- **EAP-TLS:** This is a certificate-based method and only requires SSID and EAP-IDF.
- **PEAP:** This is a Protected EAP method. Username and Password are mandatory.
- **EAP-TTLS:** This is a credential-based method. Only server authentication is mandatory while user authentication is optional. Username and Password are mandatory. It supports different Phase2 methods, such as:
  - MSCHAP and MSCHAP-V2.
- **EAP-FAST:** This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, `USE_MBEDTLS_CRYPTO` flag should be disabled to use this feature.

Detailed information on creating certificates and how to run wpa2 enterprise example on ESP32 can be found in `wifi/wifi_enterprise`.

**4.32.16 Wi-Fi Aware™ (NAN)**

Wi-Fi Aware™ or NAN (Neighbor Awareness Networking) is a protocol that allows Wi-Fi devices to discover services in their proximity. NAN uses direct device-to-device communication and does not require any Internet or AP connection.

Multiple NAN devices in the vicinity will form a NAN cluster which allows them to communicate with each other. NAN devices in a cluster synchronise their clocks and listen to each other periodically on Channel 6. Devices can advertise (Publish) or seek for (Subscribe) services within their NAN Cluster using Service Discovery protocols. Matching of services is done by service name and optionally matching filters. Once a Subscriber gets a match with a Publisher, it can either send a message (Follow-up) or establish a datapath (NDP) with the Publisher. After NDP is setup both devices will obtain an IPv6 address and can use it for communication.

Please note that NAN Datapath security is not supported i.e., the data packets will go out unencrypted. NAN uses a separate interface for Discovery and Datapath, which is other than that used for STA and AP. NAN operates in standalone mode, which means co-existence with STA or AP interface is not supported.

Refer to ESP-IDF examples `examples/wifi/wifi_aware/nan_publisher/README.md` and `examples/wifi/wifi_aware/nan_subscriber/README.md` to setup a NAN Publisher and Subscriber.

**4.32.17 Wireless Network Management**

Wireless Network Management allows client devices to exchange information about the network topology, including information related to RF environment. This makes each client network-aware, facilitating overall improvement in the performance of the wireless network. It is part of 802.11v specification. It also enables the client to support Network assisted Roaming. - Network assisted Roaming: Enables WLAN to send messages to associated clients, resulting clients to associate with APs with better link metrics. This is useful for both load balancing and in directing poorly connected clients.
Current implementation of 802.11v includes support for BSS transition management frames.

### 4.32.18 Radio Resource Measurement

Radio Resource Measurement (802.11k) is intended to improve the way traffic is distributed within a network. In a WLAN, each device normally connects to the access point (AP) that provides the strongest signal. Depending on the number and geographic locations of the subscribers, this arrangement can sometimes lead to excessive demand on one AP and underutilization of others, resulting in degradation of overall network performance. In a network conforming to 802.11k, if the AP having the strongest signal is loaded to its full capacity, a wireless device can be moved to one of the underutilized APs. Even though the signal may be weaker, the overall throughput is greater because more efficient use is made of the network resources.

Current implementation of 802.11k includes support for beacon measurement report, link measurement report, and neighbor request.

Refer ESP-IDF example examples/wifi/roaming/README.md to set up and use these APIs. Example code only demonstrates how these APIs can be used, and the application should define its own algorithm and cases as required.

### 4.32.19 Fast BSS Transition

Fast BSS transition (802.11R FT), is a standard to permit continuous connectivity aboard wireless devices in motion, with fast and secure client transitions from one Basic Service Set (abbreviated BSS, and also known as a base station or more colloquially, an access point) to another performed in a nearly seamless manner avoiding 802.11 4 way handshake. 802.11R specifies transitions between access points by redefining the security key negotiation protocol, allowing both the negotiation and requests for wireless resources to occur in parallel. The key derived from the server to be cached in the wireless network, so that a reasonable number of future connections can be based on the cached key, avoiding the 802.1X process.

ESP32 station supports FT for WPA2-PSK networks. Do note that ESP32 station only support FT over the air protocol only.

A config option `CONFIG_ESP_WIFI_11R_SUPPORT` and configuration parameter `ft_enabled` in `wifi_sta_config_t` is provided to enable 802.11R support for station. Refer ESP-IDF example examples/wifi/roaming/README.md for further details.

### 4.32.20 ESP32 Wi-Fi Power-saving Mode

#### Station Sleep

Currently, ESP32 Wi-Fi supports the Modem-sleep mode which refers to the legacy power-saving mode in the IEEE 802.11 protocol. Modem-sleep mode works in station-only mode and the station must connect to the AP first. If the Modem-sleep mode is enabled, station will switch between active and sleep state periodically. In sleep state, RF, PHY and BB are turned off in order to reduce power consumption. Station can keep connection with AP in modem-sleep mode.

Modem-sleep mode includes minimum and maximum power-saving modes. In minimum power-saving mode, station wakes up every DTIM to receive beacon. Broadcast data will not be lost because it is transmitted after DTIM. However, it cannot save much more power if DTIM is short for DTIM is determined by AP.

In maximum power-saving mode, station wakes up in every listen interval to receive beacon. This listen interval can be set to be longer than the AP DTIM period. Broadcast data may be lost because station may be in sleep state at DTIM time. If listen interval is longer, more power is saved, but broadcast data is more easy to lose. Listen interval can be configured by calling API `esp_wifi_set_config()` before connecting to AP.

Call `esp_wifi_set_ps(WIFI_PS_MIN_MODEM)` to enable Modem-sleep minimum power-saving mode or `esp_wifi_set_ps(WIFI_PS_MAX_MODEM)` to enable Modem-sleep maximum power-saving mode after calling `esp_wifi_init()`. When station connects to AP, Modem-sleep will start. When station disconnects from AP, Modem-sleep will stop.
Call esp_wifi_set_ps(WIFI_PS_NONE) to disable Modem-sleep mode entirely. Disabling it increases power consumption, but minimizes the delay in receiving Wi-Fi data in real time. When Modem-sleep mode is enabled, the delay in receiving Wi-Fi data may be the same as the DTIM cycle (minimum power-saving mode) or the listening interval (maximum power-saving mode).

Note that in coexist mode, Wi-Fi will remain active only during Wi-Fi time slice, and sleep during non Wi-Fi time slice even if esp_wifi_set_ps(WIFI_PS_NONE) is called. Please refer to coexist policy.

The default Modem-sleep mode is WIFI_PS_MIN_MODEM.

### AP Sleep

Currently, ESP32 AP does not support all of the power-saving feature defined in Wi-Fi specification. To be specific, the AP only caches unicast data for the stations connect to this AP, but does not cache the multicast data for the stations. If stations connected to the ESP32 AP are power-saving enabled, they may experience multicast packet loss.

In the future, all power-saving features will be supported on ESP32 AP.

### Disconnected State Sleep

Disconnected state is the duration without Wi-Fi connection between esp_wifi_start() to esp_wifi_stop().

Currently, ESP32 Wi-Fi supports sleep mode in disconnected state if running at station mode. This feature could be configured by Menuconfig choice CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE.

If CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE is enabled, RF, PHY and BB would be turned off in disconnected state when IDLE. The current would be same with current at modem-sleep.

The choice CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE would be selected by default, while it would be selected forcefully in Menuconfig at coexistence mode.

### Connectionless Modules Power-saving

Connectionless modules are those Wi-Fi modules not relying on Wi-Fi connection, e.g ESP-NOW, DPP, FTM. These modules start from esp_wifi_start(), working until esp_wifi_stop().

Currently, if ESP-NOW works at station mode, its supported to sleep at both connected state and disconnected state.

### Connectionless Modules TX

For each connectionless module, its supported to TX at any sleeping time without any extra configuration.

Meanwhile, esp_wifi_80211_tx() is supported at sleep as well.

### Connectionless Modules RX

For each connectionless module, two parameters shall be configured to RX at sleep, which are Window and Interval.

At the start of Interval time, RF, PHY, BB would be turned on and kept for Window time. Connectionless Module could RX in the duration.

**Interval**

- There is only one Interval. Its configured by esp_wifi_set_connectionless_interval(). The unit is milliseconds.
- The default value of Interval is ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE.
- Event WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START would be posted at the start of Interval. Since Window also starts at that moment, its recommended to TX in that event.
- At connected state, the start of Interval would be aligned with TBTT.
Window

- Each connectionless module has its own Window after start. Connectionless Modules Power-saving would work with the max one among them.
- Window is configured by `module_name_set_wake_window()`. The unit is milliseconds.
- The default value of Window is the maximum.

Table 32: RF, PHY and BB usage under different circumstances

<table>
<thead>
<tr>
<th>Interval</th>
<th>ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window 0</td>
<td>not used</td>
</tr>
<tr>
<td>1 - maximum</td>
<td>default mode</td>
</tr>
</tbody>
</table>

Table 32: RF, PHY and BB usage under different circumstances

**Default Mode** If **Interval** is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE` with non-zero Window, Connectionless Modules Power-saving would work in default mode.

In default mode, RF, PHY, BB would be kept on if no coexistence with non-Wi-Fi protocol.

With coexistence, RF, PHY, BB resources are allocated by coexistence module to Wi-Fi connectionless module and non-Wi-Fi module, using time-division method. In default mode, Wi-Fi connectionless module is allowed to use RF, BB, PHY periodically under a stable performance.

It's recommended to configure Connectionless Modules Power-saving to default mode if there is Wi-Fi connectionless module coexists with non-Wi-Fi module.

### 4.32.21 ESP32 Wi-Fi Throughput

The table below shows the best throughput results gained in Espressif’s lab and in a shielded box.

<table>
<thead>
<tr>
<th>Type/Throughput</th>
<th>Air In Lab</th>
<th>Shield-box</th>
<th>Test Tool</th>
<th>IDF Version (commit ID)</th>

<tr>
<td>TCP TX</td>
<td>20 MBit/s</td>
<td>75 MBit/s</td>
<td>iperf example</td>
<td>15575346</td>
</tr>
</tbody>
</table>

When the throughput is tested by iperf example, the sdkconfig is `examples/wifi/iperf/sdkconfig.defaults.esp32`.

### 4.32.22 Wi-Fi 80211 Packet Send

The `esp_wifi_80211_tx()` API can be used to:

- Send the beacon, probe request, probe response, and action frame.
- Send the non-QoS data frame.

It cannot be used for sending encrypted or QoS frames.

**Preconditions of Using esp_wifi_80211_tx()**

- The Wi-Fi mode is station, or AP, or station/AP.
Either `esp_wifi_set_promiscuous(true)`, or `esp_wifi_start()`, or both of these APIs return `ESP_OK`. This is because Wi-Fi hardware must be initialized before `esp_wifi_80211_tx()` is called. In ESP32, both `esp_wifi_set_promiscuous(true)` and `esp_wifi_start()` can trigger the initialization of Wi-Fi hardware.

- The parameters of `esp_wifi_80211_tx()` are hereby correctly provided.

**Data Rate**

- The default data rate is 1 Mbps.
- Can set any rate through `esp_wifi_config_80211_tx_rate()` API.
- Can set any bandwidth through `esp_wifi_set_bandwidth()` API.

**Side-Effects to Avoid in Different Scenarios**

Theoretically, if the side-effects the API imposes on the Wi-Fi driver or other stations/APs are not considered, a raw 802.11 packet can be sent over the air with any destination MAC, any source MAC, any BSSID, or any other types of packet. However, robust or useful applications should avoid such side-effects. The table below provides some tips and recommendations on how to avoid the side-effects of `esp_wifi_80211_tx()` in different scenarios.
### Scenario Description

#### No Wi-Fi connection

In this scenario, no Wi-Fi connection is set up, so there are no side-effects on the Wi-Fi driver. If `en_sys_seq==true`, the Wi-Fi driver is responsible for the sequence control. If `en_sys_seq==false`, the application needs to ensure that the buffer has the correct sequence.

Theoretically, the MAC address can be any address. However, this may impact other stations/APs with the same MAC/BSSID.

Side-effect example#1 The application calls `esp_wifi_80211_tx()` to send a beacon with `BSSID == mac_x` in AP mode, but the `mac_x` is not the MAC of the AP interface. Moreover, there is another AP, e.g., “other-AP”, whose BSSID is `mac_x`. If this happens, an “unexpected behavior” may occur, because the stations which connect to the “other-AP” cannot figure out whether the beacon is from the “other-AP” or the `esp_wifi_80211_tx()`.

To avoid the above-mentioned side-effects, it is recommended that:

- If `esp_wifi_80211_tx()` is called in station mode, the first MAC should be a multicast MAC or the exact target-device’s MAC, while the second MAC should be that of the station interface.
- If `esp_wifi_80211_tx()` is called in AP mode, the first MAC should be a multicast MAC or the exact target-device’s MAC, while the second MAC should be that of the AP interface.

The recommendations above are only for avoiding side-effects and can be ignored when there are good reasons.

#### Have Wi-Fi connection

When the Wi-Fi connection is already set up, and the sequence is controlled by the application, the latter may impact the sequence control of the Wi-Fi connection as a whole. So, the `en_sys_seq` need to be true, otherwise `ESP_ERR_INVALID_ARG` is returned.

The MAC-address recommendations in the “No Wi-Fi connection” scenario also apply to this scenario.

If the Wi-Fi mode is station mode, the MAC address1 is the MAC of AP to which the station is connected, and the MAC address2 is the MAC of station interface, it is said that the packet is sent from the station to AP. Otherwise, if the Wi-Fi is in AP mode, the MAC address1 is the MAC of the station that connects to this AP, and the MAC address2 is the MAC of AP interface, it is said that the packet is sent from the AP to station. To avoid conflicting with Wi-Fi connections, the following checks are applied:

- If the packet type is data and is sent from the station to AP, the ToDS bit in IEEE 80211 frame control should be 1 and the FromDS bit should be 0. Otherwise, the packet will be discarded by Wi-Fi driver.
- If the packet type is data and is sent from the AP to station, the ToDS bit in IEEE 80211 frame control should be 0 and the FromDS bit should be 1. Otherwise, the packet will be discarded by Wi-Fi driver.
- If the packet is sent from station to AP or from AP to station, the Power Management, More Data, and Re-Transmission bits should be 0. Otherwise, the packet will be discarded by Wi-Fi driver.

`ESP_ERR_INVALID_ARG` is returned if any check fails.

### 4.32.23 Wi-Fi Sniffer Mode

The Wi-Fi sniffer mode can be enabled by `esp_wifi_set_promiscuous()`. If the sniffer mode is enabled, the following packets can be dumped to the application:

- 802.11 Management frame.
- 802.11 Data frame, including MPDU, AMPDU, and AMSDU.
- 802.11 MIMO frame, for MIMO frame, the sniffer only dumps the length of the frame.
- 802.11 Control frame.
- 802.11 CRC error frame.

The following packets will NOT be dumped to the application:

- Other 802.11 error frames.
For frames that the sniffer **can** dump, the application can additionally decide which specific type of packets can be filtered to the application by using `esp_wifi_set_promiscuous_filter()` and `esp_wifi_set_promiscuous_ctrl_filter()`. By default, it will filter all 802.11 data and management frames to the application.

The Wi-Fi sniffer mode can be enabled in the Wi-Fi mode of `WIFI_MODE_NULL`, `WIFI_MODE_STA`, `WIFI_MODE_AP`, or `WIFI_MODE_APSTA`. In other words, the sniffer mode is active when the station is connected to the AP, or when the AP has a Wi-Fi connection. Please note that the sniffer has a **great impact** on the throughput of the station or AP Wi-Fi connection. Generally, the sniffer should be enabled **only if** the station/AP Wi-Fi connection does not experience heavy traffic.

Another noteworthy issue about the sniffer is the callback `wifi_promiscuous_cb_t`. The callback will be called directly in the Wi-Fi driver task, so if the application has a lot of work to do for each filtered packet, the recommendation is to post an event to the application task in the callback and defer the real work to the application task.

### 4.32.24 Wi-Fi Multiple Antennas

The Wi-Fi multiple antennas selecting can be depicted as following picture:

```
| Enabled | |
|---------|
| Antenna 0 | \__\______ |
|          |    \   \__GPI0[0] <----- antenna_select[0] ---| |
|         |    \__\______ \__GPI0[1] <----- antenna_select[1] ---| |
|         |    \   \__antenna 15 |
|         |    \   \__antenna 1 |
```

ESP32 supports up to sixteen antennas through external antenna switch. The antenna switch can be controlled by up to four address pins - `antenna_select[0:3]`. Different input value of `antenna_select[0:3]` means selecting different antenna. For example, the value `0b1011` means the antenna 11 is selected. The default value of `antenna_select[3:0]` is `0b0000`, which means the antenna 0 is selected by default.

Up to four GPIOs are connected to the four active high antenna select pins. ESP32 can select the antenna by control the GPIO[0:3]. The API `esp_wifi_set_ant_gpio()` is used to configure which GPIOs are connected to antenna_selects. If GPIO[x] is connected to antenna_select[x], then gpio_config->gpio_cfg[x].gpio_select should be set to 1 and gpio_config->gpio_cfg[x].gpio_num should be provided.

For the specific implementation of the antenna switch, there may be illegal values in `antenna_select[0:3]`. It means that ESP32 may support less than sixteen antennas through the switch. For example, ESP32-WROOM-DA which uses RTC6603SP as the antenna switch, supports two antennas. Two GPIOs are connected to two active high antenna selection inputs. The value `0b01` means the antenna 0 is selected, the value `0b10` means the antenna 1 is selected. Values `0b00` and `0b11` are illegal.

Although up to sixteen antennas are supported, only one or two antennas can be simultaneously enabled for RX/TX. The API `esp_wifi_set_ant()` is used to configure which antennas are enabled.

The enabled antennas selecting algorithm is also configured by `esp_wifi_set_ant()`. The RX/TX antenna mode can be `WIFI_ANT_MODE_ANT0`, `WIFI_ANT_MODE_ANT1`, or `WIFI_ANT_MODE_AUTO`. If the antenna mode is `WIFI_ANT_MODE_ANT0`, the enabled antenna 0 is selected for RX/TX data. If the antenna mode is `WIFI_ANT_MODE_ANT1`, the enabled antenna 1 is selected for RX/TX data. Otherwise, Wi-Fi automatically selects the enabled antenna that has better signal.

If the RX antenna mode is `WIFI_ANT_MODE_AUTO`, the default antenna mode also needs to be set, because the RX antenna switching only happens when some conditions are met. For example, the RX antenna starts to switch if
Chapter 4. API Guides

the RSSI is lower than -65 dBm or another antenna has better signal. RX uses the default antenna if the conditions are not met. If the default antenna mode is WiFi_ANT_MODE_ANT1, the enabled antenna 1 is used as the default RX antenna, otherwise the enabled antenna 0 is used.

Some limitations need to be considered:

- The TX antenna can be set to WiFi_ANT_MODE_AUTO only if the RX antenna mode is WiFi_ANT_MODE_AUTO, because TX antenna selecting algorithm is based on RX antenna in WiFi_ANT_MODE_AUTO type.
- When the TX antenna mode or RX antenna mode is configured to WiFi_ANT_MODE_AUTO the switching mode will easily trigger the switching phase, as long as there is deterioration of the RF signal. So in situations where the RF signal is not stable, the antenna switching will occur frequently, resulting in an RF performance that may not meet expectations.
- Currently, Bluetooth® does not support the multiple antennas feature, so please do not use multiple antennas related APIs.

Following is the recommended scenarios to use the multiple antennas:

- The applications can always choose to select a specified antenna or implement their own antenna selecting algorithm, e.g., selecting the antenna mode based on the information collected by the application. Refer to ESP-IDF example examples/wifi/antenna/README.md for the antenna selecting algorithm design.
- Both RX/TX antenna modes are configured to WiFi_ANT_MODE_ANT0 or WiFi_ANT_MODE_ANT1.

Wi-Fi Multiple Antennas Configuration

Generally, following steps can be taken to configure the multiple antennas:

- Configure which GPIOs are connected to the antenna_selects. For example, if four antennas are supported and GPIO20/GPIO21 are connected to antenna_select[0]/antenna_select[1], the configurations look like:

```c
wifi_ant_gpio_config_t ant_gpio_config = {
    .gpio_cfg[0] = { .gpio_select = 1, .gpio_num = 20 },
    .gpio_cfg[1] = { .gpio_select = 1, .gpio_num = 21 }
};
```

- Configure which antennas are enabled and how RX/TX use the enabled antennas. For example, if antenna1 and antenna3 are enabled, the RX needs to select the better antenna automatically and uses antenna1 as its default antenna, the TX always selects the antenna3. The configuration looks like:

```c
wifi_ant_config_t config = {
    .rx_ant_mode = WiFi_ANT_MODE_AUTO,
    .rx_ant_default = WiFi_ANT_ANT0,
    .tx_ant_mode = WiFi_ANT_MODE_ANT1,
    .enabled_ant0 = 1,
    .enabled_ant1 = 3
};
```

4.32.25 Wi-Fi Channel State Information

Channel state information (CSI) refers to the channel information of a Wi-Fi connection. In ESP32, this information consists of channel frequency responses of sub-carriers and is estimated when packets are received from the transmitter. Each channel frequency response of sub-carrier is recorded by two bytes of signed characters. The first one is imaginary part and the second one is real part. There are up to three fields of channel frequency responses according to the type of received packet. They are legacy long training field (LLTF), high throughput LTF (HT-LTF), and space time block code HT-LTF (STBC-HT-LTF). For different types of packets which are received on channels with different state, the sub-carrier index and total bytes of signed characters of CSI are shown in the following table.
### Table 4.1: CSI Information Table

<table>
<thead>
<tr>
<th>Channel</th>
<th>Secondary Channel</th>
<th>Pack Information</th>
<th>Channel Bandwidth</th>
<th>STBC</th>
<th>Sub-carrier Index</th>
<th>Total Bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>non</td>
<td>below</td>
<td>20 MHz</td>
<td>non</td>
<td>-0<del>31, -32</del>1</td>
<td>128</td>
</tr>
<tr>
<td></td>
<td>non</td>
<td>above</td>
<td>20 MHz</td>
<td>non</td>
<td>-0<del>31, -32</del>1</td>
<td>256</td>
</tr>
<tr>
<td></td>
<td>HT</td>
<td>below</td>
<td>20 MHz</td>
<td>non</td>
<td>-0<del>31, -32</del>1</td>
<td>384</td>
</tr>
<tr>
<td></td>
<td>HT</td>
<td>above</td>
<td>40 MHz</td>
<td>non</td>
<td>-0<del>31, -32</del>1</td>
<td>128</td>
</tr>
</tbody>
</table>

All of the information in the table can be found in the structure `wifi_csi_info_t`.

- Secondary channel refers to `secondary_channel` field of `rx_ctrl` field.
- Signal mode of packet refers to `sig_mode` field of `rx_ctrl` field.
- Channel bandwidth refers to `chbw` field of `rx_ctrl` field.
- STBC refers to `stbc` field of `rx_ctrl` field.
- Total bytes refers to `len` field.
- The CSI data corresponding to each Long Training Field (LTF) type is stored in a buffer starting from the buffer field. Each item is stored as two bytes: imaginary part followed by real part. The order of each item is the same as the sub-carrier in the table. The order of LTF is: LLTF, HT-LTF, STBC-HT-LTF. However, all 3 LTFs may not be present, depending on the channel and packet information (see above).
- If `first_word_invalid` field of `wifi_csi_info_t` is true, it means that the first four bytes of CSI data is invalid due to a hardware limitation in ESP32.
- More information like RSSI, noise floor of RF, receiving time and antenna is in the `rx_ctrl` field.

When imaginary part and real part data of sub-carrier are used, please refer to the table below.

```
<table>
<thead>
<tr>
<th>PHY standard</th>
<th>Sub-carrier range</th>
<th>Pilot sub-carrier</th>
<th>Sub-carrier (total/data)</th>
</tr>
</thead>
<tbody>
<tr>
<td>802.11a/g</td>
<td>-26 to +26</td>
<td>-21, -7, +7, +21</td>
<td>52 total, 48 usable</td>
</tr>
<tr>
<td>802.11n, 20 MHz</td>
<td>-28 to +28</td>
<td>-21, -7, +7, +21</td>
<td>56 total, 52 usable</td>
</tr>
<tr>
<td>802.11n, 40 MHz</td>
<td>-57 to +57</td>
<td>-53, -25, -11, +11, +25, +53</td>
<td>114 total, 108 usable</td>
</tr>
</tbody>
</table>
```

**Note:**

- For STBC packet, CSI is provided for every space-time stream without CSD (cyclic shift delay). As each cyclic shift on the additional chains shall be -200 ns, only the CSD angle of first space-time stream is recorded in sub-carrier 0 of HT-LTF and STBC-HT-LTF for there is no channel frequency response in sub-carrier 0. CSD[10:0] is 11 bits, ranging from -pi to pi.
- If LLTF, HT-LTF, or STBC-HT-LTF is not enabled by calling API `esp_wifi_set_csi_config()`, the total bytes of CSI data will be fewer than that in the table. For example, if LLTF and HT-LTF is not enabled.
and STBC-HT-LTF is enabled, when a packet is received with the condition above/HT/40MHz/STBC, the total bytes of CSI data is 244 ((61 + 60) * 2 + 2 = 244. The result is aligned to four bytes, and the last two bytes are invalid).

4.32.26 Wi-Fi Channel State Information Configure

To use Wi-Fi CSI, the following steps need to be done.

- Select Wi-Fi CSI in menuconfig. Go to Menuconfig > Components config > Wi-Fi > Wi-Fi CSI (Channel State Information).
- Set CSI receiving callback function by calling API esp_wifi_set_csi_rx_cb().
- Configure CSI by calling API esp_wifi_set_csi_config().
- Enable CSI by calling API esp_wifi_set_csi().

The CSI receiving callback function runs from Wi-Fi task. So, do not do lengthy operations in the callback function. Instead, post necessary data to a queue and handle it from a lower priority task. Because station does not receive any packet when it is disconnected and only receives packets from AP when it is connected, it is suggested to enable sniffer mode to receive more CSI data by calling esp_wifi_set_promiscuous().

4.32.27 Wi-Fi HT20/40

ESP32 supports Wi-Fi bandwidth HT20 or HT40 and does not support HT20/40 coexist. esp_wifi_set_bandwidth() can be used to change the default bandwidth of station or AP. The default bandwidth for ESP32 station and AP is HT40.

In station mode, the actual bandwidth is firstly negotiated during the Wi-Fi connection. It is HT40 only if both the station and the connected AP support HT40, otherwise it is HT20. If the bandwidth of connected AP is changes, the actual bandwidth is negotiated again without Wi-Fi disconnecting.

Similarly, in AP mode, the actual bandwidth is negotiated between AP and the stations that connect to the AP. It is HT40 if the AP and one of the stations support HT40, otherwise it is HT20.

In station/AP coexist mode, the station/AP can configure HT20/40 seperately. If both station and AP are negotiated to HT40, the HT40 channel should be the channel of station because the station always has higher priority than AP in ESP32. For example, the configured bandwidth of AP is HT40, the configured primary channel is 6, and the configured secondary channel is 10. The station is connected to an router whose primary channel is 6 and secondary channel is 2, then the actual channel of AP is changed to primary 6 and secondary 2 automatically.

Theoretically, the HT40 can gain better throughput because the maximum raw physical (PHY) data rate for HT40 is 150 Mbps while it is 72 Mbps for HT20. However, if the device is used in some special environment, e.g., there are too many other Wi-Fi devices around the ESP32 device, the performance of HT40 may be degraded. So if the applications need to support same or similar scenarios, it is recommended that the bandwidth is always configured to HT20.

4.32.28 Wi-Fi QoS

ESP32 supports all the mandatory features required in WFA Wi-Fi QoS Certification.

Four ACs (Access Category) are defined in Wi-Fi specification, and each AC has its own priority to access the Wi-Fi channel. Moreover, a map rule is defined to map the QoS priority of other protocol, e.g., 802.11D or TCP/IP precedence is mapped to Wi-Fi AC.

The table below describes how the IP Precedences are mapped to Wi-Fi ACs in ESP32. It also indicates whether the AMPDU is supported for this AC. The table is sorted from high to low priority. That is to say, the AC_VO has the highest priority.
### Chapter 4. API Guides

<table>
<thead>
<tr>
<th>IP Precedence</th>
<th>Wi-Fi AC</th>
<th>Support AMPDU?</th>
</tr>
</thead>
<tbody>
<tr>
<td>6, 7</td>
<td>AC_VO (Voice)</td>
<td>No</td>
</tr>
<tr>
<td>4, 5</td>
<td>AC_VI (Video)</td>
<td>Yes</td>
</tr>
<tr>
<td>3, 0</td>
<td>AC_BE (Best Effort)</td>
<td>Yes</td>
</tr>
<tr>
<td>1, 2</td>
<td>AC_BK (Background)</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The application can make use of the QoS feature by configuring the IP precedence via socket option IP_TOS. Here is an example to make the socket to use VI queue:

```c
const int ip_precedence_vi = 4;
const int ip_precedence_offset = 5;
int priority = (ip_precedence_vi << ip_precedence_offset);
setsockopt(socket_id, IPPROTO_IP, IP_TOS, &priority, sizeof(priority));
```

Theoretically, the higher priority AC has better performance than the lower priority AC. However, it is not always true. Here are some suggestions about how to use the Wi-Fi QoS:

- Some really important application traffic can be put into the AC_VO queue. But avoid using the AC_VO queue for heavy traffic, as it may impact the management frames which also use this queue. Eventually, it is worth noting that the AC_VO queue does not support AMPDU, and its performance with heavy traffic is no better than other queues.
- Avoid using more than two precedences supported by different AMPDUs, e.g., when socket A uses precedence 0, socket B uses precedence 1, and socket C uses precedence 2. This can be a bad design because it may need much more memory. To be specific, the Wi-Fi driver may generate a Block Ack session for each precedence and it needs more memory if the Block Ack session is set up.

#### 4.32.29 Wi-Fi AMSDU

ESP32 supports receiving and transmitting AMSDU. AMSDU TX is disabled by default, since enable AMSDU TX need more memory. Select `CONFIG_ESP_WIFI_AMSDU_TX_ENABLED` to enable AMSDU Tx feature, it depends on `CONFIG_SPIRAM`.

#### 4.32.30 Wi-Fi Fragment

supports Wi-Fi receiving fragment, but does not support Wi-Fi transmitting fragment.

#### 4.32.31 WPS Enrollee

ESP32 supports WPS enrollee feature in Wi-Fi mode `WIFI_MODE_STA` or `WIFI_MODE_APSTA`. Currently, ESP32 supports WPS enrollee type PBC and PIN.

#### 4.32.32 Wi-Fi Buffer Usage

This section is only about the dynamic buffer configuration.

**Why Buffer Configuration Is Important**

In order to get a high-performance system, consider the memory usage/configuration carefully for the following reasons:

- the available memory in ESP32 is limited.
- currently, the default type of buffer in LwIP and Wi-Fi drivers is “dynamic”, which means that both the LwIP and Wi-Fi share memory with the application. Programmers should always keep this in mind; otherwise, they will face a memory issue, such as “running out of heap memory”.
it is very dangerous to run out of heap memory, as this will cause ESP32 an “undefined behavior”. Thus, enough heap memory should be reserved for the application, so that it never runs out of it.

the Wi-Fi throughput heavily depends on memory-related configurations, such as the TCP window size and Wi-Fi RX/TX dynamic buffer number.

the peak heap memory that the ESP32 LwIP/Wi-Fi may consume depends on a number of factors, such as the maximum TCP/UDP connections that the application may have.

the total memory that the application requires is also an important factor when considering memory configuration.

Due to these reasons, there is not a good-for-all application configuration. Rather, it is recommended to consider memory configurations separately for every different application.

Dynamic vs. Static Buffer

The default type of buffer in Wi-Fi drivers is “dynamic”. Most of the time the dynamic buffer can significantly save memory. However, it makes the application programming a little more difficult, because in this case the application needs to consider memory usage in Wi-Fi.

LwIP also allocates buffers at the TCP/IP layer, and this buffer allocation is also dynamic. See LwIP documentation section about memory use and performance.

Peak Wi-Fi Dynamic Buffer

The Wi-Fi driver supports several types of buffer (refer to Wi-Fi Buffer Configure). However, this section is about the usage of the dynamic Wi-Fi buffer only. The peak heap memory that Wi-Fi consumes is the theoretically-maximum memory that the Wi-Fi driver consumes. Generally, the peak memory depends on:

- $b_{rx}$ the number of dynamic RX buffers that are configured
- $b_{tx}$ the number of dynamic TX buffers that are configured
- $m_{rx}$ the maximum packet size that the Wi-Fi driver can receive
- $m_{tx}$ the maximum packet size that the Wi-Fi driver can send

So, the peak memory that the Wi-Fi driver consumes ($p$) can be calculated with the following formula:

$$ p = (b_{rx} \times m_{rx}) + (b_{tx} \times m_{tx}) $$

Generally, the dynamic TX long buffers and dynamic TX long long buffers can be ignored, because they are management frames which only have a small impact on the system.

4.32.33 How to Improve Wi-Fi Performance

The performance of ESP32 Wi-Fi is affected by many parameters, and there are mutual constraints between each parameter. A proper configuration cannot only improve performance, but also increase available memory for applications and improve stability.

This section briefly explains the operating mode of the Wi-Fi/LwIP protocol stack and the role of each parameter. It also gives several recommended configuration ranks to help choose the appropriate rank according to the usage scenario.

Protocol Stack Operation Mode

The ESP32 protocol stack is divided into four layers: Application, LwIP, Wi-Fi, and Hardware.

- During receiving, hardware puts the received packet into DMA buffer, and then transfers it into the RX buffer of Wi-Fi and LwIP in turn for related protocol processing, and finally to the application layer. The Wi-Fi RX buffer and the LwIP RX buffer shares the same buffer by default. In other words, the Wi-Fi forwards the packet to LwIP by reference by default.
During sending, the application copies the messages to be sent into the TX buffer of the LwIP layer for TCP/IP encapsulation. The messages will then be passed to the TX buffer of the Wi-Fi layer for MAC encapsulation and wait to be sent.

Parameters

Increasing the size or number of the buffers mentioned above properly can improve Wi-Fi performance. Meanwhile, it will reduce available memory to the application. The following is an introduction to the parameters that users need to configure:

RX direction:

- **CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM** This parameter indicates the number of DMA buffer at the hardware layer. Increasing this parameter will increase the sender’s one-time receiving throughput, thereby improving the Wi-Fi protocol stack ability to handle burst traffic.
- **CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM** This parameter indicates the number of RX buffer in the Wi-Fi layer. Increasing this parameter will improve the performance of packet reception. This parameter needs to match the RX buffers size of the LwIP layer.
- **CONFIG_ESP_WIFI_RX_BA_WIN** This parameter indicates the size of the AMPDU BA Window at the receiving end. This parameter should be configured to the smaller value between twice of **CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM** and **CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM**.
- **CONFIG_LWIP_TCP_WND_DEFAULT** This parameter represents the RX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_RX_BUFFER_NUM (KB) to reach a high and stable performance. Meanwhile, in case of multiple streams, this value needs to be reduced proportionally.

TX direction:

- **CONFIG_ESP_WIFI_TX_BUFFER** This parameter indicates the type of TX buffer, it is recommended to configure it as a dynamic buffer, which can make full use of memory.
- **CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM** This parameter indicates the number of TX buffer on the Wi-Fi layer. Increasing this parameter will improve the performance of packet sending. The parameter value needs to match the TX buffer size of the LwIP layer.
- **CONFIG_LWIP_TCP SND BUF_DEFAULT** This parameter represents the TX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_TX_BUFFER_NUM (KB) to reach a high and stable performance. In case of multiple streams, this value needs to be reduced proportionally.

Throughput optimization by placing code in IRAM:
Chapter 4. API Guides

- **CONFIG_ESP_WIFI_IRAM_OPT** If this option is enabled, some Wi-Fi functions are moved to IRAM, improving throughput. This increases IRAM usage by 15 kB.
- **CONFIG_ESP_WIFI_RX_IRAM_OPT** If this option is enabled, some Wi-Fi RX functions are moved to IRAM, improving throughput. This increases IRAM usage by 16 kB.
- **CONFIG_LWIP_IRAM_OPTIMIZATION** If this option is enabled, some LwIP functions are moved to IRAM, improving throughput. This increases IRAM usage by 13 kB.

**Note:** The buffer size mentioned above is fixed as 1.6 KB.

**How to Configure Parameters**

The memory of ESP32 is shared by protocol stack and applications.

Here, several configuration ranks are given. In most cases, the user should select a suitable rank for parameter configuration according to the size of the memory occupied by the application.

The parameters not mentioned in the following table should be set to the default.

<table>
<thead>
<tr>
<th>Rank</th>
<th>Iperf</th>
<th>TX prior</th>
<th>High-performance</th>
<th>RX prior</th>
<th>Default</th>
<th>Memory saving</th>

<td>54.7</td>
</tr>
</tbody>
</table>

**Note:** The test was performed with a single stream in a shielded box using an ASUS RT-N66U router. ESP32’s CPU is dual core with 240 MHz. ESP32’s flash is in QIO mode with 80 MHz.

**Ranks:**

- **Iperf rank** ESP32 extreme performance rank used to test extreme performance.
- **High-performance rank** The ESP32’s high-performance configuration rank, suitable for scenarios where the application occupies less memory and has high-performance requirements. In this rank, users can choose to use the RX prior rank or the TX prior rank according to the usage scenario.
Chapter 4. API Guides

- **Default rank** ESP32’s default configuration rank, the available memory, and performance are in balance.
- **Memory saving rank** This rank is suitable for scenarios where the application requires a large amount of memory, and the transceiver performance will be reduced in this rank.
- **Minimum rank** This is the minimum configuration rank of ESP32. The protocol stack only uses the necessary memory for running. It is suitable for scenarios where there is no requirement for performance and the application requires lots of space.

**Using PSRAM**

PSRAM is generally used when the application takes up a lot of memory. In this mode, the `CONFIG_ESP_WIFI_TX_BUFFER` is forced to be static. `CONFIG_ESP_WIFI_STATIC_TX_BUFFER_NUM` indicates the number of DMA buffers at the hardware layer, and increasing this parameter can improve performance. The following are the recommended ranks for using PSRAM:

<table>
<thead>
<tr>
<th>Rank</th>
<th>Iperf</th>

**4.32.34 Wi-Fi Menuconfig**

**Wi-Fi Buffer Configure**

If you are going to modify the default number or type of buffer, it would be helpful to also have an overview of how the buffer is allocated/freed in the data path. The following diagram shows this process in the TX direction:

![TX Buffer Allocation Diagram](image-url)
Chapter 4. API Guides

Description:

- The application allocates the data which needs to be sent out.
- The application calls TCPIP-/Socket-related APIs to send the user data. These APIs will allocate a PBUF used in LwIP, and make a copy of the user data.
- When LwIP calls a Wi-Fi API to send the PBUF, the Wi-Fi API will allocate a “Dynamic Tx Buffer” or “Static Tx Buffer”, make a copy of the LwIP PBUF, and finally send the data.

The following diagram shows how buffer is allocated/freed in the RX direction:

![RX Buffer Allocation Diagram]

Description:

- The Wi-Fi hardware receives a packet over the air and puts the packet content to the “Static Rx Buffer”, which is also called “RX DMA Buffer”.
- The Wi-Fi driver allocates a “Dynamic Rx Buffer”, makes a copy of the “Static Rx Buffer”, and returns the “Static Rx Buffer” to hardware.
- The Wi-Fi driver delivers the packet to the upper-layer (LwIP), and allocates a PBUF for holding the “Dynamic Rx Buffer”.
- The application receives data from LwIP.

The diagram shows the configuration of the Wi-Fi internal buffer.
<table>
<thead>
<tr>
<th>Buffer Type</th>
<th>Alloc Type</th>
<th>Default</th>
<th>Configurable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static RX Buffer</td>
<td>Static</td>
<td>10 * 1600 Bytes</td>
<td>Yes</td>
<td>This is a kind of DMA memory. It is initialized in <code>esp_wifi_init()</code> and freed in <code>esp_wifi_deinit()</code>. The ‘Static Rx Buffer’ forms the hardware receiving list. Upon receiving a frame over the air, hardware writes the frame into the buffer and raises an interrupt to the CPU. Then, the Wi-Fi driver reads the content from the buffer and returns the buffer back to the list. If needs be, the application can reduce the memory statically allocated by Wi-Fi. It can reduce this value from 10 to 6 to save 6400 Bytes of memory. It is not recommended to reduce the configuration to a value less than 6 unless the AMPDU feature is disabled.</td>
</tr>
<tr>
<td>Dynamic RX Buffer</td>
<td>Dynamic</td>
<td>32</td>
<td>Yes</td>
<td>The buffer length is variable and it depends on the received frames’ length. When the Wi-Fi driver receives a frame from the ‘Hardware Rx Buffer’, the ‘Dynamic Rx Buffer’ needs to be allocated from the heap. The number of the Dynamic Rx Buffer, configured in the menuconfig, is used to limit the total un-freed Dynamic Rx Buffer number.</td>
</tr>
<tr>
<td>Dynamic TX Buffer</td>
<td>Dynamic</td>
<td>32</td>
<td>Yes</td>
<td>This is a kind of DMA memory. It is allocated to the heap. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a ‘Dynamic TX Buffer’ and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffers are mutually exclusive.</td>
</tr>
<tr>
<td>Static TX Buffer</td>
<td>Static</td>
<td>16 * 1600 Bytes</td>
<td>Yes</td>
<td>This is a kind of DMA memory. It is initialized in <code>esp_wifi_init()</code> and freed in <code>esp_wifi_deinit()</code>. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a ‘Static TX Buffer’ and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffers are mutually exclusive. The TX buffer must be a DMA buffer. For this reason, if PSRAM is enabled, the TX buffer must be static.</td>
</tr>

<td>32</td>
<td>NO</td>
<td>Wi-Fi driver’s internal buffer.</td>
</tr>
</tbody>
</table>
Chapter 4. API Guides

Wi-Fi NVS Flash

If the Wi-Fi NVS flash is enabled, all Wi-Fi configurations set via the Wi-Fi APIs will be stored into flash, and the Wi-Fi driver will start up with these configurations the next time it powers on/reboots. However, the application can choose to disable the Wi-Fi NVS flash if it does not need to store the configurations into persistent memory, or has its own persistent storage, or simply due to debugging reasons, etc.

Wi-Fi Aggregate MAC Protocol Data Unit (AMPDU)

ESP32 supports both receiving and transmitting AMPDU, and the AMPDU can greatly improve the Wi-Fi throughput.

Generally, the AMPDU should be enabled. Disabling AMPDU is usually for debugging purposes.

4.32.35 Troubleshooting

Please refer to a separate document with Espressif Wireshark User Guide.

Espressif Wireshark User Guide

1. Overview

1.1 What Is Wireshark? Wireshark (originally named “Ethereal”) is a network packet analyzer that captures network packets and displays the packet data as detailed as possible. It uses WinPcap as its interface to directly capture network traffic going through a network interface controller (NIC).

You could think of a network packet analyzer as a measuring device used to examine what is going on inside a network cable, just like a voltmeter is used by an electrician to examine what is going on inside an electric cable.

In the past, such tools were either very expensive, proprietary, or both. However, with the advent of Wireshark, all that has changed.

Wireshark is released under the terms of the GNU General Public License, which means you can use the software and the source code free of charge. It also allows you to modify and customize the source code.

Wireshark is, perhaps, one of the best open source packet analyzers available today.

1.2 Some Intended Purposes Here are some examples of how Wireshark is typically used:

- Network administrators use it to troubleshoot network problems.
- Network security engineers use it to examine security problems.
- Developers use it to debug protocol implementations.
- People use it to learn more about network protocol internals.

Beside these examples, Wireshark can be used for many other purposes.

1.3 Features The main features of Wireshark are as follows:

- Available for UNIX and Windows
- Captures live packet data from a network interface
- Displays packets along with detailed protocol information
- Opens/saves the captured packet data
- Imports/exports packets into a number of file formats, supported by other capture programs
- Advanced packet filtering
- Searches for packets based on multiple criteria
• Colorizes packets according to display filters
• Calculates statistics
• …and a lot more!

1.4 Wireshark Can or Cannot Do

• **Live capture from different network media.**
  Wireshark can capture traffic from different network media, including wireless LAN.

• **Import files from many other capture programs.**
  Wireshark can import data from a large number of file formats, supported by other capture programs.

• **Export files for many other capture programs.**
  Wireshark can export data into a large number of file formats, supported by other capture programs.

• **Numerous protocol dissectors.**
  Wireshark can dissect, or decode, a large number of protocols.

• **Wireshark is not an intrusion detection system.**
  It will not warn you if there are any suspicious activities on your network. However, if strange things happen, Wireshark might help you figure out what is really going on.

• **Wireshark does not manipulate processes on the network, it can only perform “measurements” within it.**
  Wireshark does not send packets on the network or influence it in any other way, except for resolving names (converting numerical address values into a human readable format), but even that can be disabled.

1. Where to Get Wireshark

You can get Wireshark from the official website: [https://www.wireshark.org/download.html](https://www.wireshark.org/download.html)

Wireshark can run on various operating systems. Please download the correct version according to the operating system you are using.

This demonstration uses Wireshark 2.2.6 on Linux.

a) Start Wireshark

On Linux, you can run the shell script provided below. It starts Wireshark, then configures NIC and the channel for packet capture.

```bash
ifconfig $1 down
iwconfig $1 mode monitor
iwconfig $1 channel $2
ifconfig $1 up
Wireshark&
```

In the above script, the parameter $1 represents NIC and $2 represents channel. For example, `wlan0 in ./xxx.sh wlan0 6`, specifies the NIC for packet capture, and 6 identifies the channel of an AP or Soft-AP.

b) Run the Shell Script to Open Wireshark and Display Capture Interface

c) Select the Interface to Start Packet Capture

As the red markup shows in the picture above, many interfaces are available. The first one is a local NIC and the second one is a wireless NIC.

Please select the NIC according to your requirements. This document will use the wireless NIC to demonstrate packet capture.

Double click `wlan0` to start packet capture.

d) Set up Filters

Since all packets in the channel will be captured, and many of them are not needed, you have to set up filters to get the packets that you need.

Please find the picture below with the red markup, indicating where the filters should be set up.
Welcome to Wireshark

Capture

Fig. 71: Wireshark Capture Interface

*Fig. 72: Setting up Filters in Wireshark*
Chapter 4. API Guides

Click Filter, the top left blue button in the picture below. The display filter dialogue box will appear.

- Fig. 73: Display Filter Dialogue Box

Click the Expression button to bring up the Filter Expression dialogue box and set the filter according to your requirements.

**The quickest way:** enter the filters directly in the toolbar.

Click on this area to enter or modify the filters. If you enter a wrong or unfinished filter, the built-in syntax check turns the background red. As soon as the correct expression is entered, the background becomes green.

The previously entered filters are automatically saved. You can access them anytime by opening the drop down list.

For example, as shown in the picture below, enter two MAC addresses as the filters and click Apply (the blue arrow). In this case, only the packet data transmitted between these two MAC addresses will be captured.

**e) Packet List**

You can click any packet in the packet list and check the detailed information about it in the box below the list. For example, if you click the first packet, its details will appear in that box.

**f) Stop/Start Packet Capture**

As shown in the picture below, click the red button to stop capturing the current packet.

Click the top left blue button to start or resume packet capture.

**g) Save the Current Packet**

On Linux, go to File -> Export Packet Dissections -> As Plain Text File to save the packet.

Please note that All packets, Displayed and All expanded must be selected.

By default, Wireshark saves the captured packet in a libpcap file. You can also save the file in other formats, e.g., txt, to analyze it in other tools.

### 4.33 Wi-Fi Security

#### 4.33.1 ESP32 Wi-Fi Security Features

- Support for Protected Management Frames (PMF)
- Support for WPA3-Personal
Fig. 74: Filter Expression Dialogue Box

Fig. 75: Filter Toolbar

Fig. 76: Example of MAC Addresses applied in the Filter Toolbar
Chapter 4. API Guides

Fig. 77: Example of Packet List Details

Fig. 78: Stopping Packet Capture

Fig. 79: Starting or Resuming the Packets Capture
• Support for Opportunistic Wireless Encryption (OWE)

In addition to traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), ESP32 Wi-Fi supports state-of-the-art security protocols, namely Protected Management Frames (PMF), Wi-Fi Protected Access 3 and Enhanced Open™ based on Opportunistic Wireless Encryption. WPA3 provides better privacy and robustness against known attacks on traditional modes. Enhanced Open™ enhances the security and privacy of users connecting to open (public) Wireless Networks without authentication.

### 4.33.2 Protected Management Frames (PMF)

#### Introduction

In Wi-Fi, management frames such as beacons, probes, authentication/deauthentication, and association/dissociation are used by non-AP stations to scan and connect to an AP. Unlike data frames, these frames are sent unencrypted.

An attacker can use eavesdropping and packet injection to send spoofed authentication/deauthentication or association/dissociation frames at the right time, leading to attacks such as Denial-of-Service (DOS) and man-in-the-middle.

PMF provides protection against these attacks by encrypting unicast management frames and providing integrity checks for broadcast management frames. These include deauthentication, disassociation, and robust management frames. It also provides a Secure Association (SA) teardown mechanism to prevent spoofed association/authentication frames from disconnecting already connected clients.

There are three types of PMF configuration modes on both the station and AP sides:

- PMF Optional
- PMF Required
- PMF Disabled

#### API & Usage

ESP32 supports PMF in both the station and SoftAP mode. For both, the default mode is PMF Optional. For even higher security, PMF Required mode can be enabled by setting the `required` flag in `pmf_cfg` while using the `esp_wifi_set_config()` API. This results in the device only connecting to a PMF-enabled device and
rejecting others. PMF Optional can be disabled using `esp_wifi_disable_pmf_config()` API. If SoftAP is started in WPA3 or WPA2/WPA3 mixed mode, trying to disable PMF results in an error.

| Attention: | capable flag in pmf_cfg is deprecated and set to true internally. This is to take the additional security benefit of PMF whenever possible. |

## 4.3.3.3 Wi-Fi Enterprise

### Introduction

Enterprise security is the secure authentication mechanism for enterprise wireless networks. It uses the RADIUS server for authentication of network users before connecting to the Access Point (AP). The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, PEAP, and EAP-FAST. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both.

| Note: | ESP32 supports Wi-Fi Enterprise only in station mode. |

ESP32 supports **WPA2-Enterprise** and **WPA3-Enterprise**. WPA3-Enterprise builds upon the foundation of WPA2-Enterprise with the additional requirement of using Protected Management Frames (PMF) and server certificate validation on all WPA3 connections. **WPA3-Enterprise also offers an additional secure mode using 192-bit minimum-strength security protocols and cryptographic tools to better protect sensitive data.** The 192-bit security mode offered by WPA3-Enterprise ensures the right combination of cryptographic tools is used and sets a consistent baseline of security within a WPA3 network. WPA3-Enterprise 192-bit mode is only supported by modules having `SOC_WIFI_GCMP_SUPPORT` support. Enable `CONFIG_ESP_WIFI_SUITE_B_192` flag to support WPA3-Enterprise with 192-bit mode.

**ESP32 supports the following EAP methods:**

- **EAP-TLS**: This is a certificate-based method and only requires SSID and EAP-IDF.
- **PEAP**: This is a Protected EAP method. Usernames and passwords are mandatory.
- **EAP-TTLS**: This is a credential-based method. Only server authentication is mandatory while user authentication is optional. Username and Password are mandatory. It supports different Phase2 methods, such as:
  - **PAP**: Password Authentication Protocol.
  - **CHAP**: Challenge Handshake Authentication Protocol.
  - **MSCHAP and MSCHAP-V2**.
- **EAP-FAST**: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, `CONFIG_ESP_WIFI_MBEDTLS_TLS_CLIENT` flag should be disabled to use this feature.

Example `wifi/wifi_enterprise` demonstrates all the supported Wi-Fi Enterprise methods except EAP-FAST. Please refer `wifi/wifi_eap_fast` for the EAP-FAST example. EAP method can be selected from the Example Configuration menu in `idf.py menuconfig`. Refer to `examples/wiki/wiki_enterprise/README.md` for information on how to generate certificates and run the example.

## 4.3.3.4 WPA3-Personal

### Introduction

Wi-Fi Protected Access-3 (WPA3) is a set of enhancements to Wi-Fi access security intended to replace the current WPA2 standard. It includes new features and capabilities that offer significantly better protection against different types of attacks. It improves upon WPA2-Personal in the following ways:

- **WPA3 uses Simultaneous Authentication of Equals (SAE)**, which is a password-authenticated key agreement method based on Diffie-Hellman key exchange. Unlike WPA2, the technology is resistant to offline-dictionary
attacks, where the attacker attempts to determine a shared password based on a captured 4-way handshake without any further network interaction.

- Disallows outdated protocols such as TKIP, which is susceptible to simple attacks like MIC key recovery attacks.
- Mandates Protected Management Frames (PMF), which provides protection for unicast and multicast robust management frames which include Disassoc and Deauth frames. This means that the attacker cannot disrupt an established WPA3 session by sending forged Assoc frames to the AP or Deauth/Disassoc frames to the station.
- Provides forward secrecy, which means the captured data cannot be decrypted even if the password is compromised after data transmission.

ESP32 station also supports following additional Wi-Fi CERTIFIED WPA3™ features:

- **Transition Disable**: WPA3 defines transition modes for client devices so that they can connect to a network even when some of the APs in that network do not support the strongest security mode. Client device implementations typically configure network profiles in a transition mode by default. However, such a client device could be subject to an active downgrade attack in which the attacker causes the client device to use a lower security mode in order to exploit a vulnerability with that mode. WPA3 has introduced the Transition Disable feature to mitigate such attacks, by enabling client devices to change from a transition mode to an “only” mode when connecting to a network, once that network indicates it fully supports the higher security mode. Enable `transition_disable` in `wifi_sta_config_t` to enable this feature for ESP32 station.

- **SAE PUBLIC-KEY (PK)**: As the password at small public networks is shared with multiple users, it may be relatively easy for an attacker to find out the password, which is sufficient to launch an evil twin attack. Such attacks are prevented by an extension to WPA3-Personal called SAE-PK. The SAE-PK authentication exchange is very similar to the regular SAE exchange, with the addition of a digital signature sent by the AP to the client device. The client device validates the public key asserted by the AP based on the password fingerprint and verifies the signature using the public key. So even if the attacker knows the password, it does not know the private key to generate a valid signature, and therefore the client device is protected against an evil twin attack. Enable `CONFIG_ESP_WIFI_ENABLE_SAE_PK` and `sae_pk_mode` in `wifi_sta_config_t` to add support of SAE PK for ESP32 station.

- **SAE PWE Methods**: ESP32 station as well as SoftAP supports SAE Password Element derivation methods *Hunting And Pecking* and *Hash to Element (H2E)*. H2E is computationally efficient as it uses fewer iterations than Hunt and Peck, and also it mitigates side-channel attacks. These can be configured using the parameter `sae_pwe_h2e` from `wifi_sta_config_t` and `wifi_ap_config_t` for station and SoftAP respectively. Hunt and peck, H2E both can be enabled by using `WPA3_SAE_PWE_BOTH` configuration.

Please refer to the *Security* section of Wi-Fi Alliance’s official website for further details.

### Setting up WPA3 Personal with ESP32

A configuration option `CONFIG_ESP_WIFI_ENABLE_WPA3_SAE` is provided to enable/disable WPA3 for the station. By default, it is kept enabled. If disabled, ESP32 will not be able to establish a WPA3 connection. Also under the Wi-Fi component, a configuration option `CONFIG_ESP_WIFI_SOFTAP_SAE_SUPPORT` is provided to enable/disable WPA3 for SoftAP. Additionally, since PMF is mandated by WPA3 protocol, PMF Optional is set by default for station and SoftAP. PMF Required can be configured using Wi-Fi configuration. For WPA3 SoftAP, PMF Required is mandatory and will be configured and stored in NVS implicitly if not specified by the user.

Refer to *Protected Management Frames (PMF)* on how to set this mode.

After configuring all required settings for the WPA3-Personal station, application developers need not worry about the underlying security mode of the AP. WPA3-Personal is now the highest supported protocol in terms of security, so it is automatically selected for the connection whenever available. For example, if an AP is configured to be in WPA3 Transition Mode, where it advertises as both WPA2 and WPA3 capable, the station chooses WPA3 for the connection with the above settings.

After configuring all required setting for WPA3-Personal SoftAP, application developers have to set `WIFI_AUTH_WPA3_PSK` for `authmode` in `wifi_ap_config_t` to start AP in WPA3 security. SoftAP can be also configured to use `WIFI_AUTH_WPA2_WPA3_PSK` mixed mode.

Note that binary size will be increased by about 6.5 kilobytes after enabling `CONFIG_ESP_WIFI_SOFTAP_SAE_SUPPORT`. 
4.33.5 Wi-Fi Enhanced Open™

Introduction

Enhanced Open™ is used for providing security and privacy to users connecting to open (public) wireless networks, particularly in scenarios where user authentication is not desired or distribution of credentials impractical. Each user is provided with unique individual encryption keys that protect data exchange between a user device and the Wi-Fi network. Protected Management Frames further protect management traffic between the access point and the user device. Enhanced Open™ is based on the Opportunistic Wireless Encryption (OWE) standard. OWE Transition Mode enables a seamless transition from Open unencrypted WLANs to OWE WLANs without adversely impacting the end-user experience.

Note: ESP32 supports Wi-Fi Enhanced Open™ only in station mode.

Setting up OWE with ESP32

A configuration option `CONFIG_ESP_WIFI_ENABLE_WPA3_OWE_STA` and configuration parameter `owe_enabled` in `wifi_sta_config_t` is provided to enable OWE support for the station. To use OWE transition mode, along with the configuration provided above, `authmode` from `wifi_scan_threshold_t` should be set to `WIFI_AUTH_OPEN`.
Chapter 5

Security Guides

5.1 Overview

5.1.1 Security

This guide provides an overview of the overall security features available in various Espressif solutions. It is highly recommended to consider this guide while designing the products with the Espressif platform and the ESP-IDF software stack from the security perspective.

Goals

High level security goals are as follows:

1. Preventing untrustworthy code from being executed
2. Protecting the identity and integrity of the code stored in the off-chip flash memory
3. Securing device identity
4. Secure storage for confidential data
5. Authenticated and encrypted communication from the device

Platform Security

Secure Boot The Secure Boot feature ensures that only authenticated software can execute on the device. The Secure Boot process forms a chain of trust by verifying all mutable software entities involved in the Application Startup Flow. Signature verification happens during both boot-up as well as in OTA updates.

Please refer to Secure Boot V2 for detailed documentation about this feature.

For ESP32 before ECO3, please refer to Secure Boot.

Important: It is highly recommended that Secure Boot be enabled on all production devices.

Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Always keep the signing key private. A leak of this key will compromise the Secure Boot system.
• Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
• Ensure that all security eFuses have been correctly programmed, including disabling of the debug interfaces, non-required boot mediums (e.g., UART DL mode), etc.

**Flash Encryption**  The Flash Encryption feature helps to encrypt the contents on the off-chip flash memory and thus provides the confidentiality aspect to the software or data stored in the flash memory. Please refer to *Flash Encryption* for detailed information about this feature.

**Flash Encryption Best Practices**

- It is recommended to use flash Encryption release mode for the production use-cases.
- It is recommended to have a unique flash encryption key per device.
- Enable *Secure Boot* as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

**Debug Interfaces**

**JTAG**

- JTAG interface stays disabled if any of the security features are enabled. Please refer to *JTAG with Flash Encryption or Secure Boot* for more information.
- JTAG interface can also be disabled in the absence of any other security features using *eFuse API*.

**UART Download Mode**  For ESP32 ECO3 case, UART Download mode stays disabled if any of the security features are enabled in their release configuration. Alternatively, it can also be disabled by calling `esp_efuse_disable_rom_download_mode()` at runtime.

**Important:**  If UART Download mode is disabled then *esptool.py* cannot work on the device.

**Network Security**

**Wi-Fi**  In addition to the traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), Wi-Fi driver in ESP-IDF also supports additional state-of-the-art security protocols. Please refer to the *Wi-Fi Security* for detailed documentation.

**TLS (Transport Layer Security)**  It is recommended to use TLS (Transport Layer Security) in all external communications (e.g., cloud communication, OTA updates) from the ESP device. ESP-IDF supports *Mbed TLS* as the official TLS stack.

TLS is default integrated in *ESP HTTP Client, HTTPS Server* and several other components that ship with ESP-IDF.

**Note:**  It is recommended to use the ESP-IDF protocol components in their default configuration, which has been ensured to be secure. Disabling of HTTPS and similar security-critical configurations should be avoided.

**ESP-TLS Abstraction**  ESP-IDF provides an abstraction layer for the most-used TLS functionalities. Hence, it is recommended that an application uses the API exposed by *ESP-TLS*.

**TLS Server Verification**  section highlights diverse ways in which the identity of server could be established on the device side.
ESP Certificate Bundle  The ESP x509 Certificate Bundle API provides an easy way to include a bundle of custom x509 root certificates for TLS server verification. The certificate bundle is the easiest way to verify the identity of almost all standard TLS servers.

**Important:** It is highly recommended to verify the identity of the server based on X.509 certificates to avoid establishing communication with the fake server.

Managing Root Certificates  Root Certificates embedded inside the application must be managed carefully. Any update to the root certificate list or the ESP x509 Certificate Bundle can have an impact on the TLS connection with the remote endpoint. This includes a connection to the OTA update server. In some cases, the problem shall be visible on the next OTA update and it may leave device unable to perform OTA updates forever.

Root certificates list update could have following reasons:

- New firmware has different set of remote endpoint(s).
- Existing certificate has expired.
- The certificate has been added or retracted from the upstream certificate bundle.
- The certificate list changed due to market share statistics (CONFIG_MBEDTLS_CERTIFICATE_BUNDLE_DEFAULT_CMN case).

Some guidelines to consider on this topic:

- Please consider enabling OTA rollback and then keep the successful connection to the OTA update server as the checkpoint to cancel the rollback process. This ensures that the newly updated firmware can successfully reach till the OTA update server, otherwise rollback process will go back to the previous firmware on the device.
- If you plan to enable the CONFIG_MBEDTLS_HAVE_TIME_DATE option then please consider to have sufficient number of trusted certificates and the time sync mechanism (SNTP) in place.

Product Security

Secure Provisioning  Secure Provisioning refers to a process of secure on-boarding of the ESP device on to the Wi-Fi network. This mechanism also allows provision of additional custom configuration data during the initial provisioning phase from the provisioning entity, e.g., Smartphone.

ESP-IDF provides various security schemes to establish a secure session between ESP and the provisioning entity, they are highlighted at Security Schemes.

Please refer to the Wi-Fi Provisioning documentation for details and the example code for this feature.

**Note:** Espressif provides Android and iOS Phone Apps along with their sources, so that it could be easy to further customize them as per the product requirement.

Secure OTA (Over-the-air) Updates

- OTA Updates must happen over secure transport, e.g., HTTPS.
- ESP-IDF provides a simplified abstraction layer ESP HTTPS OTA for this.
- If Secure Boot is enabled, then the server should host the signed application image.
- If Flash Encryption is enabled, then no additional steps are required on the server side, encryption shall be taken care on the device itself during flash write.
- OTA update Rollback Process can help to switch the application as active only after its functionality has been verified.

Anti-Rollback Protection  Anti-rollback protection feature ensures that device only executes the application that meets the security version criteria as stored in its eFuse. So even though the application is trusted and signed by legitimate key, it may contain some revoked security feature or credential. Hence, device must reject any such application.
ESP-IDF allows this feature for the application only and it is managed through 2nd stage bootloader. The security version is stored in the device eFuse and it is compared against the application image header during both bootup and over-the-air updates.

Please see more information to enable this feature in the Anti-rollback guide.

**Encrypted Firmware Distribution**  Encrypted firmware distribution during over-the-air updates ensures that the application stays encrypted in transit from the server to the device. This can act as an additional layer of protection on top of the TLS communication during OTA updates and protect the identity of the application.

Please see working example for this documented in OTA Upgrades with Pre-Encrypted Firmware section.

**Secure Storage**  Secure storage refers to the application-specific data that can be stored in a secure manner on the device, i.e., off-chip flash memory. This is typically a read-write flash partition and holds device specific configuration data, e.g., Wi-Fi credentials.

ESP-IDF provides the NVS (Non-volatile Storage) management component which allows encrypted data partitions. This feature is tied with the platform Flash Encryption feature described earlier.

Please refer to the NVS Encryption for detailed documentation on the working and instructions to enable this feature.

**Important:**  By default, ESP-IDF components writes the device specific data into the default NVS partition, including Wi-Fi credentials too, and it is recommended to protect this data using NVS Encryption feature.

**Secure Device Control**  ESP-IDF provides capability to control an ESP device over Wi-Fi + HTTP or BLE in a secure manner using ESP Local Control component.

Please refer to the ESP Local Control for detailed documentation about this feature.

**Security Policy**

The ESP-IDF GitHub repository has attached Security Policy Brief.

**Advisories**

- Espressif publishes critical Security Advisories, which includes security advisories regarding both hardware and software.
- The specific advisories of the ESP-IDF software components are published through the GitHub repository.

**Software Updates**  Critical security issues in the ESP-IDF components, and third-party libraries are fixed as and when we find them or when they are reported to us. Gradually, we make the fixes available in all applicable release branches in ESP-IDF.

Applicable security issues and CVEs for the ESP-IDF components, third-party libraries are mentioned in the ESP-IDF release notes.

**Important:**  We recommend periodically updating to the latest bugfix version of the ESP-IDF release to have all critical security fixes available.
5.2 Features

5.2.1 Flash Encryption

This is a quick start guide to ESP32’s flash encryption feature. Using application code as an example, it demonstrates how to test and verify flash encryption operations during development and production.

Introduction

Flash encryption is intended for encrypting the contents of the ESP32’s off-chip flash memory. Once this feature is enabled, firmware is flashed as plaintext, and then the data is encrypted in place on the first boot. As a result, physical readout of flash will not be sufficient to recover most flash contents.

Secure Boot is a separate feature which can be used together with flash encryption to create an even more secure environment.

Important: For production use, flash encryption should be enabled in the “Release” mode only.

Important: Enabling flash encryption limits the options for further updates of ESP32. Before using this feature, read the document and make sure to understand the implications.

Encrypted Partitions

With flash encryption enabled, the following types of data are encrypted by default:

- Second Stage Bootloader (Firmware Bootloader)
- Partition Table
- NVS Key Partition
- Otadata
- All app type partitions

Other types of data can be encrypted conditionally:

- Any partition marked with the encrypted flag in the partition table. For details, see Encrypted Partition Flag.
- Secure Boot bootloader digest if Secure Boot is enabled (see below).

Relevant eFuses

The flash encryption operation is controlled by various eFuses available on ESP32. The list of eFuses and their descriptions is given in the table below. The names in eFuse column are also used by espefuse.py tool. For usage in the eFuse API, modify the name by adding ESP_EFUSE_, for example: esp_efuse_read_field_bit(ESP_EFUSE_DISABLE_DL_ENCRYPT).
Table 1: eFuses Used in Flash Encryption

<table>
<thead>
<tr>

<tr>
<td>DISABLE_DL_DECRYPT</td>
<td>If set, disables flash decryption while running in UART Firmware Download mode.</td>
<td>1</td>
</tr>
<tr>
<td>FLASH_CRYPT_CNT</td>
<td>A 2^n number that indicating whether the contents of flash have been encrypted. • If an odd number of bits are set (e.g., 0b00000001 or 0b00001111), this indicates the contents of flash are encrypted. The contents will need to be transparently decrypted when read. • If an even number of bits are set (e.g., 0b00000000 or 0b00000111), this indicates the contents of flash are unencrypted (i.e., plain text). With each successive unencrypted flash update (e.g., flashing a new unencrypted binary) and encryption of the flash (via the Enable flash encryption on boot option), the next MSB of FLASH_CRYPT_CNT is set.</td>
<td>7</td>
</tr>
</tbody>
</table>

Note:
- R/W access control is available for all the eFuse bits listed in the table above.
- The default value of these bits is 0 after manufacturing.

Read and write access to eFuse bits is controlled by appropriate fields in the registers WR_DIS and RD_DIS. For more information on ESP32 eFuses, see eFuse manager. To change protection bits of eFuse field using espefuse.py, use these two commands: read_protect_efuse and write_protect_efuse. Example espefuse.py write_protect_efuse DISABLE_DL_ENCRYPT.

Flash Encryption Process

Assuming that the eFuse values are in their default states and the firmware bootloader is compiled to support flash encryption, the flash encryption process executes as shown below:

1. On the first power-on reset, all data in flash is un-encrypted (plaintext). The ROM bootloader loads the firmware bootloader.
2. Firmware bootloader reads the FLASH_CRYPT_CNT eFuse value (0b00000000). Since the value is 0 (even number of bits set), it configures and enables the flash encryption block. It also sets the FLASH_CRYPT_CONFIG eFuse to 0xF. For more information on the flash encryption block, see ESP32 Technical Reference Manual > eFuse Controller (eFuse) > Flash Encryption Block [PDF].
3. Firmware bootloader first checks if a valid key is already present in the eFuse (e.g., burned using espefuse tool), then the process of key generation is skipped and the same key is used for flash encryption process. Otherwise, Firmware bootloader uses RNG (random) module to generate an AES-256 bit key and then writes it into the flash_encryption eFuse. The key cannot be accessed via software as the write and read protection bits for the flash_encryption eFuse are set. The flash encryption operations happen entirely by hardware, and the key cannot be accessed via software.
4. Flash encryption block encrypts the flash contents - the firmware bootloader, applications and partitions marked as encrypted. Encrypting in-place can take time, up to a minute for large partitions.
5. Firmware bootloader sets the first available bit in `FLASH_CRYPT_CNT (0b0000001)` to mark the flash contents as encrypted. Odd number of bits is set.

6. For **Development Mode**, the firmware bootloader sets only the eFuse bits `DISABLE_DL_DECRIPT` and `DISABLE_DL_CACHE` to allow the UART bootloader to re-flash encrypted binaries. Also, the `FLASH_CRYPT_CNT` eFuse bits are NOT write-protected.

7. For **Release Mode**, the firmware bootloader sets the eFuse bits `DISABLE_DL_ENCRYPT`, `DISABLE_DL_DECRIPT`, and `DISABLE_DL_CACHE` to 1 to prevent the UART bootloader from decrypting the flash contents. It also write-protecs the `FLASH_CRYPT_CNT` eFuse bits. To modify this behavior, see **Enabling UART Bootloader Encryption/Decryption**.

8. The device is then rebooted to start executing the encrypted image. The firmware bootloader calls the flash decryption block to decrypt the flash contents and then loads the decrypted contents into IRAM.

During the development stage, there is a frequent need to program different plaintext flash images and test the flash encryption process. This requires that Firmware Download mode is able to load new plaintext images as many times as it might be needed. However, during manufacturing or production stages, Firmware Download mode should not be allowed to access flash contents for security reasons.

Hence, two different flash encryption configurations were created: for development and for production. For details on these configurations, see Section **Flash Encryption Configuration**.

### Flash Encryption Configuration

The following flash encryption modes are available:

- **Development Mode** - recommended for use only during development. In this mode, it is still possible to flash new plaintext firmware to the device, and the bootloader will transparently encrypt this firmware using the key stored in hardware. This allows, indirectly, to read out the plaintext of the firmware in flash.

- **Release Mode** - recommended for manufacturing and production. In this mode, flashing plaintext firmware to the device without knowing the encryption key is no longer possible.

This section provides information on the mentioned flash encryption modes and step by step instructions on how to use them.

**Development Mode** During development, you can encrypt flash using either an ESP32 generated key or external host-generated key.

**Using ESP32 Generated Key** Development mode allows you to download multiple plaintext images using Firmware Download mode.

To test flash encryption process, take the following steps:

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in **Relevant eFuses**. See how to check **ESP32 Flash Encryption Status**.

2. In **Project Configuration Menu**, do the following:

   - **Enable flash encryption on boot**.
   - **Select encryption mode** (Development mode by default).
   - **Select UART ROM download mode** (enabled by default). Note that for the ESP32 target, the choice is only available when `CONFIG_ESP32_REV_MIN` level is set to 3 (ESP32 V3).
   - **Select the appropriate bootloader log verbosity**.
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See **Bootloader Size**.

3. Run the command given below to build and flash the complete images.
**Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

A sample output of the first ESP32 boot after enabling flash encryption is given below:

```

Sample program to check Flash Encryption
This is ESP32 chip with 2 CPU cores, WiFi/BT/BLE, silicon revision 1, 4MB external...

Flash encryption feature is enabled
Flash encryption mode is DEVELOPMENT
Flash in encrypted mode with flash_crypt_cnt = 1
Halting...

At this stage, if you need to update and re-flash binaries, see Re-flashing Updated Partitions.

Using Host Generated Key  It is possible to pre-generate a flash encryption key on the host computer and burn it into the eFuse. This allows you to pre-encrypt data on the host and flash already encrypted data without needing
a plaintext flash update. This feature can be used in both Development Mode and Release Mode. Without a pre-generated key, data is flashed in plaintext and then ESP32 encrypts the data in-place.

**Note:** This option is not recommended for production, unless a separate key is generated for each individual device.

To use a host generated key, take the following steps:

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in Relevant eFuses. See how to check ESP32 Flash Encryption Status.

2. Generate a random key by running:

   ```
   espssecure.py generate_flash_encryption_key my_flash_encryption_key.bin
   ```

3. **Before the first encrypted boot,** burn the key into your device’s eFuse using the command below. This action can be done **only once**.

   ```
   espefuse.py --port PORT burn_key flash_encryption my_flash_encryption_key.bin
   ```

   If the key is not burned and the device is started after enabling flash encryption, the ESP32 will generate a random key that software cannot access or modify.

4. In Project Configuration Menu, do the following:
   - Enable flash encryption on boot
   - Select encryption mode (Development mode by default)
   - Select the appropriate bootloader log verbosity
   - Save the configuration and exit.

   Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See **Bootloader Size**.

5. Run the command given below to build and flash the complete images.

   ```
   idf.py flash monitor
   ```

   **Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

If using Development Mode, then the easiest way to update and re-flash binaries is **Re-flashing Updated Partitions**.

If using Release Mode, then it is possible to pre-encrypt the binaries on the host and then flash them as ciphertext. See **Manually Encrypting Files**.

**Re-flashing Updated Partitions** If you update your application code (done in plaintext) and want to re-flash it, you will need to encrypt it before flashing. To encrypt the application and flash it in one step, run:

```
idf.py encrypted-app-flash monitor
```

If all partitions needs to be updated in encrypted format, run:
Release Mode  In Release mode, UART bootloader cannot perform flash encryption operations. New plaintext images can ONLY be downloaded using the over-the-air (OTA) scheme which will encrypt the plaintext image before writing to flash.

To use this mode, take the following steps:

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in Relevant eFuses. See how to check ESP32 Flash Encryption Status.

2. In Project Configuration Menu, do the following:
   - Enable flash encryption on boot
   - Select Release mode (Note that once Release mode is selected, the DISABLE_DL_Encrypt and DISABLE_DL_Decrypt eFuse bits will be burned to disable flash encryption hardware in ROM Download Mode.)
   - Select UART ROM download mode (Permanently disabled (recommended)) (Note that this option is only available when CONFIG_ESP32_REV_MIN is set to 3 (ESP32 V3).) The default choice is to keep UART ROM download mode enabled, however it is recommended to permanently disable this mode to reduce the options available to an attacker.
   - Select the appropriate bootloader log verbosity
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See Bootloader Size.

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

Once the flash encryption is enabled in Release mode, the bootloader will write-protect the FLASH_CRYPT_CNT eFuse.

For subsequent plaintext field updates, use OTA scheme.

Note: If you have pre-generated the flash encryption key and stored a copy, and the UART download mode is not permanently disabled via CONFIG_SECURE_UART_ROM_DL_MODE (ESP32 V3 only), then it is possible to update the flash locally by pre-encrypting the files and then flashing the ciphertext. See Manually Encrypting Files.

Best Practices  When using Flash Encryption in production:

- Do not reuse the same flash encryption key between multiple devices. This means that an attacker who copies encrypted data from one device cannot transfer it to a second device.
• When using ESP32 V3, if the UART ROM Download Mode is not needed for a production device then it should be disabled to provide an extra level of protection. Do this by calling `esp_efuse_disable_rom_download_mode()` during application startup. Alternatively, configure the project `CONFIG_ESP32_REV_MIN` level to 3 (targeting ESP32 V3 only) and select the `CONFIG_SECURE_UART_ROM_DL_MODE` to “Permanently disable ROM Download Mode (recommended)”. The ability to disable ROM Download Mode is not available on earlier ESP32 versions.

• Enable `Secure Boot` as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

**Enable Flash Encryption Externally**

In the process mentioned above, flash encryption related eFuses which ultimately enable flash encryption are programmed through the firmware bootloader. Alternatively, all the eFuses can be programmed with the help of `espefuse` tool. Please refer [Enable Flash Encryption Externally](#) for more details.

**Possible Failures**

Once flash encryption is enabled, the `FLASH_CRYPT_CNT` eFuse value will have an odd number of bits set. It means that all the partitions marked with the encryption flag are expected to contain encrypted ciphertext. Below are the three typical failure cases if the ESP32 is erroneously loaded with plaintext data:

1. If the bootloader partition is re-flashed with a plaintext firmware bootloader image, the ROM bootloader will fail to load the firmware bootloader resulting in the following failure:

```
rst:0x3 (SW_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
flash read err, 1000
ets_main.c 371
ets Jun 8 2016 00:22:57
```

2. If the firmware bootloader is encrypted, but the partition table is re-flashed with a plaintext partition table image, the bootloader will fail to read the partition table resulting in the following failure:

```
rst:0x3 (SW_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00
```

---

**Note:** This error also appears if the flash contents are erased or corrupted.

ESP32 Flash Encryption Status

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in Relevant eFuses.
To check if flash encryption on your ESP32 device is enabled, do one of the following:

• flash the application example security/flash_encryption onto your device. This application prints the FLASH_CRYPT_CNT eFuse value and if flash encryption is enabled or disabled.
• Find the serial port name under which your ESP32 device is connected, replace PORT with your port name in the following command, and run it:

```bash
esefuse.py -p PORT summary
```
Reading and Writing Data in Encrypted Flash

ESP32 application code can check if flash encryption is currently enabled by calling `esp_flash_encryption_enabled()`. Also, a device can identify the flash encryption mode by calling `esp_get_flash_encryption_mode()`.

Once flash encryption is enabled, be more careful with accessing flash contents from code.

Scope of Flash Encryption  Whenever the `FLASH_CRYPT_CNT` eFuse is set to a value with an odd number of bits, all flash content accessed via the MMU’s flash cache is transparently decrypted. It includes:

- Executable application code in flash (IROM).
- All read-only data stored in flash (DROM).
- Any data accessed via `spi_flash_mmap()`.
- The firmware bootloader image when it is read by the ROM bootloader.

Important: The MMU flash cache unconditionally decrypts all existing data. Data which is stored unencrypted in flash memory will also be “transparently decrypted” via the flash cache and will appear to software as random garbage.

Reading from Encrypted Flash  To read data without using a flash cache MMU mapping, you can use the partition read function `esp_partition_read()`. This function will only decrypt data when it is read from an encrypted partition. Data read from unencrypted partitions will not be decrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also use the following SPI flash API functions:

- `esp_flash_read()` to read raw (encrypted) data which will not be decrypted
- `esp_flash_read_encrypted()` to read and decrypt data

Data stored using the Non-Volatile Storage (NVS) API is always stored and read decrypted from the perspective of flash encryption. It is up to the library to provide encryption feature if required. Refer to NVS Encryption for more details.

Writing to Encrypted Flash  It is recommended to use the partition write function `esp_partition_write()`. This function will only encrypt data when it is written to an encrypted partition. Data written to unencrypted partitions will not be encrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also pre-encrypt and write data using the function `esp_flash_write_encrypted()`.

Also, the following ROM function exist but not supported in esp-idf applications:

- `esp_rom_spiflash_write_encrypted` pre-encrypts and writes data to flash
- `SPIWrite` writes unencrypted data to flash

Since data is encrypted in blocks, the minimum write size for encrypted data is 16 bytes and the alignment is also 16 bytes.

Updating Encrypted Flash

OTA Updates  OTA updates to encrypted partitions will automatically write encrypted data if the function `esp_partition_write()` is used.

Before building the application image for OTA updating of an already encrypted device, enable the option `Enable flash encryption on boot` in project configuration menu.

For general information about ESP-IDF OTA updates, please refer to OTA.
**Updating Encrypted Flash via Serial**  
Flashing an encrypted device via serial bootloader requires that the serial bootloader download interface has not been permanently disabled via eFuse.

In Development Mode, the recommended method is **Re-flashing Updated Partitions**.

In Release Mode, if a copy of the same key stored in eFuse is available on the host then it is possible to pre-encrypt files on the host and then flash them. See **Manually Encrypting Files**.

**Disabling Flash Encryption**

If flash encryption was enabled accidentally, flashing of plaintext data will soft-brick the ESP32. The device will reboot continuously, printing the error `flash read err, 1000 or invalid header: 0xXXXXXX`.

For flash encryption in Development mode, encryption can be disabled by burning the `FLASH_CRYPT_CNT` eFuse. It can only be done three times per chip by taking the following steps:

1. In **Project Configuration Menu**, disable **Enable flash encryption on boot**, then save and exit.
2. Open project configuration menu again and **double-check** that you have disabled this option! If this option is left enabled, the bootloader will immediately re-enable encryption when it boots.
3. With flash encryption disabled, build and flash the new bootloader and application by running `idf.py flash`.
4. Use `espefuse.py` (in `components/esptool_py/esptool`) to disable the `FLASH_CRYPT_CNT` by running:
   ```
espefuse.py burn_efuse FLASH_CRYPT_CNT
```

Reset the ESP32. Flash encryption will be disabled, and the bootloader will boot as usual.

**Key Points About Flash Encryption**

- Flash memory contents is encrypted using AES-256. The flash encryption key is stored in the `flash_encryption` eFuse internal to the chip and, by default, is protected from software access.
- The flash encryption algorithm is AES-256, where the key is “tweaked” with the offset address of each 32 byte block of flash. This means that every 32-byte block (two consecutive 16 byte AES blocks) is encrypted with a unique key derived from the flash encryption key.
- Flash access is transparent via the flash cache mapping feature of ESP32 - any flash regions which are mapped to the address space will be transparently decrypted when read.
- Some data partitions might need to remain unencrypted for ease of access or might require the use of flash-friendly update algorithms which are ineffective if the data is encrypted. NVS partitions for non-volatile storage cannot be encrypted since the NVS library is not directly compatible with flash encryption. For details, refer to **NVS Encryption**.
- If flash encryption might be used in future, the programmer must keep it in mind and take certain precautions when writing code that uses encrypted flash.
- If secure boot is enabled, re-flashing the bootloader of an encrypted device requires a “Re-flashable” secure boot digest (see **Flash Encryption and Secure Boot**).

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See **Bootloader Size**.

**Important:** Do not interrupt power to the ESP32 while the first boot encryption pass is running. If power is interrupted, the flash contents will be corrupted and will require flashing with unencrypted data again. In this case, re-flashing will not count towards the flashing limit.
Limitations of Flash Encryption

Flash encryption protects firmware against unauthorised readout and modification. It is important to understand the limitations of the flash encryption feature:

- Flash encryption is only as strong as the key. For this reason, we recommend keys are generated on the device during first boot (default behaviour). If generating keys off-device, ensure proper procedure is followed and do not share the same key between all production devices.
- Not all data is stored encrypted. If storing data on flash, check if the method you are using (library, API, etc.) supports flash encryption.
- Flash encryption does not prevent an attacker from understanding the high-level layout of the flash. This is because the same AES key is used for every pair of adjacent 16 byte AES blocks. When these adjacent 16 byte blocks contain identical content (such as empty or padding areas), these blocks will encrypt to produce matching pairs of encrypted blocks. This may allow an attacker to make high-level comparisons between encrypted devices (i.e., to tell if two devices are probably running the same firmware version).
- For the same reason, an attacker can always tell when a pair of adjacent 16 byte blocks (32 byte aligned) contain two identical 16 byte sequences. Keep this in mind if storing sensitive data on the flash, design your flash storage so this does not happen (using a counter byte or some other non-identical value every 16 bytes is sufficient). NVS Encryption deals with this and is suitable for many uses.
- Flash encryption alone may not prevent an attacker from modifying the firmware of the device. To prevent unauthorised firmware from running on the device, use flash encryption in combination with Secure Boot.

Flash Encryption and Secure Boot

It is recommended to use flash encryption in combination with Secure Boot. However, if Secure Boot is enabled, additional restrictions apply to device re-flashing:

- OTA Updates are not restricted, provided that the new app is signed correctly with the Secure Boot signing key.
- Plaintext serial flash updates are only possible if the Re-flashable Secure Boot mode is selected and a Secure Boot key was pre-generated and burned to the ESP32 (refer to Secure Boot). In such configuration, idf.py bootloader will produce a pre-digested bootloader and secure boot digest file for flashing at offset 0x0. When following the plaintext serial re-flashing steps it is necessary to re-flash this file before flashing other plaintext data.
- Re-flashing via Pregenerated Flash Encryption Key is still possible, provided the bootloader is not re-flashed. Re-flashing the bootloader requires the same Re-flashable option to be enabled in the Secure Boot config.

Advanced Features

The following section covers advanced features of flash encryption.

Encrypted Partition Flag

Some partitions are encrypted by default. Other partitions can be marked in the partition table description as requiring encryption by adding the flag encrypted to the partitions’ flag field. As a result, data in these marked partitions will be treated as encrypted in the same manner as an app partition.

<table>
<thead>
<tr>
<th># Name, Type, SubType, Offset, Size, Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvs, data, nvs, 0x9000, 0x6000</td>
</tr>
<tr>
<td>phy_init, data, phy, 0xf000, 0x1000</td>
</tr>
<tr>
<td>factory, app, factory, 0x10000, 1M</td>
</tr>
<tr>
<td>secret_data, 0x40, 0x01, 0x20000, 256K, encrypted</td>
</tr>
</tbody>
</table>

For details on partition table description, see partition table.

Further information about encryption of partitions:

- Default partition tables do not include any encrypted data partitions.
- With flash encryption enabled, the app partition is always treated as encrypted and does not require marking.
If flash encryption is not enabled, the flag “encrypted” has no effect.
You can also consider protecting phy_init data from physical access, readout, or modification, by marking
the optional phy partition with the flag encrypted.
The nvs partition cannot be encrypted, because the NVS library is not directly compatible with flash encryption.

**Enabling UART Bootloader Encryption/Decryption**  On the first boot, the flash encryption process burns by
default the following eFuses:

- DISABLE_DL_ENCRYPT which disables flash encryption operation when running in UART bootloader boot
  mode.
- DISABLE_DL_DECRYPT which disables transparent flash decryption when running in UART bootloader
  mode, even if the eFuse FLASH_CRYPT_CNT is set to enable it in normal operation.
- DISABLE_DL_CACHE which disables the entire MMU flash cache when running in UART bootloader mode.

However, before the first boot you can choose to keep any of these features enabled by burning only selected eFuses
and write-protect the rest of eFuses with unset value 0. For example:

```bash
espsecure.py --port PORT burn_efuse DISABLE_DL_DECRYPT
espsecure.py --port PORT write_protect_efuse DISABLE_DL_ENCRYPT
```

**Important:** Leaving DISABLE_DL_DECRYPT unset (0) makes flash encryption useless.

An attacker with physical access to the chip can use UART bootloader mode with custom stub code to read out the
flash contents.

**Setting FLASH_CRYPT_CONFIG**  The eFuse FLASH_CRYPT_CONFIG determines the number of bits in the
flash encryption key which are “tweaked” with the block offset. For details, see Flash Encryption Algorithm.

On the first boot of the firmware bootloader, this value is set to the maximum 0xF.

It is possible to burn this eFuse manually and write protect it before the first boot in order to select different tweak
values. However, this is not recommended.

It is strongly recommended to never write-protect FLASH_CRYPT_CONFIG when it is unset. Otherwise, its value
will remain zero permanently, and no bits in the flash encryption key will be tweaked. As a result, the flash encryption
algorithm will be equivalent to AES ECB mode.

**JTAG Debugging**  By default, when Flash Encryption is enabled (in either Development or Release mode) then
JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables flash
encryption.

See JTAG with Flash Encryption or Secure Boot for more information about using JTAG Debugging with Flash
Encryption.

**Manually Encrypting Files**  Manually encrypting or decrypting files requires the flash encryption key to be pre-
burned in eFuse (see Using Host Generated Key) and a copy to be kept on the host. If the flash encryption is configured
in Development Mode then it is not necessary to keep a copy of the key or follow these steps, the simpler Re-flashing
Updated Partitions steps can be used.

The key file should be a single raw binary file (example: key.bin).

For example, these are the steps to encrypt the file build/my-app.bin to flash at offset 0x10000. Run espsecure.py as follows:

```bash
espsecure.py encrypt_flash_data --keyfile /path/to/key.bin --address 0x10000 --
output my-app-ciphertext.bin build/my-app.bin
```
The file `my-app-ciphertext.bin` can then be flashed to offset 0x10000 using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds.

**Note:** If the flashed ciphertext file is not recognized by the ESP32 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset.

If your ESP32 uses non-default `FLASH_CRYPT_CONFIG` value in eFuse then you will need to pass the `--flash_crypt_conf` argument to `espsecure.py` to set the matching value. This will not happen if the device configured flash encryption by itself, but may happen if burning eFuses manually to enable flash encryption.

The command `espsecure.py decrypt_flash_data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

**Technical Details**

The following sections provide some reference information about the operation of flash encryption.

**Flash Encryption Algorithm**

- AES-256 operates on 16-byte blocks of data. The flash encryption engine encrypts and decrypts data in 32-byte blocks - two AES blocks in series.
- The main flash encryption key is stored in the `flash_encryption` eFuse and, by default, is protected from further writes or software readout.
- AES-256 key size is 256 bits (32 bytes) read from the `flash_encryption` eFuse. The hardware AES engine uses the key in reversed byte order as compared to the storage order in `flash_encryption`.
  - If the `CODING_SCHEME` eFuse is set to 0 (default, “None” Coding Scheme) then the eFuse key block is 256 bits and the key is stored as-is (in reversed byte order).
  - If the `CODING_SCHEME` eFuse is set to 1 (3/4 Encoding) then the eFuse key block is 192 bits (in reversed byte order), so overall entropy is reduced. The hardware flash encryption still operates on a 256-bit key, after being read (and un-reversed), the key is extended as `key = key[0:255] + key[64:127]`.
- AES algorithm is used inverted in flash encryption, so the flash encryption “encrypt” operation is AES decrypt and the “decrypt” operation is AES encrypt. This is for performance reasons and does not alter the efficiency of the algorithm.
- Each 32-byte block (two adjacent 16-byte AES blocks) is encrypted with a unique key. The key is derived from the main flash encryption key in `flash_encryption`, XORed with the offset of this block in the flash (a “key tweak”).
- The specific tweak depends on the `FLASH_CRYPT_CONFIG` eFuse setting. This is a 4-bit eFuse where each bit enables XORing of a particular range of the key bits:
  - Bit 1, bits 0-66 of the key are XORed.
  - Bit 2, bits 67-131 of the key are XORed.
  - Bit 3, bits 132-194 of the key are XORed.
  - Bit 4, bits 195-256 of the key are XORed.
- It is recommended that `FLASH_CRYPT_CONFIG` is always left at the default value 0xF, so that all key bits are XORed with the block offset. For details, see Setting `FLASH_CRYPT_CONFIG`.
- The high 19 bits of the block offset (bit 5 to bit 23) are XORed with the main flash encryption key. This range is chosen for two reasons: the maximum flash size is 16MB (24 bits), and each block is 32 bytes so the least significant 5 bits are always zero.
- There is a particular mapping from each of the 19 block offset bits to the 256 bits of the flash encryption key to determine which bit is XORed with which. See the variable `_FLASH_ENCRYPTION_TWEAK_PATTERN` in the `espsecure.py` source code for complete mapping.
- To see the full flash encryption algorithm implemented in Python, refer to the `_flash_encryption_operation()` function in the `espsecure.py` source code.
5.2.2 Secure Boot

**Important:** All references in this document are related to Secure Boot V1 (The AES based Secure Boot Scheme). ESP32 Revision 3 onwards, the preferred secure boot scheme is Secure Boot V2. Please refer to Secure Boot V2 document for ESP32 Revision 3 or ESP32-S2.

Secure Boot is a feature for ensuring only your code can run on the chip. Data loaded from flash is verified on each reset.

Secure Boot is separate from the Flash Encryption feature, and you can use secure boot without encrypting the flash contents. However, for a secure environment both should be used simultaneously. See Secure Boot & Flash Encryption for more details.

**Important:** Enabling secure boot limits your options for further updates of your ESP32. Make sure to read this document thoroughly and understand the implications of enabling secure boot.

**Background**

- Most data is stored in flash. Flash access does not need to be protected from physical access in order for secure boot to function, because critical data is stored (non-software-accessible) in Efuses internal to the chip.
- Efuses are used to store the secure bootloader key (in efuse BLOCK2), and also a single Efuse bit (ABS_DONE_0) is burned (written to 1) to permanently enable secure boot on the chip. For more details on Efuses, see ESP32 Technical Reference Manual > eFuse Controller (eFuse) [PDF].
- To understand the secure boot process, first familiarise yourself with the standard Application Startup Flow.
- Both stages of the boot process (initial software bootloader load, and subsequent partition & app loading) are verified by the secure boot process, in a “chain of trust” relationship.

**Secure Boot Process Overview**

This is a high level overview of the secure boot process. Step by step instructions are supplied under How To Enable Secure Boot. Further in-depth details are supplied under Technical Details:

1. The options to enable secure boot are provided in the Project Configuration Menu, under “Secure Boot Configuration”.
2. Secure Boot defaults to signing images and partition table data during the build process. The “Secure boot private signing key” config item is a file path to a ECDSA public/private key pair in a PEM format file.
3. The software bootloader image is built by esp-idf with secure boot support enabled and the public key (signature verification) portion of the secure boot signing key compiled in. This software bootloader image is flashed at offset 0x1000.
4. On first boot, the software bootloader follows the following process to enable secure boot:
   - Hardware secure boot support generates a device secure bootloader key (generated via hardware RNG, then stored read/write protected in efuse), and a secure digest. The digest is derived from the key, an IV, and the bootloader image contents.
   - The secure digest is flashed at offset 0x0 in the flash.
   - Depending on Secure Boot Configuration, efuses are burned to disable JTAG and the ROM BASIC interpreter (it is strongly recommended these options are turned on.)
   - Bootloader permanently enables secure boot by burning the ABS_DONE_0 efuse. The software bootloader then becomes protected (the chip will only boot a bootloader image if the digest matches.)
5. On subsequent boots the ROM bootloader sees that the secure boot efuse is burned, reads the saved digest at 0x0 and uses hardware secure boot support to compare it with a newly calculated digest. If the digest does not match then booting will not continue. The digest and comparison are performed entirely by hardware, and the calculated digest is not readable by software. For technical details see Secure Boot Hardware Support.
6. When running in secure boot mode, the software bootloader uses the secure boot signing key (the public key of which is embedded in the bootloader itself, and therefore validated as part of the bootloader) to verify the signature appended to all subsequent partition tables and app images before they are booted.
Keys

The following keys are used by the secure boot process:

- **secure bootloader key** is a 256-bit AES key that is stored in Efuse block 2. The bootloader can generate this key itself from the internal hardware random number generator, the user does not need to supply it (it is optionally possible to supply this key, see Re-Flashable Software Bootloader). The Efuse holding this key is read & write protected (preventing software access) before secure boot is enabled.
  - By default, the Efuse Block 2 Coding Scheme is “None” and a 256 bit key is stored in this block. On some ESP32s, the Coding Scheme is set to 3/4 Encoding (CODING_SCHEME efuse has value 1) and a 192 bit key must be stored in this block.
  
  For more details, see ESP32 Technical Reference Manual > eFuse Controller (eFuse) > System Parameter coding_scheme [PDF].

  The algorithm operates on a 256 bit key in all cases, 192 bit keys are extended by repeating some bits (Secure Bootloader Digest Algorithm).

- **secure boot signing key** is a standard ECDSA public/private key pair (see Image Signing Algorithm) in PEM format.
  - The public key from this key pair (for signature verification but not signature creation) is compiled into the software bootloader and used to verify the second stage of booting (partition table, app image) before booting continues. The public key can be freely distributed, it does not need to be kept secret.
  - The private key from this key pair **must be securely kept private**, as anyone who has this key can authenticate to any bootloader that is configured with secure boot and the matching public key.

Bootloader Size

Enabling Secure boot and/or flash encryption will increase the size of bootloader, which might require updating partition table offset. See **Bootloader Size**.

How To Enable Secure Boot

1. Open the Project Configuration Menu, navigate to “Secure Boot Configuration” and select the option “One-time Flash”. (To understand the alternative “Reflashable” choice, see Re-Flashable Software Bootloader.)
2. Select a name for the secure boot signing key. This option will appear after secure boot is enabled. The file can be anywhere on your system. A relative path will be evaluated from the project directory. The file does not need to exist yet.
3. Set other menuconfig options (as desired). Pay particular attention to the “Bootloader Config” options, as you can only flash the bootloader once. Then exit menuconfig and save your configuration
4. The first time you run make, if the signing key is not found then an error message will be printed with a command to generate a signing key via espsecure.py generate_signing_key.

**Important:** A signing key generated this way will use the best random number source available to the OS and its Python installation (/dev/urandom on OSX/Linux and CryptGenRandom() on Windows). If this random number source is weak, then the private key will be weak.

**Important:** For production environments, we recommend generating the keypair using openssl or another industry standard encryption program. See Generating Secure Boot Signing Key for more details.

5. Run idf.py bootloader to build a secure boot enabled bootloader. The build output will include a prompt for a flashing command, using esptool.py write_flash.
6. When you are ready to flash the bootloader, run the specified command (you have to enter it yourself, this step is not performed by make) and then wait for flashing to complete. **Remember this is a one time flash, you cannot change the bootloader after this!**
7. Run idf.py flash to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 4.
8. Reset the ESP32 and it will boot the software bootloader you flashed. The software bootloader will enable secure boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32 to verify that secure boot is enabled and no errors have occurred due to the build configuration.

Note: Secure boot will not be enabled until after a valid partition table and app image have been flashed. This is to prevent accidents before the system is fully configured.

9. On subsequent boots, the secure boot hardware will verify the software bootloader has not changed (using the secure bootloader key) and then the software bootloader will verify the signed partition table and app image (using the public key portion of the secure boot signing key).

Re-Flashable Software Bootloader

Configuration

“Secure Boot: One-Time Flash” is the recommended configuration for production devices. In this mode, each device gets a unique key that is never stored outside the device.

However, an alternative mode `CONFIG_SECURE_BOOTLOADER_MODE` is also available. This mode allows you to supply a binary key file that is used for the secure bootloader key. As you have the key file, you can generate new bootloader images and secure boot digests for them.

In the esp-idf build process, this 256-bit key file is derived from the ECDSA app signing key generated by the user (see the `Generating Secure Boot Signing Key` step below). This private key’s SHA-256 digest is used as the secure bootloader key in efuse (as-is for Coding Scheme None, or truncate to 192 bytes for 3/4 Encoding). This is a convenience so you only need to generate/protect a single private key.

Note: Although it is possible, we strongly recommend not generating one secure boot key and flashing it to every device in a production environment. The “One-Time Flash” option is recommended for production environments.

To enable a reflashable bootloader:

1. In the `Project Configuration Menu`, select “Bootloader Config” > `CONFIG_SECURE_BOOT` > `CONFIG_SECURE_BOOT_V1_ENABLED` > `CONFIG_SECURE_BOOTLOADER_MODE` > Reflashable.

2. If necessary, set the `CONFIG_SECURE_BOOTLOADER_KEY_ENCODING` based on the coding scheme used by the device. The coding scheme is shown in the `Features` line when `esptool.py` connects to the chip, or in the `espefuse.py` summary output.

3. Please follow the steps shown in `Generating Secure Boot Signing Key` to generate signing key. Path of the generated key file must be specified in “Secure Boot Configuration” menu.

4. Run `idf.py bootloader`. A binary key file will be created, derived from the private key that is used for signing. Two sets of flashing steps will be printed - the first set of steps includes an `espefuse.py burn_key secure_boot_v1 path_to/secure-bootloader-key-xxx.bin` command which is used to write the bootloader key to efuse. (Flashing this key is a one-time-only process.) The second set of steps can be used to reflash the bootloader with a pre-calculated digest (generated during the build process).

5. Resume from `Step 6 of the one-time flashing process`, to flash the bootloader and enable secure boot. Watch the console log output closely to ensure there were no errors in the secure boot configuration.
Generating Secure Boot Signing Key

The build system will prompt you with a command to generate a new signing key via `espsecure.py generate_signing_key`. This uses the python-ecdsa library, which in turn uses Python’s `os.urandom()` as a random number source.

The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source, and using the best available EC key generation utilities.

For example, to generate a signing key using the openssl command line:
```
openssl ecparam -name prime256v1 -genkey -noout -out my_secure_boot_signing_key.pem
```

Remember that the strength of the secure boot system depends on keeping the signing key private.

Remote Signing of Images

For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default esp-idf secure boot configuration). The `espsecure.py` command line program can be used to sign app images & partition table data for secure boot, on a remote system.

To use remote signing, disable the option “Sign binaries during build”. The private signing key does not need to be present on the build system. However, the public (signature verification) key is required because it is compiled into the bootloader (and can be used to verify image signatures during OTA updates).

To extract the public key from the private key:

```
espsecure.py extract_public_key --keyfile PRIVATE_SIGNING_KEY PUBLIC_VERIFICATION_KEY
```

The path to the public signature verification key needs to be specified in the menuconfig under “Secure boot public signature verification key” in order to build the secure bootloader.

After the app image and partition table are built, the build system will print signing steps using `espsecure.py`:

```
espsecure.py sign_data --keyfile PRIVATE_SIGNING_KEY BINARY_FILE
```

The above command appends the image signature to the existing binary. You can use the `--output` argument to write the signed binary to a separate file:

```
espsecure.py sign_data --keyfile PRIVATE_SIGNING_KEY --output SIGNED_BINARY_FILE BINARY_FILE
```

Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the secure boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using `espsecure.py`. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all secure boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.
- Use secure boot in combination with Flash Encryption to prevent local readout of the flash contents.

Technical Details

The following sections contain low-level reference descriptions of various secure boot elements:
### Secure Boot Hardware Support
The first stage of secure boot verification (checking the software bootloader) is done via hardware. The ESP32’s Secure Boot support hardware can perform three basic operations:

1. Generate a random sequence of bytes from a hardware random number generator.
2. Generate a digest from data (usually the bootloader image from flash) using a key stored in Efuse block 2. The key in Efuse can (& should) be read/write protected, which prevents software access. For full details of this algorithm see Secure Bootloader Digest Algorithm. The digest can only be read back by software if Efuse ABS_DONE_0 is not burned (i.e still 0).
3. Generate a digest from data (usually the bootloader image from flash) using the same algorithm as step 2 and compare it to a pre-calculated digest supplied in a buffer (usually read from flash offset 0x0). The hardware returns a true/false comparison without making the digest available to software. This function is available even when Efuse ABS_DONE_0 is burned.

### Secure Bootloader Digest Algorithm
Starting with an “image” of binary data as input, this algorithm generates a digest as output. The digest is sometimes referred to as an “abstract” in hardware documentation.

For a Python version of this algorithm, see the espsecure.py tool in the components/esptool_py directory (specifically, the digest_secure_bootloader command).

Items marked with (^) are to fulfill hardware restrictions, as opposed to cryptographic restrictions.

1. Read the AES key from efuse block 2, in reversed byte order. If Coding Scheme is set to 3/4 Encoding, extend the 192 bit key to 256 bits using the same algorithm described in Flash Encryption Algorithm.
2. Prefix the image with a 128 byte randomly generated IV.
3. If the image length is not modulo 128, pad the image to a 128 byte boundary with 0xFF. (^)
4. For each 16 byte plaintext block of the input image: - Reverse the byte order of the plaintext input block (^) - Apply AES256 in ECB mode to the plaintext input block. - Reverse the byte order of the ciphertext output block. (^) - Append to the overall ciphertext output.
5. Byte-swap each 4 byte word of the ciphertext (^)
6. Calculate SHA-512 of the ciphertext.
7. Byte-swap each 4 byte word of the above calculated digest. (^)

Output digest is 192 bytes of data: The 128 byte IV, followed by the 64 byte SHA-512 digest.

### Image Signing Algorithm
Deterministic ECDSA as specified by RFC 6979.

- Curve is NIST256p (openssl calls this curve “prime256v1”, it is also sometimes called secp256r1).
- Hash function is SHA256.
- Key format used for storage is PEM.
  - In the bootloader, the public key (for signature verification) is flashed as 64 raw bytes.
- Image signature is 68 bytes - a 4 byte version word (currently zero), followed by a 64 bytes of signature data. These 68 bytes are appended to an app image or partition table data.

### Manual Commands
Secure boot is integrated into the esp-idf build system, so make will automatically sign an app image if secure boot is enabled. idf.py bootloader will produce a bootloader digest if menuconfig is configured for it.

However, it is possible to use the espsecure.py tool to make standalone signatures and digests.

To sign a binary image:

```
espsecure.py sign_data --keyfile ./my_signing_key.pem --output ./image_signed.bin
```

Keyfile is the PEM file containing an ECDSA private signing key.

To generate a bootloader digest:

```
espsecure.py digest_secure_bootloader --keyfile ./securebootkey.bin --output ./
```

---

Submit Document Feedback
Keyfile is the 32 byte raw secure boot key for the device.

The output of the `espsecure.py digest_secure_bootloader` command is a single file which contains both the digest and the bootloader appended to it. To flash the combined digest plus bootloader to the device:

```
esptool.py write_flash 0x0 bootloader-digest.bin
```

**Secure Boot & Flash Encryption**

If secure boot is used without *Flash Encryption*, it is possible to launch “time-of-check to time-of-use” attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both the features together.

**Signed App Verification Without Hardware Secure Boot**

The integrity of apps can be checked even without enabling the hardware secure boot option. This option uses the same app signature scheme as hardware secure boot, but unlike hardware secure boot it does not prevent the bootloader from being physically updated. This means that the device can be secured against remote network access, but not physical access. Compared to using hardware Secure Boot this option is much simpler to implement. See *How To Enable Signed App Verification* for step by step instructions.

An app can be verified on update and, optionally, be verified on boot.

- **Verification on update**: When enabled, the signature is automatically checked whenever the esp OTA_ops.h APIs are used for OTA updates. If hardware secure boot is enabled, this option is always enabled and cannot be disabled. If hardware secure boot is not enabled, this option still adds significant security against network-based attackers by preventing spoofing of OTA updates.
- **Verification on boot**: When enabled, the bootloader will be compiled with code to verify that an app is signed before booting it. If hardware secure boot is enabled, this option is always enabled and cannot be disabled. If hardware secure boot is not enabled, this option does not add significant security by itself so most users will want to leave it disabled.

**How To Enable Signed App Verification**

1. Open *Project Configuration Menu > Security features > Enable CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT*
2. “Bootloader verifies app signatures” can be enabled, which verifies app on boot.
3. By default, “Sign binaries during build” will be enabled on selecting “Require signed app images” option, which will sign binary files as a part of build process. The file named in “Secure boot private signing key” will be used to sign the image.
4. If you disable “Sign binaries during build” option then you will have to enter path of a public key file used to verify signed images in “Secure boot public signature verification key”. In this case, private signing key should be generated by following instructions in *Generating Secure Boot Signing Key*; public verification key and signed image should be generated by following instructions in *Remote Signing of Images*.

**Advanced Features**

**JTAG Debugging**  
By default, when Secure Boot is enabled then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables Secure Boot.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

**5.2.3 Secure Boot V2**

*Important*: This document is about Secure Boot V2, supported on ESP32 (ECO 3 onwards)
For ESP32 before ECO3, refer to Secure Boot. It is recommended that users use Secure Boot V2 if they have a chip version that supports it. Secure Boot V2 is safer and more flexible than Secure Boot V1.

Secure Boot V2 uses RSA-PSS based app and bootloader (Second Stage Bootloader) verification. This document can also be used as a reference for signing apps using the RSA-PSS scheme without signing the bootloader.

Secure Boot V2 and RSA scheme (App Signing Scheme) options are available for ESP32 from ECO3 onwards. To use these options in menuconfig, set CONFIG_ESP32_REV_MIN greater than or equal to Rev 3.

Background

Secure Boot protects a device from running any unauthorized (i.e., unsigned) code by checking that each piece of software that is being booted is signed. On an ESP32, these pieces of software include the second stage bootloader and each application binary. Note that the first stage bootloader does not require signing as it is ROM code thus cannot be changed.

A RSA based Secure Boot verification scheme (Secure Boot V2) is implemented on ESP32 (ECO 3 onwards).

The Secure Boot process on the ESP32 involves the following steps:

1. When the first stage bootloader loads the second stage bootloader, the second stage bootloader’s RSA-PSS signature is verified. If the verification is successful, the second stage bootloader is executed.
2. When the second stage bootloader loads a particular application image, the application’s RSA-PSS signature is verified. If the verification is successful, the application image is executed.

Advantages

- The RSA-PSS public key is stored on the device. The corresponding RSA-PSS private key is kept at a secret place and is never accessed by the device.
- Only one public key can be generated and stored in the chip during manufacturing.
- Same image format and signature verification method is applied for applications and software bootloader.
- No secrets are stored on the device. Therefore, it is immune to passive side-channel attacks (timing or power analysis, etc.)

Secure Boot V2 Process

This is an overview of the Secure Boot V2 Process. Instructions how to enable Secure Boot are supplied in section How To Enable Secure Boot V2.

Secure Boot V2 verifies the bootloader image and application binary images using a dedicated signature block. Each image has a separately generated signature block which is appended to the end of the image.

Only one signature block can be appended to the bootloader or application image in ESP32 ECO3.

Each signature block contains a signature of the preceding image as well as the corresponding RSA-3072 public key. For more details about the format, refer to Signature Block Format. A digest of the RSA-3072 public key is stored in the eFuse.

The application image is not only verified on every boot but also on each over the air (OTA) update. If the currently selected OTA app image cannot be verified, the bootloader will fall back and look for another correctly signed application image.

The Secure Boot V2 process follows these steps:

1. On startup, the ROM code checks the Secure Boot V2 bit in the eFuse. If Secure Boot is disabled, a normal boot will be executed. If Secure Boot is enabled, the boot will proceed according to the following steps.
2. The ROM code verifies the bootloader’s signature block (Verifying a Signature Block). If this fails, the boot process will be aborted.
3. The ROM code verifies the bootloader image using the raw image data, its corresponding signature block(s), and the eFuse (Verifying an Image). If this fails, the boot process will be aborted.
4. The ROM code executes the bootloader.
5. The bootloader verifies the application image’s signature block (Verifying a Signature Block). If this fails, the boot process will be aborted.
6. The bootloader verifies the application image using the raw image data, its corresponding signature blocks and the eFuse (Verifying an Image). If this fails, the boot process will be aborted. If the verification fails but another application image is found, the bootloader will then try to verify that other image using steps 5 to 7. This repeats until a valid image is found or no other images are found.
7. The bootloader executes the verified application image.

**Signature Block Format**

The signature block starts on a 4 KB aligned boundary and has a flash sector of its own. The signature is calculated over all bytes in the image including the padding bytes (Secure Padding).

The content of each signature block is shown in the following table:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Size (bytes)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Magic byte</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Version number byte (currently 0x02), 0x01 is for Secure Boot V1.</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Padding bytes, Reserved. Should be zero.</td>
</tr>
<tr>
<td>4</td>
<td>32</td>
<td>SHA-256 hash of only the image content, not including the signature block.</td>
</tr>
<tr>
<td>36</td>
<td>384</td>
<td>RSA Public Modulus used for signature verification. (value ‘n’ in RFC8017).</td>
</tr>
<tr>
<td>420</td>
<td>4</td>
<td>RSA Public Exponent used for signature verification (value ‘e’ in RFC8017).</td>
</tr>
<tr>
<td>424</td>
<td>384</td>
<td>Pre-calculated R, derived from ‘n’.</td>
</tr>
<tr>
<td>808</td>
<td>4</td>
<td>Pre-calculated M’, derived from ‘n’.</td>
</tr>
<tr>
<td>812</td>
<td>384</td>
<td>RSA-PSS Signature result (section 8.1.1 of RFC8017) of image content, computed using following PSS parameters: SHA256 hash, MGF1 function, salt length 32 bytes, default trailer field (0xBC).</td>
</tr>
<tr>
<td>1196</td>
<td>4</td>
<td>CRC32 of the preceding 1196 bytes.</td>
</tr>
<tr>
<td>1200</td>
<td>16</td>
<td>Zero padding to length 1216 bytes.</td>
</tr>
</tbody>
</table>

**Note:** R and M’ are used for hardware-assisted Montgomery Multiplication.

The remainder of the signature sector is erased flash (0xFF) which allows writing other signature blocks after previous signature block.

**Secure Padding**

In Secure Boot V2 scheme, the application image is padded to the flash MMU page size boundary to ensure that only verified contents are mapped in the internal address space. This is known as secure padding. Signature of the image is calculated after padding and then signature block (4KB) gets appended to the image.

- Default flash MMU page size is 64KB
- Secure padding is applied through the option `--secure-pad-v2` in the elf2image conversion using `esptool.py`

Following table explains the Secure Boot V2 signed image with secure padding and signature block appended:
### Table 3: Contents of a signed application

<table>
<thead>
<tr>
<th>Offset</th>
<th>Size (KB)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>580</td>
<td>Unsigned application size (as an example)</td>
</tr>
<tr>
<td>580</td>
<td>60</td>
<td>Secure padding (aligned to next 64KB boundary)</td>
</tr>
<tr>
<td>640</td>
<td>4</td>
<td>Signature block</td>
</tr>
</tbody>
</table>

**Note:** Please note that the application image always starts on the next flash MMU page size boundary (default 64KB) and hence the space left over after the signature block shown above can be utilized to store any other data partitions (e.g., `nvs`).

### Verifying a Signature Block

A signature block is “valid” if the first byte is `0xe7` and a valid CRC32 is stored at offset 1196. Otherwise it is invalid.

### Verifying an Image

An image is “verified” if the public key stored in any signature block is valid for this device, and if the stored signature is valid for the image data read from flash.

1. Compare the SHA-256 hash digest of the public key embedded in the bootloader’s signature block with the digest(s) saved in the eFuses. If public key’s hash does not match any of the hashes from the eFuses, the verification fails.
2. Generate the application image digest and match it with the image digest in the signature block. If the digests do not match, the verification fails.
3. Use the public key to verify the signature of the bootloader image, using RSA-PSS (section 8.1.2 of RFC8017) with the image digest calculated in step (2) for comparison.

### Bootloader Size

Enabling Secure boot and/or flash encryption will increase the size of bootloader, which might require updating partition table offset. See [Bootloader Size](#).

In the case when `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` is disabled, the bootloader is sector padded (4KB) using the `--pad-to-size` option in `elf2image` command of `esptool`.

### eFuse Usage

ESP32-ECO3:

- **ABS_DONE_1** - Enables Secure Boot protection on boot.
- **BLK2** - Stores the SHA-256 digest of the public key. SHA-256 hash of public key modulus, exponent, pre-calculated R & M’ values (represented as 776 bytes - offsets 36 to 812 - as per the [Signature Block Format](#)) is written to an eFuse key block. The write-protection bit must be set, but the read-protection bit must not.

The key(s) must be readable in order to give software access to it. If the key(s) is read-protected then the software reads the key(s) as all zeros and the signature verification process will fail, and the boot process will be aborted.
How To Enable Secure Boot V2

1. Open the Project Configuration Menu, in “Security features” set “Enable hardware Secure Boot in bootloader” to enable Secure Boot.

2. For ESP32, Secure Boot V2 is available only ESP32 ECO3 onwards. To view the “Secure Boot V2” option the chip revision should be changed to revision 3 (ESP32- ECO3). To change the chip revision, set “Minimum Supported ESP32 Revision” to Rev 3 in “Component Config” -> “ESP32- Specific”.

3. Specify the path to Secure Boot signing key, relative to the project directory.

4. Select the desired UART ROM download mode in “UART ROM download mode”. By default the UART ROM download mode has been kept enabled in order to prevent permanently disabling it in the development phase, this option is a potentially insecure option. It is recommended to disable the UART download mode for better security.

5. Set other menuconfig options (as desired). Then exit menuconfig and save your configuration.

6. The first time you run idf.py build, if the signing key is not found then an error message will be printed with a command to generate a signing key via espsecure.py generate Signing_key.

**Important:** A signing key generated this way will use the best random number source available to the OS and its Python installation (/dev/urandom on OSX/Linux and CryptGenRandom() on Windows). If this random number source is weak, then the private key will be weak.

**Important:** For production environments, we recommend generating the key pair using openssl or another industry standard encryption program. See Generating Secure Boot Signing Key for more details.

7. Run idf.py bootloader to build a Secure Boot enabled bootloader. The build output will include a prompt for a flashing command, using esptool.py write_flash.

8. When you are ready to flash the bootloader, run the specified command (you have to enter it yourself, this step is not performed by the build system) and then wait for flashing to complete.

9. Run idf.py flash to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 6.

**Note:** idf.py flash does not flash the bootloader if Secure Boot is enabled.

10. Reset the ESP32 and it will boot the software bootloader you flashed. The software bootloader will enable Secure Boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32 to verify that Secure Boot is enabled and no errors have occurred due to the build configuration.

**Note:** Secure boot will not be enabled until after a valid partition table and app image have been flashed. This is to prevent accidents before the system is fully configured.

**Note:** If the ESP32 is reset or powered down during the first boot, it will start the process again on the next boot.

11. On subsequent boots, the Secure Boot hardware will verify the software bootloader has not changed and the software bootloader will verify the signed app image (using the validated public key portion of its appended signature block).

**Restrictions After Secure Boot Is Enabled**

- Any updated bootloader or app will need to be signed with a key matching the digest already stored in eFuse.
• After Secure Boot is enabled, no further eFuses can be read protected. *(If Flash Encryption is enabled then the bootloader will ensure that any flash encryption key generated on first boot will already be read protected.)* If CONFIG_SECURE_BOOT_INSECURE is enabled then this behavior can be disabled, but this is not recommended.

• Please note that enabling Secure Boot or flash encryption disables the USB-OTG USB stack in the ROM, disallowing updates via the serial emulation or Device Firmware Update (DFU) on that port.

**Generating Secure Boot Signing Key**

The build system will prompt you with a command to generate a new signing key via *espsecure.py generate_signing_key*.

The `--version 2` parameter will generate the RSA 3072 private key for Secure Boot V2. Additionally `--scheme rsa3072` can be passed as well to generate RSA 3072 private key.

The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source, and using the best available RSA-PSS key generation utilities.

For example, to generate a signing key using the OpenSSL command line:

For RSA 3072

`openssl genrsa -out my_secure_boot_signing_key.pem 3072`

Remember that the strength of the Secure Boot system depends on keeping the signing key private.

**Remote Signing of Images**

**Signing Using espsecure.py** For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default esp-idf Secure Boot configuration). The espsecure.py command line program can be used to sign app images & partition table data for Secure Boot, on a remote system.

To use remote signing, disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` and build the firmware. The private signing key does not need to be present on the build system.

After the app image and partition table are built, the build system will print signing steps using espsecure.py:

```bash
espsecure.py sign_data BINARY_FILE --version 2 --keyfile PRIVATE_SIGNING_KEY
```

The above command appends the image signature to the existing binary. You can use the `--output` argument to write the signed binary to a separate file:

```bash
espsecure.py sign_data --version 2 --keyfile PRIVATE_SIGNING_KEY --output SIGNED_BINARY_FILE BINARY_FILE
```

**Signing Using Pre-calculated Signatures** If you have valid pre-calculated signatures generated for an image and their corresponding public keys, you can use these signatures to generate a signature sector and append it to the image. Note that the pre-calculated signature should be calculated over all bytes in the image including the secure-padding bytes.

In such cases, the firmware image should be built by disabling the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES`. This image will be secure-padded and to generate a signed binary use the following command:

```bash
espsecure.py sign_data --version 2 --pub-key PUBLIC_SIGNING_KEY --signature --SIGNATURE_FILE --output SIGNED_BINARY_FILE BINARY_FILE
```

The above command verifies the signature, generates a signature block (refer to [Signature Block Format](#)) and appends it to the binary file.
**Signing Using an External Hardware Security Module (HSM)**  For security reasons, you might also use an external Hardware Security Module (HSM) to store your private signing key, which cannot be accessed directly but has an interface to generate the signature of a binary file and its corresponding public key.

In such cases, disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` and build the firmware. This secure-padded image then can be used to supply the external HSM for generating a signature. Refer to **Signing using an External HSM** to generate a signed image.

---

**Note:** For all the above three remote signing workflows, the signed binary is written to the filename provided to the `--output` argument.

---

**Secure Boot Best Practices**

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all Secure Boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.
- Use Secure Boot in combination with **Flash Encryption** to prevent local readout of the flash contents.

---

**Technical Details**

The following sections contain low-level reference descriptions of various Secure Boot elements:

**Manual Commands**  Secure boot is integrated into the esp-idf build system, so `idf.py build` will sign an app image and `idf.py bootloader` will produce a signed bootloader if secure signed binaries on build is enabled. However, it is possible to use the `espsecure.py` tool to make standalone signatures and digests.

To sign a binary image:

```
 espsecure.py sign_data --version 2 --keyfile ./my_signing_key.pem --output ./image_. signed.bin image-unsigned.bin
```

Keyfile is the PEM file containing an RSA-3072 private signing key.

---

**Secure Boot & Flash Encryption**

If Secure Boot is used without **Flash Encryption**, it is possible to launch “time-of-check to time-of-use” attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both the features together.

---

**Signed App Verification Without Hardware Secure Boot**

The Secure Boot V2 signature of apps can be checked on OTA update, without enabling the hardware Secure Boot option. This option uses the same app signature scheme as Secure Boot V2, but unlike hardware Secure Boot it does not prevent an attacker who can write to flash from bypassing the signature protection.

This may be desirable in cases where the delay of Secure Boot verification on startup is unacceptable, and/or where the threat model does not include physical access or attackers writing to bootloader or app partitions in flash.

In this mode, the public key which is present in the signature block of the currently running app will be used to verify the signature of a newly updated app. (The signature on the running app is not verified during the update process, it is assumed to be valid.) In this way the system creates a chain of trust from the running app to the newly updated app.
For this reason, it is essential that the initial app flashed to the device is also signed. A check is run on app startup and the app will abort if no signatures are found. This is to try and prevent a situation where no update is possible. The app should have only one valid signature block in the first position. Note again that, unlike hardware Secure Boot V2, the signature of the running app is not verified on boot. The system only verifies a signature block in the first position and ignores any other appended signatures.

**Note:** In general, it is recommended to use full hardware Secure Boot unless certain that this option is sufficient for application security needs.

### How To Enable Signed App Verification

1. Open *Project Configuration Menu* -> Security features
2. Ensure *App Signing Scheme* is RSA. For ESP32 ECO3 chip, select *CONFIG_ESP32_REV_MIN* to Rev 3 to get RSA option available
3. Enable *CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT*
4. By default, “Sign binaries during build” will be enabled on selecting “Require signed app images” option, which will sign binary files as a part of build process. The file named in “Secure boot private signing key” will be used to sign the image.
5. If you disable “Sign binaries during build” option then all app binaries must be manually signed by following instructions in *Remote Signing of Images*.

**Warning:** It is very important that all apps flashed have been signed, either during the build or after the build.

### Advanced Features

**JTAG Debugging**  
By default, when Secure Boot is enabled then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables Secure Boot.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

### 5.3 Workflows

#### 5.3.1 Host-Based Security Workflows

**Introduction**

It is recommended to have an uninterrupted power supply while enabling security features on ESP32 SoCs. Power failures during the secure manufacturing process could cause issues that are hard to debug and, in some cases, may cause permanent boot-up failures.

This guide highlights an approach where security features are enabled with the assistance of an external host machine. Security workflows are broken down into various stages and key material is generated on the host machine; thus, allowing greater recovery chances in case of power or other failures. It also offers better timings for secure manufacturing, e.g., in the case of encryption of firmware on the host machine vs. on the device.

**Goals**

1. Simplify the traditional workflow with stepwise instructions.
2. Design a more flexible workflow as compared to the traditional firmware-based workflow.
3. Improve reliability by dividing the workflow into small operations.
4. Eliminate dependency on *Second Stage Bootloader* (firmware bootloader).

**Pre-requisite**

- `esptool`: Please make sure the `esptool` has been installed. It can be installed by running:

  ```
  pip install esptool
  ```

**Scope**

- *Enable Flash Encryption and Secure Boot V2 Externally*
- *Enable Flash Encryption Externally*
- *Enable Secure Boot V2 Externally*

**Security Workflows**

**Enable Flash Encryption and Secure Boot V2 Externally**

**Important:** It is recommended to enable both Flash Encryption and Secure Boot V2 for a production use case.

When enabling the Flash Encryption and Secure Boot V2 externally we need to enable them in the following order:

1. Enable the Flash Encryption feature by following the steps listed in *Enable Flash Encryption Externally*.
2. Enable the Secure Boot V2 feature by following the steps listed in *Enable Secure Boot V2 Externally*.

The reason for this order is as follows:

To enable the Secure Boot (SB) V2, it is necessary to keep the SB V2 key readable. To protect the key’s readability, the write protection for RD_DIS (ESP_EFUSE_WR_DIS_RD_DIS) is applied. However, this action poses a challenge when attempting to enable Flash Encryption, as the Flash Encryption (FE) key needs to remain unreadable. This conflict arises because the RD_DIS is already write-protected, making it impossible to read protect the FE key.

**Enable Flash Encryption Externally**

In this case, all the eFuses related to flash encryption are written with help of the `espefuse` tool. More details about flash encryption can be found in the *Flash Encryption Guide*.

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.
   
   See how to check *ESP32 Flash Encryption Status*.

   In this case, the flash on the chip must be erased and flash encryption must not be enabled. The chip can be erased by running:
   ```
   esptool.py --port PORT erase_flash
   ```

2. Generate a flash encryption key.
   
   A random flash encryption key can be generated by running:
   ```
   espsecure.py generate_flash_encryption_key my_flash_encryption_key.bin
   ```

3. Burn the flash encryption key into eFuse.
   
   This action **cannot be reverted**. It can be done by running:
   ```
   espefuse.py --port PORT burn_key flash_encryption my_flash_encryption_key.bin
   ```

4. Burn the `FLASH_CRYPT_CNT` eFuse.
   
   If you only want to enable flash encryption in *Development* mode and want to keep the ability to disable it in the future, Update the `FLASH_CRYPT_CNT` value in the below command from 127 to 0x1. (not recommended for production)
In the case of ESP32, you also need to burn the `FLASH_CRYPT_CONFIG`. It can be done by running:

```
esefuse.py --port PORT --chip esp32 burn_efuse FLASH_CRYPT_CNT 127
```

**Note:** At this point, the flash encryption on the device has been enabled. You may test the flash encryption process as given in step 5. Please note that the security-related eFuses have not been burned at this point. It is recommended that they should be burned in production use cases as explained in step 6.

5. Encrypt and flash the binaries.

The bootloader and the application binaries for the project must be built with Flash Encryption Release mode with default configurations.

Flash encryption Release mode can be set in the menuconfig as follows:

- *Enable flash encryption on boot*
- *Select Release mode* (Note that once Release mode is selected, the `DISABLE_DL_ENCRYPT` and `DISABLE_DL_DECRYPT` eFuse bits will be burned to disable flash encryption hardware in ROM Download Mode.)
- *Select UART ROM download mode* (Permanently disabled (recommended)) (Note that this option is only available when `CONFIG_ESP32_REV_MIN` is set to 3 (ESP32 V3).) The default choice is to keep UART ROM download mode enabled, however it is recommended to permanently disable this mode to reduce the options available to an attacker.
- *Select the appropriate bootloader log verbosity*
- *Save the configuration and exit.*

The binaries can be encrypted on the host machine by running:

```
espsecure.py encrypt_flash_data --keyfile my_flash_encryption_key.bin --address 0x1000 --output bootloader-enc.bin build/bootloader/bootloader.bin
```

```
espsecure.py encrypt_flash_data --keyfile my_flash_encryption_key.bin --address 0x8000 --output partition-table-enc.bin build/partition_table/partition-table.bin
```

```
espsecure.py encrypt_flash_data --keyfile my_flash_encryption_key.bin --address 0x10000 --output my-app-enc.bin build/my-app.bin
```

The above files can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds. In the above command the offsets are used for a sample firmware, the actual offset for your firmware can be obtained by checking the partition table entry or by running `idf.py partition-table`. When the application contains the following partition: `otadata`, `nvs_encryption_keys` they need to be encrypted as well. Please refer to *Encrypted Partitions* for more details about encrypted partitions.

**Note:** If the flashed ciphertext file is not recognized by the ESP32 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset. It is important to provide the correct offset as the ciphertext changes when the offset changes.

If your ESP32 uses non-default `FLASH_CRYPT_CONFIG value in eFuse` then you will need to pass the `--flash_crypt_conf` argument to `espsecure.py` to set the matching value. This will not happen if the device configured flash encryption by itself but may happen when burning eFuses manually to enable flash encryption.
The command `espsecure.py decrypt_flash_data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

6. Burn flash encryption-related security eFuses as listed below:

A) Burn security eFuses:

**Important:** For production use cases, it is highly recommended to burn all the eFuses listed below.

- **DISABLE_DL_ENCRYPT:** Disable the UART bootloader encryption access.
- **DISABLE_DL_DECRYPT:** Disable the UART bootloader decryption access.
- **DISABLE_DL_CACHE:** Disable the UART bootloader flash cache access.
- **JTAG_DISABLE:** Disable the JTAG

The respective eFuses can be burned by running:

```
espsecure.py burn_efuse --port PORT EFUSE_NAME 0x1
```

**Note:** Please update the EFUSE_NAME with the eFuse that you need to burn. Multiple eFuses can be burned at the same time by appending them to the above command (e.g., `EFUSE_NAME VAL EFUSE_NAME2 VAL2`). More documentation about `espsecure.py` can be found [here](#).

B) Write protect security eFuses:

After burning the respective eFuses we need to write_protect the security configurations

```
espsecure.py --port PORT write_protect_efuse MAC
```

**Note:** The write disable bit for MAC also writes disable DIS_CACHE which is required to prevent accidental burning of this bit.

C) Disable UART ROM DL mode:

**Important:**

7. Delete flash encryption key on host:

Once the flash encryption has been enabled for the device, the key **must be deleted immediately**.

This ensures that the host cannot produce encrypted binaries for the same device going forward.

This step is important to reduce the vulnerability of the flash encryption key.

**Flash Encryption Guidelines**

- It is recommended to generate a unique flash encryption key for each device for production use-cases.
- It is recommended to ensure that the RNG used by host machine to generate the flash encryption key has good entropy.
- See [Limitations of Flash Encryption](#) for more details.

**Enable Secure Boot V2 Externally** In this workflow, we shall use `espsecure` tool to generate signing keys and use the `espefuse` tool to burn the relevant eFuses. The details about the Secure Boot V2 process can be found at [Secure Boot V2 Guide](#)

1. Generate Secure Boot V2 Signing Private Key.
Chapter 5. Security Guides

The Secure Boot V2 signing key for the RSA3072 scheme can be generated by running:

```
espsecure.py generate_signing_key --version 2 --scheme rsa3072 secure_.boot_signing_key.pem
```

2. Generate Public Key Digest.

The public key digest for the private key generated in the previous step can be generated by running:

```
espsecure.py digest_sbv2_public_key --keyfile secure_boot_signing_key.pem --output digest.bin
```

3. Burn the key digest in eFuse.

The public key digest can be burned in the eFuse by running:

```
espfuse.py --port PORT --chip esp32 burn_key secure_boot_v2 digest.bin
```

4. Enable Secure Boot V2.

Secure Boot V2 eFuse can be enabled by running:

```
espfuse.py --port PORT --chip esp32 burn_efuse ABS_DONE_1
```

**Note:** At this stage the secure boot V2 has been enabled for the ESP32. The ROM bootloader shall now verify the authenticity of the Second Stage Bootloader on every bootup. You may test the secure boot process by executing Steps 5 & 6. Please note that security-related eFuses have not been burned at this point. For production use cases, all security-related eFuses must be burned as given in step 7.

5. Build the binaries.

By default, the ROM bootloader would only verify the Second Stage Bootloader (firmware bootloader). The firmware bootloader would verify the app partition only when the `CONFIG_SECURE_BOOT` option is enabled (and `CONFIG_SECURE_BOOT_VERSION` is set to `SECURE_BOOT_V2_ENABLED`) while building the bootloader.

a) Open the Project Configuration Menu, in “Security features” set “Enable hardware Secure Boot in bootloader” to enable Secure Boot.

For ESP32, Secure Boot V2 is available only for ESP32 ECO3 onwards. To view the “Secure Boot V2” option the chip revision should be changed to revision v3.0 (ECO3). To change the chip revision, set “Minimum Supported ESP32 Revision” to “Rev 3.0 (ECO3)” in “Component Config” -> “Hardware Settings” -> “Chip Revision”.

b) Disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` for the project in the Project Configuration Menu. This shall make sure that all the generated binaries are secure padded and unsigned. This step is done to avoid generating signed binaries as we are going to manually sign the binaries using espsecure tool.

After the above configurations, the bootloader and application binaries can be built with `idf.py build` command.

6. Sign and Flash the binaries.

The Secure Boot V2 workflow only verifies the bootloader and application binaries, hence only those binaries need to be signed. The other binaries (e.g., partition-table.bin) can be flashed as they are generated in the build stage.

The `bootloader.bin` and `app.bin` binaries can be signed by running:
The signatures attached to a binary can be checked by running:

```
espsecure.py signature_info_v2 bootloader-signed.bin
```

The above files along with other binaries (e.g., partition table) can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds. The flash offset for your firmware can be obtained by checking the partition table entry or by running `idf.py partition-table`.

7. **Burn relevant eFuses.**

A) **Burn security eFuses:**

**Important:** For production use cases, it is highly recommended to burn all the eFuses listed below.

- **JTAG_DISABLE:** Disable the JTAG

The respective eFuses can be burned by running:

```
espsecure.py burn_efuse --port PORT EFUSE_NAME 0x1
```

**Note:** Please update the `EFUSE_NAME` with the eFuse that you need to burn. Multiple eFuses can be burned at the same time by appending them to the above command (e.g., `EFUSE_NAME VAL EFUSE_NAME2 VAL2`). More documentation about `espsecure.py` can be found here.

B) **Secure Boot V2-related eFuses:**

i) Disable the ability for read protection:

The secure boot digest burned in the eFuse must be kept readable otherwise secure boot operation would result in a failure. To prevent the accidental enabling of read protection for this key block we need to burn the following eFuse:

```
espsecure.py -p $ESPPORT write_protect_efuse RD_DIS
```

**Important:** After this eFuse has been burned, read protection cannot be enabled for any key. E.g., if flash encryption which requires read protection for its key is not enabled at this point then it cannot be enabled afterwards. Please ensure that no eFuse keys are going to need read protection after this.

C) **Disable UART ROM DL mode:**

**Secure Boot V2 Guidelines**

- It is recommended to store the secure boot key in a highly secure place. A physical or a cloud HSM may be used for secure storage of the secure boot private key. Please take a look at *Remote Signing of Images* for more details.
Chapter 6

Migration Guides

6.1 ESP-IDF 5.x Migration Guide

6.1.1 Migration from 4.4 to 5.0

Bluetooth Classic

Bluedroid

- bt/host/bluedroid/api/include/api/esp_hf_defs.h
  - In esp_hf_cme_err_t
    * ESP_HF_CME_MEMORY_FULL renamed to ESP_HF_CME_MEMORY_FULL
    * ESP_HF_CME_MEMORY_FAILURE renamed to ESP_HF_CME_MEMORY_FAILURE

- bt/host/bluedroid/api/include/api/esp_hf_ag_api.h
  - esp_bt_hf_init(esp_bd_addr_t remote_addr) changes into esp_hf_ag_init(void)
  - esp_bt_hf_deinit(esp_bd_addr_t remote_addr) changes into esp_hf_ag_deinit(void)
  - Along with this change, the bt_bdaddr_t init and bt_bdaddr_t deinit has been removed from
    union btc_arg_t.
  - esp_bt_hf_register_callback changes into esp_hf_ag_register_callback
  - esp_bt_hf_connect changes into esp_hf_ag_slc_connect
  - esp_bt_hf_disconnect changes into esp_hf_ag_slc_disconnect
  - esp_bt_hf_connect_audio changes into esp_hf_ag_audio_connect
  - esp_bt_hf_disconnect_audio changes into esp_hf_ag_audio_disconnect
  - esp_bt_hf_vra changes into esp_hf_ag_vra_control
  - esp_bt_hf_volume_control changes into esp_hf_ag_volume_control
  - esp_hf_unat_response changes into esp_hf_ag_unknown_at_send
  - esp_bt_hf_cme_response changes into esp_hf_ag_cme_send
  - esp_bt_hf_indchange_notification changes into esp_hf_ag_devices_status_indchange
  - esp_bt_hf_cind_response changes into esp_hf_ag_cind_response
  - esp_bt_hf_cops_response changes into esp_hf_ag_cops_response
  - esp_bt_hf_clcc_response changes into esp_hf_ag_clcc_response
  - esp_bt_hf_cnum_response changes into esp_hf_ag_cnum_response
- `esp_bt_hf_bsir` changes into `esp_hf_ag_bsir`
- `esp_bt_hf_answer_call` changes into `esp_hf_ag_answer_call`
- `esp_bt_hf_reject_call` changes into `esp_hf_ag_reject_call`
- `esp_bt_hf_out_call` changes into `esp_hf_ag_out_call`
- `esp_bt_hf_register_data_callback` changes into `esp_hf_ag_register_data_callback`
- `esp_hf_outgoing_data_ready` changes into `esp_hf_ag_outgoing_data_ready`

### Bluetooth Low Energy

**Bluedroid**

The following Bluedroid macros, types, and functions have been renamed:

- `bt/host/bluedroid/api/include/api/esp_gap_ble_api.h`
  - In `esp_gap_ble_cb_event_t`:
    - `ESP_GAP_BLE_SET_PREFERED_DEFAULT_PHY_COMPLETE_EVT` renamed to `ESP_GAP_BLE_SET_PREFERRED_DEFAULT_PHY_COMPLETE_EVT`
    - `ESP_GAP_BLE_SET_PREFERED_PHY_COMPLETE_EVT` renamed to `ESP_GAP_BLE_SET_PREFERRED_PHY_COMPLETE_EVT`
    - `ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT` renamed to `ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT`
- `esp_ble_wl_operation_t` renamed to `esp_ble_wl_operation_t`
- `esp_ble_gap_cb_param_t.pkt_data_length_cmpl` renamed to `pkt_data_length_cmpl`
- `esp_ble_gap_cb_param_t.update_whitelist_cmpl.wl_operation` renamed to `wl_operation`
- `esp_ble_gap_set_prefered_default_phy` renamed to `esp_ble_gap_set_preferred_default_phy()`
- `esp_ble_gap_set_prefered_phy` renamed to `esp_ble_gap_set_preferred_phy()`

- `bt/host/bluedroid/api/include/api/esp_gatt_defs.h`
  - In `esp_gatt_status_t`:
    - `ESP_GATT_ENCRYPED_MITM` renamed to `ESP_GATT_ENCRYPTED_MITM`
    - `ESP_GATT_ENCRYPED_NO_MITM` renamed to `ESP_GATT_ENCRYPTED_NO_MITM`

**Nimble**

The following Nimble APIs have been removed:

- `bt/host/nimble/esp-hci/include/esp_nimble_hci.h`
  - Remove `esp_err_t esp_nimble_hci_and_controller_init(void)`
    - Controller initialization, enable and HCI initialization calls have been moved to `nimble_port_init`. This function can be deleted directly.
  - Remove `esp_err_t esp_nimble_hci_and_controller_deinit(void)`
    - Controller deinitialization, disable and HCI deinitialization calls have been moved to `nimble_port_deinit`. This function can be deleted directly.

**ESP-BLE-MESH**

The following ESP-BLE-MESH macro has been renamed:

- `bt/esp_ble_mesh/api/esp_ble_mesh_defs.h`
  - In `esp_ble_mesh_prov_cb_event_t`:
    - `ESP_BLE_MESH_PROVISIONER_DRIECT_ERASE_SETTINGS_COMP_EVT` renamed to `ESP_BLE_MESH_PROVISIONER_DIRECT_ERASE_SETTINGS_COMP_EVT`
Build System

Migrating from GNU Make Build System  ESP-IDF v5.0 no longer supports GNU make-based projects. Please follow the build system guide for migration.

Update Fragment File Grammar  Please follow the migrate linker script fragment files grammar chapter for migrating v3.x grammar to the new one.

Specify Component Requirements Explicitly In previous versions of ESP-IDF, some components were always added as public requirements (dependencies) to every component in the build, in addition to the common component requirements:

- driver
- efuse
- esp_timer
- lwip
- vfs
- esp_wifi
- esp_event
- esp_netif
- esp_eth
- esp_phy

This means that it was possible to include header files of those components without specifying them as requirements in idf_component_register. This behavior was caused by transitive dependencies of various common components.

In ESP-IDF v5.0, this behavior is fixed and these components are no longer added as public requirements by default. Every component depending on one of the components which isn’t part of common requirements has to declare this dependency explicitly. This can be done by adding REQUIRES <component_name> or PRIV_REQUIRES <component_name> in idf_component_register call inside component’s CMakeLists.txt. See Component Requirements for more information on specifying requirements.

Setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS Variables  ESP-IDF v5.0 includes a number of improvements to support building projects with space characters in their paths. To make that possible, there are some changes related to setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS variables in project CMakeLists.txt files.

Adding non-existent directories to COMPONENT_DIRS or EXTRA_COMPONENT_DIRS is no longer supported and will result in an error.

Using string concatenation to define COMPONENT_DIRS or EXTRA_COMPONENT_DIRS variables is now deprecated. These variables should be defined as CMake lists, instead. For example, use:

```
set(EXTRA_COMPONENT_DIRS path1 path2)
list(APPEND EXTRA_COMPONENT_DIRS path3)
```

instead of:

```
set(EXTRA_COMPONENT_DIRS "path1 path2")
set(EXTRA_COMPONENT_DIRS "${EXTRA_COMPONENT_DIRS} path3")
```

Defining these variables as CMake lists is compatible with previous ESP-IDF versions.

Update Usage of target_link_libraries with project_elf  ESP-IDF v5.0 fixes CMake variable propagation issues for components. This issue caused compiler flags and definitions that were supposed to apply to one component to be applied to every component in the project.
Chapter 6. Migration Guides

As a side effect of this, user projects from ESP-IDF v5.0 onwards must use `target_link_libraries` with `project_elf` explicitly and custom CMake projects must specify `PRIVATE`, `PUBLIC`, or `INTERFACE` arguments. This is a breaking change and is not backward compatible with previous ESP-IDF versions.

For example:

```
target_link_libraries(${project_elf} PRIVATE "-Wl,--wrap=esp_panic_handler")
```

instead of:

```
target_link_libraries(${project_elf} "-Wl,--wrap=esp_panic_handler")
```

Update CMake Version  In ESP-IDF v5.0 minimal CMake version was increased to 3.16 and versions lower than 3.16 are not supported anymore. Run `tools/idf_tools.py install cmake` to install a suitable version if your OS version doesn’t have one.

This affects ESP-IDF users who use system-provided CMake and custom CMake.

Reorder the Applying of the Target-Specific Config Files  ESP-IDF v5.0 reorders the applying order of target-specific config files and other files listed in `SDKCONFIG_DEFAULTS`. Now, target-specific files will be applied right after the file brings it in, before all latter files in `SDKCONFIG_DEFAULTS`.

For example:

```
if `''SDKCONFIG_DEFAULTS="/sdkconfig_defaults;sdkconfig_devkit1"'`, and there is a
→ file `''sdkconfig_defaults.esp32''` in the same folder, then the files will be
→ applied in the following order: (1) sdkconfig.defaults (2) sdkconfig.defaults.
→ esp32 (3) sdkconfig_devkit1.
```

If you have a key with different values in the target-specific files of the former item (e.g., `sdkconfig.defaults.esp32` above) and the latter item (e.g., `sdkconfig_devkit1.esp32` above), please note the latter will override the target-specific file of the former.

If you do want to have some target-specific config values, please put it into the target-specific file of the latter item (e.g., `sdkconfig_devkit1.esp32`).

GCC

GCC Version  The previous GCC version was GCC 8.4.0. This has now been upgraded to GCC 11.2.0 on all targets. Users that need to port their code from GCC 8.4.0 to 11.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 9
- Porting to GCC 10
- Porting to GCC 11

Warnings  The upgrade to GCC 11.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user’s code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter, and ways to suppress them.

**Warning:** Users are advised to check that a warning is indeed a false positive before attempting to suppress it.
Chapter 6. Migration Guides

-Wstringop-overflow, -Wstringop-overread, -Wstringop-truncation, and -Warray-bounds  Users that use memory/string copy/compare functions will run into one of the -Wstringop warnings if the compiler cannot properly determine the size of the memory/string. The examples below demonstrate code that triggers these warnings and how to suppress them.

```c
#pragma GCC diagnostic push
#pragma GCC diagnostic ignored "-Wstringop-overflow"
#pragma GCC diagnostic ignored "-Warray-bounds"
    memset(RTC_SLOW_MEM, 0, CONFIG_ULP_COPROC_reserve_MEM); // <<-- This line
    leads to warnings
#pragma GCC diagnostic pop
```

- Waddress-of-packed-member  GCC will issue this warning when accessing an unaligned member of a packed struct due to the incurred penalty of unaligned memory access. However, all ESP chips (on both Xtensa and RISC-V architectures) allow for unaligned memory access and incur no extra penalty. Thus, this warning can be ignored in most cases.

```c
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c: In function
    'btc_to_bta_gatt_id':
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c:105:21: warning:
    taking address of packed member of 'struct <anonymous>' may result in an
    unaligned pointer value [-Waddress-of-packed-member]
105 |    btc_to_bta_uuid(&p_dest->uuid, &p_src->uuid);
    ^~~~~~~~~~~~~
```

If the warning occurs in multiple places across multiple source files, users can suppress the warning at the CMake level as demonstrated below.

```c
set_source_files_properties(
    "host/bluedroid/bta/gatt/bta_gatto_act.c"
    "host/bluedroid/bta/gatt/bta_gatto_cache.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatts.c"
    PROPERTIES COMPILE_FLAGS -Wno-address-of-packed-member)
```

However, if there are only one or two instances, users can suppress the warning directly in the source code itself as demonstrated below.

```c
#pragma GCC diagnostic push
#pragma GCC diagnostic ignored "-Waddress-of-packed-member" // <<-- This key had been
    introduced since GCC 9
#pragma GCC diagnostic pop
```

llabs() for 64-bit Integers  The function abs() from stdlib.h takes int argument. Please use llabs() for types that are intended to be 64-bit. It is particularly important for time_t.
Chapter 6. Migration Guides

**Espressif Toolchain Changes**

**int32_t and uint32_t for Xtensa Compiler** The types `int32_t` and `uint32_t` have been changed from the previous `int` and `unsigned int` to `long` and `unsigned long` respectively for the Xtensa compiler. This change now matches upstream GCC which makes `long` integers for `int32_t` and `uint32_t` on Xtensa, RISC-V, and other architectures.

</tr>
</thead>
<tbody>
<tr>
<td>Xtensa</td>
<td>(unsigned) int</td>
<td>(unsigned) long</td>
</tr>
<tr>
<td>riscv32</td>
<td>(unsigned) long</td>
<td>(unsigned) long</td>
</tr>
</tbody>
</table>

The change mostly affects code that formats strings using types provided by `<inttypes.h>`. When using these fixed-width types (e.g., `uint32_t`), users will need to replace placeholders such as `%i` and `%x` with `PRIi32` and `PRIx32` respectively. Types not defined in `<inttypes.h>` (e.g., `int`) do not need this special formatting.

In other cases, it should be noted that enums have the `int` type.

In common, `int32_t` and `int`, as well as `uint32_t` and `unsigned int`, are different types.

If users do not make the aforementioned updates to format strings in their applications, the following error will be reported during compilation:

```
/Users/name/esp/esp-rainmaker/components/esp-insights/components/esp_diagnostics/
    include/esp_diagnostics.h:238:29: error: format '%u' expects argument of type
    'unsigned int', but argument 3 has type 'uint32_t' {aka 'long unsigned int'} [-Werror=format=]
238 | esp_diag_log_event(tag, "EV (%u) %s: " format, esp_log_timestamp(), tag,
     | ^~~~~~~~~~~~~~ ~~~~~~~~~~~~~~~~~~~
     | | uint32_t {aka long unsigned int}
```

**Removing CONFIG_COMPILER_DISABLE_GCC8_WARNINGS Build Option**

`CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` option was introduced to allow building of legacy code dating from the rigid GCC 5 toolchain. However, enough time has passed to allow for the warnings to be fixed, thus this option has been removed.

For now in GCC 11, users are advised to review their code and fix the compiler warnings where possible.

**Networking**

**Wi-Fi**

**Callback Function Type esp_now_recv_cb_t** Previously, the first parameter of `esp_now_recv_cb_t` was of type `const uint8_t *mac_addr`, which only included the address of ESP-NOW peer device.

This now changes. The first parameter is of type `esp_now_recv_info_t`, which has members `src_addr`, `des_addr` and `rx_ctrl`. Therefore, the following updates are required:

- Redefine ESP-NOW receive callback function.
- `src_addr` can be used to replace original `mac_addr`.
- `des_addr` is the destination MAC address of ESP-NOW packet, which can be unicast or broadcast address.
  
  With `des_addr`, the user can distinguish unicast and broadcast ESP-NOW packets where broadcast ESP-NOW packets can be non-encrypted even when encryption policy is configured for the ESP-NOW.
**rx_ctrl** is Rx control info of the ESP-NOW packet, which provides more information about the packet. Please refer to the ESP-NOW example: wifi/espnow/main/espnow_example_main.c

### Ethernet

**esp_eth_ioctl() API**  Previously, the *esp_eth_ioctl()* API had the following issues:

- **The third parameter (which is of type void *) would accept an int/bool type arguments (i.e., not pointers) as input in some cases. However, these cases were not documented properly.**
- **To pass int/bool type argument as the third parameter, the argument had to be “unnaturally” casted to a void * type, to prevent a compiler warning as demonstrated in the code snippet below. This casting could lead to misuse of the *esp_eth_ioctl()* function.**

```c
esp_eth_ioctl(eth_handle, ETH_CMD_S_FLOW_CTRL, (void *)true);
```

Therefore, the usage of *esp_eth_ioctl()* is now unified. Arguments to the third parameter must be passed as pointers to a specific data type to/from where data is stored/read by *esp_eth_ioctl()*.

Usage example to set Ethernet configuration:

```c
ingen_duplex_mode = ETH_DUPLEX_HALF;
esp_eth_ioctl(eth_handle, ETH_CMD_S_DUPLEX_MODE, &new_duplex_mode);
```

Usage example to get Ethernet configuration:

```c
eth_duplex_t duplex_mode;
esp_eth_ioctl(eth_handle, ETH_CMD_G_DUPLEX_MODE, &duplex_mode);
```

**KSZ8041/81 and LAN8720 Driver Update**  The KSZ8041/81 and LAN8720 drivers are updated to support more devices (i.e., generations) from their associated product families. The drivers can recognize particular chip numbers and their potential support by the driver.

As a result, the specific “chip number” function calls are replaced by generic ones as follows:

- **Removed esp_eth_phy_new_ksz8041() and esp_eth_phy_new_ksz8081(), and use esp_eth_phy_new_ksz80xx() instead**
- **Removed esp_eth_phy_new_lan8720(), and use esp_eth_phy_new_lan87xx() instead**

**ESP NETIF Glue Event Handlers**  *esp_eth_set_default_handlers()* and *esp_eth_clear_default_handlers()* functions are removed. Registration of the default IP layer handlers for Ethernet is now handled automatically. If you have already followed the suggestion to fully initialize the Ethernet driver and network interface before registering their Ethernet/IP event handlers, then no action is required (except for deleting the affected functions). Otherwise, you may start the Ethernet driver right after they register the user event handler.

**PHY Address Auto-detect**  The Ethernet PHY address auto-detect function *esp_eth_detect_phy_addr()* is renamed to *esp_eth_phy_802_3_detect_phy_addr()* and its header declaration is moved to *esp_eth/include/esp_eth_phy_802_3.h*.

**SPI-Ethernet Module Initialization**  The SPI-Ethernet Module initialization is now simplified. Previously, you had to manually allocate an SPI device using *spi_bus_add_device()* before instantiating the SPI-Ethernet MAC.

Now, you no longer need to call *spi_bus_add_device()* as SPI devices are allocated internally. As a result, the *eth_dm9051_config_t*, *eth_w5500_config_t*, and *eth_ksz8851anl_config_t* configuration structures are updated to include members for SPI device configuration (e.g., to allow fine tuning...
of SPI timing which may be dependent on PCB design). Likewise, the ETH_DM9051_DEFAULT_CONFIG, ETH_W5500_DEFAULT_CONFIG, and ETH_KSZ8851SNL_DEFAULT_CONFIG configuration initialization macros are updated to accept new input parameters. Refer to *Ethernet API Reference Guide* for an example of SPI-Ethernet Module initialization.

**Ethernet Driver** APIs for creating MAC instances (esp_eth_mac_new_{*}()) have been reworked to accept two parameters, instead of one common configuration. Now, the configuration includes:

- Vendor specific MAC configuration
- Ethernet driver MAC configuration

This is applicable to internal Ethernet MAC esp_eth_mac_new_{esp32}() as well as to external MAC devices, such as esp_eth_mac_new_{ksz8851snl}, esp_eth_mac_new_{dm9051}, and esp_eth_mac_new_{w5500}()

**TCP/IP Adapter** The TCP/IP Adapter was a network interface abstraction component used in ESP-IDF prior to v4.1. This section outlines migration from tcpip_adapter API to its successor *ESP-NETIF*.

### Updating Network Connection Code

#### Network Stack Initialization

- You may simply replace tcpip_adapter_init() with esp_netif_init(). However, please should note that the esp_netif_init() function now returns standard error codes. See ESP-NETIF for more details.
- The esp_netif_deinit() function is provided to de-initialize the network stack.
- You should also replace #include "tcpip_adapter.h" with #include "esp_netif.h".

#### Network Interface Creation

Previously, the TCP/IP Adapter defined the following network interfaces statically:

- WiFi Station
- WiFi Access Point
- Ethernet

This now changes. Network interface instance should be explicitly constructed, so that the ESP-NETIF can connect to the TCP/IP stack. For example, after the TCP/IP stack and the event loop are initialized, the initialization code for WiFi must explicitly call esp_netif_create_default_wifi_sta(); or esp_netif_create_default_wifi_ap();.

Please refer to the example initialization code for these three interfaces:

- WiFi Station: wifi/getting_started/station/main/station_example_main.c
- WiFi Access Point: wifi/getting_started/softAP/main/softap_example_main.c
- Ethernet: ethernet/basic/main/ethernet_example_main.c

#### Other tcpip_adapter API Replacement

All the tcpip_adapter functions have their esp-netif counter-part. Please refer to the esp_netif.h grouped into these sections:

- Setters/Getters
- DHCP
- DNS
- IP address
Default Event Handlers  Event handlers are moved from tcpip_adapter to appropriate driver code. There is no change from application code perspective, as all events should be handled in the same way. Please note that for IP-related event handlers, application code usually receives IP addresses in the form of an esp-netif specific struct instead of the LwIP structs. However, both structs are binary compatible.

This is the preferred way to print the address:

```
ESP_LOGI(TAG, "got ip:" IPSTR, IP2STR(&event->ip_info.ip));
```

Instead of

```
ESP_LOGI(TAG, "got ip:%s", ip4addr_ntoa(&event->ip_info.ip));
```

Since ip4addr_ntoa() is a LwIP API, the esp-netif provides esp_ip4addr_ntoa() as a replacement. However, the above method using IP2STR() is generally preferred.

IP Addresses  You are advised to use esp-netif defined IP structures. Please note that with default compatibility enabled, the LwIP structs still work.

- esp-netif IP address definitions

Peripherals

Peripheral Clock Gating  As usual, peripheral clock gating is still handled by driver itself, users do not need to take care of the peripheral module clock gating.

However, for advanced users who implement their own drivers based on hal and soc components, the previous clock gating include path has been changed from driver/periph_ctrl.h to esp_private/periph_ctrl.h.

RTC Subsystem Control  RTC control APIs have been moved from driver/rtc_cntl.h to esp_private/rtc_ctrl.h.

ADC

ADC Oneshot & Continuous Mode Drivers  The ADC oneshot mode driver has been redesigned.

- The new driver is in esp_adc component and the include path is esp_adcadc_oneshot.h.
- The legacy driver is still available in the previous include path driver/adc.h.

The ADC continuous mode driver has been moved from driver component to esp_adc component.

- The include path has been changed from driver/adc.h to esp_adcadc_continuous.h.

Attempting to use the legacy include path driver/adc.h of either driver triggers the build warning below by default. However, the warning can be suppressed by enabling the CONFIG_ADC_SUPPRESS_DEPRECATE_WARN Kconfig option.

```
legacy adc driver is deprecated, please migrate to use esp_adcadc_oneshot.h and...
  esp_adcadc_continuous.h for oneshot mode and continuous mode drivers...
```

Submit Document Feedback
ADC Calibration Driver  The ADC calibration driver has been redesigned.

- The new driver is in esp_adc component and the include path is esp_adc/adc_cali.h and esp_adc/adc_cali_scheme.h.

Legacy driver is still available by including esp_adc_cal.h. However, if users still would like to use the include path of the legacy driver, users should add esp_adc component to the list of component requirements in CMakelists.txt.

Attempting to use the legacy include path esp_adc_cal.h triggers the build warning below by default. However, the warning can be suppressed by enabling the CONFIG_ADC_CALI_SUPPRESS_DEPRECATED_WARN Kconfig option.

```
legacy adc calibration driver is deprecated, please migrate to use esp_adc/adc_---cali.h and esp_adc/adc_cali_scheme.h
```

API Changes

- The ADC power management APIs adc_power_acquire and adc_power_release have made private and moved to esp_private/adc_share_hw_ctrl.h.
  - The two APIs were previously made public due to a HW errata workaround.
  - Now, ADC power management is completely handled internally by drivers.
  - Users who still require this API can include esp_private/adc_share_hw_ctrl.h to continue using these functions.
- driver/adc2_wifi_private.h has been moved to esp_private/adc_share_hw_ctrl.h.
- Enums ADC_UNIT_BOTH, ADC_UNIT_ALTER, and ADC_UNIT_MAX in adc_unit_t have been removed.
- The following enumerations have been removed as some of their enumeration values are not supported on all chips. This would lead to the driver triggering a runtime error if an unsupported value is used.
  - Enum ADC_CHANNEL_MAX
  - Enum ADC_ATTEN_MAX
  - Enum ADC_CONV_UNIT_MAX
- API hall_sensor_read on ESP32 has been removed. Hall sensor is no longer supported on ESP32.
- API adc_set_i2s_data_source and adc_i2s_mode_init have been deprecated. Related enum adc_i2s_source_t has been deprecated. Please migrate to use esp_adc/adc_continuous.h.
- API adc_digi_filter_reset, adc_digi_filter_set_config, adc_digi_filter_get_config and adc_digi_filter_enable have been removed. These APIs behaviours are not guaranteed. Enum adc_digi_filter_idx_t, adc_digi_filter_mode_t and structure adc_digi_iir_filter_t have been removed as well.
- API esp_adc_cal_characterize has been deprecated, please migrate to adc_cali_create_scheme_curve_fitting or adc_cali_create_scheme_line_fitting instead.
- API esp_adc_cal_raw_to_voltage has been deprecated, please migrate to adc_cal_raw_to_voltage instead.
- API esp_adc_cal_get_voltage has been deprecated, please migrate to adc_oneshot_get_calibrated_result instead.

GPIO

- The previous Kconfig option RTCIO_SUPPORT_RTC_GPIO_DESC has been removed, thus the rtc_gpio_desc array is unavailable. Please use rtc_io_desc array instead.
- The user callback of a GPIO interrupt should no longer read the GPIO interrupt status register to get the GPIO’s pin number of triggering the interrupt. You should use the callback argument to determine the GPIO’s pin number instead.
  - Previously, when a GPIO interrupt occurs, the GPIO’s interrupt status register is cleared after calling the user callbacks. Thus, it was possible for users to read the GPIO’s interrupt status register inside the callback to determine which GPIO was used to trigger the interrupt.
– However, clearing the interrupt status register after calling the user callbacks can potentially cause edge-triggered interrupts to be lost. For example, if an edge-triggered interrupt is triggered/retriggered while the user callbacks are being called, that interrupt will be cleared without its registered user callback being handled.

– Now, the GPIO’s interrupt status register is cleared before invoking the user callbacks. Thus, users can no longer read the GPIO interrupt status register to determine which pin has triggered the interrupt. Instead, users should use the callback argument to pass the pin number.

Sigma-Delta Modulator  The Sigma-Delta Modulator driver has been redesigned into **SDM**.

• The new driver implements a factory pattern, where the SDM channels are managed in a pool internally, thus users do not have to fix a SDM channel to a GPIO manually.

• All SDM channels can be allocated dynamically.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path driver/sigmadelta.h. However, by default, including driver/sigmadelta.h triggers the build warning below. The warning can be suppressed by Kconfig option `CONFIG_SDM_SUPPRESS_DEPRECATED_WARN`.

```
The legacy sigma-delta driver is deprecated, please use driver/sdm.h
```

The major breaking changes in concept and usage are listed as follows:

**Breaking Changes in Concepts**

• SDM channel representation has changed from `sigmadelta_channel_t` to `sdm_channel_handle_t`, which is an opaque pointer.

• SDM channel configurations are stored in `sdm_config_t` now, instead the previous `sigmadelta_config_t`.

• In the legacy driver, users do not have to set the clock source for SDM channel. But in the new driver, users need to set a proper one in the `sdm_config_t::clk_src`. The available clock sources are listed in the `soc_periph_sdm_clk_src_t`.

• In the legacy driver, users need to set a `prescale` for the channel, which reflects the frequency in which the modulator outputs a pulse. In the new driver, users should use `sdm_config_t::sample_rate_hz` to set the over sample rate.

• In the legacy driver, users set `duty` to decide the output analog value, it is now renamed to a more appropriate name `density`.

**Breaking Changes in Usage**

• Channel configuration was done by channel allocation, in `sdm_new_channel()`. In the new driver, only the density can be changed at runtime, by `sdm_channel_set_pulse_density()`. Other parameters like gpio number and prescale are only allowed to set during channel allocation.

• Before further channel operations, users should enable the channel in advance, by calling `sdm_channel_enable()`. This function helps to manage some system level services, like Power Management.

Timer Group Driver  Timer Group driver has been redesigned into **GPTimer**, which aims to unify and simplify the usage of general purpose timer.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path driver/timer.h. However, by default, including driver/timer.h triggers the build warning below. The warning can be suppressed by the Kconfig option `CONFIG_GPTIMER_SUPPRESS_DEPRECATED_WARN`.

```
legacy timer group driver is deprecated, please migrate to driver/gptimer.h
```

The major breaking changes in concept and usage are listed as follows:
Chapter 6. Migration Guides

Breaking Changes in Concepts

- `timer_group_t` and `timer_idx_t` which used to identify the hardware timer are removed from user’s code. In the new driver, a timer is represented by `gptimer_handle_t`.
- Definition of timer clock source is moved to `gptimer_clock_source_t`, the previous `timer_src_clk_t` is not used.
- Definition of timer count direction is moved to `gptimer_count_direction_t`, the previous `timer_count_dir_t` is not used.
- Only level interrupt is supported, `timer_intr_t` and `timer_intr_mode_t` are not used.
- Auto-reload is enabled by set the `gptimer_alarm_config_t::auto_reload_on_alarm` flag. `timer_autoreload_t` is not used.

Breaking Changes in Usage

- Timer initialization is done by creating a timer instance from `gptimer_new_timer()`. Basic configurations like clock source, resolution and direction should be set in `gptimer_config_t`. Note that, specific configurations of alarm events are not needed during the installation stage of the driver.
- Alarm event is configured by `gptimer_set_alarm_action()`, with parameters set in the `gptimer_alarm_config_t`.
- Setting and getting count value are done by `gptimer_get_raw_count()` and `gptimer_set_raw_count()`. The driver does not help convert the raw value into UTC time-stamp. Instead, the conversion should be done from user’s side as the timer resolution is also known to the user.
- The driver will install the interrupt service as well if `gptimer_event_callbacks_t::on_alarm` is set to a valid callback function. In the callback, users do not have to deal with the low level registers (like “clear interrupt status”, “re-enable alarm event” and so on). So functions like `timer_group_get_intr_status_in_isr` and `timer_group_get_auto_reload_in_isr` are not used anymore.
- To update the alarm configurations when alarm event happens, one can call `gptimer_set_alarm_action()` in the interrupt callback, then the alarm will be re-enabled again.
- Alarm will always be re-enabled by the driver if `gptimer_alarm_config_t::auto_reload_on_alarm` is set to true.

## Pulse Counter Driver

Pulse counter driver has been redesigned (see PCNT), which aims to unify and simplify the usage of PCNT peripheral.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/pcnt.h`. However, including `driver/pcnt.h` triggers the build warning below by default. The warning can be suppressed by the Kconfig option `CONFIG_PCNT.SuppressDeprecatedWarn`.

```
legacy pcnt driver is deprecated, please migrate to use driver/pulse_cnt.h
```

The major breaking changes in concept and usage are listed as follows:

### Breaking Changes in Concepts

- `pcnt_port_t`, `pcnt_unit_t` and `pcnt_channel_t` which used to identify the hardware unit and channel are removed from user’s code. In the new driver, PCNT unit is represented by `pcnt_unit_handle_t`, likewise, PCNT channel is represented by `pcnt_channel_handle_t`. Both of them are opaque pointers.
- `pcnt_evt_type_t` is not used any more, they have been replaced by a universal Watch Point Event. In the event callback `pcnt_watch_cb_t`, it is still possible to distinguish different watch points from `pcnt_watch_event_data_t`.
- `pcnt_count_mode_t` is replaced by `pcnt_channel_edge_action_t`, and `pcnt_ctrl_mode_t` is replaced by `pcnt_channel_level_action_t`.

### Breaking Changes in Usage

- Previously, the PCNT unit configuration and channel configuration were combined into a single function: `pcnt_unit_config`. They are now split into the two factory APIs: `pcnt_new_unit()` and `pcnt_new_channel()` respectively.
  - Only the count range is necessary for initializing a PCNT unit. GPIO number assignment has been moved to `pcnt_new_channel()`.
  - High/Low control mode and positive/negative edge count mode are set by stand-alone functions: `pcnt_channel_set_edge_action()` and `pcnt_channel_set_level_action()`.
- `pcnt_get_counter_value` is replaced by `pcnt_unit_get_count()`.
- `pcnt_counter_pause` is replaced by `pcnt_unit_stop()`.
- `pcnt_counter_resume` is replaced by `pcnt_unit_start()`.
- `pcnt_counter_clear` is replaced by `pcnt_unit_clear_count()`.
- `pcnt_intr_enable` and `pcnt_intr_disable` are removed. In the new driver, the interrupt is enabled by registering event callbacks `pcnt_unit_register_event_callbacks()`.
- `pcnt_event_enable` and `pcnt_event_disable` are removed. In the new driver, the PCNT events are enabled/disabled by adding/removing watch points `pcnt_unit_add_watch_point()`, `pcnt_unit_remove_watch_point()`.
- `pcnt_set_event_value` is removed. In the new driver, event value is also set when adding watch point by `pcnt_unit_add_watch_point()`. 
• pcnt_get_event_value and pcnt_get_event_status are removed. In the new driver, these information are provided by event callback pcnt_watch_cb in the pcnt_watch_event_data_t.
• pcnt_isr_register and pcnt_isr_unregister are removed. Register of the ISR handler from user’s code is no longer permitted. Users should register event callbacks instead by calling pcnt_unit_register_event_callbacks().
• pcnt_set_pin is removed and the new driver no longer allows the switching of the GPIO at runtime. If users want to change to other GPIOs, please delete the existing PCNT channel by pcnt_del_channel() and reinstall with the new GPIO number by pcnt_new_channel().
• pcnt_filter_enable, pcnt_filter_disable and pcnt_set_filter_value are replaced by pcnt_unit_set_glitch_filter(). Meanwhile, pcnt_get_filter_value has been removed.
• pcnt_set_mode is replaced by pcnt_channel_set_edge_action() and pcnt_channel_set_level_action().
• pcnt_isr_service_install, pcnt_isr_service_unregister, pcnt_isr_handler_add and pcnt_isr_handler_remove are replaced by pcnt_unit_register_event_callbacks(). The default ISR handler is lazy installed in the new driver.

**RMT Driver**  RMT driver has been redesigned (see RMT transceiver), which aims to unify and extend the usage of RMT peripheral.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path driver/rmt.h. However, including driver/rmt.h triggers the build warning below by default. The warning can be suppressed by the Kconfig option **CONFIG_RMT_SUPPRESS_DEPRECATED_WARN**.

The legacy RMT driver is deprecated, please use driver/rmt_tx.h and/or driver/rmt_rx.h

The major breaking changes in concept and usage are listed as follows:

### Breaking Changes in Concepts

- rmt_channel_t which used to identify the hardware channel are removed from user space. In the new driver, RMT channel is represented by rmt_channel_handle_t. The channel is dynamically allocated by the driver, instead of designated by user.
- rmt_item32_t is replaced by rmt_symbol_word_t, which avoids a nested union inside a struct.
- rmt_mem_t is removed, as we do not allow users to access RMT memory block (a.k.a. an RMTMEM) directly. Direct access to RMTMEM does not make sense but make mistakes, especially when the RMT channel also connected with a DMA channel.
- rmt_mem_owner_t is removed, as the ownership is controlled by driver, not by user anymore.
- rmt_source_clk_t is replaced by rmt_clock_source_t, and note they are not binary compatible.
- rmt_data_mode_t is removed, the RMT memory access mode is configured to always use Non-FIFO and DMA mode.
- rmt_idle_level_t is removed, as the driver has stand alone install functions for TX and RX channels.
- rmt_idle_level_t is removed, setting IDLE level for TX channel is available in rmt_transmit_config_t::eot_level.
- rmt_carrier_level_t is removed, setting carrier polarity is available in rmt_carrier_config_t::polarity_active_low.
- rmt_channel_status_t and rmt_channel_status_result_t are removed, they are not used anywhere.
- Transmitting by RMT channel does not expect user to prepare the RMT symbols, instead, user needs to provide an RMT Encoder to tell the driver how to convert user data into RMT symbols.

### Breaking Changes in Usage

- Channel installation has been separated for TX and RX channels into rmt_new_tx_channel() and rmt_new_rx_channel().
• `rmt_set_clk_div` and `rmt_get_clk_div` are removed. Channel clock configuration can only be done during channel installation.
• `rmt_set_rx_idle_thresh` and `rmt_get_rx_idle_thresh` are removed. In the new driver, the RX channel IDLE threshold is redesigned into a new concept `rmt_receive_config_t::signal_range_max_ns`.
• `rmt_set_mem_block_num` and `rmt_get_mem_block_num` are removed. In the new driver, the memory block number is determined by `rmt_tx_channel_config_t::mem_block_symbols` and `rmt_rx_channel_config_t::mem_block_symbols`.
• `rmt_set_tx_carrier` is removed. The new driver uses `rmt_apply_carrier()` to set carrier behavior.
• `rmt_set_mem_pd` and `rmt_get_mem_pd` are removed. The memory power is managed by the driver automatically.
• `rmt_set_mem_owner` and `rmt_get_mem_owner` are removed. RMT memory owner guard is added automatically by the driver.
• `rmt_set_source_clk` and `rmt_get_source_clk` are removed. Configuring clock source is only possible during channel installation by `rmt_tx_channel_config_t::clk_src` and `rmt_rx_channel_config_t::clk_src`.
• `rmt_set_rx_filter` is removed. In the new driver, the filter threshold is redesigned into a new concept `rmt_receive_config_t::signal_range_min_ns`.
• `rmt_set_idle_level` and `rmt_get_idle_level` are removed. Setting IDLE level for TX channel is available in `rmt_transmit_config_t::eot_level`.
• `rmt_set_rx_intr_en`, `rmt_set_err_intr_en`, `rmt_set_rx_intr_en`, `rmt_set_tx_intr_en` and `rmt_set_rx_thr_intr_en` are removed. The new driver does not allow user to turn on/off interrupt from user space. Instead, it provides callback functions.
• `rmt_set_gpio` and `rmt_set_pin` are removed. The new driver does not support to switch GPIO dynamically at runtime.
• `rmt_config` is removed. In the new driver, basic configuration is done during the channel installation stage.
• `rmt_isr_register` and `rmt_isr_deregister` are removed, the interrupt is allocated by the driver itself.
• `rmt_driver_install` is replaced by `rmt_new_tx_channel()` and `rmt_new_rx_channel()`.
• `rmt_driver_uninstall` is replaced by `rmt_del_channel()`.
• `rmt_fill_tx_items`, `rmt_write_items` and `rmt_write_sample` are removed. In the new driver, user needs to provide an encoder to “translate” the user data into RMT symbols.
• `rmt_get_counter_clock` is removed, as the channel clock resolution is configured by user from `rmt_tx_channel_config_t::resolution_hz`.
• `rmt_wait_tx_done` is replaced by `rmt_tx_wait_all_done()`.
• `rmt_translator_init`, `rmt_translator_set_context` and `rmt_translator_get_context` are removed. In the new driver, the translator has been replaced by the RMT encoder.
• `rmt_get_ringbuf_handle` is removed. The new driver does not use Ringbuffer to save RMT symbols. Instead, the incoming data are saved to the user provided buffer directly. The user buffer can even be mounted to DMA link internally.
• `rmt_register_tx_end_callback` is replaced by `rmt_tx_register_event_callbacks()`, where user can register `rmt_tx_event_callbacks_t::on_trans_done` event callback.
• `rmt_set_intr_enable_mask` and `rmt_clr_intr_enable_mask` are removed, as the interrupt is handled by the driver, user does not need to take care of it.
• `rmt_add_channel_to_group` and `rmt_remove_channel_from_group` are replaced by RMT sync manager. Please refer to `rmt_new_sync_manager()`.
• `rmt_set_tx_loop_count` is removed. The loop count in the new driver is configured in `rmt_transmit_config_t::loop_count`.
• rmt_enable_tx_loop_autostop is removed. In the new driver, TX loop auto stop is always enabled if available, it is not configurable anymore.

**LCD**

• The LCD panel initialization flow is slightly changed. Now the `esp_lcd_panel_init()` will not turn on the display automatically. User needs to call `esp_lcd_panel_disp_on_off()` to manually turn on the display. Note, this is different from turning on backlight. With this breaking change, user can flash a predefined pattern to the screen before turning on the screen. This can help avoid random noise on the screen after a power on reset.
  - `esp_lcd_panel_disp_off()` is deprecated, please use `esp_lcd_panel_disp_on_off()` instead.
  - `dc_as_cmd_phase` is removed. The SPI LCD driver currently does not support a 9-bit SPI LCD. Please always use a dedicated GPIO to control the LCD D/C line.

• The way to register RGB panel event callbacks has been moved from the `esp_lcd_rgb_panel_config_t` into a separate API `esp_lcd_rgb_panel_register_event_callbacks()`. However, the event callback signature is not changed.
  - Previous `relax_on_idle` flag in `esp_lcd_rgb_panel_config_t` has been renamed into `esp_lcd_rgb_panel_config_t::refresh_on_demand`, which expresses the same meaning but with a clear name.
  - If the RGB LCD is created with the `refresh_on_demand` flag enabled, the driver will not start a refresh in the `esp_lcd_panel_draw_bitmap()`. Now users have to call `esp_lcd_rgb_panel_refresh()` to refresh the screen by themselves.
  - `esp_lcd_color_space_t` is deprecated, please use `lcd_color_space_t` to describe the color space, and use `lcd_rgb_element_order_t` to describe the data order of RGB color.

**MCPWM** MCPWM driver was redesigned (see MCPWM), meanwhile, the legacy driver is deprecated.

The new driver’s aim is to make each MCPWM submodule independent to each other, and give the freedom of resource connection back to users.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/mcpwm.h`. However, using legacy driver triggers the build warning below by default. This warning can be suppressed by the Kconfig option `CONFIG_MCPWM_SUPPRESS_DEPRECATE_WARN`.

```c
legacy MCPWM driver is deprecated, please migrate to the new driver (include_/driver/mcpwm_prelude.h)
```

The major breaking changes in concept and usage are listed as follows:

**Breaking Changes in Concepts** The new MCPWM driver is object-oriented, where most of the MCPWM submodule has a driver object associated with it. The driver object is created by factory function like `mcpwm_new_timer()`. IO control function always needs an object handle, in the first place.

The legacy driver has an inappropriate assumption, that is the MCPWM operator should be connected to different MCPWM timer. In fact, the hardware does not have such limitation. In the new driver, a MCPWM timer can be connected to multiple operators, so that the operators can achieve the best synchronization performance.

The legacy driver presets the way to generate a PWM waveform into a so called `mcpwm_duty_type_t`. However, the duty cycle modes listed there are far from sufficient. Likewise, legacy driver has several preset `mcpwm_deadtime_type_t`, which also does not cover all the use cases. What is more, user usually gets confused by the name of the duty cycle mode and dead-time mode. In the new driver, there are no such limitation, but user has to construct the generator behavior from scratch.

In the legacy driver, the ways to synchronize the MCPWM timer by GPIO, software and other timer module are not unified. It increased learning costs for users. In the new driver, the synchronization APIs are unified.
Chapter 6. Migration Guides

The legacy driver has mixed the concepts of “Fault detector” and “Fault handler”. Which make the APIs very confusing to users. In the new driver, the fault object just represents a failure source, and we introduced a new concept “brake” to express the concept of “Fault handler”. What is more, the new driver supports software fault.

The legacy drive only provides callback functions for the capture submodule. The new driver provides more useful callbacks for various MCPWM submodules, like timer stop, compare match, fault enter, brake, etc.

- \texttt{mcpwm\_io\_signals\_t} and \texttt{mcpwm\_pin\_config\_t} are not used. GPIO configuration has been moved into submodule’s configuration structure.
- \texttt{mcpwm\_timer\_t}, \texttt{mcpwm\_generator\_t} are not used. Timer and generator are represented by \texttt{mcpwm\_timer\_handle\_t} and \texttt{mcpwm\_gen\_handle\_t}.
- \texttt{mcpwm\_fault\_signal\_t} and \texttt{mcpwm\_sync\_signal\_t} are not used. Fault and sync source are represented by \texttt{mcpwm\_fault\_handle\_t} and \texttt{mcpwm\_sync\_handle\_t}.
- \texttt{mcpwm\_capture\_signal\_t} is not used. A capture channel is represented by \texttt{mcpwm\_cap\_channel\_handle\_t}.

Breaking Changes in Usage

- \texttt{mcpwm\_gpio\_init} and \texttt{mcpwm\_set\_pin}: GPIO configurations are moved to submodule’s own configuration. e.g., set the PWM GPIO in \texttt{mcpwm\_generator\_config\_t::gen\_gpio\_num}.
- \texttt{mcpwm\_init}: To get an expected PWM waveform, users need to allocated at least one MCPWM timer and MCPWM operator, then connect them by calling \texttt{mcpwm\_operator\_connect\_timer()}. After that, users should set the generator’s actions on various events by calling e.g., \texttt{mcpwm\_generator\_set\_actions\_on\_timer\_event()}, \texttt{mcpwm\_generator\_set\_actions\_on\_compare\_event()}.
- \texttt{mcpwm\_group\_set\_resolution}: in the new driver, the group resolution is fixed to the maximum, usually it is 80 MHz.
- \texttt{mcpwm\_timer\_set\_resolution}: MCPWM Timer resolution is set in \texttt{mcpwm\_timer\_config\_t::resolution\_hz}.
- \texttt{mcpwm\_set\_frequency}: PWM frequency is determined by \texttt{mcpwm\_timer\_config\_t::resolution\_hz}, \texttt{mcpwm\_timer\_config\_t::count\_mode} and \texttt{mcpwm\_timer\_config\_t::period\_ticks}.
- \texttt{mcpwm\_set\_duty}: To set the PWM duty cycle, users should call \texttt{mcpwm\_comparator\_set\_compare\_value()} to change comparator’s threshold.
- \texttt{mcpwm\_set\_duty\_type}: There is no preset duty cycle types. The duty cycle type is configured by setting different generator actions. e.g., \texttt{mcpwm\_generator\_set\_actions\_on\_timer\_event()}.
- \texttt{mcpwm\_set\_signal\_high} and \texttt{mcpwm\_set\_signal\_low} are replaced by \texttt{mcpwm\_generator\_set\_force\_level()}. In the new driver, it is implemented by setting force action for the generator, instead of changing the duty cycle to 0% or 100% at the background.
- \texttt{mcpwm\_start} and \texttt{mcpwm\_stop} are replaced by \texttt{mcpwm\_timer\_start\_stop()} and \texttt{mcpwm\_timer\_set\_period\_ticks()}. You have more modes to start and stop the MCPWM timer, see \texttt{mcpwm\_timer\_start\_stop\_cmd\_t}.
- \texttt{mcpwm\_carrier\_init} is replaced by \texttt{mcpwm\_operator\_apply\_carrier()}. \texttt{mcpwm\_carrier\_enable} and \texttt{mcpwm\_carrier\_disable}: Enabling and disabling carrier submodule is done automatically by checking whether the carrier configuration structure \texttt{mcpwm\_carrier\_config\_t} is NULL.
- \texttt{mcpwm\_carrier\_set\_frequency} is replaced by \texttt{mcpwm\_carrier\_config\_t::frequency\_hz}.
- \texttt{mcpwm\_carrier\_set\_duty\_cycle} is replaced by \texttt{mcpwm\_carrier\_config\_t::duty\_cycle}.
- \texttt{mcpwm\_carrier\_oneshot\_mode\_enable} is replaced by \texttt{mcpwm\_carrier\_config\_t::first\_pulse\_duration\_us}.
- \texttt{mcpwm\_carrier\_oneshot\_mode\_disable} is removed. Disabling the first pulse (a.k.a the one-shot pulse) in the carrier is never supported by the hardware.
- \texttt{mcpwm\_carrier\_output\_invert} is replaced by \texttt{mcpwm\_carrier\_config\_t::invert\_before\_module\_and\_in\_after\_module}.
- \texttt{mcpwm\_deadtime\_enable} and \texttt{mcpwm\_deadtime\_disable} are replaced by \texttt{mcpwm\_generator\_set\_dead\_time()}.
- \texttt{mcpwm\_fault\_init} is replaced by \texttt{mcpwm\_new\_gpio\_fault()}. \texttt{mcpwm\_fault\_set\_oneshot\_mode} are replaced by \texttt{mcpwm\_operator\_set\_brake\_on\_fault()} and \texttt{mcpwm\_generator\_set\_actions\_on\_brake\_event()}.
- \texttt{mcpwm\_capture\_enable} is removed. It is duplicated to \texttt{mcpwm\_capture\_enable\_channel()}. \texttt{mcpwm\_capture\_disable} is removed. It is duplicated to \texttt{mcpwm\_capture\_capture\_disable\_channel()}. Espressif Systems 2885 Release v5.3-dev-277-gc8243465e4
**Migration Guides**

- `mcpwm_capture_enable_channel` and `mcpwm_capture_disable_channel` are replaced by `mcpwm_capture_channel_enable()` and `mcpwm_capture_channel_disable()`.
- `mcpwm_capture_signal_get_value` and `mcpwm_capture_signal_get_edge`: Capture timer count value and capture edge are provided in the capture event callback, via `mcpwm_capture_event_data_t`. Capture data are only valuable when capture event happens. Providing single API to fetch capture data is meaningless.
- `mcpwm_sync_enable` is removed. It is duplicated to `mcpwm_sync_configure()`.
- `mcpwm_sync_configure` is replaced by `mcpwm_timer_set_phase_on_sync()`.
- `mcpwm_sync_disable` is equivalent to setting `mcpwm_timer_sync_phase_config_t::sync_src` to NULL.
- `mcpwm_set_timer_sync_output` is replaced by `mcpwm_timer_config_t::sync_src`.
- `mcpwm_timer_trigger_soft_sync` is replaced by `mcpwm_soft_sync_activate()`.
- `mcpwm_sync_invert_gpio_synchro` is equivalent to setting `mcpwm_gpio_sync_config_t::active_neg`.
- `mcpwm_isr_register` is removed. You can register various event callbacks instead. For example, to register capture event callback, users can use `mcpwm_capture_channel_register_event_callbacks()`.

**I2S Driver**

The I2S driver has been redesigned (see I2S Driver), which aims to rectify the shortcomings of the driver that were exposed when supporting all the new features of ESP32-C3 & ESP32-S3. The new driver’s APIs are available by including corresponding I2S module’s header files `driver/i2s/include/driver/i2s_std.h`, `driver/i2s/include/driver/i2s_pdm.h`, or `driver/i2s/include/driver/i2s_tdm.h`.

Meanwhile, the old driver’s APIs in `driver/deprecated/driver/i2s.h` are still supported for backward compatibility. But there will be warnings if users keep using the old APIs in their projects, these warnings can be suppressed by the Kconfig option CONFIG_I2S_SUPPRESS_DEPRECATED_WARN.

Here is the general overview of the current I2S files:

Breaking changes in Concepts

**Independent TX/RX channels**

The minimum control unit in new I2S driver are now individual TX/RX channels instead of an entire I2S controller (that consists of multiple channels).

- The TX and RX channels of the same I2S controller can be controlled separately, meaning that they are configured such that they can be started or stopped separately.

Submit Document Feedback
The `i2s_chan_handle_t` handle type is used to uniquely identify I2S channels. All the APIs require the channel handle and users need to maintain the channel handles by themselves.

- On the ESP32-C3 and ESP32-S3, TX and RX channels in the same controller can be configured to different clocks or modes.
- However, on the ESP32 and ESP32-S2, the TX and RX channels of the same controller still share some hardware resources. Thus, configurations may cause one channel to affect another channel in the same controller.
- The channels can be registered to an available I2S controller automatically by setting `i2s_port_t::I2S_NUM_AUTO` as I2S port ID which causes the driver to search for the available TX/RX channels. However, the driver also supports registering channels to a specific port.
- In order to distinguish between TX/RX channels and sound channels, the term “channel” in the context of the I2S driver only refers to TX/RX channels. Meanwhile, sound channels are referred to as “slots”.

### I2S Mode Categorization

I2S communication modes are categorized into the following three modes. Note that:

- **Standard mode**: Standard mode always has two slots, it can support Philips, MSB, and PCM (short frame sync) formats. Please refer to `driver/i2s/include/driver/i2s_std.h` for more details.
- **PDM mode**: PDM mode only supports two slots with 16-bit data width, but the configurations of PDM TX and PDM RX are slightly different. For PDM TX, the sample rate can be set by `i2s_pdm_tx_clk_config_t::sample_rate`, and its clock frequency depends on the up-sampling configuration. For PDM RX, the sample rate can be set by `i2s_pdm_rx_clk_config_t::sample_rate`, and its clock frequency depends on the down-sampling configuration. Please refer to `driver/i2s/include/driver/i2s_pdm.h` for details.
- **TDM mode**: TDM mode can support up to 16 slots. It can work in Philips, MSB, PCM (short frame sync), and PCM (long frame sync) formats. Please refer to `driver/i2s/include/driver/i2s_tdm.h` for details.

When allocating a new channel in a specific mode, users should initialize that channel by its corresponding function. It is strongly recommended to use the helper macros to generate the default configurations in case the default values are changed in the future.

### Independent Slot and Clock Configuration

The slot configurations and clock configurations can be configured separately.

- Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()`, or `i2s_channel_init_tdm_mode()` to initialize the slot/clock/gpio_pin configurations.
- Calling `i2s_channel_reconfig_std_slot()`, `i2s_channel_reconfig_pdm_rx_slot()`, `i2s_channel_reconfig_pdm_tx_slot()`, or `i2s_channel_reconfig_tdm_slot()` can change the slot configurations after initialization.
- Calling `i2s_channel_reconfig_std_clock()`, `i2s_channel_reconfig_pdm_rx_clock()`, `i2s_channel_reconfig_pdm_tx_clock()`, or `i2s_channel_reconfig_tdm_clock()` can change the clock configurations after initialization.
- Calling `i2s_channel_reconfig_std_gpio()`, `i2s_channel_reconfig_pdm_rx_gpio()`, `i2s_channel_reconfig_pdm_tx_gpio()`, or `i2s_channel_reconfig_tdm_gpio()` can change the GPIO configurations after initialization.

### Misc

- States and state-machine are adopted in the new I2S driver to avoid APIs called in wrong state.
- ADC and DAC modes are removed. They are only supported in their own drivers and the legacy I2S driver.

### Breaking Changes in Usage

To use the new I2S driver, please follow these steps:

1. Call `i2s_new_channel()` to acquire channel handles. We should specify the work role and I2S port in this step. Besides, the TX or RX channel handle will be generated by the driver. Inputting both two TX and RX channel handles is not necessary but at least one handle is needed. In the case of inputting both two handles, the driver will work at the duplex mode. Both TX and RX channels will be available on a same port, and they will share the MCLK, BCLK and WS signal. But if only one of the TX or RX channel handle is inputted, this channel will only work in the simplex mode.
2. Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()` or `i2s_channel_init_tdm_mode()` to initialize the channel to the specified mode. Corresponding slot, clock and GPIO configurations are needed in this step.

3. (Optional) Call `i2s_channel_register_event_callback()` to register the ISR event callback functions. I2S events now can be received by the callback function synchronously, instead of from the event queue asynchronously.

4. Call `i2s_channel_enable()` to start the hardware of I2S channel. In the new driver, I2S does not start automatically after installed, and users are supposed to know clearly whether the channel has started or not.

5. Read or write data by `i2s_channel_read()` or `i2s_channel_write()`. Certainly, only the RX channel handle is supposed to be inputted in `i2s_channel_read()` and the TX channel handle in `i2s_channel_write()`.

6. (Optional) The slot, clock and GPIO configurations can be changed by corresponding ‘reconfig’ functions, but `i2s_channel_disable()` must be called before updating the configurations.

7. Call `i2s_channel_disable()` to stop the hardware of I2S channel.

8. Call `i2s_del_channel()` to delete and release the resources of the channel if it is not needed any more, but the channel must be disabled before deleting it.

**TWAI Driver** The deprecated CAN peripheral driver is removed. Please use TWAI driver instead (i.e., include `driver/twai.h` in your application).

**Register Access Macros** Previously, all register access macros could be used as expressions, so the following was allowed:

```c
uint32_t val = REG_SET_BITS(reg, bits, mask);
```

In ESP-IDF v5.0, register access macros which write or read-modify-write the register can no longer be used as expressions, and can only be used as statements. This applies to the following macros: `REG_WRITE`, `REG_SET_BIT`, `REG_CLR_BIT`, `REG_SET_BITS`, `REG_SET_FIELD`, `WRITE_PERI_REG`, `CLEAR_PERI_REG`, `CLEAR_PERI_REG_MASK`, `SET_PERI_REG_BITS`, `SET_PERI_REG_MASK`.

To store the value which would have been written into the register, split the operation as follows:

```c
uint32_t new_val = REG_READ(reg) | mask;
REG_WRITE(reg, new_val);
```

To get the value of the register after modification (which may be different from the value written), add an explicit read:

```c
REG_SET_BITS(reg, bits, mask);
uint32_t new_val = REG_READ(reg);
```

**Protocols**

**Mbed TLS** For ESP-IDF v5.0, Mbed TLS has been updated from v2.x to v3.1.0.

For more details about Mbed TLS’ s migration from version 2.x to version 3.0 or greater, please refer to the official guide.

**Breaking Changes (Summary)**

**Most Structure Fields Are Now Private**
- Direct access to fields of structures (struct types) declared in public headers is no longer supported.
Chapter 6. Migration Guides

- Appropriate accessor functions (getter/setter) must be used for the same. A temporary workaround would be to use `MBEDTLS_PRIVATE` macro (not recommended).
- For more details, refer to the official guide.

**SSL**

- Removed support for TLS 1.0, 1.1, and DTLS 1.0
- Removed support for SSL 3.0

**Deprecated Functions Were Removed from Cryptography Modules**

- The functions `mbedtls_*_ret()` (related to MD, SHA, RIPEMD, RNG, HMAC modules) was renamed to replace the corresponding functions without _ret appended and updated return value.
- For more details, refer to the official guide.

**Deprecated Config Options** Following are some of the important config options deprecated by this update. The configs related to and/or dependent on these have also been deprecated.

- `MBEDTLS_SSL_PROTO_SSL3` : Support for SSL 3.0
- `MBEDTLS_SSL_PROTO_TLS1` : Support for TLS 1.0
- `MBEDTLS_SSL_PROTO_TLS1_1` : Support for TLS 1.1
- `MBEDTLS_SSL_PROTO_DTLS` : Support for DTLS 1.1 (Only DTLS 1.2 is supported now)
- `MBEDTLS_DES_C` : Support for 3DES ciphersuites
- `MBEDTLS_RC4_MODE` : Support for RC4-based ciphersuites

Note: This list includes only major options configurable through `idf.py menuconfig`. For more details on deprecated options, refer to the official guide.

**Miscellaneous**

**Disabled Diffie-Hellman Key Exchange Modes** The Diffie-Hellman Key Exchange modes have now been disabled by default due to security risks (see warning text here). Related configs are given below:

- `MBEDTLS_DHM_C` : Support for the Diffie-Hellman-Merkle module
- `MBEDTLS_KEY_EXCHANGE_DHE_PSK` : Support for Diffie-Hellman PSK (pre-shared-key) TLS authentication modes
- `MBEDTLS_KEY_EXCHANGE_DHE_RSA` : Support for cipher suites with the prefix `TLS-DHE-RSA-WITH-`

Note: During the initial step of the handshake (i.e., `client_hello`), the server selects a cipher from the list that the client publishes. As the DHE_PSK/DHE_RSA ciphers have now been disabled by the above change, the server would fail back to an alternative cipher; if in a rare case, it does not support any other cipher, the handshake would fail. To retrieve the list of ciphers supported by the server, one must attempt to connect with the server with a specific cipher from the client-side. Few utilities can help do this, e.g., `sslscan`.

**Remove certs Module from X509 Library**

- The `mbedtls/certs.h` header is no longer available in mbedtls 3.1. Most applications can safely remove it from the list of includes.
Breaking Change for esp_crt_bundle_set API

- The esp_crt_bundle_set() API now requires one additional argument named bundle_size. The return type of the API has also been changed to esp_err_t from void.

Breaking Change for esp_ds_rsa_sign API

- The esp_ds_rsa_sign() API now requires one less argument. The argument mode is no longer required.

HTTPS Server

Breaking Changes (Summary) Names of variables holding different certs in httpd_ssl_config_t structure have been updated.

- httpd_ssl_config::servercert variable inherits role of cacert_pem variable.
- httpd_ssl_config::servercert_len variable inherits role of cacert_len variable
- httpd_ssl_config::cacert_pem variable inherits role of client_verify_cert_pem variable
- httpd_ssl_config::cacert_len variable inherits role of client_verify_cert_len variable

The return type of the httpd_ssl_stop() API has been changed to esp_err_t from void.

ESP HTTPS OTA

Breaking Changes (Summary)

- The function esp_https_ota() now requires pointer to esp_https_ota_config_t as argument instead of pointer to esp_http_client_config_t.

ESP-TLS

Breaking Changes (Summary)

esp_tls_t Structure Is Now Private The esp_tls_t has now been made completely private. You cannot access its internal structures directly. Any necessary data that needs to be obtained from the ESP-TLS handle can be done through respective getter/setter functions. If there is a requirement of a specific getter/setter function, please raise an issue on ESP-IDF.

The list of newly added getter/setter function is as as follows:

- esp_tls_get_ssl_context() - Obtain the ssl context of the underlying ssl stack from the ESP-TLS handle.

Function Deprecations And Recommended Alternatives Following table summarizes the deprecated functions removed and their alternatives to be used from ESP-IDF v5.0 onwards.

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>esp_tls_conn_new()</td>
<td>esp_tls_conn_new_sync()</td>
</tr>
<tr>
<td>esp_tls_conn_delete()</td>
<td>esp_tls_conn_destroy()</td>
</tr>
</tbody>
</table>

- The function esp_tls_conn_http_new() has now been termed as deprecated. Please use the alternative function esp_tls_conn_http_new_sync() (or its asynchronous esp_tls_conn_http_new_async()). Note that the alternatives need an additional parameter esp_tls_t, which has to be initialized using the esp_tls_init() function.
HTTP Server

Breaking Changes (Summary)

• http_server.h header is no longer available in esp_http_server. Please use esp_http_server.h instead.

ESP HTTP Client

Breaking Changes (Summary)

• The functions esp_http_client_read() and esp_http_client_fetch_headers() now return an additional return value -ESP_ERR_HTTP_EAGAIN for timeout errors - call timed-out before any data was ready.

TCP Transport

Breaking Changes (Summary)

• The function esp_transport_read() now returns 0 for a connection timeout and < 0 for other errors. Please refer esp_tcp_transport_err_t for all possible return values.

MQTT Client

Breaking Changes (Summary)

• esp_mqtt_client_config_t have all fields grouped in sub structs.

Most common configurations are listed below:

• Broker address now is set in esp_mqtt_client_config_t::broker::address::uri
• Security related to broker verification in esp_mqtt_client_config_t::broker::verification
• Client username is set in esp_mqtt_client_config_t::credentials::username
• esp_mqtt_client_config_t no longer supports the user_context field. Please use esp_mqtt_client_register_event() instead for registering an event handler; the last argument event_handler_arg can be used to pass user context to the handler.

ESP-Modbus

Breaking Changes (Summary) The ESP-IDF component freemodbus has been removed from ESP-IDF and is supported as a separate component. Additional information for the ESP-Modbus component can be found in the separate repository:

• ESP-Modbus component on GitHub

The main component folder of the new application shall include the component manager manifest file idf_component.yml as in the example below:

```
dependencies:
  espessif/esp-modbus:
    version: "^1.0"
```
Chapter 6. Migration Guides

The esp-modbus component can be found in component manager registry. Refer to component manager documentation for more information on how to set up the component manager.

For applications targeting v4.x releases of ESP-IDF that need to use new esp-modbus component, adding the component manager manifest file idf_component.yml will be sufficient to pull in the new component. However, users should also exclude the legacy freemodbus component from the build. This can be achieved using the statement below in the project’s CMakeLists.txt:

```
set(EXCLUDE_COMPONENTS freemodbus)
```

Provisioning

Protocomm The pop field in the protocomm_set_security() API is now deprecated. Please use the sec_params field instead of pop. This parameter should contain the structure (including the security parameters) as required by the protocol version used.

For example, when using security version 2, the sec_params parameter should contain the pointer to the structure of type protocomm_security2_params_t.

Wi-Fi Provisioning

• The pop field in the wifi_prov_mgr_start_provisioning() API is now deprecated. For backward compatibility, pop can be still passed as a string for security version 1. However, for security version 2, the wifi_prov_sec_params argument needs to be passed instead of pop. This parameter should contain the structure (containing the security parameters) as required by the protocol version used. For example, when using security version 2, the wifi_prov_sec_params parameter should contain the pointer to the structure of type wifi_prov_security2_params_t. For security 1, the behaviour and the usage of the API remain the same.
• The API wifi_prov_mgr_is_provisioned() does not return ESP_ERR_INVALID_STATE error any more. This API now works without any dependency on provisioning manager initialization state.

ESP Local Control The pop field in the esp_local_ctrl_proto_sec_cfg_t API is now deprecated. Please use the sec_params field instead of pop. This field should contain the structure (containing the security parameters) as required by the protocol version used.

For example, when using security version 2, the sec_params field should contain pointer to the structure of type esp_local_ctrl_security2_params_t.

Removed or Deprecated Components

Components Moved to ESP-IDF Component Registry Following components are removed from ESP-IDF and moved to ESP-IDF Component Registry:

• libsodium
• cbor
• jsmn
• esp_modem
• nghttp
• mdns
• esp_websocket_client
•asio
•freemodbus
Chapter 6. Migration Guides

- sh2lib
- expat
- coap
- esp-cryptoauthlib
- qrcode
- tjpgd
- esp_serial_slave_link
- tinyusb

Note: Please note that http parser functionality which was previously part of nghttp component is now part of http_parser component.

These components can be installed using idf.py add-depending dependency command.

For example, to install libsodium component with the exact version X.Y, run idf.py add-depending lib-

sodium==X.Y.

To install libsodium component with the latest version compatible to X.Y according to semver rules, run idf.py add-depending libshodium~X.Y.

To find out which versions of each component are available, open https://components.espressif.com, search for the component by its name and check the versions listed on the component page.

Deprecated Components The following components are removed since they were deprecated in ESP-IDF v4.x:
- tcpip_adapter. Please use the ESP-NETIF component instead; you can follow the TCP/IP Adapter.

Note: OpenSSL-API component is no longer supported. It is not available in the IDF Component Registry, either. Please use ESP-TLS or mbedtls API directly.

Note: esp_adc_cal component is no longer supported. New adc calibration driver is in esp_adc component. Legacy adc calibration driver has been moved into esp_adc component. To use legacy esp_adc_cal driver APIs, you should add esp_adc component to the list of component requirements in CMakeLists.txt. Also check Peripherals Migration Guide for more details.

The targets components are no longer necessary after refactoring and have been removed:

- esp32
- esp32s2
- esp32s3
- esp32c2
- esp32c3
- esp32h2

Storage

New Component for the Partition APIs Breaking change: all the Partition API code has been moved to a new component esp_partition. For the complete list of affected functions and data-types, see header file esp_partition.h.

These API functions and data-types were previously a part of the spi_flash component, and thus possible dependencies on the spi_flash in existing applications may cause the build failure, in case of direct esp_partition_* APIs/data-types use (for instance, fatal error: esp_partition.h: No such file or directory at lines with #include "esp_partition.h"). If you encounter such an issue, please update your project’s CMakeLists.txt file as follows:

Original dependency setup:
Updated dependency setup:

```
idf_component_register(...
  REQUIRES spi_flash esp_partition)
```

**Note:** Please update relevant REQUIRES or PRIV_REQUIRES section according to your project. The above-presented code snippet is just an example.

If the issue persists, please let us know and we will assist you with your code migration.

**SDMMC/SDSPI** SD card frequency on SDMMC/SDSPI interface can be now configured through `sdmmc_host_t.max_freq_khz` to a specific value, not only `SDMMC_FREQ_PROBING` (400 kHz), `SDMMC_FREQ_DEFAULT` (20 MHz), or `SDMMC_FREQ_HIGHSPEED` (40 MHz). Previously, in case you have specified a custom frequency other than any of the above-mentioned values, the closest lower-or-equal one was selected anyway.

Now, the underlaying drivers calculate the nearest fitting value, given by available frequency dividers instead of an enumeration item selection. This could cause troubles in communication with your SD card without a change of the existing application code. If you encounter such an issue, please, keep trying different frequencies around your desired value unless you find the one working well. To check the frequency value calculated and actually applied, use `void sdmmc_card_print_info(FILE* stream, const sdmmc_card_t* card)` function.

**FatFs** FatFs is now updated to v0.14. As a result, the function signature of `f_mkfs()` has changed. The new signature is `FRESULT f_mkfs (const TCHAR* path, const MKFS_PARM* opt, void* work, UINT len);` which uses `MKFS_PARM` struct as a second argument.

**Partition Table** The partition table generator no longer supports misaligned partitions. When generating a partition table, ESP-IDF only accepts partitions with offsets that align to 4 KB. This change only affects generating new partition tables. Reading and writing to already existing partitions remains unchanged.

**VFS** The `esp_vfs_semihost_register()` function signature is changed as follows:

- The new signature is `esp_err_t esp_vfs_semihost_register(const char* base_path);`
- The `host_path` parameter of the old signature no longer exists. Instead, the OpenOCD command `ESP_SEMIHOST_BASEDIR` should be used to set the full path on the host.

**Function Signature Changes** The following functions now return `esp_err_t` instead of `void` or `nvs_iterator_t`. Previously, when parameters were invalid or when something goes wrong internally, these functions would `assert()` or return a `nullptr`. With an `esp_err_t` returned, you can get better error reporting.

- `nvs_entry_find()`
- `nvs_entry_next()`
- `nvs_entry_info()`

Because the `esp_err_t` return type changes, the usage patterns of `nvs_entry_find()` and `nvs_entry_next()` become different. Both functions now modify iterators via parameters instead of returning an iterator.

The old programming pattern to iterate over an NVS partition was as follows:
nvs_iterator_t it = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY);
while (it != NULL) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info);
    printf("key '%s', type '%d'", info.key, info.type);
    it = nvs_entry_next(it);
}

The new programming pattern to iterate over an NVS partition is now:

nvs_iterator_t it = nullptr;
esp_err_t res = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY, &it);
while (res == ESP_OK) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info); // Can omit error check if parameters are guaranteed to be non-NULL
    printf("key '%s', type '%d'", info.key, info.type);
    res = nvs_entry_next(&it);
}

nvs_release_iterator(it);

**Iterator Validity** Note that because the function signature changes, if there is a parameter error, you may get an invalid iterator from nvs_entry_find(). Hence, it is important to initialize the iterator to NULL before using nvs_entry_find(), so that you can avoid complex error checking before calling nvs_release_iterator(). A good example is the programming pattern above.

**Removed SDSPI Deprecated API** Structure sdspi_slot_config_t and function sdspi_host_init_slot() are removed, and replaced by structure sdspi_device_config_t and function sdspi_host_init_device() respectively.

**ROM SPI Flash** In versions before v5.0, ROM SPI flash functions were included via esp32/**/rom/spi_flash.h. Thus, code written to support different ESP chips might be filled with ROM headers of different targets. Furthermore, not all of the APIs could be used on all ESP chips.

Now, the common APIs are extracted to esp_rom_spiflash.h. Although it is not a breaking change, you are strongly recommended to only use the functions from this header (i.e., prefixed with esp_rom_spiflash and included by esp_rom_spiflash.h) for better cross-compatibility between ESP chips.

To make ROM SPI flash APIs clearer, the following functions are also renamed:

- esp_rom_spiflash_lock() to esp_rom_spiflash_set_bp()
- esp_rom_spiflash_unlock() to esp_rom_spiflash_clear_bp()

**SPI Flash Driver** The esp_flash_speed_t enum type is now deprecated. Instead, you may now directly pass the real clock frequency value to the flash configuration structure. The following example demonstrates how to configure a flash frequency of 80MHz:

```c
esp_flash_spi_device_config_t dev_cfg = {
    // Other members
    .freq_mhz = 80,
    // Other members
};
```
Legacy SPI Flash Driver  To make SPI flash drivers more stable, the legacy SPI flash driver is removed from v5.0. The legacy SPI flash driver refers to default spi_flash driver since v3.0, and the SPI flash driver with configuration option `CONFIG_SPI_FLASH_USE_LEGACY_IMPL` enabled since v4.0. The major breaking change here is that the legacy spi_flash driver is no longer supported from v5.0. Therefore, the legacy driver APIs and the `CONFIG_SPI_FLASH_USE_LEGACY_IMPL` configuration option are both removed. Please use the new spi_flash driver’s APIs instead.

<table>
<thead>
<tr>
<th>Removed items</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>spi_flash_erase_sector()</code></td>
<td><code>esp_flash_erase_region()</code></td>
</tr>
<tr>
<td><code>spi_flash_erase_range()</code></td>
<td><code>esp_flash_erase_region()</code></td>
</tr>
<tr>
<td><code>spi_flash_write()</code></td>
<td><code>esp_flash_write()</code></td>
</tr>
<tr>
<td><code>spi_flash_read()</code></td>
<td><code>esp_flash_read()</code></td>
</tr>
<tr>
<td><code>spi_flash_write_encrypted()</code></td>
<td><code>esp_flash_write_encrypted()</code></td>
</tr>
<tr>
<td><code>spi_flash_read_encrypted()</code></td>
<td><code>esp_flash_read_encrypted()</code></td>
</tr>
</tbody>
</table>

**Note:** New functions with prefix `esp_flash` accept an additional `esp_flash_t*` parameter. You can simply set it to NULL. This will make the function to run the main flash (`esp_flash_default_chip`).

The `esp_spi_flash.h` header is deprecated as system functions are no longer public. To use flash memory mapping APIs, you may include `spi_flash_mmap.h` instead.

System

Inter-Processor Call  IPC (Inter-Processor Call) feature is no longer a stand-alone component and has been integrated into the `esp_system` component. Thus, any project presenting a `CMakeLists.txt` file with the parameters `PRIV_REQUIRES esp_ipc` or `REQUIRES esp_ipc` should be modified to simply remove these options as the `esp_system` component is included by default.

ESP Clock  The ESP Clock API (functions/types/macros prefixed with `esp_clk`) has been made into a private API. Thus, the previous include paths `#include "ESP32/clk.h"` and `#include "esp_clk.h"` have been removed. If users still require usage of the ESP Clock API (though this is not recommended), it can be included via `#include "esp_private/esp_clk.h"`.

**Note:** Private APIs are not stable and are no longer subject to the ESP-IDF versioning scheme’s breaking change rules. Thus, it is not recommended for users to continue calling private APIs in their applications.

Cache Error Interrupt  The Cache Error Interrupt API (functions/types/macros prefixed with `esp_cache_err`) has been made into a private API. Thus, the previous include path `#include "ESP32/cache_err_int.h"` has been removed. If users still require usage of the Cache Error Interrupt API (though this is not recommended), it can be included via `#include "esp_private/cache_err_int.h"`.

`bootloader_support`

- The function `bootloader_common_get_reset_reason()` has been removed. Please use the function `esp_rom_get_reset_reason()` in the ROM component.
The functions `esp_secure_boot_verify_sbv2_signature_block()` and `esp_secure_boot_verify_rsa_signature_block()` have been removed without replacement. We do not expect users to use these directly. If they are indeed still necessary, please open a feature request on GitHub explaining why these functions are necessary to you.

**Brownout** The Brownout API (functions/types/macros prefixed with `esp_brownout`) has been made into a private API. Thus, the previous include path `#include "brownout.h"` has been removed. If users still require usage of the Brownout API (though this is not recommended), it can be included via `#include "esp_private/brownout.h"`.

**Trax** The Trax API (functions/types/macros prefixed with `trax_`) has been made into a private API. Thus, the previous include path `#include "trax.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/trax.h"`.

**ROM** The previously deprecated ROM-related header files located in `components/esp32/rom/` (old include path: `rom/*.h`) have been moved. Please use the new target-specific path from `components/esp_rom/include/ESP32/` (new include path: `ESP32/rom/*.h`).

**esp_hw_support**

- The header files `soc/cpu.h` have been deleted and deprecated CPU util functions have been removed. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header files `hal/cpu_ll.h`, `hal/cpu_hal.h`, `hal/soc_ll.h`, `hal/soc_hal.h` and `interrupt_controller_hal.h` CPU API functions have been deprecated. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header file `compare_set.h` have been deleted. ESP-IDF developers should use `esp_cpu_compare_and_set()` function provided in `esp_cpu.h` instead.
- `esp_cpu_get_ccount()`, `esp_cpu_set_ccount()` and `esp_cpu_in_ocd_debug_mode()` were removed from `esp_cpu.h`. ESP-IDF developers should use respectively `esp_cpu_get_cycle_count()`, `esp_cpu_set_cycle_count()` and `esp_cpu_dbg_isAttached()` instead.
- The header file `esp_intr.h` has been deleted. Please include `esp_intr_alloc.h` to allocate and manipulate interrupts.
- The Panic API (functions/types/macros prefixed with `esp_panic`) has been made into a private API. Thus, the previous include path `#include "esp_panic.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/panic_reason.h"`. Besides, developers should include `esp_debug_helpers.h` instead to use any debug-related helper functions, e.g., print backtrace.
- The header file `soc_log.h` is now renamed to `esp_hw_log.h` and has been made private. Users are encouraged to use logging APIs provided under `esp_log.h` instead.
- The header files `spinlock.h`, `clk_ctrl_os.h`, and `rtc_wdt.h` must now be included without the `soc` prefix. For example, `#include "spinlock.h"`.
- `esp_chip_info()` returns the chip version in the format = 100 * major eFuse version + minor eFuse version. Thus, the revision in the `esp_chip_info_t` structure is expanded to `uint16_t` to fit the new format.

**PSRAM**

- The target-specific header file `spiram.h` and the header file `esp_spiram.h` have been removed. A new component `esp_psram` is created instead. For PSRAM/SPIRAM-related functions, users now include `esp_psram.h` and set the `esp_psram` component as a component requirement in their `CMakeLists.txt` project files.
- `esp_spiram_get_chip_size` and `esp_spiram_get_size` have been deleted. You should use `esp_psram_get_size` instead.
eFuse

- The parameter type of function `esp_secure_boot_read_key_digests()` changed from `ets_secure_boot_key_digests_t*` to `esp_secure_boot_key_digests_t*`. The new type is the same as the old one, except that the `allow_key_revoke` flag has been removed. The latter was always set to `true` in current code, not providing additional information.
- Added eFuse wafer revisions: major and minor. The `esp_efuse_get_chip_ver()` API is not compatible with these changes, so it was removed. Instead, please use the following APIs: `efuse_hal_get_major_chip_version()`, `efuse_hal_get_minor_chip_version()` or `efuse_hal_chip_revision()`.

`esp_common` `EXT_RAM_ATTR` is deprecated. Use the new macro `EXT_RAM_BSS_ATTR` to put `.bss` on PSRAM.

`esp_system`

- The header files `esp_random.h`, `esp_mac.h`, and `esp_chip_info.h`, which were all previously indirectly included via the header file `esp_system.h`, must now be included directly. These indirect inclusions from `esp_system.h` have been removed.
- The Backtrace Parser API (functions/types/macros prefixed with `esp_eh_frame_`) has been made into a private API. Thus, the previous include path `#include "eh_frame_parser.h"` has been removed. If users still require usage of the Backtrace Parser API (though this is not recommended), it can be included via `#include "esp_private/eh_frame_parser.h"`.
- The Interrupt Watchdog API (functions/types/macros prefixed with `esp_int_wdt_`) has been made into a private API. Thus, the previous include path `#include "esp_int_wdt.h"` has been removed. If users still require usage of the Interrupt Watchdog API (though this is not recommended), it can be included via `#include "esp_private/esp_int_wdt.h"`.

SoC Dependency

- Public API headers listed in the Doxyfiles will not expose unstable and unnecessary SoC header files, such as `soc/soc.h` and `soc/rtc.h`. That means the user has to explicitly include them in their code if these “missing” header files are still wanted.
- Kconfig option `LEGACY_INCLUDE_COMMON_HEADERS` is also removed.
- The header file `soc/soc_memory_types.h` has been deprecated. Users should use the `esp_memory_utils.h` instead. Including `soc/soc_memory_types.h` will bring a build warning like `soc_memory_types.h` is deprecated, please migrate to `esp_memory_utils.h`.

APP Trace One of the timestamp sources has changed from the legacy timer group driver to the new `GPTimer`. Kconfig choices like `APPTRACE_SV_TS_SOURCE_TIMER00` has been changed to `APPTRACE_SV_TS_SOURCE_GPTIMER`. User no longer need to choose the group and timer ID.

`esp_timer` The FRC2-based legacy implementation of `esp_timer` available on ESP32 has been removed. The simpler and more efficient implementation based on the LAC timer is now the only option.

ESP Image The image SPI speed enum definitions have been renamed.

- Enum `ESP_IMAGE_SPI_SPEED_80M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_1`.
- Enum `ESP_IMAGE_SPI_SPEED_40M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_2`.
- Enum `ESP_IMAGE_SPI_SPEED_26M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_3`.
- Enum `ESP_IMAGE_SPI_SPEED_20M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_4`.
Task Watchdog Timers

- The API for `esp_task_wdt_init()` has changed as follows:
  - Configuration is now passed as a configuration structure.
  - The function will now handle subscribing of the idle tasks if configured to do so.
- The former `CONFIG_ESP_TASK_WDT` configuration option has been renamed to `CONFIG_ESP_TASK_WDT_INIT` and a new `CONFIG_ESP_TASK_WDT_EN` option has been introduced.

FreeRTOS

Legacy API and Data Types

Previously, the configENABLE_BACKWARD_COMPATIBILITY option was set by default, thus allowing pre FreeRTOS v8.0.0 function names and data types to be used. The configENABLE_BACKWARD_COMPATIBILITY is now disabled by default, thus legacy FreeRTOS names/types are no longer supported by default. Users should do one of the followings:

- Update their code to remove usage of legacy FreeRTOS names/types.
- Enable the `CONFIG_FREERTOS_ENABLE_BACKWARD_COMPATIBILITY` to explicitly allow the usage of legacy names/types.

Tasks Snapshot

The header `task_snapshot.h` has been removed from `freertos/task.h`. ESP-IDF developers should include `freertos/task_snapshot.h` if they need tasks snapshot API.

The function `vTaskGetSnapshot()` now returns `BaseType_t`. Return value shall be `pdTRUE` on success and `pdFALSE` otherwise.

FreeRTOS Asserts

Previously, FreeRTOS asserts were configured separately from the rest of the system using the `FREERTOS_ASSERT` kconfig option. This option has now been removed and the configuration is now done through `COMPILER_OPTIMIZATION_ASSERTION_LEVEL`.

Port Macro API

The file `portmacro_deprecated.h` which was added to maintain backward compatibility for deprecated APIs is removed. Users are advised to use the alternate functions for the deprecated APIs as listed below:

- `portENTER_CRITICAL_NESTED()` is removed. Users should use the `portSET_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `portEXIT_CRITICAL_NESTED()` is removed. Users should use the `portCLEAR_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `vPortCPUInitializeMutex()` is removed. Users should use the `spinlock_initialize()` function instead.
- `vPortCPUAcquireMutex()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUAcquireMutexTimeout()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUReleaseMutex()` is removed. Users should use the `spinlock_release()` function instead.

App Update

- The functions `esp_ota_get_app_description()` and `esp_ota_get_app_elf_sha256()` have been termed as deprecated. Please use the alternative functions `esp_app_get_description()` and `esp_app_get_elf_sha256()` respectively. These functions have now been moved to a new component `esp_app_format`. Please refer to the header file `esp_app_desc.h`.
Chapter 6. Migration Guides

Bootloader Support

- The `esp_app_desc_t` structure, which used to be declared in `esp_app_format.h`, is now declared in `esp_app_desc.h`.
- The function `bootloader_common_get_partition_description()` has now been made private. Please use the alternative function `esp_ota_get_partition_description()`. Note that this function takes `esp_partition_t` as its first argument instead of `esp_partition_pos_t`.

Chip Revision  The bootloader checks the chip revision at the beginning of the application loading. The application can only be loaded if the version is $\geq$ `CONFIG_ESP32_REV_MIN` and $<\text{CONFIG_ESP32_REV_MAX_FULL}`.

During the OTA upgrade, the version requirements and chip revision in the application header are checked for compatibility. The application can only be updated if the version is $\geq$ `CONFIG_ESP32_REV_MIN` and $<\text{CONFIG_ESP32_REV_MAX_FULL}`.

Tools

ESP-IDF Monitor  ESP-IDF Monitor makes the following changes regarding baud-rate:

- ESP-IDF monitor now uses the custom console baud-rate (`CONFIG_ESP_CONSOLE_UART_BAUDRATE`) by default instead of 115200.
- Setting a custom baud from menuconfig is no longer supported.
- A custom baud-rate can be specified from command line with the `idf.py monitor -b <baud>` command or through setting environment variables.
- Please note that the baud-rate argument has been renamed from `-B` to `-b` in order to be consistent with the global baud-rate `idf.py -b <baud>`. Run `idf.py monitor --help` for more information.

Deprecated Commands  `idf.py` sub-commands and `cmake` target names have been unified to use hyphens (`-`) instead of underscores (`_`). Using a deprecated sub-command or target name will produce a warning. Users are advised to migrate to using the new sub-commands and target names. The following changes have been made:

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>efuse_common_table</td>
<td>efuse-common-table</td>
</tr>
<tr>

</tr>
</tbody>
</table>

Esptool  The `CONFIG_ESPTOOLPY_FLASHSIZE_DETECT` option has been renamed to `CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE` and has been disabled by default. New and existing projects migrated to ESP-IDF v5.0 have to set `CONFIG_ESPTOOLPY_FLASHSIZE`. If this is not possible due to an unknown flash size at build time, then `CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE` can be enabled. However, once enabled, to keep the digest valid, an SHA256 digest is no longer appended to the image when updating the binary header with the flash size during flashing.
Windows Environment  The Msys/Mingw-based Windows environment support got deprecated in ESP-IDF v4.0 and was entirely removed in v5.0. Please use ESP-IDF Tools Installer to set up a compatible environment. The options include Windows Command Line, Power Shell and the graphical user interface based on Eclipse IDE. In addition, a VS Code-based environment can be set up with the supported plugin: https://github.com/espressif/vscode-esp-idf-extension.

6.1.2 Migration from 5.0 to 5.1

GCC

GCC Version  The previous GCC version was GCC 11.2.0. This has now been upgraded to GCC 12.2.0 on all targets. Users that need to port their code from GCC 11.2.0 to 12.2.0 should refer to the series of official GCC porting guides listed below:

• Porting to GCC 12

Warnings  The upgrade to GCC 12.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user’s code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter and ways to fix them.

-Wuse-after-free  Typically, this warning should not produce false-positives for release-level code. But this may appear in test cases. There is an example of how it was fixed in ESP-IDF’s test_realloc.c.

```c
void *x = malloc(64);
void *y = realloc(x, 48);
TEST_ASSERT_EQUAL_PTR(x, y);
```

Pointers may be converted to int to avoid warning -Wuse-after-free.

```c
int x = (int) malloc(64);
int y = (int) realloc((void *) x, 48);
TEST_ASSERT_EQUAL_UINT32((uint32_t) x, (uint32_t) y);
```

-Waddress  GCC 12.2.0 introduces an enhanced version of the -Waddress warning option, which is now more eager in detecting the checking of pointers to an array in if-statements.

The following code triggers the warning:

```c
char array[8];
...
if (array)
    memset(array, 0xff, sizeof(array));
```

Eliminating unnecessary checks resolves the warning.

```c
char array[8];
...
memset(array, 0xff, sizeof(array));
```
**RISC-V Builds Outside of ESP-IDF** The RISC-V extensions `zicsr` and `zifencei` have been separated from the `I` extension. GCC 12 reflects this change, and as a result, when building for RISC-V ESP32 chips outside of the ESP-IDF framework, you must include the `_zicsr_zifencei` postfix when specifying the `-march` option in your build system.

Example:

```
riscv32-esp-elf-gcc main.c -march=rv32imac
```

Now is replaced with:

```
riscv32-esp-elf-gcc main.c -march=rv32imac_zicsr_zifencei
```

**Peripherals**

**DAC** DAC driver has been redesigned (see `DAC API Reference`), which aims to unify the interface and extend the usage of DAC peripheral. Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/dac.h`. However, by default, including `driver/dac.h` will bring a build warning like `The legacy DAC driver is deprecated, please use 'driver/dac_oneshot.h', 'driver/dac_cosine.h' or 'driver/dac_continuous.h' instead. The warning can be suppressed by the Kconfig option `CONFIG_DAC_SUPPRESS_DEPRECATED_WARN`. The major breaking changes in concept and usage are listed as follows:

**Breaking Changes in Concepts**
- `dac_channel_t` which was used to identify the hardware channel are removed from user space. The channel index now starts from 0, so please use `DAC_CHAN_0` and `DAC_CHAN_1` instead. And in the new driver, DAC channels can be selected by using `dac_channel_mask_t`. And these channels can be allocated in a same channel group which is represented by `dac_channels_handle_t`.
- `dac_cw_scale_t` is replaced by `dac_cosine_atten_t` to decouple the legacy driver and the new driver.
- `dac_cw_phase_t` is replaced by `dac_cosine_phase_t`. The enumerate value is now the phase angle directly.
- `dac_cw_config_t` is replaced by `dac_cosine_config_t`, but the `en_ch` field is removed because it should be specified while allocating the channel group.

**Breaking Changes in Usage**
- `dac_pad_get_io_num` is removed.
- `dac_output_voltage` is replaced by `dac_oneshot_output_voltage()`.
- `dac_output_enable` is removed. For oneshot mode, it will be enabled after the channel is allocated.
- `dac_output_disable` is removed. For oneshot mode, it will be disabled before the channel is deleted.
- `dac_cw_generator_enable` is replaced by `dac_cosine_start()`.
- `dac_cw_generator_disable` is replaced by `dac_cosine_stop()`.
- `dac_cw_generator_config` is replaced by `dac_cosine_new_channel()`.
- `dac_i2s_enable` is replaced by `dac_continuous_enable()`, but it needs to allocate the continuous DAC channel first by `dac_continuous_new_channels()`.
- `dac_i2s_disable` is replaced by `dac_continuous_disable()`.

**GPSPI** Following items are deprecated. Since ESP-IDF v5.1, GPSPI clock source is configurable.
- `spi_get_actual_clock` is deprecated, you should use `spi_device_get_actual_freq()` instead.
LEDC

- `soc_periph_ledc_clk_src_legacy_t::LEDC_USE_RTC8M_CLK` is deprecated. Please use `LEDC_USE_RC_FAST_CLK` instead.

Storage

**FatFs** `esp_vfs_fat_sdmmcUnmount()` is now deprecated, and you can use `esp_vfs_fat_sdcardUnmount()` instead. This API is deprecated in previous ESP-IDF versions, but without a deprecation warning or migration guide. Since ESP-IDF v5.1, calling this `esp_vfs_fat_sdmmcUnmount()` API will generate a deprecation warning.

**SPI_FLASH**

- `spi_flash_get_counters()` is deprecated, please use `esp_flash_get_counters()` instead.
- `spi_flash_dump_counters()` is deprecated, please use `esp_flash_dump_counters()` instead.
- `spi_flash_reset_counters()` is deprecated, please use `esp_flash_reset_counters()` instead.

Networking

**SNTP** SNTP module now provides thread safe APIs to access lwIP functionality. It is recommended to use `ESP_NETIF` API. Please refer to the chapter `SNTP API` for more details.

System

FreeRTOS

**Dynamic Memory Allocation**

In the past, FreeRTOS commonly utilized the function `malloc()` to allocate dynamic memory. As a result, if an application allowed `malloc()` to allocate memory from external RAM (by configuring the `CONFIG_SPIRAM_USE` option as `CONFIG_SPIRAM_USE_MALLOC`), FreeRTOS had the potential to allocate dynamic memory from external RAM, and the specific location was determined by the heap allocator.

**Note:** Dynamic memory allocation for tasks (which are likely to consume the most memory) were an exception to the scenario above. FreeRTOS would use a separate memory allocation function to guarantee that dynamic memory allocate for a task was always placed in internal RAM.

Allowing FreeRTOS objects (such as queues and semaphores) to be placed in external RAM becomes an issue if those objects are accessed while the cache is disabled (such as during SPI flash write operations) and would lead to a cache access errors (see `Fatal Errors` for more details).
Therefore, FreeRTOS has been updated to always use internal memory (i.e., DRAM) for dynamic memory allocation. Calling FreeRTOS creation functions (e.g., `xTaskCreate()`, `xQueueCreate()`) guarantees that the memory allocated for those tasks/objects is from internal memory (see FreeRTOS Heap for more details).

**Warning:** If you previously relied on `CONFIG_SPIRAM_USE` to place FreeRTOS objects into external memory, this change will lead to increased usage of internal memory due the FreeRTOS objects now being allocated there.

To place a FreeRTOS task/object into external memory, it is now necessary to do so explicitly. The following methods can be employed:

- Allocate the task/object using one of the `...CreateWithCaps()` API such as `xTaskCreateWithCaps()` and `xQueueCreateWithCaps()` (see IDF Additional API for more details).
- Manually allocate external memory for those objects using `heap_caps_malloc()`, then create the objects from the allocated memory using one of the `...CreateStatic()` FreeRTOS functions.

**Power Management**

- `esp_pm_config_esp32xx_t` is deprecated, use `esp_pm_config_t` instead.
- `esp32xx/pm.h` is deprecated, use `esp.pm.h` instead.

### 6.1.3 Migration from 5.1 to 5.2

**GCC**

**GCC Version** The previous GCC version was GCC 12.2.0. This has now been upgraded to GCC 13.2.0 on all targets. Users that need to port their code from GCC 12.2.0 to 13.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 13

**Common Porting Problems and Fixes**

**stdio.h No Longer Includes sys/types.h**

**Issue** Compilation errors may occur in code that previously worked with the old toolchain. For example:

```
#include <stdio.h>
clock_t var; // error: expected specifier-qualifier-list before 'clock_t'
```

**Solution** To resolve this issue, the correct header must be included. Refactor the code like this:

```
#include <time.h>
clock_t var;
```

**Peripherals**
UART

- UART_FIFO_LEN is deprecated. Please use UART_HW_FIFO_LEN instead.

I2C

I2C driver has been redesigned (see I2C API Reference), which aims to unify the interface and extend the usage of I2C peripheral. Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path driver/i2c.h.

The major breaking changes in concept and usage are listed as follows:

**Major Changes in Concepts**

- i2c_config_t which was used to configure the I2C bus, but it doesn’t really tell whether to configure master or slave. So in the new design, master and slave initialization are separate, user can call i2c_master_bus_config_t or i2c_slave_config_t.
- i2c_mode_t which was used to tell whether I2C controller works in slave mode or master mode. This enumerator has been deprecated. In the new driver, users don’t need to manually set the mode anymore since master and slave APIs are different.
- i2c_rw_t which was used to tell whether I2C master controller is performing a write or a read operation. This is now deprecated.
- i2c_addr_mode_t was renamed to i2c_addr_bit_len_t.
- In the legacy driver, operations needed to be chained with a command list (dynamically or statically created). The new driver now handles this internally, making the operations more size and space efficient.
- Capability flags like I2C_SCLK_SRC_FLAG_FOR_NORMAL are used to select clock source in the legacy driver. In the new driver, users can select clock source directly.

**Major Changes in Usage**

- I2C bus initialization is done in two parts: first, initialization of the bus with i2c_new_master_bus(), then, initialization of the I2C device with i2c_master_bus_add_device().
- i2c_reset_tx_fifo and i2c_reset_rx_fifo have been removed, since it is never required to reset the fifo by users. Whole bus can still be reset by calling i2c_master_bus_reset.
- i2c_cmd_link_xxx functions have been removed, user doesn’t need to use link to link commands on its own.
- i2c_master_write_to_device has been renamed to i2c_master_transmit.
- i2c_master_read_from_device has been renamed to i2c_master_receive.
- i2c_master_write_read_device has been renamed to i2c_master_transmit_receive
- i2c_slave_write_buffer has been renamed to i2c_slave_transmit
- i2c_slave_read_buffer has been renamed to i2c_slave_receive

**Protocols**

CoAP  CoAP examples have been moved to idf-extra-components repository.

HTTP2  http2_request example has been moved to idf-extra-components repository.

System

FreeRTOS
**Task Snapshot**  The Task Snapshot API has been made private due to a lack of a practical way for the API to be used from user code (the scheduler must be halted before the API can be called).

As a result, the `#include "freertos/task_snapshot.h"` include path has been deprecated.

**WiFi**

**WiFi Enterprise Security**  APIs defined in `esp_wpa2.h` have been deprecated. Please use newer APIs from `esp_eap_client.h`.

### 6.1.4 Migration from 5.2 to 5.3

**Peripherals**

In order to control the dependence of other components on drivers at a smaller granularity, the original peripheral drivers under the `driver` component were split into separate components:

- `esp_driver_gptimer` - Driver for general purpose timers
- `esp_driver_pcnt` - Driver for pulse counter
- `esp_driver_gpio` - Driver for GPIO

For compatibility, the original `driver` component is still treated as an all-in-one component by registering these `esp_driver_xyz` components as its public dependencies. In other words, you do not need to modify the CMake file of an existing project, but you now have a way to specify the specific peripheral driver that your project depends on.

Originally, you may have used `linker.lf` to specify the link location of some driver functions in memory space, but now, because the location of the driver files have been moved, you need to make changes your `linker.lf` file accordingly. For example, a `linker.lf` file with the following entries:

```
[mapping:my_mapping_scheme]
archive: libdriver.a
entries:
gpio (noflash)
```

Should be changed to:

```
[mapping:my_mapping_scheme]
archive: libesp_driver_gpio.a
entries:
gpio (noflash)
```
Chapter 7

Libraries and Frameworks

7.1 Cloud Frameworks

ESP32 supports multiple cloud frameworks using agents built on top of ESP-IDF. Here are the pointers to various supported cloud frameworks’ agents and examples:

7.1.1 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. ESP RainMaker on GitHub.

7.1.2 AWS IoT

https://github.com/espressif/esp-aws-iot is an open source repository for ESP32 based on Amazon Web Services’ aws-iot-device-sdk-embedded-C.

7.1.3 Azure IoT

https://github.com/espressif/esp-azure is an open source repository for ESP32 based on Microsoft Azure’s azure-iot-sdk-c SDK.

7.1.4 Google IoT Core

https://github.com/espressif/esp-google-iot is an open source repository for ESP32 based on Google’s iot-device-sdk-embedded-c SDK.

7.1.5 Aliyun IoT

https://github.com/espressif/esp-aliyun is an open source repository for ESP32 based on Aliyun’s iotkit-embedded SDK.

7.1.6 Joylink IoT

https://github.com/espressif/esp-joylink is an open source repository for ESP32 based on Joylink’s joylink_dev_sdk SDK.
7.1.7 Tencent IoT

https://github.com/espressif/esp-welink is an open source repository for ESP32 based on Tencent’s welink SDK.

7.1.8 Tencent IoT

https://github.com/espressif/esp-qcloud is an open source repository for ESP32 based on Tencent’s qcloud-iot-sdk-embedded-c SDK.

7.1.9 Baidu IoT

https://github.com/espressif/esp-baidu-iot is an open source repository for ESP32 based on Baidu’s iot-sdk-c SDK.

7.2 Espressif’s Frameworks

Here you will find a collection of the official Espressif libraries and frameworks.

7.2.1 Espressif Audio Development Framework

The ESP-ADF is a comprehensive framework for audio applications including:

- CODEC’s HAL
- Music players and recorders
- Audio processing
- Bluetooth speakers
- Internet radios
- Hands-free devices
- Speech decognition

This framework is available on GitHub: ESP-ADF.

7.2.2 ESP-CSI

ESP-CSI is an experimental implementation that uses the Wi-Fi Channel State Information to detect the presence of a human body.

See the ESP-CSI project for more information.

7.2.3 Espressif DSP Library

The library provides algorithms optimized specifically for digital signal processing applications. This library supports:

- Matrix multiplication
- Dot product
- FFT (Fast Fourier Transform)
- IIR (Infinite Impulse Response)
- FIR (Finite Impulse Response)
- Vector math operations

This library is available on Github: ESP-DSP library.
7.2.4 ESP-WIFI-MESH Development Framework

This framework is based on the ESP-WIFI-MESH protocol with the following features:

- Fast network configuration
- Stable upgrade
- Efficient debugging
- LAN control
- Various application demos

This framework is available on Github: ESP-MDF.

7.2.5 ESP-WHO

The ESP-WHO is a face detection and recognition framework using the ESP32 and camera.

This framework is available on Github: ESP-WHO.

7.2.6 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. Using ESP RainMaker, you can create AIoT devices from the firmware to the integration with voice-assistant, phone apps and cloud backend.

This project is available on Github: ESP RainMaker on GitHub.

7.2.7 ESP-IoT-Solution

ESP-IoT-Solution contains commonly used device drivers and code frameworks when developing IoT systems. The device drivers and code frameworks within the ESP-IoT-Solution are organized as separate components, allowing them to be easily integrated into an ESP-IDF project.

ESP-IoT-Solution includes:

- Device drivers for sensors, display, audio, GUI, input, actuators, etc.
- Framework and documentation for low power, security, storage, etc.
- Guide for Espressif open source solutions from practical application point.

This solution is available on Github: ESP-IoT-Solution on GitHub.

7.2.8 ESP-Protocols

The ESP-Protocols repository contains a collection of protocol components for ESP-IDF. The code within ESP-Protocols is organized into separate components, allowing them to be easily integrated into an ESP-IDF project. Additionally, each component is available in IDF Component Registry.

ESP-Protocols components:

- esp_modem enables connectivity with GSM/LTE modems using AT commands or PPP protocol. See the esp_modem documentation.
- mdns (mDNS) is a multicast UDP service that is used to provide local network service and host discovery. See the mdns documentation.
- esp_websocket_client is a managed component for ESP-IDF that contains implementation of WebSocket protocol client for ESP32. See the esp_websocket_client documentation. For details of WebSocket protocol client, see WebSocket_protocol_client.
- asio is a cross-platform C++ library, see https://think-async.com/Asio/. It provides a consistent asynchronous model using a modern C++ approach. See the asio documentation.
7.2.9 ESP-BSP

The ESP-BSP repository contains Board Support Packages (BSPs) for various Espressif’s and third-party development boards. BSPs help to quickly get started with a supported board. Usually they contain pinout definition and helper functions that will initialize peripherals for the specific board. Additionally, the BSPs contain drivers for external chips populated on the development board, such as sensors, displays, audio codecs, etc.

7.2.10 ESP-IDF-CXX

ESP-IDF-CXX contains C++ wrappers for part of ESP-IDF. The focuses are on ease of use, safety, automatic resource management. They also move error checking from runtime to compile time to prevent running failure. There are C++ classes for ESP-Timer, I2C, SPI, GPIO and other peripherals or features of ESP-IDF. ESP-IDF-CXX is available as a component from the component registry. Please check the project’s README.md for more information.
Chapter 8

Contributions Guide

We welcome contributions to the ESP-IDF project!

8.1 How to Contribute

Contributions to ESP-IDF - fixing bugs, adding features, adding documentation - are welcome. We accept contributions via Github Pull Requests.

8.2 Before Contributing

Before sending us a Pull Request, please consider this list of points:

- Is the contribution entirely your own work, or already licensed under an Apache License 2.0 compatible Open Source License? If not then we unfortunately cannot accept it. Please check the Copyright Header Guide for additional information.
- Does any new code conform to the ESP-IDF Style Guide?
- Have you installed the pre-commit hook for ESP-IDF project?
- Does the code documentation follow requirements in Documenting Code?
- Is the code adequately commented for people to understand how it is structured?
- Is there documentation or examples that go with code contributions? There are additional suggestions for writing good examples in examples readme.
- Are comments and documentation written in clear English, with no spelling or grammar errors?
- Example contributions are also welcome. Please check the Creating Examples guide for these.
- If the contribution contains multiple commits, are they grouped together into logical changes (one major change per pull request)? Are any commits with names like “fixed typo” squashed into previous commits?
- If you are unsure about any of these points, please open the Pull Request anyhow and then ask us for feedback.

8.3 Pull Request Process

After you open the Pull Request, there will probably be some discussion in the comments field of the request itself. Once the Pull Request is ready to merge, it will first be merged into our internal git system for in-house automated testing.

If this process passes, it will be merged into the public GitHub repository.
8.4 Legal Part

Before a contribution can be accepted, you will need to sign our *Contributor Agreement*. You will be prompted for this automatically as part of the Pull Request process.

8.5 Related Documents

8.5.1 Espressif IoT Development Framework Style Guide

About This Guide

Purpose of this style guide is to encourage use of common coding practices within the ESP-IDF.

Style guide is a set of rules which are aimed to help create readable, maintainable, and robust code. By writing code which looks the same way across the code base we help others read and comprehend the code. By using same conventions for spaces and newlines we reduce chances that future changes will produce huge unreadable diffs. By following common patterns for module structure and by using language features consistently we help others understand code behavior.

We try to keep rules simple enough, which means that they can not cover all potential cases. In some cases one has to bend these simple rules to achieve readability, maintainability, or robustness.

When doing modifications to third-party code used in ESP-IDF, follow the way that particular project is written. That will help propose useful changes for merging into upstream project.

C Code Formatting

Naming

- Any variable or function which is only used in a single source file should be declared `static`.
- Public names (non-static variables and functions) should be namespaced with a per-component or per-unit prefix, to avoid naming collisions. ie `esp_vfs_register()` or `esp_console_run()`. Starting the prefix with `esp_` for Espressif-specific names is optional, but should be consistent with any other names in the same component.
- Static variables should be prefixed with `s_` for easy identification. For example, `static bool s_invert`.
- Avoid unnecessary abbreviations (ie shortening `data` to `dat`), unless the resulting name would otherwise be very long.

Indentation

Use 4 spaces for each indentation level. Do not use tabs for indentation. Configure the editor to emit 4 spaces each time you press tab key.

Vertical Space

Place one empty line between functions. Do not begin or end a function with an empty line.

```c
void function1()
{
    do_one_thing();
    do_another_thing();
} // INCORRECT, do not place empty line here

void function2()
{
    int var = 0;
    while (var < SOME_CONSTANT) {
        do_stuff(&var);
    } // INCORRECT, do not use an empty line here
```
The maximum line length is 120 characters as long as it does not seriously affect the readability.

**Horizontal Space** Always add single space after conditional and loop keywords:

```c
if (condition) { // correct
    // ...
}
switch (n) { // correct
    case 0:
        // ...
}
for (int i = 0; i < CONST; ++i) { // INCORRECT
    // ...
}
```

Add single space around binary operators. No space is necessary for unary operators. It is okay to drop space around multiply and divide operators:

```c
const int y = y0 + (x - x0) * (y1 - y0) / (x1 - x0); // correct
const int y = y0 + (x - x0) * (y1 - y0) / (x1 - x0); // also okay
int y_cur = -y;
++y_cur;
const int y = y0 + (x-x0) * (y1-y0) / (x1-x0); // INCORRECT
```

No space is necessary around . and -> operators.

Sometimes adding horizontal space within a line can help make code more readable. For example, you can add space to align function arguments:

```c
esp_rom_gpio_connect_in_signal(PIN_CAM_D6, I2S0I_DATA_IN14_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_D7, I2S0I_DATA_IN15_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_HREF, I2S0I_H_ENABLE_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_PCLK, I2S0I_DATA_IN15_IDX, false);
```

Note however that if someone goes to add new line with a longer identifier as first argument (e.g., PIN_CAM_VSYNC), it will not fit. So other lines would have to be realigned, adding meaningless changes to the commit.

Therefore, use horizontal alignment sparingly, especially if you expect new lines to be added to the list later.

Never use TAB characters for horizontal alignment.

Never add trailing whitespace at the end of the line.

**Braces**

- Function definition should have a brace on a separate line:

```
// This is correct:
void function(int arg)
{
}
```
• Within a function, place opening brace on the same line with conditional and loop statements:

```c
if (condition) {
    do_one();
} else if (other_condition) {
    do_two();
}
```

**Comments**  Use `//` for single line comments. For multi-line comments it is okay to use either `//` on each line or a `/* */` block.

Although not directly related to formatting, here are a few notes about using comments effectively.

• Do not use single comments to disable some functionality:

```c
void init_something()
{
    setup_dma();
    // load_resources();  // WHY is this thing commented, asks the reader?
    start_timer();
}
```

• If some code is no longer required, remove it completely. If you need it you can always look it up in git history of this file. If you disable some call because of temporary reasons, with an intention to restore it in the future, add explanation on the adjacent line:

```c
void init_something()
{
    setup_dma();
    // TODO: we should load resources here, but loader is not fully integrated yet.
    // load_resources();
    start_timer();
}
```

• Same goes for `#if 0 ... #endif` blocks. Remove code block completely if it is not used. Otherwise, add comment explaining why the block is disabled. Do not use `#if 0 ... #endif` or comments to store code snippets which you may need in the future.

• Do not add trivial comments about authorship and change date. You can always look up who modified any given line using git. E.g., this comment adds clutter to the code without adding any useful information:

```c
void init_something()
{
    setup_dma();
    // XXX add 2016-09-01
    init_dma_list();
    fill_dma_item(0);
    // end XXX add
    start_timer();
}
```

**Line Endings**  Commits should only contain files with LF (Unix style) endings.

Windows users can configure git to check out CRLF (Windows style) endings locally and commit LF endings by setting the `core.autocrlf` setting. *Github has a document about setting this option* <github-line-endings>.
If you accidentally have some commits in your branch that add LF endings, you can convert them to Unix by running this command in an MSYS2 or Unix terminal (change directory to the IDF working directory and check the correct branch is currently checked out, beforehand):

```
git rebase --exec 'git diff-tree --no-commit-id --name-only -r HEAD | xargs --dos2unix && git commit -a --amend --no-edit --allow-empty' master
```

(Note that this line rebases on master, change the branch name at the end to rebase on another branch.)

For updating a single commit, it is possible to run `dos2unix FILENAME` and then run `git commit --amend`

**Formatting Your Code**

ESP-IDF uses Astyle to format source code. The configuration is stored in `tools/ci/astyle-rules.yml` file.

Initially, all components are excluded from formatting checks. You can enable formatting checks for the component by removing it from `components_not_formatted_temporary` list. Then run:

```
pre-commit run --files <path_to_files> astyle_py
```

Alternatively, you can run `astyle_py` manually. You can install it with `pip install astyle_py==VERSION`. Make sure you have the same version installed as the one specified in `.pre-commit-config.yaml` file. With `astyle_py` installed, run:

```
astyle_py --rules=$IDF_PATH/tools/ci/astyle-rules.yml <path-to-file>
```

**Type Definitions**

Should be snake_case, ending with _t suffix:

```c
typedef int signed_32_bit_t;
```

**Enum**

 Enums should be defined through the `typedef` and be namespaced:

```c
typedef enum
{
    MODULE_FOO_ONE,
    MODULE_FOO_TWO,
    MODULE_FOO_THREE
} module_foo_t;
```

**Assertions**

The standard C `assert()` function, defined in `assert.h` should be used to check conditions that should be true in source code. In the default configuration, an assert condition that returns `false` or `0` will call `abort()` and trigger a **Fatal Error**.

`assert()` should only be used to detect unrecoverable errors due to a serious internal logic bug or corruption, where it is not possible for the program to continue. For recoverable errors, including errors that are possible due to invalid external input, an **error value should be returned**.

**Note:** When asserting a value of type `esp_err_t`` is equal to ``ESP_OK, use the `ESP_ERROR_CHECK` Macro instead of an `assert()`.

It is possible to configure ESP-IDF projects with assertions disabled (see `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL`). Therefore, functions called in an `assert()` statement should not have side-effects.

It is also necessary to use particular techniques to avoid “variable set but not used” warnings when assertions are disabled, due to code patterns such as:
int res = do_something();
assert(res == 0);

Once the `assert` is optimized out, the `res` value is unused and the compiler will warn about this. However the function `do_something()` must still be called, even if assertions are disabled.

When the variable is declared and initialized in a single statement, a good strategy is to cast it to `void` on a new line. The compiler will not produce a warning, and the variable can still be optimized out of the final binary:

```c
int res = do_something();
assert(res == 0);
(void)res;
```

If the variable is declared separately, for example if it is used for multiple assertions, then it can be declared with the GCC attribute `__attribute__((unused))`. The compiler will not produce any unused variable warnings, but the variable can still be optimized out:

```c
int res __attribute__((unused));
res = do_something();
assert(res == 0);
res = do_something_else();
assert(res != 0);
```

**Header File Guards**

All public facing header files should have preprocessor guards. A pragma is preferred:

```c
#pragma once
```

over the following pattern:

```c
#ifndef FILE_NAME_H
#define FILE_NAME_H
...
#endif // FILE_NAME_H
```

In addition to guard macros, all C header files should have `extern "C"` guards to allow the header to be used from C++ code. Note that the following order should be used: `pragma once`, then any `#include` statements, then `extern "C"` guards:

```c
#pragma once
#include <stdint.h>
#ifndef __cplusplus
.extern "C" {
#endif
/* declarations go here */
#endif
```

**Include Statements**

When writing `#include` statements, try to maintain the following order:
• C standard library headers.
• Other POSIX standard headers and common extensions to them (such as `sys/queue.h`).
• Common IDF headers (`esp_log.h, esp_system.h, esp_timer.h, esp_sleep.h, etc.`)
• Headers of other components, such as FreeRTOS.
• Public headers of the current component.
• Private headers.

Use angle brackets for C standard library headers and other POSIX headers (`#include <stdio.h>`).
Use double quotes for all other headers (`#include "esp_log.h"`).

**C++ Code Formatting**

The same rules as for C apply. Where they are not enough, apply the following rules.

**File Naming**  
C++ Header files have the extension `.hpp`. C++ source files have the extension `.cpp`. The latter is important for the compiler to distinguish them from normal C source files.

**Naming**  
- **Class and struct** names shall be written in CamelCase with a capital letter as beginning. Member variables and methods shall be in snake_case. An exception from CamelCase is if the readability is severely decreased, e.g., in `GPIOOutput`, then an underscore `_` is allowed to make it more readable: `GPIO_Output`.
- **Namespaces** shall be in lower snake_case.
- **Templates** are specified in the line above the function declaration.
- **Interfaces in terms of Object-Oriented Programming** shall be named without the suffix `...Interface`. Later, this makes it easier to extract interfaces from normal classes and vice versa without making a breaking change.

**Member Order in Classes**  
In order of precedence:

- First put the public members, then the protected, then private ones. Omit public, protected or private sections without any members.
- First put constructors/destructors, then member functions, then member variables.

For example:

```cpp
class ForExample {
public:
    // first constructors, then default constructor, then destructor
    ForExample(double example_factor_arg);
    ForExample();
    ~ForExample();

    // then remaining public methods
    set_example_factor(double example_factor_arg);

    // then public member variables
    uint32_t public_data_member;

private:
    // first private methods
    void internal_method();

    // then private member variables
    double example_factor;
};
```
Spacing

- Do not indent inside namespaces.
- Put `public`, `protected` and `private` labels at the same indentation level as the corresponding `class` label.

Simple Example

```cpp
// file spaceship.h
#ifndef SPACESHIP_H_
#define SPACESHIP_H_
#include <cstdlib>
namespace spaceships {
  class SpaceShip {
    public:
      SpaceShip(size_t crew);
      size_t get_crew_size() const;
    private:
      const size_t crew;
    }
  class SpaceShuttle : public SpaceShip {
    public:
      SpaceShuttle();
    }
  class Sojuz : public SpaceShip {
    public:
      Sojuz();
  }
  template<typename T>
  class CargoShip {
    public:
      CargoShip(const T &cargo);
    private:
      T cargo;
  }
} // namespace spaceships
#endif // SPACESHIP_H_

// file spaceship.cpp
#include "spaceship.h"
namespace spaceships {
  SpaceShip::SpaceShip(size_t crew) : crew(crew) { }
  size_t SpaceShip::get_crew_size() const
  { return crew; }
} (continues on next page)
```
SpaceShuttle::SpaceShuttle() : SpaceShip(7) {
    // doing further initialization
}

Sojuz::Sojuz() : SpaceShip(3) {
    // doing further initialization
}

template <typename T>
CargoShip<T>::CargoShip(const T &cargo) : cargo(cargo) {}

} // namespace spaceships

CMake Code Style

- Indent with four spaces.
- Maximum line length 120 characters. When splitting lines, try to focus on readability where possible (for example, by pairing up keyword/argument pairs on individual lines).
- Do not put anything in the optional parentheses after endforeach(), endif(), etc.
- Use lowercase (with underscores) for command, function, and macro names.
- For locally scoped variables, use lowercase (with underscores).
- For globally scoped variables, use uppercase (WITH_UNDERSCORES).
- Otherwise follow the defaults of the cmake-lint project.

Configuring the Code Style for a Project Using EditorConfig

EditorConfig helps developers define and maintain consistent coding styles between different editors and IDEs. The EditorConfig project consists of a file format for defining coding styles and a collection of text editor plugins that enable editors to read the file format and adhere to defined styles. EditorConfig files are easily readable and they work nicely with version control systems.

For more information, see EditorConfig Website.

Third Party Component Code Styles

ESP-IDF integrates a number of third party components where these components may have differing code styles.

FreeRTOS The code style adopted by FreeRTOS is described in the FreeRTOS style guide. Formatting of FreeRTOS source code is automated using Uncrustify, thus a copy of the FreeRTOS code style’s Uncrustify configuration (uncrustify.cfg) is stored within ESP-IDF FreeRTOS component.

If a FreeRTOS source file is modified, the updated file can be formatted again by following the steps below:

1. Ensure that Uncrustify (v0.69.0) is installed on your system
2. Run the following command on the update FreeRTOS source file (where source.c is the path to the source file that requires formatting).

```
uncrustify -c $IDF_PATH/components/freertos/FreeRTOS-Kernel/uncrustify.cfg --replace source.c --no-backup
```

Documenting Code

Please see the guide here: Documenting Code.
8.5.2 Install Pre-commit Hook for ESP-IDF Project

**Required Dependency**

Python 3.8.* or above. This is our recommended Python version for ESP-IDF developers.

If you still have Python versions not compatible, update your Python versions before installing the pre-commit hook.

**Install pre-commit**

Run `pip install pre-commit`

**Install pre-commit Hook**

1. Go to the ESP-IDF project directory.
2. Run `pre-commit install --allow-missing-config --t pre-commit --t commit-msg`. Install hook by this approach will let you commit successfully even in branches without the `.pre-commit-config.yaml`
3. pre-commit hook will run automatically when you are running `git commit` command

**Uninstall pre-commit Hook**

Run `pre-commit uninstall`

**What Is More?**

For detailed usage, please refer to the documentation of `pre-commit`.

**Common Problems For Windows Users**

/usr/bin/env: python: Permission denied.

   If you are in Git Bash, please check the python executable location by run `which python`.
   If the executable is under `~/AppData/Local/Microsoft/WindowsApps/`, then it is a link to Windows AppStore, not a real one.
   Please install Python manually and update this in your PATH environment variable.

Your USERPROFILE contains non-ASCII characters.

   `pre-commit` may fail when initializing an environment for a particular hook when the path of `pre-commit`'s cache contains non-ASCII characters. The solution is to set `PRE_COMMIT_HOME` to a path containing only standard characters before running pre-commit.
CMD: set PRE_COMMIT_HOME=C:\somepath\pre-commit
PowerShell: $Env:PRE_COMMIT_HOME = "C:\somepath\pre-commit"
git bash: export PRE_COMMIT_HOME="/c/somepath/pre-commit"

8.5.3 Documenting Code

The purpose of this description is to provide a quick summary of the documentation style used in `espressif/esp-idf` repository and how to add new documentation.

Introduction

When documenting code for this repository, please follow Doxygen style. You are doing it by inserting special commands, for instance `@param`, into standard comments blocks, for example:

```
/**
 * @param ratio this is oxygen to air ratio
 */
```

Doxygen can phrase the code, extract the commands together with subsequent text, and build documentation out of it.

Typical comment block, that contains documentation of a function, looks like below:

```
@brief disable GPIO wake-up function.
@param gpio_num: GPIO number
@return ESP_OK: success
```

Doxygen supports a couple of formatting styles. It also gives you great flexibility on the level of details to include in documentation. To get familiar with available features, please check data-rich and very well-organized Doxygen Manual.

Why We Need Doxygen?

The ultimate goal is to ensure that all the code is consistently documented, so we can use tools like Sphinx and Breathe to aid preparation and automatic updates of API documentation when the code changes.

With these tools, the above piece of code renders like below:
**Go for It!**

When writing code for this repository, please follow guidelines below:

1. Document all building blocks of code, including functions, structs, typedefs, enums, macros, etc. Provide enough information about purpose, functionality, and limitations of documented items, as you would like to see them documented when reading the code by others.

2. Documentation of function should describe what this function does. If it accepts input parameters and returns some value, all of them should be explained.

3. Do not add a data type before parameter or any other characters besides spaces. All spaces and line breaks are compressed into a single space. If you like to break a line, then break it twice.

4. If function has void input or does not return any value, then skip `@param` or `@return`.

---

```c
**/*
340 * @brief disable GPIO wake-up function.
341 * @param gpio_num: GPIO number
342 * @return ESP_OK: success ESP_ERR_INVALID_ARG: parameter error
343 * @esp_err gpio_wakeup_disable(gpio_num_t gpio_num);
345 */

esp_err gpio_wakeup_disable(gpio_num_t gpio_num)
{
    // Disable GPIO wake-up function.
    Return
    ESP_OK: success ESP_ERR_INVALID_ARG: parameter error
    Parameters
    • gpio_num -
    GPIO number
}
```
5. When documenting a `define` as well as members of a `struct` or `enum`, place specific comment like below after each member.

```c
/*!
 * typedef enum {
 *   NVS_READONLY, /* Read only */
 *   NVS_READONLYWRITE, /* Read and write */
 *   } nvs_open_mode;
 */
```

6. To provide well-formatted lists, break the line after command (like `@return` in the example below).

```c
/*
 * @return
 * - ESP_OK if erase operation was successful
 * - ESP_ERR_NVSD_INVALID_HANDLE if handle has been closed or is NULL
 * - ESP_ERR_NVSD_READONLY if handle was opened as read only
 * - ESP_ERR_NVSD_NOT_FOUND if the requested key does not exist
 * - other error codes from the underlying storage driver
 */
```

7. Overview of functionality of documented header file, or group of files that make a library, should be placed in a separate README.rst file of the same directory. If this directory contains header files for different APIs, then the file name should be apiname-readme.rst.

**Go One Extra Mile**

Here are a couple of tips on how you can make your documentation even better and more useful to the reader and writer.

When writing code, please follow the guidelines below:

1. Add code snippets to illustrate implementation. To do so, enclose snippet using `@code{c}` and `@endcode` commands.

```c
/*
 * @code{c}
 * // Example of using nvs_get_i32:
 * int32_t max_buffer_size = 4096; // default value
 * esp_err_t err = nvs_get_i32(my_handle, "max_buffer_size", &max_buffer_size);
 * assert(err == ESP_OK || err == ESP_ERR_NVSD_NOT_FOUND);
 * // if ESP_ERR_NVSD_NOT_FOUND was returned, max_buffer_size will still
 * // have its default value.
 */
```
The code snippet should be enclosed in a comment block of the function that it illustrates.

2. To highlight some important information use command `@attention` or `@note`.

```
* @attention
* 1. This API only impact WIFI_MODE_STA or WIFI_MODE_APSTA mode
* 2. If the ESP32 is connected to an AP, call esp_wifi_disconnect to disconnect.
```

Above example also shows how to use a numbered list.

3. To provide common description to a group of similar functions, enclose them using `/** @} */` markup commands.

```
/** @} */
/**
 * @brief common description of similar functions
 *
 */
void first_similar_function (void);
void second_similar_function (void);
/** @} */
```

For practical example see `nvs_flash/include/nvs.h`.

4. You may want to go even further and skip some code like repetitive defines or enumerations. In such case, enclose the code within `/** @cond */` and `/** @endcond */` commands. Example of such implementation is provided in `esp_driver_gpio/include/driver/gpio.h`.

5. Use markdown to make your documentation even more readable. You will add headers, links, tables and more.

```
```

**Note:** Code snippets, notes, links, etc., will not make it to the documentation, if not enclosed in a comment block associated with one of the documented objects.

6. Prepare one or more complete code examples together with description. Place description to a separate file `README.md` in specific folder of `examples` directory.

**Standardize Document Format**

When it comes to text, please follow guidelines below to provide well-formatted Markdown (.md) or reST (.rst) documents.

1. Please ensure that one paragraph is written in one line. Do not break lines like below. Breaking lines to enhance readability is only suitable for writing code. To make the text easier to read, it is recommended to place an empty line to separate the paragraph.

2. Please make the line number of CN and EN documents consistent like below. The benefit of this approach is that it can save time for both writers and translators. When non-bilingual writers need to update text, they only need to update the same line in the corresponding CN or EN document. For translators, if documents are updated in English, then translators can quickly locate where to update in the corresponding CN document later. Besides, by comparing the total number of lines in EN and CN documents, you can quickly find out whether the CN version lags behind the EN version.
Fig. 1: One line for one paragraph (click to enlarge)

Fig. 2: No line breaks within the same paragraph (click to enlarge)

Fig. 3: Keep the line number for EN and CN documents consistent (click to enlarge)
Building Documentation

The documentation is built with the esp-docs Python package, which is a wrapper around Sphinx.

To install it simply do:

```
pip install esp-docs
```

After a successful install then the documentation can be built from the docs folder with:

```
build-docs build
```

or for specific target and language with:

```
build-docs -t esp32 -l en build
```

For more in-depth documentation about esp-docs features please see the documentation at esp-docs.

Wrap Up

We love good code that is doing cool things. We love it even better, if it is well-documented, so we can quickly make it run and also do the cool things.

Go ahead, contribute your code and documentation!

8.5.4 Creating Examples

Each ESP-IDF example is a complete project that someone else can copy and adapt the code to solve their own problem. Examples should demonstrate ESP-IDF functionality, while keeping this purpose in mind.

Structure

- The main directory should contain a source file named (something)_example_main.c with the main functionality.
- If the example has additional functionality, split it logically into separate C or C++ source files under main and place a corresponding header file in the same directory.
- If the example has a lot of additional functionality, consider adding a components directory to the example project and make some example-specific components with library functionality. Only do this if the components are specific to the example, if they are generic or common functionality then they should be added to ESP-IDF itself.
- The example should have a README.md file. Use the template example README and adapt it for your particular example.
- Examples should have a pytest_<example name>.py file for running an automated example test. If submitting a GitHub Pull Request which includes an example, it is OK not to include this file initially. The details can be discussed as part of the Pull Request. Please refer to IDF Tests with Pytest Guide for details.

General Guidelines

Example code should follow the Espressif IoT Development Framework Style Guide.
Chapter 8. Contributions Guide

Checklist

Checklist before submitting a new example:

- Example project name (in README.md) uses the word “example”. Use “example” instead of “demo”, “test” or similar words.
- Example does one distinct thing. If the example does more than one thing at a time, split it into two or more examples.
- Example has a README.md file which is similar to the template example README.
- Functions and variables in the example are named according to naming section of the style guide. For non-static names which are only specific to the example’s source files, you can use example or something similar as a prefix.
- All code in the example is well structured and commented.
- Any unnecessary code (old debugging logs, commented-out code, etc.) is removed from the example.
- Options in the example (like network names, addresses, etc) are not hard-coded. Use configuration items if possible, or otherwise declare macros or constants.
- Configuration items are provided in a KConfig.projbuild file with a menu named “Example Configuration”. See existing example projects to see how this is done.
- All original example code has a license header saying it is “in the public domain / CC0”, and a warranty disclaimer clause. Alternatively, the example is licensed under Apache License 2.0. See existing examples for headers to adapt from.
- Any adapted or third party example code has the original license header on it. This code must be licensed compatible with Apache License 2.0.

8.5.5 API Documentation Template

**Note:** *INSTRUCTIONS*

1. Use this file (docs/en/api-reference/template.rst) as a template to document API.
2. Change the filename to the name of the header file that represents the documented API.
3. Include respective files with descriptions from the API folder using ..include::
   - README.rst
   - example.rst
   - ...
4. Optionally provide description right in this file.
5. Once done, remove all instructions like this one and any superfluous headers.

**Overview**

**Note:** *INSTRUCTIONS*

1. Provide overview where and how this API may be used.
2. Include code snippets to illustrate functionality of particular functions when applicable.
3. To distinguish between sections, use the following **heading levels**:
   - # with overline, for parts
   - * with overline, for chapters
   - = for sections
   - – for subsections
   - ^ for subsubsections
   - * for paragraphs
Chapter 8. Contributions Guide

Application Example

Note: INSTRUCTIONS

1. Prepare one or more practical examples to demonstrate functionality of this API.
2. Each example should follow pattern of projects located in esp-idf/examples/ folder.
3. Place example in this folder, and add README.md file.
4. Provide overview of demonstrated functionality in README.md.
5. With good overview readers should be able to understand what example does without opening the source code.
6. Depending on complexity of example, break down description of code into parts and provide overview of functionality of each part.
7. Include flow diagram and screenshots of application output if applicable.
8. Finally add in this section synopsis of each example together with link to respective folder in esp-idf/examples/.

API Reference

Note: INSTRUCTIONS

1. ESP-IDF repository provides automatic update of API reference documentation using code markup retrieved by Doxygen from header files.
2. Update is done on each documentation build by invoking Sphinx extension esp_extensions/run_doxygen.py for all header files listed in the INPUT statement of docs/doxygen/Doxyfile.
3. Each line of the INPUT statement (other than a comment that begins with ##) contains a path to header file *.h that is used to generate corresponding *.inc files:

```plaintext
## Wi-Fi - API Reference
../components/esp32/include/esp_wifi.h \\ ..components/esp32/include/esp_smartconfig.h \
```

4. When the headers are expanded, any macros defined by default in sdkconfig.h as well as any macros defined in SOC-specific include/soc/*_caps.h headers will be expanded. This allows the headers to include or exclude material based on the IDF_TARGET value.
5. The *.inc files contain formatted reference of API members generated automatically on each documentation build. All *.inc files are placed in Sphinx _build directory. To see directives generated, e.g., esp_wifi.h, run python gen-dxd.py esp32/include/esp_wifi.h.
6. To show contents of *.inc file in documentation, include it as follows:

```plaintext
.. include-build-file:: inc/esp_wifi.inc
```

For example see docs/en/api-reference/network/esp_wifi.rst

Below is the list of common . doxygen... directives:

- Functions -.. doxygenfunction:: name_of_function
- Unions -.. doxygenunion:: name_of_union
- Structures -.. doxygenstruct:: name_of_structure together with :members:
- Macros -.. doxygendefine:: name_of_define
- Type Definitions -.. doxygentypedef:: name_of_type
- Enumerations -.. doxygenenum:: name_ofEnumeration

See Breathe documentation for additional information.

To provide a link to header file, use the link custom role directive as follows:

```
* :component_file:`path_to/header_file.h`
```
8. In any case, to generate API reference, the file `docs/doxygen/Doxyfile` should be updated with paths to `*.h` headers that are being documented.
9. When changes are committed and documentation is built, check how this section has been rendered. Correct annotations in respective header files, if required.

8.5.6 Contributor Agreement

**Individual Contributor Non-Exclusive License Agreement Including the Traditional Patent License OPTION**

Thank you for your interest in contributing to this Espressif project hosted on GitHub ( “We” or “Us” ).

The purpose of this contributor agreement ( “Agreement” ) is to clarify and document the rights granted by contributors to Us. To make this document effective, please follow the instructions in the Contributions Guide.

1. **DEFINITIONS**

   **You** means the Individual Copyright owner who submits a Contribution to Us. If You are an employee and submit the Contribution as part of your employment, You must have had Your employer approve this Agreement or sign the Entity version of this Agreement.

   **Contribution** means any original work of authorship (software and/or documentation) including any modifications or additions to an existing work, Submitted by You to Us, in which You own the Copyright. If You do not own the Copyright in the entire work of authorship, please contact Us by submitting a comment on GitHub.

   **Copyright** means all rights protecting works of authorship owned or controlled by You, including copyright, moral and neighboring rights, as appropriate, for the full term of their existence including any extensions by You.

   **Material** means the software or documentation made available by Us to third parties. When this Agreement covers more than one software project, the Material means the software or documentation to which the Contribution was Submitted. After You Submit the Contribution, it may be included in the Material.

   **Submit** means any form of physical, electronic, or written communication sent to Us, including but not limited to electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, Us, but excluding communication that is conspicuously marked or otherwise designated in writing by You as “Not a Contribution.”

   **Submission Date** means the date You Submit a Contribution to Us.

   **Documentation** means any non-software portion of a Contribution.

2. **COPYRIGHT LICENSE**

2.1 **Grant of Copyright License to Us**

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, NON-exclusive, perpetual and irrevocable license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, under the Copyright covering the Contribution to use the Contribution by all means, including, but not limited to:

- to publish the Contribution
- to modify the Contribution, to prepare derivative works based upon or containing the Contribution and to combine the Contribution with other software code
- to reproduce the Contribution in original or modified form
- to distribute, to make the Contribution available to the public, display and publicly perform the Contribution in original or modified form

2.2 Moral Rights remain unaffected to the extent they are recognized and not waivable by applicable law. Notwithstanding, You may add your name in the header of the source code files of Your Contribution and We will respect this attribution when using Your Contribution.
3. PATENT LICENSE  3.1 Grant of Patent License to US

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, non-exclusive, perpetual and irrevocable (except as stated in Section 3.2) patent license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, to make, have made, use, sell, offer for sale, import and otherwise transfer the Contribution and the Contribution in combination with the Material (and portions of such combination). This license applies to all patents owned or controlled by You, whether already acquired or hereafter acquired, that would be infringed by making, having made, using, selling, offering for sale, importing or otherwise transferring of Your Contribution(s) alone or by combination of Your Contribution(s) with the Material.

3.2 Revocation of Patent License

You reserve the right to revoke the patent license stated in section 3.1 if We make any infringement claim that is targeted at your Contribution and not asserted for a Defensive Purpose. An assertion of claims of the Patents shall be considered for a “Defensive Purpose” if the claims are asserted against an entity that has filed, maintained, threatened, or voluntarily participated in a patent infringement lawsuit against Us or any of Our licensees.

4. DISCLAIMER  THE CONTRIBUTION IS PROVIDED “AS IS”. MORE PARTICULARLY, ALL EXPRESSED OR IMPLIED WARRANTIES INCLUDING, WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT ARE EXPRESSLY DISCLAIMED BY YOU TO US AND BY US TO YOU. TO THE EXTENT THAT ANY SUCH WARRANTIES CANNOT BE DISCLAIMED, SUCH WARRANTY IS LIMITED IN DURATION TO THE MINIMUM PERIOD PERMITTED BY LAW.

5. Consequential Damage Waiver  TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT WILL YOU OR US BE LIABLE FOR ANY LOSS OF PROFITS, LOSS OF ANTICIPATED SAVINGS, LOSS OF DATA, INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL AND EXEMPLARY DAMAGES ARISING OUT OF THIS AGREEMENT REGARDLESS OF THE LEGAL OR EQUITABLE THEORY (CONTRACT, TORT OR OTHERWISE) UPON WHICH THE CLAIM IS BASED.

6. Approximation of Disclaimer and Damage Waiver  IF THE DISCLAIMER AND DAMAGE WAIVER MENTIONED IN SECTION 4 AND SECTION 5 CANNOT BE GIVEN LEGAL EFFECT UNDER APPLICABLE LOCAL LAW, REVIEWING COURTS SHALL APPLY LOCAL LAW THAT MOST CLOSELY APPROXIMATES AN ABSOLUTE WAIVER OF ALL CIVIL LIABILITY IN CONNECTION WITH THE CONTRIBUTION.

7. Term  7.1 This Agreement shall come into effect upon Your acceptance of the terms and conditions.

7.2 In the event of a termination of this Agreement, sections 4, 5, 6, 7 and 8 shall survive such termination and shall remain in full force thereafter. For the avoidance of doubt, Contributions that are already licensed under a free and open source license at the date of the termination shall remain in full force after the termination of this Agreement.

8. Miscellaneous  8.1 This Agreement and all disputes, claims, actions, suits or other proceedings arising out of this agreement or relating in any way to it shall be governed by the laws of People’s Republic of China excluding its private international law provisions.

8.2 This Agreement sets out the entire agreement between You and Us for Your Contributions to Us and overrides all other agreements or understandings.

8.3 If any provision of this Agreement is found void and unenforceable, such provision will be replaced to the extent possible with a provision that comes closest to the meaning of the original provision and that is enforceable. The terms and conditions set forth in this Agreement shall apply notwithstanding any failure of essential purpose of this Agreement or any limited remedy to the maximum extent possible under law.

8.4 You agree to notify Us of any facts or circumstances of which you become aware that would make this Agreement inaccurate in any respect.
8.5.7 Copyright Header Guide

ESP-IDF is released under the Apache License 2.0 with some additional third-party copyrighted code released under various licenses. For further information please refer to the list of copyrights and licenses.

This page explains how the source code should be properly marked with a copyright header. ESP-IDF uses the Software Package Data Exchange (SPDX) format which is short and can be easily read by humans or processed by automated tools for copyright checks.

How to Check the Copyright Headers

Please make sure you have installed the pre-commit hooks which contain a copyright header checker as well. The checker can suggest a header if it is not able to detect a properly formatted SPDX header.

What If the Checker’s Suggestion Is Incorrect?

No automated checker (no matter how good is) can replace humans. So the developer’s responsibility is to modify the offered header to be in line with the law and the license restrictions of the original code on which the work is based on. Certain licenses are not compatible between each other. Such corner cases will be covered by the following examples.

The checker can be configured with the tools/ci/check_copyright_config.yaml configuration file. Please check the options it offers and consider updating it in order to match the headers correctly.

Common Examples of Copyright Headers

The simplest case is when the code is not based on any licensed previous work, e.g., it was written completely from scratch. Such code can be decorated with the following copyright header and put under the license of ESP-IDF:

```c
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Apache-2.0
 */
```
Less Restrictive Parts of ESP-IDF  Some parts of ESP-IDF are deliberately under less restrictive licenses in order to ease their re-use in commercial closed source projects. This is the case for ESP-IDF examples which are in Public domain or under the Creative Commons Zero Universal (CC0) license. The following header can be used in such source files:

```cpp
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * * SPDX-License-Identifier: Unlicense OR CC0-1.0
 */
```

The option allowing multiple licenses joined with the OR keyword from the above example can be achieved with the definition of multiple allowed licenses in the tools/ci/check_copyright_config.yaml configuration file. Please use this option with care and only selectively for a limited part of ESP-IDF.

Third Party Licenses  Code licensed under different licenses, modified by Espressif Systems and included in ESP-IDF cannot be licensed under Apache License 2.0 not even if the checker suggests it. It is advised to keep the original copyright header and add an SPDX before it.

The following example is a suitable header for a code licensed under the “GNU General Public License v2.0 or later” held by John Doe with some additional modifications done by Espressif Systems:

```cpp
/*
 * SPDX-FileCopyrightText: 1991 John Doe
 * *
 * SPDX-License-Identifier: GPL-2.0-or-later
 * *
 * SPDX-FileContributor: 2019-2023 Espressif Systems (Shanghai) CO LTD
 */
```

The licenses can be identified and the short SPDX identifiers can be found in the official SPDX license list. Other very common licenses are the GPL-2.0-only, the BSD-3-Clause, and the BSD-2-Clause.

In exceptional case, when a license is not present on the SPDX license list, it can be expressed by using the LicenseRef-[idString] custom license identifier, for example LicenseRef-Special-License. The full license text must be added into the LICENSES directory under Special-License filename.

```cpp
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * *
 * SPDX-License-Identifier: LicenseRef-Special-License
 */
```

Dedicated LicenseRef-Included custom license identifier can be used to express a situation when the custom license is included directly in the source file.

```cpp
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * *
 * SPDX-License-Identifier: LicenseRef-Included
 * *
 * <Full custom license text>
 */
```

The configuration stored in tools/ci/check_copyright_config.yaml offers features useful for third party licenses:

- A different license can be defined for the files part of a third party library.
- The check for a selected set of files can be permanently disabled. Please use this option with care and only in cases when none of the other options are suitable.
8.5.8  pytest in ESP-IDF

ESP-IDF has numerous types of tests that are meant to be executed on an ESP chip (known as on target testing). Target tests are usually compiled as part of an IDF project used for testing (known as a test app), where test apps follow the same build, flash, and monitor process of any other standard IDF project.

Typically, on target testing will require a connected host (e.g., a PC) that is responsible for triggering a particular test case, providing test data, and inspecting test results.

ESP-IDF uses the pytest framework (and some pytest plugins) on the host side to automate on target testing. This guide introduces pytest in ESP-IDF and covers the following concepts:

1. The different types of test apps in ESP-IDF.
2. Using the pytest framework in Python scripts to automate target testing.
3. ESP-IDF Continuous Integration (CI) target testing process.
4. How to run target tests locally with pytest.
5. pytest tips and tricks.

**Note:** In ESP-IDF, we use the following pytest plugins by default:

- `pytest-embedded` with default services `esp, idf`
- `pytest-rerunfailures`

All the concepts and usages introduced in this guide are based on the default behavior of these plugins, thus may not be available in vanilla pytest.

**Installation**

All dependencies could be installed by running the install script with the `--enable-pytest` argument:

```
$ install.sh --enable-pytest
```

**Common Issues During Installation**

**No Package ‘dbus-1’ Found**

```
configure: error: Package requirements (dbus-1 >= 1.8) were not met:
No package 'dbus-1' found
Consider adjusting the PKG_CONFIG_PATH environment variable if you
installed software in a non-standard prefix.
```

If you encounter the error message above, you may need to install some missing packages.

If you are using Ubuntu, you may need to run:

```
sudo apt-get install libdbus-glib-1-dev
```

or

```
sudo apt-get install libdbus-1-dev
```

For other Linux distributions, please Google the error message above and find which missing packages need to be installed for your particular distribution.
Invalid Command ‘bdist_wheel’

```
error: invalid command 'bdist_wheel'
```

If you encounter the error message above, you may need to install some missing Python packages such as:

```
python -m pip install -U pip
```

or

```
python -m pip install wheel
```

**Note:** Before running the pip commands, please make sure you are using the IDF Python virtual environment.

**Test Apps**

ESP-IDF contains different types of test apps that can be automated using pytest.

**Component Tests**  ESP-IDF components typically contain component specific test apps that execute component specific unit tests. Component test apps are the recommended way to test components. All the test apps should be located under `${IDF_PATH}/components/<COMPONENT_NAME>/test_apps`, for example:

```
components/
  ├── my_component/
  │   └── include/
  │   └── ...
  │   └── test_apps/
  │       ├── test_app_1/
  │       │   └── main/
  │       │       └── ...
  │       │       └── CMakelists.txt
  │       │       └── pytest_my_component_app_1.py
  │       └── test_app_2/
  │           └── ...
  │           ∼ pytest_my_component_app_2.py
  │       └── parent_folder/
  │           ├── test_app_3/
  │           │   └── ...
  │           │   └── pytest_my_component_app_3.py
  │           └── ...
  ├── my_component.c
  │   └── CMakelists.txt
```

**Example Tests**  The purpose of ESP-IDF examples is to demonstrate parts of ESP-IDF functionality to users (refer to Examples Readme for more information).

However, to ensure that these examples operate correctly, examples can be treated as test apps and executed automatically by using pytest. All examples should be located under `${IDF_PATH}/examples`, with tested example including a Python test script, for example:

```
examples/
  └── parent_folder/
      └── example_1/
          └── main/
               └── ...
               └── CMakelists.txt
               └── pytest_example_1.py
```
Custom Tests  
Custom Tests are tests that aim to test some arbitrary functionality of ESP-IDF, thus are not intended to demonstrate IDF functionality to users in any way.

All custom test apps are located under `${IDF_PATH}/tools/test_apps`. For more information please refer to the Custom Test Readme.

pytest in ESP-IDF

pytest Execution Process

1. Bootstrapping Phase
   Create session-scoped caches:
   a. port-target cache
   b. port-app cache

2. Collection Phase
   A. Gather all Python files with the prefix pytest_.
   B. Gather all test functions with the prefix test_.
   C. Apply the params, and duplicate the test functions.
   D. Filter the test cases with CLI options. For the detailed usages, see Filter the Test Cases.

3. Execution Phase
   A. Construct the fixtures. In ESP-IDF, the common fixtures are initialized in this order:
      a. pexpect_proc: pexpect instance
      b. app: IdfApp instance
         The test app’s information (e.g., sdkconfig, flash_files, partition_table, etc) would be parsed at this phase.
      c. serial: IdfSerial instance
         The port of the host to which the target is connected is auto-detected. In the case of multiple targets connected to the host, the test target’s type is parsed from the app. The test app binary files are flashed to the test target automatically.
      d. dut: IdfDut instance
   B. Run the real test function.
   C. Deconstruct the fixtures in this order:
      a. dut
         i. close the serial port.
         ii. (Only for apps with Unity test framework) generate JUnit report of the Unity test cases.
      b. serial
      c. app
      d. pexpect_proc: Close the file descriptor
   D. (Only for apps with Unity test framework)
      If dut.expect_from_unity_output() is called, an AssertionError is raised upon detection of a Unity test failure.

4. Reporting Phase
   A. Generate JUnit report of the test functions.
   B. Modify the JUnit report test case name into ESP-IDF test case ID format: `<target>.<config>.<test function name>`.

5. Finalizatoin Phase (Only for apps with Unity test framework)
   Combine the JUnit reports if the JUnit reports of the Unity test cases are generated.
Basic Example  This following Python test script example is taken from pytest_console_basic.py.

```python
@ pytest.mark.esp32
@ pytest.mark.esp32c3
@ pytest.mark.generic
@ pytest.mark.parametrize('config', ['history', 'nohistory'], indirect=True)
def test_console_advanced(config: str, dut: IdfDut) -> None:
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```

To demonstrate how pytest is typically used in an ESP-IDF test script, let us go through this simple test script line by line in the following subsections.

Target Markers  Pytest markers can be used to indicate which targets (i.e., which ESP chip) a particular test case should should run on. For example:

```python
@ pytest.mark.esp32  # <-- support esp32
@ pytest.mark.esp32c3  # <-- support esp32c3
@ pytest.mark.generic  # <-- test env "generic"
```

The example above indicates that a particular test case is supported on the ESP32 and ESP32-C3. Furthermore, the target’s board type should be generic. For more details regarding the generic type, you may run pytest --markers to get detailed information regarding all markers.

Note:  If the test case can be run on all targets officially supported by ESP-IDF (call idf.py --list-targets for more details), you can use a special marker supported_targets to apply all of them in one line.

Parameterized Markers  You can use pytest.mark.parametrize with config to apply the same test to different apps with different sdkconfig files. For more information about sdkconfig.ci.xxx files, please refer to the Configuration Files section under this readme.

```python
@ pytest.mark.parametrize('config', ['history', 'nohistory'], indirect=True)  # <-- `indirect=True` is required
```

Overall, this test function would be replicated to 4 test cases:

- esp32.history.test_console_advanced
- esp32.nohistory.test_console_advanced
- esp32c3.history.test_console_advanced
- esp32c3.nohistory.test_console_advanced

Testing Serial Output  To ensure that test has executed successfully on target, the test script can test that serial output of the target using the dut.expect() function, for example:

```python
def test_console_advanced(config: str, dut: IdfDut) -> None:  # The value of_
    # argument `config` is assigned by the parameterization.
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```
The `dut.expect(...)` will first compile the expected string into a regex, which in turn is then used to seek through the serial output until the compiled regex is matched, or until a timeout occurs.

Please pay extra attention to the expected string when it contains regex keyword characters (e.g., parentheses, square brackets). Alternatively, you may use `dut.expect_exact(...)` that will attempt to match the string without converting it into regex.

For more information regarding the different types of `expect` functions, please refer to the pytest-embedded Expecting documentation.

### Advanced Examples

**Multi-Target Tests with the Same App** In some cases a test may involve multiple targets running the same test app. In this case, multiple DUTs can be instantiated using `parameterize`, for example:

```python
@ pytest.mark.esp32
@ pytest.mark.esp32s3
@ pytest.mark.usb_host
@ pytest.mark.parametrize('count', [2, ], indirect=True)
def test_usb_host(dut: Tuple[IdfDut, IdfDut]) -> None:
    device = dut[0]  # <-- assume the first dut is the device
    host = dut[1]    # <-- and the second dut is the host
    ...
```

After setting the param `count` to 2, all these fixtures are changed into tuples.

**Multi-Target Tests with Different Apps** In some cases (in particular protocol tests), a test may involve multiple targets running different test apps (e.g., separate targets to act as master and slave). In this case, multiple DUTs with different test apps can be instantiated using `parameterize`.

This code example is taken from `pytest_wifi_getting_started.py`.

```python
@ pytest.mark.esp32
@ pytest.mark.multi_dut_generic
@ pytest.mark.parametrize(
    'count, app_path', [
        (2,  
         f'{os.path.join(os.path.dirname(__file__), "softAP")||os.path.join(os.path.dirname(__file__), "station")]},
         indirect=True)
    def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
        softap = dut[0]  
        station = dut[1]  
        ...
```

Here the first DUT was flashed with the app `softAP`, and the second DUT was flashed with the app `station`.

**Note:** Here the `app_path` should be set with absolute path. The `__file__` macro in Python would return the absolute path of the test script itself.

**Multi-Target Tests with Different Apps and Targets** This code example is taken from `pytest_wifi_getting_started.py`. As the comment says, for now it is not running in the ESP-IDF CI.
@pytest.mark.parametrize(
    'count, app_path, target', [
        (2, 'f(os.path.join(os.path.dirname(__file__), "softAP"))|/os.path.join(os.
            path.dirname(__file__), "station"))',
        'esp32|esp32s2',
        (2, 'f(os.path.join(os.path.dirname(__file__), "softAP"))|/os.path.join(os.
            path.dirname(__file__), "station"))',
        'esp32s2|esp32',
    ], indirect=True,
)
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]

Overall, this test function would be replicated to 2 test cases:

- softAP with ESP32 target, and station with ESP32-S2 target
- softAP with ESP32-S2 target, and station with ESP32 target

Support Different Targets with Different sdkconfig Files  This code example is taken from `pytest_panic.py` as an advanced example.

```python
CONFIGS = [
    pytest.param('coredump_flash_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
            esp32s2]),
    pytest.param('coredump_file_sha', marks=[pytest.mark.esp32]), # sha256
    only supported on esp32
    pytest.param('coredump_uart_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
            esp32s2]),
    pytest.param('coredump_uart_file_crc', marks=[pytest.mark.esp32, pytest.mark.
            esp32s2]),
    pytest.param('gdbstub', marks=[pytest.mark.esp32, pytest.mark.esp32s2]),
    pytest.param('panic', marks=[pytest.mark.esp32, pytest.mark.esp32s2]),
]
@ pytest.mark.parametrize('config', CONFIGS, indirect=True)
```

Custom Classes  Usually, you may want to write a custom class under these conditions:

1. Add more reusable functions for a certain number of DUTs.
2. Add custom setup and teardown functions in different phases described in Section `pytest Execution Process`

This code example is taken from `panic/conf/test.py`.

```python
class PanicTestDut(IdfDut):
    ...

@ pytest.fixture(scope='module')
def monkeypatch_module(request: FixtureRequest) -> MonkeyPatch:
    mp = MonkeyPatch()
    request.addfinalizer(mp.undo)
    return mp

@ pytest.fixture(scope='module', autouse=True)
```
def replace_dut_class(monkeypatch_module: MonkeyPatch) -> None:
    monkeypatch_modulesetattr('pytest_embedded_idf.dut.IdfDut', PanicTestDut)

monkeypatch_module provides a module-scoped monkeypatch fixture.
replace_dut_class is a module-scoped autouse fixture. This function replaces the IdfDut class with your custom class.

**Mark Flaky Tests**  Certain test cases are based on Ethernet or Wi-Fi. However, the test may be flaky due to networking issues. Thus, it is possible to mark a particular test case as flaky.

This code example is taken from pytest_esp_eth.py.
```python
@pytest.mark.flaky(reruns=3, reruns_delay=5)
def test_esp_eth_ip101(dut: IdfDut) -> None:
    ...
```

This flaky marker means that if the test function failed, the test case would rerun for a maximum of 3 times with 5 seconds delay.

**Mark Known Failures**  Sometimes, a test can consistently fail for the following reasons:

- The feature under test (or the test itself) has a bug.
- The test environment is unstable (e.g., due to network issues) leading to a high failure ratio.

Now you may mark this test case with marker xfail with a user-friendly readable reason.

This code example is taken from pytest_panic.py.
```python
@pytest.mark.xfail(config.getvalue("target") == "esp32s2", reason='raised
←IllegalInstruction instead')
def test_cache_error(dut: PanicTestDut, config: str, test_func_name: str) -> None:
```

This marker means that test is a known failure on the ESP32-S2.

**Mark Nightly Run Test Cases**  Some test cases are only triggered in nightly run pipelines due to a lack of runners.

```python
@pytest.mark.nightly_run
```

This marker means that the test case would only be run with env var NIGHTLY_RUN or INCLUDE_NIGHTLY_RUN.

**Mark Temporarily Disabled in CI**  Some test cases which can pass locally may need to be temporarily disabled in CI due to a lack of runners.

```python
@pytest.mark.temp_skip_ci(targets=['esp32', 'esp32s2'], reason='lack of runners')
```

This marker means that the test case could still be run locally with pytest --target esp32, but will not run in CI.

**Run Unity Test Cases**  For component-based unit test apps, all single-board test cases (including normal test cases and multi-stage test cases) can be run using the following command:

```python
def test_component_ut(dut: IdfDut):
    dut.run_all_single_board_cases()
```

Using this command will skip all the test cases containing the [ignore] tag.

If you need to run a group of test cases, you may run:
```python
def test_component_ut(dut: IdfDut):
    dut.run_all_single_board_cases(group='psram')
```

It would trigger all test cases with the [psram] tag.

You may also see that there are some test scripts with the following statements, which are deprecated. Please use the suggested one as above.

```python
def test_component_ut(dut: IdfDut):
    dut.expect_exact('Press ENTER to see the list of tests')
    dut.write('*')
    dut.expect_unity_test_output()
```

For further reading about our unit testing in ESP-IDF, please refer to our unit testing guide.

### Running Tests in CI

The workflow in CI is simple, build jobs > target test jobs.

#### Build Jobs

**Build Job Names**

- Component-based Unit Tests: `build_pytest_components_<target>`
- Example Tests: `build_pytest_examples_<target>`
- Custom Tests: `build_pytest_test_apps_<target>`

**Build Job Commands**

The command used by CI to build all the relevant tests is: `python $IDF_PATH/tools/ci/ci_build_apps.py <parent_dir> --target <target> -vv --pytest-apps`

All apps which supported the specified target would be built with all supported sdkconfig files under `build_<target>_<config>`.

For example, if you run `python $IDF_PATH/tools/ci/ci_build_apps.py $IDF_PATH/examples/system/console/basic --target esp32 --pytest-apps`, the folder structure would be like this:

```
basic
├── build_esp32_history/
│   ├── ...
├── build_esp32_nohistory/
│   ├── ...
├── main/
│   └── CMakeLists.txt
├── pytest_console_basic.py
└── ...
```

All the build folders would be uploaded as artifacts under the same directories.

#### Target Test Jobs

**Target Test Job Names**

- Component-based Unit Tests: `component_ut_pytest_<target>_<test_env>`
- Example Tests: `example_test_pytest_<target>_<test_env>`
- Custom Tests: `test_app_test_pytest_<target>_<test_env>`
**Target Test Job Commands**  The command used by CI to run all the relevant tests is: `pytest <parent_dir> --target <target> -m <test_env_marker>`

All test cases with the specified target marker and the test env marker under the parent folder would be executed.

The binaries in the target test jobs are downloaded from build jobs. the artifacts would be placed under the same directories.

**Running Tests Locally**

First you need to install ESP-IDF with additional Python requirements:

```
$ cd $IDF_PATH
$ bash install.sh --enable-pytest
$ . ./export.sh
```

By default, the pytest script will look for the build directory in this order:

- `build_<target>_<sdkconfig>`
- `build_<target>`
- `build_<sdkconfig>`
- `build`

Which means, the simplest way to run pytest is calling `idf.py build`.

For example, if you want to run all the esp32 tests under the `example/get-started/hello_world` folder, you should run:

```
$ cd examples/get-started/hello_world
$ idf.py build
$ pytest --target esp32
```

If you have multiple `sdkconfig` files in your test app, like those `sdkconfig.ci.*` files, the simple `idf.py build` won’t apply the extra `sdkconfig` files. Let us take `$IDF_PATH/examples/system/console/basic` as an example.

If you want to test this app with config history, and build with `idf.py build`, you should run:

```
$ cd examples/system/console/basic
$ idf.py -DSDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig.ci.history" build
$ pytest --target esp32 --sdkconfig history
```

If you want to build and test with all `sdkconfig` files at the same time, you should use our CI script as a helper script:

```
$ cd examples/system/console/basic
$ python $IDF_PATH/tools/ci/ci_build_apps.py . --target esp32 -vv --pytest-apps
$ pytest --target esp32
```

The app with `sdkconfig.ci.history` will be built in `build_esp32_history`, and the app with `sdkconfig.ci.nohistory` will be built in `build_esp32_nohistory`. `pytest --target esp32` will run tests on both apps.

**Tips and Tricks**

**Filter the Test Cases**

- Filter by target with `pytest --target <target>`
  `pytest` would run all the test cases that support specified target.
- Filter by `sdkconfig` file with `pytest --sdkconfig <sdkconfig>`
  If `<sdkconfig>` is default, `pytest` would run all the test cases with the `sdkconfig` file `sdkconfig.defaults`.
  In other cases, `pytest` would run all the test cases with `sdkconfig` file `sdkconfig.ci.<sdkconfig>`. 
Add New Markers  We are using two types of custom markers, target markers which indicate that the test cases should support this target, and env markers which indicate that the test cases should be assigned to runners with these tags in CI.

You can add new markers by adding one line under the `${IDF_PATH}/conftest.py`. If it is a target marker, it should be added into `TARGET_MARKERS`. If it is a marker that specifies a type of test environment, it should be added into `ENV_MARKERS`. The syntax should be: `<marker_name>: <marker_description>`.

Generate JUnit Report  You can call `pytest` with `--junitxml <filepath>` to generate the JUnit report. In ESP-IDF, the test case name would be unified as `<target>.<config>.<function_name>`.

Skip Auto Flash Binary  Skipping auto-flash binary every time would be useful when you are debugging your test script.

You can call `pytest` with `--skip-autoflash` to achieve it.

Record Statistics  Sometimes you may need to record some statistics while running the tests, like the performance test statistics.

You can use `record_xml_attribute` fixture in your test script, and the statistics would be recorded as attributes in the JUnit report.

Logging System  Sometimes you may need to add some extra logging lines while running the test cases.

You can use `Python logging module` to achieve this.

Useful Logging Functions (as Fixture)

**log_performance**

```python
def test_hello_world(dut: IdfDut,
    log_performance: Callable[[str, object], None],
) -> None:
    log_performance('test', 1)
```

The above example would log the performance item with pre-defined format: `[performance][test]: 1` and record it under the `properties` tag in the JUnit report if `--junitxml <filepath>` is specified. The JUnit test case node would look like:

```
<testcase class="examples.get-started.hello_world.pytest_hello_world" file="examples/get-started/hello_world/pytest_hello_world.py" line="13" name="esp32.default.test_hello_world" time="8.389">
  <properties>
    <property name="test" value="1"/>
  </properties>
</testcase>
```

**check_performance**  We provide C macros `TEST_PERFORMANCE_LESS_THAN` and `TEST_PERFORMANCE_GREATER_THAN` to log the performance item and check if the value is in the valid range. Sometimes the performance item value could not be measured in C code, so we also provide a Python function for the same purpose. Please note that using C macros is the preferred approach, since the Python function could not recognize the threshold values of the same performance item under different ifdef blocks well.
def test_hello_world(
    dut: IdfDut,
    check_performance: Callable[[str, float, str], None],
) -> None:
    check_performance('RSA_2048KEY_PUBLIC_OP', 123, 'esp32')
    check_performance('RSA_2048KEY_PUBLIC_OP', 19001, 'esp32')

The above example would first get the threshold values of the performance item RSA_2048KEY_PUBLIC_OP from components/idf_test/include/idf_performance.h and the target-specific one components/idf_test/include/esp32/idf_performance_target.h, then check if the value reached the minimum limit or exceeded the maximum limit.

Let us assume the value of IDF_PERFORMANCE_MAX_RSA_2048KEY_PUBLIC_OP is 19000. so the first check_performance line would pass and the second one would fail with warning: [Performance] RSA_2048KEY_PUBLIC_OP value is 19001, doesn't meet pass standard 19000.0.

Chapter 9

ESP-IDF Versions

The ESP-IDF GitHub repository is updated regularly, especially the master branch where new development takes place.

For production use, there are also stable releases available.

9.1 Releases

The documentation for the current stable release version can always be found at this URL:

Documentation for the latest version (master branch) can always be found at this URL:

The full history of releases can be found on the GitHub repository Releases page. There you can find release notes, links to each version of the documentation, and instructions for obtaining each version.

9.2 Which Version Should I Start With?

• For production purposes, use the current stable version. Stable versions have been manually tested, and are updated with “bugfix releases” which fix bugs without changing other functionality (see Versioning Scheme for more details). Every stable release version can be found on the Releases page. Also refer to Compatibility Between ESP-IDF Releases and Revisions of Espressif SoCs to make sure the ESP-IDF version you selected is compatible with the chip revision you are going to produce with.
• For prototyping, experimentation or for developing new ESP-IDF features, use the latest version (master branch in Git). The latest version in the master branch has all the latest features and has passed automated testing, but has not been completely manually tested (“bleeding edge”).
• If a required feature is not yet available in a stable release, but you do not want to use the master branch, it is possible to check out a pre-release version or a release branch. It is recommended to start from a stable version and then follow the instructions for Updating to a Pre-Release Version or Updating to a Release Branch.
• If you plan to use another project which is based on ESP-IDF, please check the documentation of that project to determine the version(s) of ESP-IDF it is compatible with.

See Updating ESP-IDF if you already have a local copy of ESP-IDF and wish to update it.
9.3 Versioning Scheme

ESP-IDF uses Semantic Versioning. This means that:

- **Major Releases**, like v3.0, add new functionality and may change functionality. This includes removing deprecated functionality.
  
  If updating to a new major release (for example, from v2.1 to v3.0), some of your project’s code may need updating and functionality may need to be re-tested. The release notes on the Releases page include lists of Breaking Changes to refer to.

- **Minor Releases** like v3.1 add new functionality and fix bugs but will not change or remove documented functionality, or make incompatible changes to public APIs.
  
  If updating to a new minor release (for example, from v3.0 to v3.1), your project’s code does not require updating, but you should re-test your project. Pay particular attention to the items mentioned in the release notes on the Releases page.

- **Bugfix Releases** like v3.0.1 only fix bugs and do not add new functionality.
  
  If updating to a new bugfix release (for example, from v3.0 to v3.0.1), you do not need to change any code in your project, and you only need to re-test the functionality directly related to bugs listed in the release notes on the Releases page.

9.4 Support Periods

Each ESP-IDF major and minor release version has an associated support period. After this period, the release is End of Life and no longer supported.

The ESP-IDF Support Period Policy explains this in detail, and describes how the support periods for each release are determined.

Each release on the Releases page includes information about the support period for that particular release.

As a general guideline:

- If starting a new project, use the latest stable release.
- If you have a GitHub account, click the “Watch” button in the top-right of the Releases page and choose “Releases only”. GitHub will notify you whenever a new release is available. Whenever a bug fix release is available for the version you are using, plan to update to it.
- If possible, periodically update the project to a new major or minor ESP-IDF version (for example, once a year.) The update process should be straightforward for Minor updates, but may require some planning and checking of the release notes for Major updates.
- Always plan to update to a newer release before the release you are using becomes End of Life.

Each ESP-IDF major and minor release (V4.1, V4.2, etc) is supported for 30 months after the initial stable release date.

Supported means that the ESP-IDF team will continue to apply bug fixes, security fixes, etc to the release branch on GitHub, and periodically make new bugfix releases as needed.

Support period is divided into “Service” and “Maintenance” period:

<table>
<thead>
<tr>
<th>Period</th>
<th>Duration</th>
<th>Recommended for new projects?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>12 months</td>
<td>Yes</td>
</tr>
<tr>
<td>Maintenance</td>
<td>18 months</td>
<td>No</td>
</tr>
</tbody>
</table>

During the Service period, bugfixes releases are more frequent. In some cases, support for new features may be added during the Service period (this is reserved for features which are needed to meet particular regulatory requirements or standards for new products, and which carry a very low risk of introducing regressions.)

During the Maintenance period, the version is still supported but only bugfixes for high severity issues or security issues will be applied.

Using an “In Service” version is recommended when starting a new project.
Users are encouraged to upgrade all projects to a newer ESP-IDF release before the support period finishes and the release becomes End of Life (EOL). It is our policy to not continue fixing bugs in End of Life releases.

Pre-release versions (betas, previews, -rc and -dev versions, etc) are not covered by any support period. Sometimes a particular feature is marked as “Preview” in a release, which means it is also not covered by the support period.

The ESP-IDF Programming Guide has information about the different versions of ESP-IDF (major, minor, bugfix, etc).

### 9.5 Checking the Current Version

The local ESP-IDF version can be checked by using idf.py:

```
idf.py --version
```

The ESP-IDF version is also compiled into the firmware and can be accessed (as a string) via the macro `IDF_VER`. The default ESP-IDF bootloader will print the version on boot (the version information is not always updated if the code in the GitHub repo is updated, it only changes if there is a clean build or if that particular source file is recompiled).

If writing code that needs to support multiple ESP-IDF versions, the version can be checked at compile time using compile-time macros.

Examples of ESP-IDF versions:
Chapter 9. ESP-IDF Versions

<table>
<thead>
<tr>
<th>Version String</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>v3.2-dev-306-gbeb3611ca</td>
<td>Master branch pre-release.</td>
</tr>
<tr>
<td></td>
<td>- v3.2-dev - in development for version 3.2.</td>
</tr>
<tr>
<td></td>
<td>- 306 - number of commits after v3.2 development started.</td>
</tr>
<tr>
<td></td>
<td>- beb3611ca - commit identifier.</td>
</tr>
<tr>
<td>v3.0.2</td>
<td>Stable release, tagged v3.0.2.</td>
</tr>
<tr>
<td>v3.1-beta1-75-g346d6b0ea</td>
<td>Beta version in development (on a release branch).</td>
</tr>
<tr>
<td></td>
<td>- v3.1-beta1 - pre-release tag.</td>
</tr>
<tr>
<td></td>
<td>- 75 - number of commits after the pre-release beta tag was assigned.</td>
</tr>
<tr>
<td></td>
<td>- 346d6b0ea - commit identifier.</td>
</tr>
<tr>
<td>v3.0.1-dirty</td>
<td>Stable release, tagged v3.0.1.</td>
</tr>
<tr>
<td></td>
<td>- dirty means that there are modifications in the local ESP-IDF directory.</td>
</tr>
</tbody>
</table>

9.6 Git Workflow

The development (Git) workflow of the Espressif ESP-IDF team is as follows:

- New work is always added on the master branch (latest version) first. The ESP-IDF version on master is always tagged with -dev (for “in development”), for example v3.1-dev.
- Changes are first added to an internal Git repository for code review and testing but are pushed to GitHub after automated testing passes.
- When a new version (developed on master) becomes feature complete and “beta” quality, a new branch is made for the release, for example release/v3.1. A pre-release tag is also created, for example v3.1-beta1. You can see a full list of branches and a list of tags on GitHub. Beta pre-releases have release notes which may include a significant number of Known Issues.
- As testing of the beta version progresses, bug fixes will be added to both the master branch and the release branch. New features for the next release may start being added to master at the same time.
- Once testing is nearly complete a new release candidate is tagged on the release branch, for example v3.1-rc1. This is still a pre-release version.
- If no more significant bugs are found or reported, then the final Major or Minor Version is tagged, for example v3.1. This version appears on the Releases page.
- As bugs are reported in released versions, the fixes will continue to be committed to the same release branch.
- Regular bugfix releases are made from the same release branch. After manual testing is complete, a bugfix release is tagged (i.e., v3.1.1) and appears on the Releases page.

9.7 Updating ESP-IDF

Updating ESP-IDF depends on which version(s) you wish to follow:

- Updating to Stable Release is recommended for production use.
Chapter 9. ESP-IDF Versions

- Updating to Master Branch is recommended for the latest features, development use, and testing.
- Updating to a Release Branch is a compromise between the first two.

Note: These guides assume that you already have a local copy of ESP-IDF cloned. To get one, check Step 2 in the Getting Started guide for any ESP-IDF version.

9.7.1 Updating to Stable Release

To update to a new ESP-IDF release (recommended for production use), this is the process to follow:

- Check the Releases page regularly for new releases.
- When a bugfix release for the version you are using is released (for example, if using v3.0.1 and v3.0.2 is released), check out the new bugfix version into the existing ESP-IDF directory.
- In Linux or macOS system, please run the following commands to update the local branch to vX.Y.Z:

```
cd $IDF_PATH
git fetch
git checkout vX.Y.Z
```

Note: If you installed the stable release via zip file instead of using git, it might not be possible to update versions using the commands. In this case, update by downloading a new zip file and replacing the entire IDF_PATH directory with its contents.

9.7.2 Updating to a Pre-Release Version

It is also possible to git checkout a tag corresponding to a pre-release version or release candidate, the process is the same as Updating to Stable Release.

Pre-release tags are not always found on the Releases page. Consult the list of tags on GitHub for a full list. Caveats for using a pre-release are similar to Updating to a Release Branch.

9.7.3 Updating to Master Branch

Note: Using Master branch means living “on the bleeding edge” with the latest ESP-IDF code.

To use the latest version on the ESP-IDF master branch, this is the process to follow:

- In Linux or macOS system, please run the following commands to check out to the master branch locally:

```
cd $IDF_PATH
git checkout master
```

- In the Windows system, please replace cd $IDF_PATH with cd %IDF_PATH%.
- Periodically, re-run git pull to pull the latest version of master. Note that you may need to change your project or report bugs after updating your master branch.
To switch from master to a release branch or stable version, run `git checkout` as shown in the other sections.

**Important:** It is strongly recommended to regularly run `git pull` and then `git submodule update --init --recursive` so a local copy of master does not get too old. Arbitrary old master branch revisions are effectively unsupportable “snapshots” that may have undocumented bugs. For a semi-stable version, try Updating to a Release Branch instead.

## 9.7.4 Updating to a Release Branch

In terms of stability, using a release branch is part-way between using the master branch and only using stable releases. A release branch is always beta quality or better, and receives bug fixes before they appear in each stable release.

You can find a list of branches on GitHub. For example, in Linux or macOS system, you can execute the following commands to follow the branch for ESP-IDF v3.1, including any bugfixes for future releases like v3.1.1, etc:

```
(cd $IDF_PATH
git fetch
git checkout release/v3.1
git pull
git submodule update --init --recursive
```

In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`. Each time you `git pull` this branch, ESP-IDF will be updated with fixes for this release.

**Note:** There is no dedicated documentation for release branches. It is recommended to use the documentation for the closest version to the branch which is currently checked out.
Chapter 10

Resources

10.1 PlatformIO

10.1.1 What Is PlatformIO?

PlatformIO is a cross-platform embedded development environment with out-of-the-box support for ESP-IDF.

Since ESP-IDF support within PlatformIO is not maintained by the Espressif team, please report any issues with PlatformIO directly to its developers in the official PlatformIO repositories.

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in the official PlatformIO documentation.

10.1.2 Installation

- **PlatformIO IDE** is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms.
- **PlatformIO Core (CLI)** is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services.
10.1.3 Configuration

Please go through the official PlatformIO configuration guide for ESP-IDF.

10.1.4 Tutorials

- ESP-IDF and ESP32-DevKitC: debugging, unit testing, project analysis

10.1.5 Project Examples

Please check ESP-IDF page in the official PlatformIO documentation

10.1.6 Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Learn more about integrations with other IDEs or Text Editors
- Get help from PlatformIO community

10.2 CLion

10.2.1 What Is CLion?

CLion is a cross-platform integrated Development Environment (IDE) for C and C++ programming. CLion also provides dedicated support for ESP-IDF, allowing developers to seamlessly work with the ESP-IDF framework.

10.2.2 Installation

To install CLion, please follow the instructions provided in Install CLion for your operating system (Windows, macOS, or Linux).

10.2.3 Configuration

To configure an ESP-IDF project in CLion, please refer to the guide on Configure an ESP CMake project in CLion. This guide will walk you through the necessary steps to set up your project properly.

10.2.4 Resources

For more information about CLion and ESP-IDF integration, please refer to the following resource:

- CLion Documentation: The official documentation for CLion provides detailed information on various aspects of the IDE, including ESP-IDF integration.

10.3 VisualGDB

10.3.1 What Is VisualGDB?

VisualGDB is a powerful extension for Microsoft Visual Studio that provides advanced development tools and features for embedded systems, including support for the ESP-IDF framework. VisualGDB allows you to leverage the familiar
and feature-rich Visual Studio environment for your ESP-IDF projects, enabling efficient coding, debugging, and deployment.

10.3.2 Installation

Please download and install VisualGDB by following the steps stated in VisualGDB download and installation.

10.3.3 Configuration

Creating Advanced ESP32 Projects with ESP-IDF provide basic steps about how to configure an ESP-IDF project in VisualGDB.

You can also refer to Advanced ESP-IDF Project Structure to get a more comprehensive impression for developing ESP-IDF projects using VisualGDB.

10.3.4 Resources

For more information about VisualGDB and ESP-IDF integration, refer to the following resources:

• VisualGDB Documentation: The official documentation for VisualGDB provides comprehensive guides and tutorials on using VisualGDB with ESP-IDF.

For inquiries related to these third-party tools, we recommend seeking assistance from the respective tool’s support channels or user communities.

10.4 Useful Links

• The esp32.com forum is a place to ask questions and find community resources.
• Check the Issues section on GitHub if you find a bug or have a feature request. Please check existing Issues before opening a new one.
• A comprehensive collection of solutions, practical applications, components and drivers based on ESP-IDF is available in ESP IoT Solution repository. In most of cases descriptions are provided both in English and in 中文.
• To develop applications using Arduino platform, refer to Arduino core for the ESP32, ESP32-S2 and ESP32-C3.
• Several books have been written about ESP32 and they are listed on Espressif web site.
• If you’re interested in contributing to ESP-IDF, please check the Contributions Guide.
• For additional ESP32 product related information, please refer to documentation section of Espressif site.
• Download latest and previous versions of this documentation in PDF and HTML format.

Copyrights and Licenses

11.1 Software Copyrights

All original source code in this repository is Copyright (C) 2015-2023 Espressif Systems. This source code is licensed under the Apache License 2.0 as described in the file LICENSE.

Additional third party copyrighted code is included under the following licenses.

Where source code headers specify Copyright & License information, this information takes precedence over the summaries made here.

Some examples use external components which are not Apache licensed, please check the copyright description in each example source code.

11.1.1 Firmware Components

These third party libraries can be included into the application (firmware) produced by ESP-IDF.

- **Newlib** is licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB.
- **Xtensa header files** are Copyright (C) 2013 Tensilica Inc and are licensed under the MIT License as reproduced in the individual header files.
- Original parts of **FreeRTOS** (components/freertos) are Copyright (C) 2017 Amazon.com, Inc. or its affiliates are licensed under the MIT License, as described in license.txt.
- Original parts of **LWIP** (components/lwip) are Copyright (C) 2001, 2002 Swedish Institute of Computer Science and are licensed under the BSD License as described in COPYING file.
- **wpa_supplicant** Copyright (c) 2003-2022 Jouni Malinen <j@w1.fi> and contributors and licensed under the BSD license.
- **Fast PBKDF2** Copyright (c) 2015 Joseph Birr-Pixton and licensed under CC0 Public Domain Dedication license.
- **FreeBSD net80211** Copyright (c) 2004-2008 Sam Leffler, Erno Consulting and licensed under the BSD license.
- **argtable3** argument parsing library Copyright (C) 1998-2001,2003-2011,2013 Stewart Heitmann and licensed under 3-clause BSD license. argtable3 also includes the following software components. For details, please see argtable3 LICENSE file.
  - C Hash Table library, Copyright (c) 2002, Christopher Clark and licensed under 3-clause BSD license.
  - The Better String library, Copyright (c) 2014, Paul Hsieh and licensed under 3-clause BSD license.
  - TCL library, Copyright the Regents of the University of California, Sun Microsystems, Inc., Scriptics Corporation, ActiveState Corporation and other parties, and licensed under TCL/TK License.
- **linenoise** line editing library Copyright (c) 2010-2014 Salvatore Sanfilippo, Copyright (c) 2010-2013 Pieter Noordhuis, licensed under 2-clause BSD license.
- **FatFS** library, Copyright (C) 2017 ChaN, is licensed under a BSD-style license.
Chapter 11. Copyrights and Licenses

- cJSON library, Copyright (c) 2009-2017 Dave Gamble and cJSON contributors, is licensed under MIT license as described in LICENSE file.
- micro-ecc library, Copyright (c) 2014 Kenneth MacKay, is licensed under 2-clause BSD license.
- Mbed TLS library, Copyright (c) 2006-2018 ARM Limited, is licensed under Apache License 2.0 as described in LICENSE file.
- SPIFFS library, Copyright (c) 2013-2017 Peter Andersson, is licensed under MIT license as described in LICENSE file.
- SD/MMC driver is derived from OpenBSD SD/MMC driver, Copyright (c) 2006 Uwe Stuehler, and is licensed under BSD license.
- ESP-MQTT MQTT Package (contiki-mqtt) - Copyright (c) 2014, Stephen Robinson, MQTT-ESP - Tuan PM <tuannpm at live dot com> is licensed under Apache License 2.0 as described in LICENSE file.

11.5 TJpgDec License

TJpgDec - Tiny JPEG Decompressor R0.01 (C) ChaN, 2011

The TJpgDec is a generic JPEG decompressor module for tiny embedded systems. This is a free software that opened for education, research and commercial developments under license policy of following terms.

Copyright (C) 2011, ChaN, all right reserved.

- The TJpgDec module is a free software and there is NO WARRANTY.
- No restriction on use. You can use, modify and redistribute it for personal, non-profit or commercial products UNDER YOUR RESPONSIBILITY.
- Redistributions of source code must retain the above copyright notice.
Chapter 12

About

This is documentation of ESP-IDF, the framework to develop applications for ESP32 chip by Espressif.

The ESP32 is 2.4 GHz Wi-Fi and Bluetooth combo, which integrates one or two Xtensa® 32-bit LX6 CPU, with up to 600 DMIPS processing power.

![Diagram of ESP-IDF development process]

Fig. 1: Espressif IoT Integrated Development Framework

The ESP-IDF, Espressif IoT Development Framework, provides toolchain, API, components and workflows to develop applications for ESP32 using Windows, Linux and macOS operating systems.
Chapter 13

Switch Between Languages

The ESP-IDF Programming Guide is now available in two languages. Please refer to the English version if there is any discrepancy.

- English
- Chinese

You can easily change from one language to another by clicking the language link you can find at the top of every document that has a translation.

Fatal Errors

Overview

In certain situations, execution of the program can not be continued in a well defined way. In ESP-IDF, these situations include:

</tbody>
</table>

### Example Events

- `ESP_GATTC_WRITE_DESCR_EVT`: Handles write descriptor events.
- `ESP_GATTC_WRITE_CHAR_EVT`: Handles write characteristic events.
- `ESP_GATTC_UNREG_FOR_NOTIFY_EVT`: Handles unregister for notify events.
- `ESP_GATTC_UNREG_EVT`: Handles unregister events.
- `ESP_GATTC_SRVC_CHG_EVT`: Handles service change events.
- `ESP_GATTC_SET_ASSOC_EVT`: Handles set association events.
- `ESP_GATTC_SEARCH_CMPL_EVT`: Handles search completion events.
- `ESP_GATTC_SCAN_FLT_STATUS_EVT`: Handles scan filter status events.
- `ESP_GATTC_SCAN_FLT_PARAM_EVT`: Handles scan filter parameter events.
- `ESP_GATTC_SCAN_FLT_CFG_EVT`: Handles scan filter configuration events.
- `ESP_GATTC_REG_FOR_NOTIFY_EVT`: Handles register for notify events.
- `ESP_GATTC_REG_EVT`: Handles register events.
- `ESP_GATTC_READ_MULTIPLE_EVT`: Handles read multiple events.
- `ESP_GATTC_READ_DESCR_EVT`: Handles read descriptor events.
- `ESP_GATTC_PREP_WRITE_EVT`: Handles prepare write events.
- `ESP_GATTC_OPEN_EVT`: Handles open events.
- `ESP_GATTC_NOTIFY_EVT`: Handles notify events.
- `ESP_GATTC_MULT_ADV_UPD_EVT`: Handles multi-attribute update events.
- `ESP_GATTC_MULT_ADV_DIS_EVT`: Handles multi-attribute discovery events.
- `ESP_GATTC_MULT_ADV_DATA_EVT`: Handles multi-attribute data events.
- `ESP_GATTC_GET_ADDR_LIST_EVT`: Handles get address list events.
- `ESP_GATTC_EXEC_EVT`: Handles execution events.
- `ESP_GATTC_ENC_CMPL_CB_EVT`: Handles encryption completion events.

### Related Types

- `C++ struct`: Represents a specific data structure.
- `C++ enum`: Represents an enumerated type.
- `C++ member`: Represents a member of a structure.

</table>

**Note:** The above table lists some of the key components and members of the ESP32 System. The table includes various types such as functions, enumerators, members, and structs. Each entry is denoted by a unique identifier followed by its corresponding type and line number. The table entries are aligned logically, with each member or function grouped under its respective category.
