### 1.10 How Many Ways to Authenticate the Devices During Provisioning? Which Way Was Used in the provided examples ?

There are four authentication methods, i.e., No OOB, Static OOB, Output OOB and Input OOB. In the provided examples, No OOB is used.

### 1.11 What Information Can Be Carried by the Advertising Packets of the Unprovisioned Device Before Provisioning into the Network?

- Device UUID
- OOB Info
- URL Hash (optional)

### 1.12 Can Such Information Be Used for Device Identification?

For example, each unprovisioned device contains a unique Device UUID, which can be used for device identification.

### 1.13 How Is the Unicast Address Assigned When the Node Provisioned by Provisioner Contains Multiple Elements?

- Provisioner will assign an unicast address for the primary element of the node, and unicast address of the remaining elements are incremented one by one.
- For example: If an unprovisioned device has three elements, i.e., the primary element, the second element and the third element. After provisioning, the primary element address of the node is 0x0002 while the second element address is 0x0003, and the third element address is 0x0004.

### 1.14 How Can Provisioner Get and Parse the Composition Data of Nodes Through Configuration Client Model?

- Provisioner can get the Composition Data of nodes using the *Configuration Client Model* API `esp_ble_mesh_config_client_set_state()` with `comp_data_get` in the parameter `esp_ble_mesh_cfg_client_get_state_t` set properly.
- Users can refer to the following code to parse the Composition Data:

```
#include <stdio.h>
#include <string.h>
#include <stdint.h>

//test date: 0C001A0001000800030000010501000000800100001003103F002A00
//0C00 1A00 0100 0800 0300 0001 05 01 0000 0080 0100 0010 0310 3F002A00

// CID is 0x000C
// PID is 0x001A
// VID is 0x0001
// CRPL is 0x0008
// Features is 0x0003 - Relay and Friend features.
// Loc is "front" - 0x0100
// NumS is 5
// NumV is 1
// The Bluetooth SIG Models supported are: 0x0000, 0x8000, 0x0001, 0x1000,
→ 0x1003
// The Vendor Models supported are: Company Identifier 0x003F and Model_
→Identifier 0x002A

typedef struct {
    int16_t cid;
    int16_t pid;
    int16_t vid;
}
```

(continues on next page)

(continued from previous page)

```

                   0x00, 0x10, 0x03, 0x10,
                   0x3F, 0x00, 0x2A, 0x00};

int ret;

ret = decode_comp_data(&head, &data, mystr, sizeof(mystr));
if (ret == -1) {
    printf("decode_comp_data error");
}
}

```

### 1.15 How Can Provisioner Further Configure Nodes Through Obtained Composition Data?

Provisioner do the following configuration by calling the *Configuration Client Model* API `esp_ble_mesh_config_client_set_state()`.

- Add AppKey to nodes with `app_key_add` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Add subscription address to the models of nodes with `model_sub_add` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Set publication information to the models of nodes with `model_pub_set` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.

### 1.16 Can Nodes Add Corresponding Configurations for Themselves?

This method can be used in special cases like testing period.

- Here is an example to show nodes add new group addresses for their models.

```

esp_err_t example_add_fast_prov_group_address(uint16_t model_id, uint16_t
↪group_addr)
{
    const esp_ble_mesh_comp_t *comp = NULL;
    esp_ble_mesh_elem_t *element = NULL;
    esp_ble_mesh_model_t *model = NULL;
    int i, j;

    if (!ESP_BLE_MESH_ADDR_IS_GROUP(group_addr)) {
        return ESP_ERR_INVALID_ARG;
    }

    comp = esp_ble_mesh_get_composition_data();
    if (!comp) {
        return ESP_FAIL;
    }

    for (i = 0; i < comp->element_count; i++) {
        element = &comp->elements[i];
        model = esp_ble_mesh_find_sig_model(element, model_id);
        if (!model) {
            continue;
        }
        for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
            if (model->groups[j] == group_addr) {

```

(continues on next page)

(continued from previous page)

```

        break;
    }
}
if (j != ARRAY_SIZE(model->groups)) {
    ESP_LOGW(TAG, "%s: Group address already exists, element_
↪index: %d", __func__, i);
    continue;
}
for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
    if (model->groups[j] == ESP_BLE_MESH_ADDR_UNASSIGNED) {
        model->groups[j] = group_addr;
        break;
    }
}
if (j == ARRAY_SIZE(model->groups)) {
    ESP_LOGE(TAG, "%s: Model is full of group addresses, element_
↪index: %d", __func__, i);
}
}

return ESP_OK;
}

```

---

**Note:** When the NVS storage of the node is enabled, group address added and AppKey bound by this method will not be saved in the NVS when the device is powered off currently. These configuration information can only be saved if they are configured by Configuration Client Model.

---

### 1.17 How Does Provisioner Control Nodes by Grouping?

Generally there are two approaches to implement group control in ESP-BLE-MESH network, group address approach and virtual address approach. And supposing there are 10 devices, i.e., five devices with blue lights and five devices with red lights.

- Method 1: 5 blue lights can subscribe to a group address, 5 red lights subscribe to another one. By sending messages to different group addresses, Provisioner can realize group control.
- Method 2: 5 blue lights can subscribe to a virtual address, 5 red lights subscribe to another one. By sending messages to different virtual addresses, Provisioner can realize group control.

### 1.18 How Does Provisioner Add Nodes to Multiple Subnets?

Provisioner can add multiple NetKeys to nodes during configuration, and nodes sharing the same NetKey belong to the same subnet. Provisioner can communicate with nodes on different subnets by using different NetKeys.

### 1.19 How Does Provisioner Know If a Node in the Mesh Network Is Offline?

Node offline is usually defined as: the condition that the node cannot be properly communicated with other nodes in the mesh network due to power failure or some other reasons.

There is no connection between nodes and nodes in the ESP-BLE-MESH network. They communicate with each other through advertising channels.

An example is given here to show how to detect a node is offline by Provisioner.

- The node can periodically send heartbeat messages to Provisioner. And if Provisioner failed to receive heartbeat messages in a certain period, the node is considered to be offline.

---

**Note:** The heartbeat message should be designed into a single package (less than 11 bytes), so the transmission and reception of it can be more efficient.

---

### 1.20 What Operations Should Be Performed When Provisioner Removes Nodes from the Network?

Usually when Provisioner tries to remove node from the mesh network, the procedure includes three main steps:

- Firstly, Provisioner adds the node that need to be removed to the “blacklist” .
- Secondly, Provisioner performs the *Key Refresh procedure*.
- Lastly, the node performs node reset procedure, and switches itself to an unprovisioned device.

### 1.21 In the Key Refresh Procedure, How Does Provisioner Update the Netkey Owned by Nodes?

- Provisioner updates the NetKey of nodes using the *Configuration Client Model* API `esp_ble_mesh_config_client_set_state()` with `net_key_update` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Provisioner updates the AppKey of nodes using the *Configuration Client Model* API `esp_ble_mesh_config_client_set_state()` with `app_key_update` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.

### 1.22 How Does Provisioner Manage Nodes in the Mesh Network?

ESP-BLE-MESH implements several functions related to basic node management in the example, such as `esp_ble_mesh_store_node_info()`. And ESP-BLE-MESH also provides the API `esp_ble_mesh_provisioner_set_node_name()` which can be used to set the node’s local name and the API `esp_ble_mesh_provisioner_get_node_name()` which can be used to get the node’s local name.

### 1.23 What Does Provisioner Need When Trying to Control the Server Model of Nodes?

Provisioner must include corresponding client model before controlling the server model of nodes.

Provisioner shall add its local NetKey and AppKey.

- Provisioner add NetKey by calling the API `esp_ble_mesh_provisioner_add_local_net_key()`.
- Provisioner add AppKey by calling the API `esp_ble_mesh_provisioner_add_local_app_key()`.

Provisioner shall configure its own client model.

- Provisioner bind AppKey to its own client model by calling the API `esp_ble_mesh_provisioner_bind_app_key_to_local_model()`.

### 1.24 How Does Provisioner Control the Server Model of Nodes?

ESP-BLE-MESH supports all SIG-defined client models. Provisioner can use these client models to control the server models of nodes. And the client models are divided into 6 categories with each category has the corresponding functions.

- Configuration Client Model
  - The API `esp_ble_mesh_config_client_get_state()` can be used to get the `esp_ble_mesh_cfg_client_get_state_t` values of Configuration Server Model.
  - The API `esp_ble_mesh_config_client_set_state()` can be used to set the `esp_ble_mesh_cfg_client_set_state_t` values of Configuration Server Model.
- Health Client Model
  - The API `esp_ble_mesh_health_client_get_state()` can be used to get the `esp_ble_mesh_health_client_get_state_t` values of Health Server Model.

- The API `esp_ble_mesh_health_client_set_state()` can be used to set the `esp_ble_mesh_health_client_set_state_t` values of Health Server Model.
- **Generic Client Models**
  - The API `esp_ble_mesh_generic_client_get_state()` can be used to get the `esp_ble_mesh_generic_client_get_state_t` values of Generic Server Models.
  - The API `esp_ble_mesh_generic_client_set_state()` can be used to set the `esp_ble_mesh_generic_client_set_state_t` values of Generic Server Models.
- **Lighting Client Models**
  - The API `esp_ble_mesh_light_client_get_state()` can be used to get the `esp_ble_mesh_light_client_get_state_t` values of Lighting Server Models.
  - The API `esp_ble_mesh_light_client_set_state()` can be used to set the `esp_ble_mesh_light_client_set_state_t` values of Lighting Server Models.
- **Sensor Client Models**
  - The API `esp_ble_mesh_sensor_client_get_state()` can be used to get the `esp_ble_mesh_sensor_client_get_state_t` values of Sensor Server Model.
  - The API `esp_ble_mesh_sensor_client_set_state()` can be used to set the `esp_ble_mesh_sensor_client_set_state_t` values of Sensor Server Model.
- **Time and Scenes Client Models**
  - The API `esp_ble_mesh_time_scene_client_get_state()` can be used to get the `esp_ble_mesh_time_scene_client_get_state_t` values of Time and Scenes Server Models.
  - The API `esp_ble_mesh_time_scene_client_set_state()` can be used to set the `esp_ble_mesh_time_scene_client_set_state_t` values of Time and Scenes Server Models.

## 2. Node Development

### 2.1 What Kind of Models Are Included by Nodes?

- In ESP-BLE-MESH, nodes are all composed of a series of models with each model implements some functions of the node.
- Model has two types, client model and server model. Client model can get and set the states of server model.
- Model can also be divided into SIG model and vendor model. All behaviors of SIG models are officially defined while behaviors of vendor models are defined by users.

### 2.2 Is the Format of Messages Corresponding to Each Model Fixed?

- Messages, which consist of opcode and payload, are divided by opcode.
- The type and the format of the messages corresponding to models are both fixed, which means the messages transmitted between models are fixed.

### 2.3 Which Functions Can Be Used to Send Messages with the Models of Nodes?

- For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` to send messages.
- For server models, users can use the API `esp_ble_mesh_server_model_send_msg()` to send messages.
- For publication, users call the API `esp_ble_mesh_model_publish()` to publish messages.

### 2.4 How to Achieve the Transmission of Messages Without Packet Loss?

Acknowledged message is needed if users want to transmit messages without packet loss. The default time to wait for corresponding response is set in `CONFIG_BLE_MESH_CLIENT_MSG_TIMEOUT`. If the sender waits for the response until the timer expires, the corresponding timeout event would be triggered.

---

**Note:** Response timeout can be set in the API `esp_ble_mesh_client_model_send_msg()`. The default value (4 seconds) would be applied if the parameter `msg_timeout` is set to **0**.

---

### 2.5 How to Send Unacknowledged Messages?

For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` with the parameter `need_rsp` set to `false` to send unacknowledged messages.

For server models, the messages sent by using the API `esp_ble_mesh_server_model_send_msg()` are always unacknowledged messages.

### 2.6 How to Add Subscription Address to Models?

Subscription address can be added through Configuration Client Model.

### 2.7 What Is the Difference Between Messages Sent and Published by Models?

Messages sent by calling the API `esp_ble_mesh_client_model_send_msg()` or `esp_ble_mesh_server_model_send_msg()` will be sent in the duration determined by the Network Transmit state.

Messages published by calling the API `esp_ble_mesh_model_publish()` will be published determined by the Model Publication state. And the publication of messages is generally periodic or with a fixed number of counts. The publication period and publication count are controlled by the Model Publication state, and can be configured through Configuration Client Model.

### 2.8 How Many Bytes Can Be Carried When Sending Unsegmented Messages?

The total payload length (which can be set by users) of unsegmented message is 11 octets, so if the opcode of the message is 2 octets, then the message can carry 9-octets of valid information. For vendor messages, due to the 3-octets opcode, the remaining payload length is 8 octets.

### 2.9 When Should the Relay Feature of Nodes Be Enabled?

Users can enable the Relay feature of all nodes when nodes detected in the mesh network are sparse.

For dense mesh network, users can choose to just enable the Relay feature of several nodes.

And users can enable the Relay feature by default if the mesh network size is unknown.

### 2.10 When Should the Proxy Feature of Node Be Enabled?

If the unprovisioned device is expected to be provisioned by a phone, then it should enable the Proxy feature since almost all the phones do not support sending ESP-BLE-MESH packets through advertising bearer currently. And after the unprovisioned device is provisioned successfully and becoming a Proxy node, it will communicate with the phone using GATT bearer and using advertising bearer to communicate with other nodes in the mesh network.

### 2.11 How to Use the Proxy Filter?

The Proxy filter is used to reduce the number of Network PDUs exchanged between a Proxy Client (e.g., the phone) and a Proxy Server (e.g., the node). And with the Proxy filter, Proxy Client can explicitly request to receive only mesh messages with certain destination addresses from Proxy Server.

### 2.12 When a Message Can Be Relayed by a Relay Node?

If a message need to be relayed, the following conditions should be met.

- The message is in the mesh network.
- The message is not sent to the unicast address of the node.
- The value of TTL in the message is greater than 1.

### 2.13 If a Message Is Segmented into Several Segments, Should the Other Relay Nodes Just Relay When One of These Segments Is Received or Wait Until the Message Is Received Completely?

Relay nodes will forward segments when one of them are received rather than keeping waiting until all the segments are received.

### 2.14 What Is the Principle of Reducing Power Consumption Using Low Power Feature?

- When the radio is turned on for listening, the device is consuming energy. When low power feature of the node is enabled, it will turn off its radio in the most of the time.
- And cooperation is needed between low power node and friend node, thus low power node can receive messages at an appropriate or lower frequency without the need to keep listening.
- When there are some new messages for low power node, its friend node will store the messages for it. And low power node can poll friend nodes to see if there are new messages at a fixed interval.

### 2.15 How to Continue the Communication on the Network After Powering-down and Powering-up Again?

Enable the configuration `Store ESP-BLE-MESH Node configuration persistently` in `menuconfig`.

### 2.16 How to Send out the Self-test Results of Nodes?

It is recommended that nodes can publish its self-test results periodically through Health Server Model.

### 2.17 How to Transmit Information Between Nodes?

One possible application scenario for transmitting information between nodes is that spray nodes would be triggered once smoke alarm detected high smoke concentration. There are two approaches in implementation.

- Approach 1 is that spray node subscribes to a group address. When smoke alarm detects high smoke concentration, it will publish a message whose destination address is the group address which has been subscribed by spray node.
- Approach 2 is that Provisioner can configure the unicast address of spray node to the smoke alarm. When high smoke concentration is detected, smoke alarm can use send messages to the spray node with the spray node's unicast address as the destination address.

### 2.18 Is Gateway a Must for Nodes Communication?

- Situation 1: nodes only communicate within the mesh network. In this situation, no gateway is need. ESP-BLE-MESH network is a flooded network, messages in the network have no fixed paths, and nodes can communicate with each other freely.
- Situation 2: if users want to control the nodes remotely, for example turn on some nodes before getting home, then a gateway is needed.

### 2.19 When Will the IV Update Procedure Be Performed?

IV Update procedure would be performed once sequence number of messages sent detected by the bottom layer of node reached a critical value.

## 2.20 How to Perform IV Update Procedure?

Nodes can perform IV Update procedure with Secure Network Beacon.

## 3. ESP-BLE-MESH and Wi-Fi Coexistence

### 3.1 Which Modes Does Wi-Fi Support When it Coexists with ESP-BLE-MESH?

Currently only Wi-Fi station mode supports the coexistence.

### 3.2 Why Is the Wi-Fi Throughput So Low When Wi-Fi and ESP-BLE-MESH Coexist?

Some configurations in menuconfig shall be enabled to support PSRAM.

- `ESP32-C3-specific>Support for external, SPI-connected RAM>Try to allocate memories of Wi-Fi and LWIP...`
- `Bluetooth>Bluedroid Enable>BT/BLE will first malloc the memory from the PSRAM`
- `Bluetooth>Bluedroid Enable>Use dynamic memory allocation in BT/BLE stack`
- `Bluetooth>Bluetooth controller>BLE full scan feature supported`
- `Wi-Fi>Software controls Wi-Fi/Bluetooth coexistence>Wi-Fi`

## 4. Fast Provisioning

### 4.1 Why Is Fast Provisioning Needed?

Normally when they are several unprovisioned devices, users can provision them one by one. But when it comes to a large number of unprovisioned devices (e.g., 100), provisioning them one by one will take huge amount of time. With fast provisioning, users can provision 100 unprovisioned devices in about 50 seconds.

### 4.2 Why EspBleMesh App Would Wait for a Long Time During Fast Provisioning?

After the App provisioned one Proxy node, it will disconnect from the App during fast provisioning, and reconnect with the App when all the nodes are provisioned.

### 4.3 Why Is the Number of Node Addresses Displayed in the App Is More than That of Existing Node Addresses?

Each time after a fast provisioning process, and before starting a new one, the node addresses in the App should be cleared, otherwise the number of the node address will be incorrect.

### 4.4 What Is the Usage of the count Value Which Was Input in EspBleMesh App?

The **count** value is provided to the Proxy node which is provisioned by the App so as to determine when to start Proxy advertising in advance.

### 4.5 When will Configuration Client Model of the node running fast\_prov\_server example start to work?

Configuration Client Model will start to work after the Temporary Provisioner functionality is enabled.

### 4.6 Will the Temporary Provisioner Functionality Be Enabled All the Time?

After the nodes receive messages used to turn on/off lights, all the nodes will disable its Temporary Provisioner functionality and become nodes.

**5. Log Help** You can find meaning of errors or warnings when they appear at the bottom of ESP-BLE-MESH stack.

#### **5.1 What Is the Meaning of Warning ran out of retransmit attempts?**

When the node transmits a segmented message, and due to some reasons, the receiver does not receive the complete message. Then the node will retransmit the message. When the retransmission count reaches the maximum number, which is 4 currently, then this warning will appear.

#### **5.2 What Is the Meaning of Warning Duplicate found in Network Message Cache?**

When the node receives a message, it will compare the message with the ones stored in the network cache. If the same has been found in the cache, which means it has been received before, then the message will be dropped.

#### **5.3 What Is the Meaning of Warning Incomplete timer expired?**

When the node does not receive all the segments of a segmented message during a certain period (e.g., 10 seconds), then the Incomplete timer will expire and this warning will appear.

#### **5.4 What Is the Meaning of Warning No matching TX context for ack?**

When the node receives a segment ack and it does not find any self-send segmented message related with this ack, then this warning will appear.

#### **5.5 What Is the Meaning of Warning No free slots for new incoming segmented messages?**

When the node has no space for receiving new segmented message, this warning will appear. Users can make the space larger through the configuration `CONFIG_BLE_MESH_RX_SEG_MSG_COUNT`.

#### **5.6 What Is the Meaning of Error Model not bound to Appkey 0x0000?**

When the node sends messages with a model and the model has not been bound to the AppKey with AppKey Index 0x000, then this error will appear.

#### **5.7 What Is the Meaning of Error Busy sending message to DST xxxx?**

This error means client model of the node has transmitted a message to the target node and now is waiting for a response, users can not send messages to the same node with the same unicast address. After the corresponding response is received or timer is expired, then another message can be sent.

## **6. Example Help**

### **6.1 How Are the ESP-BLE-MESH Callback Functions Classified?**

- The API `esp_ble_mesh_register_prov_callback()` is used to register callback function used to handle provisioning and networking related events.
- The API `esp_ble_mesh_register_config_client_callback()` is used to register callback function used to handle Configuration Client Model related events.
- The API `esp_ble_mesh_register_config_server_callback()` is used to register callback function used to handle Configuration Server Model related events.
- The API `esp_ble_mesh_register_health_client_callback()` is used to register callback function used to handle Health Client Model related events.
- The API `esp_ble_mesh_register_health_server_callback()` is used to register callback function used to handle Health Server Model related events.

- The API `esp_ble_mesh_register_generic_client_callback()` is used to register callback function used to handle Generic Client Models related events.
- The API `esp_ble_mesh_register_light_client_callback()` is used to register callback function used to handle Lighting Client Models related events.
- The API `esp_ble_mesh_register_sensor_client_callback()` is used to register callback function used to handle Sensor Client Model related events.
- The API `esp_ble_mesh_register_time_scene_client_callback()` is used to register callback function used to handle Time and Scenes Client Models related events.
- The API `esp_ble_mesh_register_custom_model_callback()` is used to register callback function used to handle vendor model and unrealized server models related events.

## 7. Others

### 7.1 How to Print the Message Context?

The examples use `ESP_LOG_BUFFER_HEX()` to print the message context while the ESP-BLE-MESH protocol stack uses `bt_hex()`.

### 7.2 Which API Can Be Used to Restart ESP32-C3?

The API `esp_restart()`.

### 7.3 How to Monitor the Remaining Space of the Stack of a Task?

The API `vTaskList()` can be used to print the remaining space of the task stack periodically.

### 7.4 How to Change the Level of Log Without Changing the Menuconfig Output Level?

The API `esp_log_level_set()` can be used to change the log output level rather than using menuconfig to change it.

## Terminology

Table 11: Table 1 ESP-BLE-MESH Terminology - Role

Term	Official Definition	Detailed Explanation
Un-provisioned Device	A device that is not a member of a mesh network is known as an unprovisioned device.	Examples: lighting devices, temperature control devices, manufacturing equipment and electric doors, etc.
Node	A node is a provisioned device.	The role of unprovisioned device will change to node after being provisioned to ESP-BLE-MESH network. Nodes (such as lighting devices, temperature control devices, manufacturing equipment, and electric doors) are devices that can send, receive, or relay messages in ESP-BLE-MESH network, and they can optionally support one or more subnets.
Relay Node	A node that supports the Relay feature and has the Relay feature enabled is known as a Relay node.	Relay nodes can receive and resend ESP-BLE-MESH messages, so the messages can be transferred further. Users can decide whether or not to enable forwarding function of nodes according to nodes' status. Messages can be relayed for multiple times, and each relay is considered as a "hop". Messages can hop up to 126 times, which is enough for message transmission in a wide area.
Proxy Node	A node that supports the Proxy feature and has the Proxy feature enabled is known as a Proxy node.	Proxy nodes receive messages from one bearer (it generally includes advertising bearer and GATT bearer) and resend it from another one. The purpose is to connect communication equipment that only support GATT bearer to ESP-BLE-MESH network. Generally, mobile apps need a Proxy node to access Mesh network. Without Proxy nodes, mobile apps cannot communicate with members in Mesh network.
Friend Node	A node that supports the Friend feature, has the Friend feature enabled, and has a friendship with a node that supports the Low Power feature is known as a Friend node.	Friend node, like the backup of Low Power node (LPN), can store messages that are sent to Low Power node and security updates; the stored information will be transferred to Low Power node when Low Power node needs it. Low Power node must establish "friendship" with another node that supports the Friend Feature to reduce duty cycle of its receiver, thus power consumption of Low Power node can be reduced. Low Power node needs to find a Friend node to establish a friendship with it. The process involved is called "friendship establishment". Cooperation between Low Power node and Friend nodes enables Low Power node to schedule the use of the radio, thus Low Power node can receive messages at an appropriate or lower frequency without the need of keeping listening. Low Power node will poll Friend node to see if there is new message.
Low Power Node	A node that supports the Low Power feature and has a friendship with a node that supports the Friend feature is known as a Low Power node.	By polling, Low Power node gets information from Friend node, such as messages, security updates, and etc.
Provisioner	A node that is capable of adding a device to a mesh network.	The device that can provision unprovisioned devices is called a Provisioner. This process usually needs to be implemented through an app that is typically provided by the product manufacturer and can be used on a gateway, a smartphone, tablet or other carriers.

Table 12: Table 2 ESP-BLE-MESH Terminology - Composition

Term	Official Definition	Detailed Explanation
State	A value representing a condition of an element that is exposed by an element of a node.	Each node in a ESP-BLE-MESH network has an independent set of state values that indicate certain states of the device, like brightness, and color of lighting device. Change of state value will lead to change of the physical state of devices. For example, changing the on/off state of a device is actually turning on/off the device.
Model	A model defines the basic functionality of a node.	A node may contain multiple models, and each model defines basic functionalities of nodes, like the states needed by the nodes, the messages controlling the states, and actions resulted from messages handling. The function implementation of the nodes is based on models, which can be divided into SIG Model and Vendor Model, with the former defined by SIG and latter defined by users.
Element	An addressable entity within a device.	A node can contain one or more elements, with each having a unicast address and one or more models, and the models contained by the same element must not be the same.
Composition Data State	The Composition Data state contains information about a node, the elements it includes, and the supported models.	By reading the value of the Composition Data state, users can know basic information of the node, such as the number of elements, and the models in each element. Provisioner gets this message to further provision the device, such as configuring subscription address and publishing address of nodes.

Table 13: Table 3 ESP-BLE-MESH Terminology - Features

Term	Official Definition	Detailed Explanation
Low Power Feature	The ability to operate within a mesh network at significantly reduced receiver duty cycles only in conjunction with a node supporting the Friend feature.	Low Power feature reduces power consumption of nodes. When a Low Power node is searching for a Friend node, and there are multiple Friend nodes nearby, it selects the most suitable Friend node through algorithm.
Friend Feature	The ability to help a node supporting the Low Power feature to operate by storing messages destined for those nodes.	By enabling friend feature, the node can help to store information for Low Power node. The nodes enabled with friend feature may cause more power and memory consumption.
Relay Feature	The ability to receive and retransmit mesh messages over the advertising bearer to enable larger networks.	The relay feature enables ESP-BLE-MESH messages to hop among nodes for multiple times, and the transmission distance can exceed the range of direct radio transmission between two nodes, thereby covering the entire network. When a node is enabled with the relay feature to relay messages, it only relays the messages of its own subnet, and does not relay the messages of other subnets. The data integrity will not be considered when the node enabled with relay feature relays segmented messages. The node would relay every segmented message once it receives one rather than waiting for the complete message.
Proxy Feature	The ability to receive and retransmit mesh messages between GATT and advertising bearers.	The purpose of the proxy feature is to allow nodes without an advertising bearer to access the ESP-BLE-MESH network. The proxy feature is typically used in nodes that need to connect to mobile apps.

Table 14: Table 4 ESP-BLE-MESH Terminology - Provisioning

Term	Official Definition	Detailed Explanation
PB-ADV	PB-ADV is a provisioning bearer used to provision a device using Generic Provisioning PDUs over the advertising channels.	PB-ADV transfers packets generated during the provisioning process over the advertising channels. This way can only be used for provisioning when provisioner and unprovisioned device both support PB-ADV.
PB-GATT	PB-GATT is a provisioning bearer used to provision a device using Proxy PDUs to encapsulate Provisioning PDUs within the Mesh Provisioning Service.	PB-GATT uses connection channels to transfer packets generated during the provisioning process. If an unprovisioned device wants to be provisioned through this method, it needs to implement the related Mesh Provisioning Service. Unprovisioned devices which don't implement such service cannot be provisioned into mesh network through PB-GATT bearer.
Provisioning	Provisioning is a process of adding an unprovisioned device to a mesh network, managed by a Provisioner.	The process of provisioning turns the “unprovisioned device” into a “node”, making it a member of the ESP-BLE-MESH network.
Authentication Method	Authentication is a step during the provisioning of nodes.	There are four authentication methods for unprovisioned devices: Output OOB, Input OOB, Static OOB, and No OOB.
Input OOB	Input Out-of-Band	For example, a Provisioner generates and displays a random number, and then prompts users to take appropriate actions to input the random number into the unprovisioned device. Taking lighting switch as an example, users can press the button for several times in a certain period of time to input the random number displayed on the Provisioner. Authentication method of the Input OOB is similar to that of Output OOB, but the role of the device is reversed.
Output OOB	Output Out-of-Band	For example, an unprovisioned device will choose a random number and output the number in a way that is compatible with its functionality. If the unprovisioned device is a bulb, it can flash a specified number of times. If the unprovisioned device has an LCD screen, the random number can display as a multi-digit value. Users who start provisioning should input the observed number to authenticate the unprovisioned device.
Static OOB	Static Out-of-Band	Authentication method of Static OOB: use Static OOB information. Use 0 as Static OOB information if No OOB information is needed. Use Static OOB information to authenticate devices which are going through provisioning if OOB information is needed.
No OOB	No Out-of-Band	Authentication method of No OOB: Set the value of the Static OOB field to 0. Using this way is like not authenticating the unprovisioned devices.

Table 15: Table 5 ESP-BLE-MESH Terminology - Address

Term	Official Definition	Detailed Explanation
Unassigned Address	This is a special address type, with a value of 0x0000. Its use indicates that an Element has not yet been configured or had a Unicast Address assigned to it.	The addresses owned by elements which has not been configured yet or no address has been allocated are unassigned addresses. These elements will not be used for messages transfer because they have no fixed address. Unassigned address is recommended to set as the value of the address before setting the address of user code.
Unicast Address	A unicast address is a unique address allocated to each element.	During provisioning, the Provisioner will assign a unicast address to each element of node within the life cycle of the nodes in the network. A unicast address may appear in the source/destination address field of a message. Messages sent to a unicast address can only be processed by the element that owns the unicast address.
Virtual Address	A virtual address represents a set of destination addresses. Each virtual address logically represents a Label UUID, which is a 128-bit value that does not have to be managed centrally.	Associated with specific UUID labels, a virtual address may serve as the publishing or subscription address of the model. A UUID label is a 128-bit value associated with elements of one or more nodes. For virtual addresses, the 15th and 14th bits are set to 1 and 0 respectively; bits from 13th to 0 are set to hash values (providing 16384 hash values). The hash is a derivation of the Label UUID. To use subscribing elements to check the full 128-bit UUID is very inefficient while hash values provide a more efficient way to determine which elements that which messages are finally sent to.
Group Address	A group address is an address that is programmed into zero or more elements	Group address is another kind of multicast address in the ESP-BLE-MESH network, which is usually used to group nodes. A message sent to the all-proxies address shall be processed by the primary element of all nodes that have the proxy functionality enabled. A message sent to the all-friends address shall be processed by the primary element of all nodes that have the friend functionality enabled. A message sent to the all-relays address shall be processed by the primary element of all nodes that have the relay functionality enabled. A message sent to the all-nodes address shall be processed by the primary element of all nodes.

Table 16: Table 6 ESP-BLE-MESH Terminology - Security

Term	Official Definition	Detailed Explanation
Device Key (DevKey)	There is also a device key, which is a special application key that is unique to each node, is known only to the node and a Configuration Client, and is used to secure communications between the node and a Configuration Client.	The device key enables you to provision the devices, configure the nodes. The device key is used to encrypt Configuration Messages, i.e., the message transferred between the Provisioner and the node when the device is configured.
Application Key (AppKey)	Application keys are used to secure communications at the upper transport layer.	Application key is used for decryption of application data before delivering application data to application layer and encryption of them during the delivery of application layer. Some nodes in the network have a specific purpose and can restrict access to potentially sensitive data based on the needs of the application. With specific application keys, these nodes are associated with specific applications. Generally speaking, the fields using different application keys include security (access control of buildings, machine rooms and CEO offices), lighting (plant, exterior building and sidewalks) and HVAC systems. Application keys are bound to Network keys. This means application keys are only used in a context of a Network key they are bound to. An application key shall only be bound to a single Network key.
Master Security Material	The master security material is derived from the network key (NetKey) and can be used by other nodes in the same network. Messages encrypted with master security material can be decoded by any node in the same network.	The corresponding friendship messages encrypted with the friendship security material: 1. Friend Poll, 2. Friend Update, 3. Friend Subscription List, add/delete/confirm, 4. The Stored Messages” sent by friend nodes to Low Power node. The corresponding friendship messages encrypted with the master security material: 1. Friend Clear, 2. Friend Clear Confirm. Based on the setup of the applications, the messages sent from the Low Power node to the friend nodes will be encrypted with the friendship security material or master security material, with the former being used by the messages transmitted between Low Power node and friend nodes and the latter being used by other network messages.

Table 17: Table 7 ESP-BLE-MESH Terminology - Message

Term	Official Definition	Detailed Explanation
Re-assembly/Segmentation	Segmentation and reassembly (SAR) is a method of communication network, which is divided into small units before transmitting packets and reassembled in a proper order at the communication receiving end.	The lower transport layer will automatically segment the message whose size is too big. The receiving end will return a response message, and the transmitting end will send the data packet again that the receiving end does not receive according to the response message. This is automatically completed by the lower transport layer. Unsegmented messages have at most 15 bytes, of which 4 bytes are transMIC, so the remaining is 11 bytes; in the case of segmentation, there are 12 valid bytes in the first several packets, and 8 in the last one. Special case: A shorter packet requires mandatory segmentation from lower transport layer, in which case the valid byte is 8 bytes.
Unacknowledged/Acknowledged	There are two types of messages: Unacknowledged or Acknowledged	Based on the whether or not the receiving end needs to send the response message, the messages sent are divided into two kinds. The sending end should set the maximum number of retransmission.

Table 18: Table 8 ESP-BLE-MESH Terminology - Foundation Models

Term	Official Definition	Detailed Explanation
Configuration Server Model	This model is used to represent a mesh network configuration of a device.	The node must contain the Configuration Server Model, which is responsible for maintaining configuration-related states. The states that Configuration Server Model maintains include: NetKey List, AppKey List, Model to AppKey List, Node Identity, Key Refresh Phase, Heartbeat Publish, Heartbeat Subscription, Network Transmit, Relay Retransmit etc.
Configuration Client Model	The model is used to represent an element that can control and monitor the configuration of a node.	The Configuration Client Model uses messages to control the state maintained by the Configuration Server Model. The Provisioner must contain the Configuration Client Model, with which the configuration messages, like Configuration Composition Data Get can be sent.
Health Server Model	This model is used to represent a mesh network diagnostics of a device.	The Health Server Model is primarily used by devices to check their states and see if there is an error. The states maintained by Health Server model include: Current Fault, Registered Fault, Health Period, and Attention Timer.
Health Client Model	The model is used to represent an element that can control and monitor the health of a node.	The Health Client Model uses messages to control the state maintained by the Health Server Model. The model can get the self-test information of other nodes through the message "Health Fault Get" .

Table 19: Table 9 ESP-BLE-MESH Terminology - Network Management

Term	Official Definition	Detailed Explanation
Key Refresh procedure	This procedure is used when the security of one or more network keys and/or one or more of the application keys has been compromised or could be compromised.	Key Refresh Procedure is used to update network key and application key of ESP-BLE-MESH network. Key Refresh Procedure is used when the security of one or more network keys and/or one or more application keys is threatened or potentially threatened. Keys are usually updated after some nodes in the network are removed.
IV (Initialization Vector) Update Procedure	A node can also use an IV Update procedure to signal to peer nodes that it is updating the IV Index.	The IV Update procedure is used to update the value of ESP-BLE-MESH network's IV Index. This value is related to the random number required for message encryption. To ensure that the value of the random number is not repeated, this value is periodically incremented. IV Index is a 32-bit value and a shared network resource. For example, all nodes in a mesh network share the same IV Index value. Starting from 0x00000000, the IV Index increments during the IV Update procedure and maintained by a specific process, ensuring the IV Index shared in the mesh network is the same. This can be done when the node believes that it has the risk of exhausting its sequence number, or when it determines that another node is nearly exhausting its sequence number. Note: The update time must not be less than 96 hours. It can be triggered when a secure network beacon is received, or when the node determines that its sequence number is greater than a certain value.

## BluFi

**Overview** The BluFi for ESP32-C3 is a Wi-Fi network configuration function via Bluetooth channel. It provides a secure protocol to pass Wi-Fi configuration and credentials to ESP32-C3. Using this information, ESP32-C3 can then connect to an AP or establish a SoftAP.

Fragmenting, data encryption, and checksum verification in the BluFi layer are the key elements of this process.

You can customize symmetric encryption, asymmetric encryption, and checksum support customization. Here we use the DH algorithm for key negotiation, 128-AES algorithm for data encryption, and CRC16 algorithm for checksum verification.

**The BluFi Flow** The BluFi networking flow includes the configuration of the SoftAP and Station.

The following uses Station as an example to illustrate the core parts of the procedure, including broadcast, connection, service discovery, negotiation of the shared key, data transmission, and connection status backhaul.

1. Set the ESP32-C3 into GATT Server mode and then it will send broadcasts with specific *advertising data*. You can customize this broadcast as needed, which is not a part of the BluFi Profile.
2. Use the App installed on the mobile phone to search for this particular broadcast. The mobile phone will connect to ESP32-C3 as the GATT Client once the broadcast is confirmed. The App used during this part is up to you.
3. After the GATT connection is successfully established, the mobile phone will send a data frame for key negotiation to ESP32-C3 (see the section *The Frame Formats Defined in BluFi* for details).
4. After ESP32-C3 receives the data frame of key negotiation, it will parse the content according to the user-defined negotiation method.
5. The mobile phone works with ESP32-C3 for key negotiation using the encryption algorithms, such as DH, RSA, or ECC.
6. After the negotiation process is completed, the mobile phone will send a control frame for security-mode setup to ESP32-C3.
7. When receiving this control frame, ESP32-C3 will be able to encrypt and decrypt the communication data using the shared key and the security configuration.
8. The mobile phone sends the data frame defined in the section of *The Frame Formats Defined in BluFi*, with the Wi-Fi configuration information to ESP32-C3, including SSID, password, etc.
9. The mobile phone sends a control frame of Wi-Fi connection request to ESP32-C3. When receiving this control frame, ESP32-C3 will regard the communication of essential information as done and get ready to connect to the Wi-Fi.
10. After connecting to the Wi-Fi, ESP32-C3 will send a control frame of Wi-Fi connection status report to the mobile phone. At this point, the networking procedure is completed.

---

### Note:

1. After ESP32-C3 receives the control frame of security-mode configuration, it will execute the operations in accordance with the defined security mode.
  2. The data lengths before and after symmetric encryption/decryption must stay the same. It also supports in-place encryption and decryption.
- 

### The Flow Chart of BluFi

Fig. 35: BluFi Flow Chart

**The Frame Formats Defined in BluFi** The frame formats for the communication between the mobile phone App and ESP32-C3 are defined as follows:

The frame format with no fragment:

Field	Value (Byte)
Type (Least Significant Bit)	1
Frame Control	1
Sequence Number	1
Data Length	1
Data	\${Data Length}
Checksum (Most Significant Bit)	2

If the frag frame bit in the **Frame Control** field is enabled, there would be a 2-byte **Total Content Length** field in the **Data** field. This **Total Content Length** field indicates the length of the remaining part of the frame and also tells the remote how much memory needs to be allocated.

The frame format with fragments:

Field	Value (Byte)
Type (Least Significant Bit)	1
Frame Control (Frag)	1
Sequence Number	1
Data Length	1
Data	<ul style="list-style-type: none"> <li>• Total Content Length: 2</li> <li>• Content: \${Data Length} - 2</li> </ul>
Checksum (Most Significant Bit)	2

Normally, the control frame does not contain data bits, except for ACK Frame.

The format of ACK Frame:

Field	Value (Byte)
Type - ACK (Least Significant Bit)	1
Frame Control	1
Sequence Number	1
Data Length	1
Data	Acked Sequence Number: 2
Checksum (Most Significant Bit)	2

#### 1. Type

**Type** field takes 1 byte and is divided into **Type** and **Subtype**. **Type** uses the lower two bits, indicating whether the frame is a data frame or a control frame. **Subtype** uses the upper six bits, indicating the specific meaning of this data frame or control frame.

- The control frame is not encrypted for the time being and supports to be verified.
- The data frame supports to be encrypted and verified.

##### 1.1 Control Frame (Binary: 0x0 b' 00)

Control Frame	Implication	Explanation	Note
0x0 (b'000000)	ACK	The data field of the ACK frame uses the same sequence value of the frame to reply to.	The data field consumes a byte and its value is the same as the sequence field of the frame to reply to.
0x1 (b'000001)	Set the ESP device to the security mode.	To inform the ESP device of the security mode to use when sending data, which is allowed to be reset multiple times during the process. Each setting affects the subsequent security mode used. If it is not set, the ESP device will send the control frame and data frame with no checksum and encryption by default. The data transmission from the mobile phone to the ESP device is controlled by this control frame.	The data field consumes a byte. The higher four bits are for the security mode setting of the control frame, and the lower four bits are for the security mode setting of the data frame. <ul style="list-style-type: none"> <li>b' 0000: no checksum and no encryption;</li> <li>b' 0001: with checksum but no encryption;</li> <li>b' 0010: no checksum but with encryption;</li> <li>b' 0011: with both checksum and encryption.</li> </ul>
0x2 (b'000010)	Set the opmode of Wi-Fi.	The frame contains opmode settings for configuring the Wi-Fi mode of the ESP device.	data[0] is for opmode settings, including: <ul style="list-style-type: none"> <li>0x00: NULL</li> <li>0x01: STA</li> <li>0x02: SoftAP</li> <li>0x03: SoftAP &amp; STA</li> </ul> Please set the SSID/Password/Max Connection Number of the AP mode in the first place if an AP gets involved.
0x3 (b'000011)	Connect the ESP device to the AP.	To notify the ESP device that the essential information has been sent and it is allowed to connect to the AP.	No data field is contained.
0x4 (b'000100)	Disconnect the ESP device from the AP.		No data field is contained.
0x5 (b'000101)	To get the information of the ESP device's Wi-Fi mode and it's status.		<ul style="list-style-type: none"> <li>No data field is contained. When receiving this control frame, the ESP device will send back a follow-up frame of Wi-Fi connection state report to the mobile phone with the information of the current opmode, connection status, SSID, and so on.</li> <li>The types of information sent to the mobile phone is defined by the application installed on the phone.</li> </ul>
0x6 (b'000110)	Disconnect the STA device from the SoftAP (in SoftAP mode).		Data[0~5] is taken as the MAC address for the STA device. If there is a second STA device, then it uses data[6-11] and the rest can be done in the same manner.
0x7 (b'000111)	Get the version information.		
0x8 (b'001000)	Disconnect the BLE GATT link.		The ESP device will disconnect the BLE GATT link after receives this command.
0x9 (b'001001)	Get the Wi-Fi list.	To get the ESP device to scan the Wi-Fi access points around	No data field is contained. When receiving this control frame, the ESP device will send back a follow-up frame of Wi-Fi list report to the mobile phone.

## 1.2 Data Frame (Binary: 0x1 b' 01)

Data Frame	Implication	Explanation	Note
0x0 (b'000000)	Send the negotiation data.	The negotiation data will be sent to the callback function registered in the application layer.	The length of the data depends on the length field.
0x1 (b'000001)	Send the SSID for STA mode.	To send the BSSID of the AP for the STA device to connect under the condition that the SSID is hidden.	Please refer to Note 1 below.
0x2 (b'000010)	Send the SSID for STA mode.	To send the SSID of the AP for the STA device to connect.	Please refer to Note 1 below.
0x3 (b'000011)	Send the password for STA mode.	To send the password of the AP for the STA device to connect.	Please refer to Note 1 below.
0x4 (b'000100)	Send the SSID for SoftAP mode.		Please refer to Note 1 below.
0x5 (b'000101)	Send the password for SoftAP mode.		Please refer to Note 1 below.
0x6 (b'000110)	Set the maximum connection number for SoftAP mode.		data[0] represents the value of the connection number, ranging from 1 to 4. When the transmission direction is ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
0x7 (b'000111)	Set the authentication mode for SoftAP mode.		data[0]: <ul style="list-style-type: none"> <li>• 0x00: OPEN</li> <li>• 0x01: WEP</li> <li>• 0x02: WPA_PSK</li> <li>• 0x03: WPA2_PSK</li> <li>• 0x04: WPA_WPA2_PSK</li> </ul> When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
0x8 (b'001000)	Set the number of channels for SoftAP mode.		data[0] represents the quantity of the supported channels, ranging from 1 to 14. When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
0x9 (b'001001)	Username	It provides the username of the GATT client when using encryption of enterprise level.	The length of the data depends on the length field.
0xa (b'001010)	CA Certification	It provides the CA Certification when using encryption of enterprise level.	Please refer to Note 2 below.
0xb (b'001011)	Client Certification	It provides the client certification when using encryption of enterprise level. Whether the private key is contained or not depends on the content of the certification.	Please refer to Note 2 below.
0xc (b'001100)	Server Certification	It provides the sever certification when using encryption of enterprise level. Whether the private key is contained or not depends on the content of the certification.	Please refer to Note 2 below.
Espressif Systems			Release v5.0.8-213-gf5fc6672ff
0xd (b'001101)	Client Private Key	It provides the private key of the client when using encryption of enterprise level.	Please refer to Note 2 below.

**Note:**

- Note 1: The length of the data depends on the data length field. When the transmission direction is from the ESP device to the mobile phone, it means to provide the mobile phone with the needed information.
- Note 2: The length of the data depends on the data length field. The frame supports to be fragmented if the data length is not long enough.

## 2. Frame Control

The **Frame Control** field takes one byte and each bit has a different meaning.

Bit	Meaning
0x01	Indicates whether the frame is encrypted. <ul style="list-style-type: none"> <li>• 1 means encrypted.</li> <li>• 0 means unencrypted.</li> </ul> The encrypted part of the frame includes the full clear data before the DATA field is encrypted (no checksum). Control frame is not encrypted, so this bit is 0.
0x02	Indicates whether a frame contains a checksum (such as SHA1, MD5, CRC) for the end of the frame. Data field includes sequence, data length, and clear text. Both the control frame and the data frame can choose whether to contain a check bit or not.
0x04	Indicates the data direction. <ul style="list-style-type: none"> <li>• 0 means from the mobile phone to the ESP device.</li> <li>• 1 means from the ESP device to the mobile phone.</li> </ul>
0x08	Indicates whether the other person is required to reply to an ACK. <ul style="list-style-type: none"> <li>• 0 indicates not required to reply to an ACK.</li> <li>• 1 indicates required to reply to an ACK.</li> </ul>
0x10	Indicates whether there are subsequent data fragments. <ul style="list-style-type: none"> <li>• 0 indicates that there is no subsequent data fragment for this frame.</li> <li>• 1 indicates that there are subsequent data fragments which used to transmit longer data.</li> </ul> In the case of a frag frame, the total length of the current content section + subsequent content section is given in the first two bytes of the data field (that is, the content data of the maximum support 64 K).
0x10~0x80	Reserved

## 3. Sequence Number

The **Sequence Number** field is the field for sequence control. When a frame is sent, the value of this field is automatically incremented by 1 regardless of the type of frame, which prevents Replay Attack. The sequence would be cleared after each reconnection.

## 4. Data Length

The **Data Length** field indicates the length of the data field, which does not include CheckSum.

## 5. Data

Content of the **Data** field can be different according to various values of Type or Subtype. Please refer to the table above.

## 6. CheckSum

The **CheckSum** field takes two bytes, which is used to check “sequence + data length + clear text data” .

**The Security Implementation of ESP32-C3**

## 1. Securing Data

To ensure that the transmission of the Wi-Fi SSID and password is secure, the message needs to be encrypted using symmetric encryption algorithms, such as AES, DES, and so on. Before using symmetric encryption algorithms, the devices are required to negotiate (or generate) a shared key using an asymmetric encryption algorithm (DH, RSA, ECC, etc).

## 2. Ensuring Data Integrity

To ensure data integrity, you need to add a checksum algorithm, such as SHA1, MD5, CRC, etc.

### 3. Securing Identity (Signature)

Algorithm like RSA can be used to secure identity. But for DH, it needs other algorithms as a companion for signature.

### 4. Replay Attack Prevention

It is added to the Sequence Number field and used during the checksum verification.

For the coding of ESP32-C3, you can determine and develop the security processing, such as key negotiation. The mobile application sends the negotiation data to ESP32-C3, and then the data will be sent to the application layer for processing. If the application layer does not process it, you can use the DH encryption algorithm provided by BluFi to negotiate the key.

The application layer needs to register several security-related functions to BluFi:

```
typedef void (*esp_blufi_negotiate_data_handler_t) (uint8_t *data, int len, uint8_t *
↳**output_data, int *output_len, bool *need_free)
```

This function is for ESP32-C3 to receive normal data during negotiation. After processing is completed, the data will be transmitted using Output\_data and Output\_len.

BluFi will send output\_data from Negotiate\_data\_handler after Negotiate\_data\_handler is called.

Here are two “\*”, which means the length of the data to be emitted is unknown. Therefore, it requires the function to allocate itself (malloc) or point to the global variable to inform whether the memory needs to be freed by NEED\_FREE.

```
typedef int (* esp_blufi_encrypt_func_t) (uint8_t iv8, uint8_t *crypt_data, int_
↳crypt_len)
```

The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as a 8-bit of IV.

```
typedef int (* esp_blufi_decrypt_func_t) (uint8_t iv8, uint8_t *crypt_data, int_
↳crypt_len)
```

The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as an 8-bit of IV.

```
typedef uint16_t (*esp_blufi_checksum_func_t) (uint8_t iv8, uint8_t *data, int len)
```

This function is used to compute CheckSum and return a value of CheckSum. BluFi uses the returned value to compare the CheckSum of the frame.

## GATT Related Instructions

**UUID** BluFi Service UUID: 0xFFFF, 16 bit

BluFi (the mobile > ESP32-C3): 0xFF01, writable

Blufi (ESP32-C3 > the mobile phone): 0xFF02, readable and callable

## 4.4 Bootloader

The ESP-IDF Software Bootloader performs the following functions:

1. Minimal initial configuration of internal modules;
2. Initialize *Flash Encryption* and/or *Secure* features, if configured;
3. Select the application partition to boot, based on the partition table and ota\_data (if any);
4. Load this image to RAM (IRAM & DRAM) and transfer management to the image that was just loaded.

Bootloader is located at the address 0x0 in the flash.

For a full description of the startup process including the the ESP-IDF bootloader, see [Application Startup Flow](#).

### 4.4.1 Bootloader compatibility

It is recommended to update to newer *versions of ESP-IDF*: when they are released. The OTA (over the air) update process can flash new apps in the field but cannot flash a new bootloader. For this reason, the bootloader supports booting apps built from newer versions of ESP-IDF.

The bootloader does not support booting apps from older versions of ESP-IDF. When updating ESP-IDF manually on an existing product that might need to downgrade the app to an older version, keep using the older ESP-IDF bootloader binary as well.

---

**Note:** If testing an OTA update for an existing product in production, always test it using the same ESP-IDF bootloader binary that is deployed in production.

---

### SPI Flash Configuration

Each ESP-IDF application or bootloader .bin file contains a header with [CONFIG\\_ESPTOOLPY\\_FLASHMODE](#), [CONFIG\\_ESPTOOLPY\\_FLASHFREQ](#), [CONFIG\\_ESPTOOLPY\\_FLASHSIZE](#) embedded in it. These are used to configure the SPI flash during boot.

The *First stage bootloader* in ROM reads the *Second stage bootloader* header information from flash and uses this information to load the rest of the *Second stage bootloader* from flash. However, at this time the system clock speed is lower than configured and not all flash modes are supported. When the *Second stage bootloader* then runs, it will reconfigure the flash using values read from the currently selected app binary's header (and NOT from the *Second stage bootloader* header). This allows an OTA update to change the SPI flash settings in use.

### 4.4.2 Log Level

The default bootloader log level is “Info” . By setting the [CONFIG\\_BOOTLOADER\\_LOG\\_LEVEL](#) option, it's possible to increase or decrease this level. This log level is separate from the log level used in the app (see [Logging library](#)).

Reducing bootloader log verbosity can improve the overall project boot time by a small amount.

### 4.4.3 Factory reset

Sometimes it is desirable to have a way for the device to fall back to a known-good state, in case of some problem with an update.

To roll back to the original “factory” device configuration and clear any user settings, configure the config item [CONFIG\\_BOOTLOADER\\_FACTORY\\_RESET](#) in the bootloader.

The factory reset mechanism allows the device to be factory reset in two ways:

- Clear one or more data partitions. The [CONFIG\\_BOOTLOADER\\_DATA\\_FACTORY\\_RESET](#) option allows users to specify which data partitions will be erased when the factory reset is executed. Users can specify the names of partitions as a comma-delimited list with optional spaces for readability. (Like this: `nvs, phy_init, nvs_custom`). Make sure that the names of partitions specified in the option are the same as those found in the partition table. Partitions of type “app” cannot be specified here.
- Boot from “factory” app partition. Enabling the [CONFIG\\_BOOTLOADER\\_OTA\\_DATA\\_ERASE](#) option will cause the device to boot from the default “factory” app partition after a factory reset (or if there is no factory app partition in the partition table then the default ota app partition is selected instead). This reset process

involves erasing the OTA data partition which holds the currently selected OTA partition slot. The “factory” app partition slot (if it exists) is never updated via OTA, so resetting to this allows reverting to a “known good” firmware application.

Either or both of these configuration options can be enabled independently.

In addition, the following configuration options control the reset condition:

- [\*CONFIG\\_BOOTLOADER\\_NUM\\_PIN\\_FACTORY\\_RESET\*](#) - The input GPIO number used to trigger a factory reset. This GPIO must be pulled low or high (configurable) on reset to trigger this.
- [\*CONFIG\\_BOOTLOADER\\_HOLD\\_TIME\\_GPIO\*](#) - this is hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.
- [\*CONFIG\\_BOOTLOADER\\_FACTORY\\_RESET\\_PIN\\_LEVEL\*](#) - configure whether a factory reset should trigger on a high or low level of the GPIO. If the GPIO has an internal pullup then this is enabled before the pin is sampled, consult the ESP32-C3 datasheet for details on pin internal pullups.

#### 4.4.4 Boot from Test Firmware

It’s possible to write a special firmware app for testing in production, and boot this firmware when needed. The project partition table will need a dedicated app partition entry for this testing app, type `app` and subtype `test` (see [\*Partition Tables\*](#)).

Implementing a dedicated test app firmware requires creating a totally separate ESP-IDF project for the test app (each project in ESP-IDF only builds one app). The test app can be developed and tested independently of the main project, and then integrated at production testing time as a pre-compiled `.bin` file which is flashed to the address of the main project’s test app partition.

To support this functionality in the main project’s bootloader, set the configuration item [\*CONFIG\\_BOOTLOADER\\_APP\\_TEST\*](#) and configure the following two items:

- [\*CONFIG\\_BOOTLOADER\\_NUM\\_PIN\\_APP\\_TEST\*](#) - GPIO number to boot TEST partition. The selected GPIO will be configured as an input with internal pull-up enabled. To trigger a test app, this GPIO must be pulled low on reset.  
Once the GPIO input is released (allowing it to be pulled up) and the device has been reboot, the normally configured application will boot (factory or any OTA app partition slot).
- [\*CONFIG\\_BOOTLOADER\\_HOLD\\_TIME\\_GPIO\*](#) - this is hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held low continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.

#### 4.4.5 Rollback

Rollback and anti-rollback features must be configured in the bootloader as well.

Consult the [\*App rollback\*](#) and [\*Anti-rollback\*](#) sections in the [\*OTA API reference document\*](#).

#### 4.4.6 Watchdog

By default, the hardware RTC Watchdog timer remains running while the bootloader is running and will automatically reset the chip if no app has successfully started after 9 seconds.

- The timeout period can be adjusted by setting [\*CONFIG\\_BOOTLOADER\\_WDT\\_TIME\\_MS\*](#) and recompiling the bootloader.
- The app’s behaviour can be adjusted so the RTC Watchdog remains enabled after app startup. The Watchdog would need to be explicitly reset (i.e., fed) by the app to avoid a reset. To do this, set the [\*CONFIG\\_BOOTLOADER\\_WDT\\_DISABLE\\_IN\\_USER\\_CODE\*](#) option, modify the app as needed, and then recompile the app.
- The RTC Watchdog can be disabled in the bootloader by disabling the [\*CONFIG\\_BOOTLOADER\\_WDT\\_ENABLE\*](#) setting and recompiling the bootloader. This is not recommended.

### 4.4.7 Bootloader Size

When enabling additional bootloader functions, including *Flash Encryption* or Secure Boot, and especially if setting a high `CONFIG_BOOTLOADER_LOG_LEVEL` level, then it is important to monitor the bootloader .bin file's size.

When using the default `CONFIG_PARTITION_TABLE_OFFSET` value 0x8000, the size limit is 0x8000 (32768) bytes.

If the bootloader binary is too large, then the bootloader build will fail with an error “Bootloader binary size [...] is too large for partition table offset” . If the bootloader binary is flashed anyhow then the ESP32-C3 will fail to boot - errors will be logged about either invalid partition table or invalid bootloader checksum.

Options to work around this are:

- Set *bootloader compiler optimization* back to “Size” if it has been changed from this default value.
- Reduce *bootloader log level*. Setting log level to Warning, Error or None all significantly reduce the final binary size (but may make it harder to debug).
- Set `CONFIG_PARTITION_TABLE_OFFSET` to a higher value than 0x8000, to place the partition table later in the flash. This increases the space available for the bootloader. If the *partition table* CSV file contains explicit partition offsets, they will need changing so no partition has an offset lower than `CONFIG_PARTITION_TABLE_OFFSET + 0x1000`. (This includes the default partition CSV files supplied with ESP-IDF.)

When Secure Boot V2 is enabled, there is also an absolute binary size limit of 64KB (0x10000 bytes) (excluding the 4 KB signature), because the bootloader is first loaded into a fixed size buffer for verification.

### 4.4.8 Fast boot from Deep Sleep

The bootloader has the `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` option which allows the wake-up time from deep sleep to be reduced (useful for reducing power consumption). This option is available when `CONFIG_SECURE_BOOT` option is disabled. Reduction of time is achieved due to the lack of image verification. During the first boot, the bootloader stores the address of the application being launched in the RTC FAST memory. And during the awakening, this address is used for booting without any checks, thus fast loading is achieved.

### 4.4.9 Custom bootloader

The current bootloader implementation allows a project to extend it or modify it. There are two ways of doing it: by implementing hooks or by overriding it. Both ways are presented in `custom_bootloader` folder in ESP-IDF examples:

- `bootloader_hooks` which presents how to connect some hooks to the bootloader initialization
- `bootloader_override` which presents how to override the bootloader implementation

In the bootloader space, you cannot use the drivers and functions from other components. If necessary, then the required functionality should be placed in the project's `bootloader_components` directory (note that this will increase its size).

If the bootloader grows too large then it can collide with the partition table, which is flashed at offset 0x8000 by default. Increase the *partition table offset* value to place the partition table later in the flash. This increases the space available for the bootloader.

## 4.5 Build System

This document explains the implementation of the ESP-IDF build system and the concept of “components” . Read this document if you want to know how to organize and build a new ESP-IDF project or component.

## 4.5.1 Overview

An ESP-IDF project can be seen as an amalgamation of a number of components. For example, for a webserver that shows the current humidity, there could be:

- The ESP-IDF base libraries (libc, ROM bindings, etc)
- The Wi-Fi drivers
- A TCP/IP stack
- The FreeRTOS operating system
- A webserver
- A driver for the humidity sensor
- Main code tying it all together

ESP-IDF makes these components explicit and configurable. To do that, when a project is compiled, the build system will look up all the components in the ESP-IDF directories, the project directories and (optionally) in additional custom component directories. It then allows the user to configure the ESP-IDF project using a text-based menu system to customize each component. After the components in the project are configured, the build system will compile the project.

### Concepts

- A “project” is a directory that contains all the files and configuration to build a single “app” (executable), as well as additional supporting elements such as a partition table, data/filesystem partitions, and a bootloader.
- “Project configuration” is held in a single file called `sdkconfig` in the root directory of the project. This configuration file is modified via `idf.py menuconfig` to customise the configuration of the project. A single project contains exactly one project configuration.
- An “app” is an executable which is built by ESP-IDF. A single project will usually build two apps - a “project app” (the main executable, ie your custom firmware) and a “bootloader app” (the initial bootloader program which launches the project app).
- “components” are modular pieces of standalone code which are compiled into static libraries (.a files) and linked into an app. Some are provided by ESP-IDF itself, others may be sourced from other places.
- “Target” is the hardware for which an application is built. A full list of supported targets in your version of ESP-IDF can be seen by running `idf.py -list-targets`.

Some things are not part of the project:

- “ESP-IDF” is not part of the project. Instead it is standalone, and linked to the project via the `IDF_PATH` environment variable which holds the path of the `esp-idf` directory. This allows the IDF framework to be decoupled from your project.
- The toolchain for compilation is not part of the project. The toolchain should be installed in the system command line `PATH`.

## 4.5.2 Using the Build System

### `idf.py`

The `idf.py` command-line tool provides a front-end for easily managing your project builds. It manages the following tools:

- [CMake](#), which configures the project to be built
- [Ninja](#) which builds the project
- [esptool.py](#) for flashing the target.

You can read more about configuring the build system using `idf.py` [here](#).

### Using CMake Directly

`idf.py` is a wrapper around [CMake](#) for convenience. However, you can also invoke CMake directly if you prefer.

When `idf.py` does something, it prints each command that it runs for easy reference. For example, the `idf.py build` command is the same as running these commands in a bash shell (or similar commands for Windows Command Prompt):

```
mkdir -p build
cd build
cmake .. -G Ninja # or 'Unix Makefiles'
ninja
```

In the above list, the `cmake` command configures the project and generates build files for use with the final build tool. In this case the final build tool is [Ninja](#): running `ninja` actually builds the project.

It's not necessary to run `cmake` more than once. After the first build, you only need to run `ninja` each time. `ninja` will automatically re-invoke `cmake` if the project needs reconfiguration.

If using CMake with `ninja` or `make`, there are also targets for more of the `idf.py` sub-commands - for example running `make menuconfig` or `ninja menuconfig` in the build directory will work the same as `idf.py menuconfig`.

---

**Note:** If you're already familiar with [CMake](#), you may find the ESP-IDF CMake-based build system unusual because it wraps a lot of CMake's functionality to reduce boilerplate. See [writing pure CMake components](#) for some information about writing more "CMake style" components.

---

**Flashing with ninja or make** It's possible to build and flash directly from `ninja` or `make` by running a target like:

```
ninja flash
```

Or:

```
make app-flash
```

Available targets are: `flash`, `app-flash` (app only), `bootloader-flash` (bootloader only).

When flashing this way, optionally set the `ESPPORT` and `ESPBAUD` environment variables to specify the serial port and baud rate. You can set environment variables in your operating system or IDE project. Alternatively, set them directly on the command line:

```
ESPPORT=/dev/ttyUSB0 ninja flash
```

---

**Note:** Providing environment variables at the start of the command like this is Bash shell Syntax. It will work on Linux and macOS. It won't work when using Windows Command Prompt, but it will work when using Bash-like shells on Windows.

---

Or:

```
make -j3 app-flash ESPPORT=COM4 ESPBAUD=2000000
```

---

**Note:** Providing variables at the end of the command line is `make` syntax, and works for `make` on all platforms.

---

### Using CMake in an IDE

You can also use an IDE with CMake integration. The IDE will want to know the path to the project's `CMakeLists.txt` file. IDEs with CMake integration often provide their own build tools (CMake calls these "generators") to build the source files as part of the IDE.

When adding custom non-build steps like “flash” to the IDE, it is recommended to execute `idf.py` for these “special” commands.

For more detailed information about integrating ESP-IDF with CMake into an IDE, see [Build System Metadata](#).

### Setting up the Python Interpreter

ESP-IDF works well with Python version 3.7+.

`idf.py` and other Python scripts will run with the default Python interpreter, i.e. `python`. You can switch to a different one like `python3 $IDF_PATH/tools/idf.py . . .`, or you can set up a shell alias or another script to simplify the command.

If using CMake directly, running `cmake -D PYTHON=python3 . . .` will cause CMake to override the default Python interpreter.

If using an IDE with CMake, setting the `PYTHON` value as a CMake cache override in the IDE UI will override the default Python interpreter.

To manage the Python version more generally via the command line, check out the tools [pyenv](#) or [virtualenv](#). These let you change the default Python version.

**Possible issues** The user of `idf.py` may sometimes experience `ImportError` described below.

```
Traceback (most recent call last):
  File "/Users/user_name/e/esp-idf/tools/kconfig_new/configgen.py", line 27, in
↪<module>
    import kconfiglib
ImportError: bad magic number in 'kconfiglib': b'\x03\xf3\r\n'
```

The exception is often caused by `.pyc` files generated by different Python versions. To solve the issue run the following command:

```
idf.py python-clean
```

### 4.5.3 Example Project

An example project directory tree might look like this:

```
- myProject/
  - CMakeLists.txt
  - sdkconfig
  - components/
    - component1/
      - CMakeLists.txt
      - Kconfig
      - src1.c
    - component2/
      - CMakeLists.txt
      - Kconfig
      - src1.c
      - include/
        - component2.h
  - main/
    - CMakeLists.txt
    - src1.c
    - src2.c
  - build/
```

This example “myProject” contains the following elements:

- A top-level project `CMakeLists.txt` file. This is the primary file which CMake uses to learn how to build the project; and may set project-wide CMake variables. It includes the file `/tools/cmake/project.cmake` which implements the rest of the build system. Finally, it sets the project name and defines the project.

- “sdkconfig” project configuration file. This file is created/updated when `idf.py menuconfig` runs, and holds configuration for all of the components in the project (including ESP-IDF itself). The “sdkconfig” file may or may not be added to the source control system of the project.
- Optional “components” directory contains components that are part of the project. A project does not have to contain custom components of this kind, but it can be useful for structuring reusable code or including third party components that aren’t part of ESP-IDF. Alternatively, `EXTRA_COMPONENT_DIRS` can be set in the top-level `CMakeLists.txt` to look for components in other places.
- “main” directory is a special component that contains source code for the project itself. “main” is a default name, the CMake variable `COMPONENT_DIRS` includes this component but you can modify this variable. See the [renaming main](#) section for more info. If you have a lot of source files in your project, we recommend grouping most into components instead of putting them all in “main”.
- “build” directory is where build output is created. This directory is created by `idf.py` if it doesn’t already exist. CMake configures the project and generates interim build files in this directory. Then, after the main build process is run, this directory will also contain interim object files and libraries as well as final binary output files. This directory is usually not added to source control or distributed with the project source code.

Component directories each contain a component `CMakeLists.txt` file. This file contains variable definitions to control the build process of the component, and its integration into the overall project. See [Component CMakeLists Files](#) for more details.

Each component may also include a `Kconfig` file defining the [component configuration](#) options that can be set via `menuconfig`. Some components may also include `Kconfig.projbuild` and `project_include.cmake` files, which are special files for [overriding parts of the project](#).

#### 4.5.4 Project CMakeLists File

Each project has a single top-level `CMakeLists.txt` file that contains build settings for the entire project. By default, the project `CMakeLists` can be quite minimal.

##### Minimal Example CMakeLists

Minimal project:

```
cmake_minimum_required(VERSION 3.16)
include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)
```

##### Mandatory Parts

The inclusion of these three lines, in the order shown above, is necessary for every project:

- `cmake_minimum_required(VERSION 3.16)` tells CMake the minimum version that is required to build the project. ESP-IDF is designed to work with CMake 3.16 or newer. This line must be the first line in the `CMakeLists.txt` file.
- `include($ENV{IDF_PATH}/tools/cmake/project.cmake)` pulls in the rest of the CMake functionality to configure the project, discover all the components, etc.
- `project(myProject)` creates the project itself, and specifies the project name. The project name is used for the final binary output files of the app - ie `myProject.elf`, `myProject.bin`. Only one project can be defined per `CMakeLists` file.

##### Optional Project Variables

These variables all have default values that can be overridden for custom behaviour. Look in [/tools/cmake/project.cmake](#) for all of the implementation details.

- `COMPONENT_DIRS`: Directories to search for components. Defaults to `IDF_PATH/components`, `PROJECT_DIR/components`, and `EXTRA_COMPONENT_DIRS`. Override this variable if you don't want to search for components in these places.
- `EXTRA_COMPONENT_DIRS`: Optional list of additional directories to search for components. Paths can be relative to the project directory, or absolute.
- `COMPONENTS`: A list of component names to build into the project. Defaults to all components found in the `COMPONENT_DIRS` directories. Use this variable to “trim down” the project for faster build times. Note that any component which “requires” another component via the `REQUIRES` or `PRIV_REQUIRES` arguments on component registration will automatically have it added to this list, so the `COMPONENTS` list can be very short.

Any paths in these variables can be absolute paths, or set relative to the project directory.

To set these variables, use the `cmake set command` ie `set (VARIABLE "VALUE")`. The `set ()` commands should be placed after the `cmake_minimum (...)` line but before the `include (...)` line.

### Renaming main component

The build system provides special treatment to the `main` component. It is a component that gets automatically added to the build provided that it is in the expected location, `PROJECT_DIR/main`. All other components in the build are also added as its dependencies, saving the user from hunting down dependencies and providing a build that works right out of the box. Renaming the `main` component causes the loss of these behind-the-scenes heavy lifting, requiring the user to specify the location of the newly renamed component and manually specifying its dependencies. Specifically, the steps to renaming `main` are as follows:

1. Rename `main` directory.
2. Set `EXTRA_COMPONENT_DIRS` in the project `CMakeLists.txt` to include the renamed `main` directory.
3. Specify the dependencies in the renamed component's `CMakeLists.txt` file via `REQUIRES` or `PRIV_REQUIRES` arguments *on component registration*.

### Overriding default build specifications

The build sets some global build specifications (compile flags, definitions, etc.) that gets used in compiling all sources from all components.

For example, one of the default build specifications set is the compile option `-Wextra`. Suppose a user wants to use override this with `-Wno-extra`, it should be done after `project ()`:

```
cmake_minimum_required(VERSION 3.16)
include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)

idf_build_set_property(COMPILE_OPTIONS "-Wno-error" APPEND)
```

This ensures that the compile options set by the user won't be overridden by the default build specifications, since the latter are set inside `project ()`.

## 4.5.5 Component CMakeLists Files

Each project contains one or more components. Components can be part of ESP-IDF, part of the project's own components directory, or added from custom component directories (*see above*).

A component is any directory in the `COMPONENT_DIRS` list which contains a `CMakeLists.txt` file.

### Searching for Components

The list of directories in `COMPONENT_DIRS` is searched for the project's components. Directories in this list can either be components themselves (ie they contain a `CMakeLists.txt` file), or they can be top-level directories whose

sub-directories are components.

When CMake runs to configure the project, it logs the components included in the build. This list can be useful for debugging the inclusion/exclusion of certain components.

### Multiple components with the same name

When ESP-IDF is collecting all the components to compile, it will do this in the order specified by `COMPONENT_DIRS`; by default, this means ESP-IDF's internal components first (`IDF_PATH/components`), then any components in directories specified in `EXTRA_COMPONENT_DIRS`, and finally the project's components (`PROJECT_DIR/components`). If two or more of these directories contain component sub-directories with the same name, the component in the last place searched is used. This allows, for example, overriding ESP-IDF components with a modified version by copying that component from the ESP-IDF components directory to the project components directory and then modifying it there. If used in this way, the ESP-IDF directory itself can remain untouched.

---

**Note:** If a component is overridden in an existing project by moving it to a new location, the project will not automatically see the new component path. Run `idf.py reconfigure` (or delete the project build folder) and then build again.

---

### Minimal Component CMakeLists

The minimal component `CMakeLists.txt` file simply registers the component to the build system using `idf_component_register`:

```
idf_component_register(SRCS "foo.c" "bar.c"
                      INCLUDE_DIRS "include"
                      REQUIRES mbedtls)
```

- `SRCS` is a list of source files (`*.c`, `*.cpp`, `*.cc`, `*.S`). These source files will be compiled into the component library.
- `INCLUDE_DIRS` is a list of directories to add to the global include search path for any component which requires this component, and also the main source files.
- `REQUIRES` is not actually required, but it is very often required to declare what other components this component will use. See [component requirements](#).

A library with the name of the component will be built and linked into the final app.

Directories are usually specified relative to the `CMakeLists.txt` file itself, although they can be absolute.

There are other arguments that can be passed to `idf_component_register`. These arguments are discussed [here](#).

See [example component requirements](#) and [example component CMakeLists](#) for more complete component `CMakeLists.txt` examples.

### Preset Component Variables

The following component-specific variables are available for use inside component `CMakeLists`, but should not be modified:

- `COMPONENT_DIR`: The component directory. Evaluates to the absolute path of the directory containing `CMakeLists.txt`. The component path cannot contain spaces. This is the same as the `CMAKE_CURRENT_SOURCE_DIR` variable.
- `COMPONENT_NAME`: Name of the component. Same as the name of the component directory.
- `COMPONENT_ALIAS`: Alias of the library created internally by the build system for the component.
- `COMPONENT_LIB`: Name of the library created internally by the build system for the component.

The following variables are set at the project level, but available for use in component CMakeLists:

- `CONFIG_*`: Each value in the project configuration has a corresponding variable available in cmake. All names begin with `CONFIG_`. [More information here](#).
- `ESP_PLATFORM`: Set to 1 when the CMake file is processed within ESP-IDF build system.

### Build/Project Variables

The following are some project/build variables that are available as build properties and whose values can be queried using `idf_build_get_property` from the component CMakeLists.txt:

- `PROJECT_NAME`: Name of the project, as set in project CMakeLists.txt file.
- `PROJECT_DIR`: Absolute path of the project directory containing the project CMakeLists. Same as the `CMAKE_SOURCE_DIR` variable.
- `COMPONENTS`: Names of all components that are included in this build, formatted as a semicolon-delimited CMake list.
- `IDF_VER`: Git version of ESP-IDF (produced by `git describe`)
- `IDF_VERSION_MAJOR`, `IDF_VERSION_MINOR`, `IDF_VERSION_PATCH`: Components of ESP-IDF version, to be used in conditional expressions. Note that this information is less precise than that provided by `IDF_VER` variable. `v4.0-dev-*`, `v4.0-beta1`, `v4.0-rc1` and `v4.0` will all have the same values of `IDF_VERSION_*` variables, but different `IDF_VER` values.
- `IDF_TARGET`: Name of the target for which the project is being built.
- `PROJECT_VER`: Project version.
  - If `CONFIG_APP_PROJECT_VER_FROM_CONFIG` option is set, the value of `CONFIG_APP_PROJECT_VER` will be used.
  - Else, if `PROJECT_VER` variable is set in project CMakeLists.txt file, its value will be used.
  - Else, if the `PROJECT_DIR/version.txt` exists, its contents will be used as `PROJECT_VER`.
  - Else, if the project is located inside a Git repository, the output of `git describe` will be used.
  - Otherwise, `PROJECT_VER` will be “1” .
- `EXTRA_PARTITION_SUBTYPES`: CMake list of extra partition subtypes. Each subtype description is a comma separated string with `type_name`, `subtype_name`, `numeric_value` format. Components may add new subtypes by appending them to this list.

Other build properties are listed [here](#).

### Controlling Component Compilation

To pass compiler options when compiling source files belonging to a particular component, use the `target_compile_options` function:

```
target_compile_options(${COMPONENT_LIB} PRIVATE -Wno-unused-variable)
```

To apply the compilation flags to a single source file, use the CMake `set_source_files_properties` command:

```
set_source_files_properties(mysrc.c
  PROPERTIES COMPILE_FLAGS
  -Wno-unused-variable
)
```

This can be useful if there is upstream code that emits warnings.

When using these commands, place them after the call to `idf_component_register` in the component CMakeLists file.

## 4.5.6 Component Configuration

Each component can also have a `Kconfig` file, alongside `CMakeLists.txt`. This contains configuration settings to add to the configuration menu for this component.

These settings are found under the “Component Settings” menu when menuconfig is run.

To create a component Kconfig file, it is easiest to start with one of the Kconfig files distributed with ESP-IDF.

For an example, see [Adding conditional configuration](#).

## 4.5.7 Preprocessor Definitions

The ESP-IDF build system adds the following C preprocessor definitions on the command line:

- `ESP_PLATFORM`: Can be used to detect that build happens within ESP-IDF.
- `IDF_VER`: Defined to a git version string. E.g. `v2.0` for a tagged release or `v1.0-275-g0efaa4f` for an arbitrary commit.

## 4.5.8 Component Requirements

When compiling each component, the ESP-IDF build system recursively evaluates its dependencies. This means each component needs to declare the components that it depends on ( “requires” ).

### When writing a component

```
idf_component_register(...  
    REQUIRES mbedtls  
    PRIV_REQUIRES console spiffs)
```

- `REQUIRES` should be set to all components whose header files are `#included` from the *public* header files of this component.
- `PRIV_REQUIRES` should be set to all components whose header files are `#included` from *any source files* in this component, unless already listed in `REQUIRES`. Also any component which is required to be linked in order for this component to function correctly.
- The values of `REQUIRES` and `PRIV_REQUIRES` should not depend on any configuration choices (`CONFIG_XXX` macros). This is because requirements are expanded before configuration is loaded. Other component variables (like include paths or source files) can depend on configuration choices.
- Not setting either or both `REQUIRES` variables is fine. If the component has no requirements except for the *Common component requirements* needed for RTOS, libc, etc.

If a components only supports some target chips (values of `IDF_TARGET`) then it can specify `REQUIRED_IDF_TARGETS` in the `idf_component_register` call to express these requirements. In this case the build system will generate an error if the component is included into the build, but does not support the selected target.

---

**Note:** In CMake terms, `REQUIRES` & `PRIV_REQUIRES` are approximate wrappers around the CMake functions `target_link_libraries(... PUBLIC ...)` and `target_link_libraries(... PRIVATE ...)`.

---

### Example of component requirements

Imagine there is a `car` component, which uses the `engine` component, which uses the `spark_plug` component:

```
- autoProject/  
  - CMakeLists.txt  
  - components/  
    - car/  
      - CMakeLists.txt  
      - car.c  
      - car.h  
    - engine/  
      - CMakeLists.txt
```

(continues on next page)

(continued from previous page)

```

- engine.c
- include/ - engine.h
- spark_plug/ - CMakeLists.txt
- spark_plug.c
- spark_plug.h

```

**Car component** The `car.h` header file is the public interface for the `car` component. This header includes `engine.h` directly because it uses some declarations from this header:

```

/* car.h */
#include "engine.h"

#ifdef ENGINE_IS_HYBRID
#define CAR_MODEL "Hybrid"
#endif

```

And `car.c` includes `car.h` as well:

```

/* car.c */
#include "car.h"

```

This means the `car/CMakeLists.txt` file needs to declare that `car` requires `engine`:

```

idf_component_register(SRCS "car.c"
                      INCLUDE_DIRS "."
                      REQUIRES engine)

```

- `SRCS` gives the list of source files in the `car` component.
- `INCLUDE_DIRS` gives the list of public include directories for this component. Because the public interface is `car.h`, the directory containing `car.h` is listed here.
- `REQUIRES` gives the list of components required by the public interface of this component. Because `car.h` is a public header and includes a header from `engine`, we include `engine` here. This makes sure that any other component which includes `car.h` will be able to recursively include the required `engine.h` also.

**Engine component** The `engine` component also has a public header file `include/engine.h`, but this header is simpler:

```

/* engine.h */
#define ENGINE_IS_HYBRID

void engine_start(void);

```

The implementation is in `engine.c`:

```

/* engine.c */
#include "engine.h"
#include "spark_plug.h"

...

```

In this component, `engine` depends on `spark_plug` but this is a private dependency. `spark_plug.h` is needed to compile `engine.c`, but not needed to include `engine.h`.

This means that the `engine/CMakeLists.txt` file can use `PRIV_REQUIRES`:

```

idf_component_register(SRCS "engine.c"
                      INCLUDE_DIRS "include"
                      PRIV_REQUIRES spark_plug)

```

As a result, source files in the `car` component don't need the `spark_plug` include directories added to their compiler search path. This can speed up compilation, and stops compiler command lines from becoming longer than necessary.

**Spark Plug Component** The `spark_plug` component doesn't depend on anything else. It has a public header file `spark_plug.h`, but this doesn't include headers from any other components.

This means that the `spark_plug/CMakeLists.txt` file doesn't need any `REQUIRES` or `PRIV_REQUIRES` clauses:

```
idf_component_register(SRCS "spark_plug.c"
                      INCLUDE_DIRS ".")
```

### Source File Include Directories

Each component's source file is compiled with these include path directories, as specified in the passed arguments to `idf_component_register`:

```
idf_component_register(..
                      INCLUDE_DIRS "include"
                      PRIV_INCLUDE_DIRS "other")
```

- The current component's `INCLUDE_DIRS` and `PRIV_INCLUDE_DIRS`.
- The `INCLUDE_DIRS` belonging to all other components listed in the `REQUIRES` and `PRIV_REQUIRES` parameters (ie all the current component's public and private dependencies).
- Recursively, all of the `INCLUDE_DIRS` of those components `REQUIRES` lists (ie all public dependencies of this component's dependencies, recursively expanded).

### Main component requirements

The component named `main` is special because it automatically requires all other components in the build. So it's not necessary to pass `REQUIRES` or `PRIV_REQUIRES` to this component. See [renaming main](#) for a description of what needs to be changed if no longer using the `main` component.

### Common component requirements

To avoid duplication, every component automatically requires some "common" IDF components even if they are not mentioned explicitly. Headers from these components can always be included.

The list of common components is: `cxx`, `newlib`, `freertos`, `esp_hw_support`, `heap`, `log`, `soc`, `hal`, `esp_rom`, `esp_common`, `esp_system`, `xtensa/riscv`.

### Including components in the build

- By default, every component is included in the build.
- If you set the `COMPONENTS` variable to a minimal list of components used directly by your project, then the build will expand to also include required components. The full list of components will be:
  - Components mentioned explicitly in `COMPONENTS`.
  - Those components' requirements (evaluated recursively).
  - The "common" components that every component depends on.
- Setting `COMPONENTS` to the minimal list of required components can significantly reduce compile times.

## Circular Dependencies

It's possible for a project to contain Component A that requires (REQUIRES or PRIV\_REQUIRES) Component B, and Component B that requires Component A. This is known as a dependency cycle or a circular dependency.

CMake will usually handle circular dependencies automatically by repeating the component library names twice on the linker command line. However this strategy doesn't always work, and it's possible the build will fail with a linker error about "Undefined reference to ...", referencing a symbol defined by one of the components inside the circular dependency. This is particularly likely if there is a large circular dependency, i.e. A->B->C->D->A.

The best solution is to restructure the components to remove the circular dependency. In most cases, a software architecture without circular dependencies has desirable properties of modularity and clean layering and will be more maintainable in the long term. However, removing circular dependencies is not always possible.

To bypass a linker error caused by a circular dependency, the simplest workaround is to increase the CMake `LINK_INTERFACE_MULTIPLICITY` property of one of the component libraries. This causes CMake to repeat this library and its dependencies more than two times on the linker command line.

For example:

```
set_property(TARGET ${COMPONENT_LIB} APPEND PROPERTY LINK_INTERFACE_MULTIPLICITY 3)
```

- This line should be placed after `idf_component_register` in the component CMakeLists.txt file.
- If possible, place this line in the component that creates the circular dependency by depending on a lot of other components. However, the line can be placed inside any component that is part of the cycle. Choosing the component that owns the source file shown in the linker error message, or the component that defines the symbol(s) mentioned in the linker error message, is a good place to start.
- Usually increasing the value to 3 (default is 2) is enough, but if this doesn't work then try increasing the number further.
- Adding this option will make the linker command line longer, and the linking stage slower.

**Advanced Workaround: Undefined Symbols** If only one or two symbols is causing a circular dependency, and all other dependencies are linear, then there is an alternative method to avoid linker errors: Specify the specific symbols required for the "reverse" dependency as undefined symbols at link time.

For example, if component A depends on component B but component B also needs to reference `reverse_ops` from component A (but nothing else), then you can add a line like the following to the component B CMakeLists.txt to resolve the cycle at link time:

```
# This symbol is provided by 'Component A' at link time
target_link_libraries(${COMPONENT_LIB} INTERFACE "-u reverse_ops")
```

- The `-u` argument means that the linker will always include this symbol in the link, regardless of dependency ordering.
- This line should be placed after `idf_component_register` in the component CMakeLists.txt file.
- If 'Component B' doesn't need to access any headers of 'Component A', only link to a few symbol(s), then this line can be used instead of any REQUIRES from B to A. This further simplifies the component structure in the build system.

See the [target\\_link\\_libraries](#) documentation for more information about this CMake function.

## Requirements in the build system implementation

- Very early in the CMake configuration process, the script `expand_requirements.cmake` is run. This script does a partial evaluation of all component CMakeLists.txt files and builds a graph of component requirements (this *graph may have cycles*). The graph is used to generate a file `component_depends.cmake` in the build directory.
- The main CMake process then includes this file and uses it to determine the list of components to include in the build (internal `BUILD_COMPONENTS` variable). The `BUILD_COMPONENTS` variable is sorted so dependencies are listed first, however as the component dependency graph has cycles this cannot be guaranteed

for all components. The order should be deterministic given the same set of components and component dependencies.

- The value of `BUILD_COMPONENTS` is logged by CMake as “Component names: “
- Configuration is then evaluated for the components included in the build.
- Each component is included in the build normally and the `CMakeLists.txt` file is evaluated again to add the component libraries to the build.

**Component Dependency Order** The order of components in the `BUILD_COMPONENTS` variable determines other orderings during the build:

- Order that `project_include.cmake` files are included into the project.
- Order that the list of header paths is generated for compilation (via `-I` argument). (Note that for a given component’s source files, only that component’s dependency’s header paths are passed to the compiler.)

**Adding Link-Time Dependencies** The ESP-IDF CMake helper function `idf_component_add_link_dependency` adds a link-only dependency between one component and another. In almost all cases, it is better to use the `PRIV_REQUIRES` feature in `idf_component_register` to create a dependency. However, in some cases, it’s necessary to add the link-time dependency of another component to this component, i.e., the reverse order to `PRIV_REQUIRES` (for example: [Overriding Default Chip Drivers](#)).

To make another component depend on this component at link time:

```
idf_component_add_link_dependency (FROM other_component)
```

Place this line after the line with `idf_component_register`.

It’s also possible to specify both components by name:

```
idf_component_add_link_dependency (FROM other_component TO that_component)
```

## 4.5.9 Overriding Parts of the Project

### `project_include.cmake`

For components that have build requirements which must be evaluated before any component `CMakeLists` files are evaluated, you can create a file called `project_include.cmake` in the component directory. This CMake file is included when `project.cmake` is evaluating the entire project.

`project_include.cmake` files are used inside ESP-IDF, for defining project-wide build features such as `esptool.py` command line arguments and the bootloader “special app”.

Unlike component `CMakeLists.txt` files, when including a `project_include.cmake` file the current source directory (`CMAKE_CURRENT_SOURCE_DIR` and working directory) is the project directory. Use the variable `COMPONENT_DIR` for the absolute directory of the component.

Note that `project_include.cmake` isn’t necessary for the most common component uses - such as adding include directories to the project, or `LDFLAGS` to the final linking step. These values can be customised via the `CMakeLists.txt` file itself. See [Optional Project Variables](#) for details.

`project_include.cmake` files are included in the order given in `BUILD_COMPONENTS` variable (as logged by CMake). This means that a component’s `project_include.cmake` file will be included after it’s all dependencies’ `project_include.cmake` files, unless both components are part of a dependency cycle. This is important if a `project_include.cmake` file relies on variables set by another component. See also [above](#).

Take great care when setting variables or targets in a `project_include.cmake` file. As the values are included into the top-level project CMake pass, they can influence or break functionality across all components!

## KConfig.projbuild

This is an equivalent to `project_include.cmake` for *Component Configuration* KConfig files. If you want to include configuration options at the top-level of `menuconfig`, rather than inside the “Component Configuration” sub-menu, then these can be defined in the `KConfig.projbuild` file alongside the `CMakeLists.txt` file.

Take care when adding configuration values in this file, as they will be included across the entire project configuration. Where possible, it’s generally better to create a KConfig file for *Component Configuration*.

`project_include.cmake` files are used inside ESP-IDF, for defining project-wide build features such as `esptool.py` command line arguments and the `bootloader` “special app”.

### 4.5.10 Configuration-Only Components

Special components which contain no source files, only `Kconfig.projbuild` and `KConfig`, can have a one-line `CMakeLists.txt` file which calls the function `idf_component_register()` with no arguments specified. This function will include the component in the project build, but no library will be built *and* no header files will be added to any include paths.

### 4.5.11 Debugging CMake

For full details about [CMake](#) and CMake commands, see the [CMake v3.16 documentation](#).

Some tips for debugging the ESP-IDF CMake-based build system:

- When CMake runs, it prints quite a lot of diagnostic information including lists of components and component paths.
- Running `cmake -DDEBUG=1` will produce more verbose diagnostic output from the IDF build system.
- Running `cmake` with the `--trace` or `--trace-expand` options will give a lot of information about control flow. See the [cmake command line documentation](#).

When included from a project CMakeLists file, the `project.cmake` file defines some utility modules and global variables and then sets `IDF_PATH` if it was not set in the system environment.

It also defines an overridden custom version of the built-in [CMake](#) `project` function. This function is overridden to add all of the ESP-IDF specific project functionality.

#### Warning On Undefined Variables

By default, `idf.py` passes the `--warn-uninitialized` flag to [CMake](#) so it will print a warning if an undefined variable is referenced in the build. This can be very useful to find buggy CMake files.

If you don’t want this behaviour, it can be disabled by passing `--no-warnings` to `idf.py`.

Browse the [/tools/cmake/project.cmake](#) file and supporting functions in [/tools/cmake/](#) for more details.

### 4.5.12 Example Component CMakeLists

Because the build environment tries to set reasonable defaults that will work most of the time, component `CMakeLists.txt` can be very small or even empty (see [Minimal Component CMakeLists](#)). However, overriding [pre-set\\_component\\_variables](#) is usually required for some functionality.

Here are some more advanced examples of component CMakeLists files.

### Adding conditional configuration

The configuration system can be used to conditionally compile some files depending on the options selected in the project configuration.

Kconfig:

```
config FOO_ENABLE_BAR
    bool "Enable the BAR feature."
    help
        This enables the BAR feature of the FOO component.
```

CMakeLists.txt:

```
set(srcs "foo.c" "more_foo.c")

if(CONFIG_FOO_ENABLE_BAR)
    list(APPEND srcs "bar.c")
endif()

idf_component_register(SRCS "${srcs}"
    ...)
```

This example makes use of the CMake [if](#) function and [list APPEND](#) function.

This can also be used to select or stub out an implementation, as such:

Kconfig:

```
config ENABLE_LCD_OUTPUT
    bool "Enable LCD output."
    help
        Select this if your board has a LCD.

config ENABLE_LCD_CONSOLE
    bool "Output console text to LCD"
    depends on ENABLE_LCD_OUTPUT
    help
        Select this to output debugging output to the lcd

config ENABLE_LCD_PLOT
    bool "Output temperature plots to LCD"
    depends on ENABLE_LCD_OUTPUT
    help
        Select this to output temperature plots
```

CMakeLists.txt:

```
if(CONFIG_ENABLE_LCD_OUTPUT)
    set(srcs lcd-real.c lcd-spi.c)
else()
    set(srcs lcd-dummy.c)
endif()

# We need font if either console or plot is enabled
if(CONFIG_ENABLE_LCD_CONSOLE OR CONFIG_ENABLE_LCD_PLOT)
    list(APPEND srcs "font.c")
endif()

idf_component_register(SRCS "${srcs}"
    ...)
```

### Conditions which depend on the target

The current target is available to CMake files via `IDF_TARGET` variable.

In addition to that, if target `xyz` is used (`IDF_TARGET=xyz`), then Kconfig variable `CONFIG_IDF_TARGET_XYZ` will be set.

Note that component dependencies may depend on `IDF_TARGET` variable, but not on Kconfig variables. Also one can not use Kconfig variables in `include` statements in CMake files, but `IDF_TARGET` can be used in such context.

### Source Code Generation

Some components will have a situation where a source file isn't supplied with the component itself but has to be generated from another file. Say our component has a header file that consists of the converted binary data of a BMP file, converted using a hypothetical tool called `bmp2h`. The header file is then included in as C source file called `graphics_lib.c`:

```
add_custom_command(OUTPUT logo.h
    COMMAND bmp2h -i ${COMPONENT_DIR}/logo.bmp -o log.h
    DEPENDS ${COMPONENT_DIR}/logo.bmp
    VERBATIM)

add_custom_target(logo DEPENDS logo.h)
add_dependencies(${COMPONENT_LIB} logo)

set_property(DIRECTORY "${COMPONENT_DIR}" APPEND PROPERTY
    ADDITIONAL_CLEAN_FILES logo.h)
```

This answer is adapted from the [CMake FAQ](#) entry, which contains some other examples that will also work with ESP-IDF builds.

In this example, `logo.h` will be generated in the current directory (the build directory) while `logo.bmp` comes with the component and resides under the component path. Because `logo.h` is a generated file, it should be cleaned when the project is cleaned. For this reason it is added to the [ADDITIONAL\\_CLEAN\\_FILES](#) property.

---

**Note:** If generating files as part of the project `CMakeLists.txt` file, not a component `CMakeLists.txt`, then use build property `PROJECT_DIR` instead of `${COMPONENT_DIR}` and `PROJECT_NAME` instead of `COMPONENT_LIB`.)

---

If a source file from another component included `logo.h`, then `add_dependencies` would need to be called to add a dependency between the two components, to ensure that the component source files were always compiled in the correct order.

### Embedding Binary Data

Sometimes you have a file with some binary or text data that you'd like to make available to your component - but you don't want to reformat the file as C source.

You can specify argument `EMBED_FILES` in the component registration, giving space-delimited names of the files to embed:

```
idf_component_register(...
    EMBED_FILES server_root_cert.der)
```

Or if the file is a string, you can use the variable `EMBED_TXTFILES`. This will embed the contents of the text file as a null-terminated string:

```
idf_component_register(...
    EMBED_TXTFILES server_root_cert.pem)
```

The file's contents will be added to the .rodata section in flash, and are available via symbol names as follows:

```
extern const uint8_t server_root_cert_pem_start[] asm("_binary_server_root_cert_
↪pem_start");
extern const uint8_t server_root_cert_pem_end[]   asm("_binary_server_root_cert_
↪pem_end");
```

The names are generated from the full name of the file, as given in `MBED_FILES`. Characters `/`, `.`, etc. are replaced with underscores. The `_binary` prefix in the symbol name is added by objcopy and is the same for both text and binary files.

To embed a file into a project, rather than a component, you can call the function `target_add_binary_data` like this:

```
target_add_binary_data(myproject.elf "main/data.bin" TEXT)
```

Place this line after the `project()` line in your project `CMakeLists.txt` file. Replace `myproject.elf` with your project name. The final argument can be `TEXT` to embed a null-terminated string, or `BINARY` to embed the content as-is.

For an example of using this technique, see the “main” component of the `file_serving` example [protocols/http\\_server/file\\_serving/main/CMakeLists.txt](https://github.com/EspressifSystem/esp-idf/blob/master/examples/protocols/http_server/file_serving/main/CMakeLists.txt) - two files are loaded at build time and linked into the firmware.

It is also possible embed a generated file:

```
add_custom_command(OUTPUT my_processed_file.bin
                    COMMAND my_process_file_cmd my_unprocessed_file.bin)
target_add_binary_data(my_target "my_processed_file.bin" BINARY)
```

In the example above, `my_processed_file.bin` is generated from `my_unprocessed_file.bin` through some command `my_process_file_cmd`, then embedded into the target.

To specify a dependence on a target, use the `DEPENDS` argument:

```
add_custom_target(my_process COMMAND ...)
target_add_binary_data(my_target "my_embed_file.bin" BINARY DEPENDS my_process)
```

The `DEPENDS` argument to `target_add_binary_data` ensures that the target executes first.

## Code and Data Placements

ESP-IDF has a feature called linker script generation that enables components to define where its code and data will be placed in memory through linker fragment files. These files are processed by the build system, and is used to augment the linker script used for linking app binary. See [Linker Script Generation](#) for a quick start guide as well as a detailed discussion of the mechanism.

## Fully Overriding The Component Build Process

Obviously, there are cases where all these recipes are insufficient for a certain component, for example when the component is basically a wrapper around another third-party component not originally intended to be compiled under this build system. In that case, it's possible to forego the ESP-IDF build system entirely by using a CMake feature called `ExternalProject`. Example component `CMakeLists.txt`:

```
# External build process for quirc, runs in source dir and
# produces libquirc.a
externalproject_add(quirc_build
    PREFIX ${COMPONENT_DIR}
    SOURCE_DIR ${COMPONENT_DIR}/quirc
    CONFIGURE_COMMAND ""
    BUILD_IN_SOURCE 1
```

(continues on next page)

```

BUILD_COMMAND make CC=${CMAKE_C_COMPILER} libquirc.a
INSTALL_COMMAND ""
)

# Add libquirc.a to the build process
add_library(quirc STATIC IMPORTED GLOBAL)
add_dependencies(quirc quirc_build)

set_target_properties(quirc PROPERTIES IMPORTED_LOCATION
    ${COMPONENT_DIR}/quirc/libquirc.a)
set_target_properties(quirc PROPERTIES INTERFACE_INCLUDE_DIRECTORIES
    ${COMPONENT_DIR}/quirc/lib)

set_directory_properties( PROPERTIES ADDITIONAL_CLEAN_FILES
    "${COMPONENT_DIR}/quirc/libquirc.a")

```

(The above CMakeLists.txt can be used to create a component named `quirc` that builds the `quirc` project using its own Makefile.)

- `externalproject_add` defines an external build system.
  - `SOURCE_DIR`, `CONFIGURE_COMMAND`, `BUILD_COMMAND` and `INSTALL_COMMAND` should always be set. `CONFIGURE_COMMAND` can be set to an empty string if the build system has no “configure” step. `INSTALL_COMMAND` will generally be empty for ESP-IDF builds.
  - Setting `BUILD_IN_SOURCE` means the build directory is the same as the source directory. Otherwise you can set `BUILD_DIR`.
  - Consult the [ExternalProject](#) documentation for more details about `externalproject_add()`
- The second set of commands adds a library target, which points to the “imported” library file built by the external system. Some properties need to be set in order to add include directories and tell CMake where this file is.
- Finally, the generated library is added to `ADDITIONAL_CLEAN_FILES`. This means `make clean` will delete this library. (Note that the other object files from the build won’t be deleted.)

**ExternalProject dependencies, clean builds** CMake has some unusual behaviour around external project builds:

- `ADDITIONAL_CLEAN_FILES` only works when “make” or “ninja” is used as the build system. If an IDE build system is used, it won’t delete these files when cleaning.
- However, the [ExternalProject](#) `configure` & `build` commands will *always* be re-run after a clean is run.
- Therefore, there are two alternative recommended ways to configure the external build command:
  1. Have the external `BUILD_COMMAND` run a full clean compile of all sources. The build command will be run if any of the dependencies passed to `externalproject_add` with `DEPENDS` have changed, or if this is a clean build (ie any of `idf.py clean`, `ninja clean`, or `make clean` was run.)
  2. Have the external `BUILD_COMMAND` be an incremental build command. Pass the parameter `BUILD_ALWAYS 1` to `externalproject_add`. This means the external project will be built each time a build is run, regardless of dependencies. This is only recommended if the external project has correct incremental build behaviour, and doesn’t take too long to run.

The best of these approaches for building an external project will depend on the project itself, its build system, and whether you anticipate needing to frequently recompile the project.

### 4.5.13 Custom sdkconfig defaults

For example projects or other projects where you don’t want to specify a full `sdkconfig` configuration, but you do want to override some key values from the ESP-IDF defaults, it is possible to create a file `sdkconfig.defaults` in the project directory. This file will be used when creating a new config from scratch, or when any new config value hasn’t yet been set in the `sdkconfig` file.

To override the name of this file or to specify multiple files, set the `SDKCONFIG_DEFAULTS` environment variable or set `SDKCONFIG_DEFAULTS` in top-level `CMakeLists.txt`. File names that are not specified as full paths are resolved relative to current project’s directory.

When specifying multiple files, use a semicolon as the list separator. Files listed first will be applied first. If a particular key is defined in multiple files, the definition in the latter file will override definitions from former files.

Some of the IDF examples include a `sdkconfig.ci` file. This is part of the continuous integration (CI) test framework and is ignored by the normal build process.

### Target-dependent `sdkconfig` defaults

In addition to `sdkconfig.defaults` file, build system will also load defaults from `sdkconfig.defaults.TARGET_NAME` file, where `TARGET_NAME` is the value of `IDF_TARGET`. For example, for `esp32` target, default settings will be taken from `sdkconfig.defaults` first, and then from `sdkconfig.defaults.esp32`.

If `SDKCONFIG_DEFAULTS` is used to override the name of defaults file/files, the name of target-specific defaults file will be derived from `SDKCONFIG_DEFAULTS` value/values using the rule above. When there are multiple files in `SDKCONFIG_DEFAULTS`, target-specific file will be applied right after the file bringing it in, before all latter files in `SDKCONFIG_DEFAULTS`

For example, if `SDKCONFIG_DEFAULTS="sdkconfig.defaults; sdkconfig_devkit1"`, and there is a file `sdkconfig.defaults.esp32` in the same folder, then the files will be applied in the following order: (1) `sdkconfig.defaults` (2) `sdkconfig.defaults.esp32` (3) `sdkconfig_devkit1`.

### 4.5.14 Flash arguments

There are some scenarios that we want to flash the target board without IDF. For this case we want to save the built binaries, `esptool.py` and `esptool write_flash` arguments. It's simple to write a script to save binaries and `esptool.py`.

After running a project build, the build directory contains binary output files (`.bin` files) for the project and also the following flashing data files:

- `flash_project_args` contains arguments to flash the entire project (app, bootloader, partition table, PHY data if this is configured).
- `flash_app_args` contains arguments to flash only the app.
- `flash_bootloader_args` contains arguments to flash only the bootloader.

You can pass any of these flasher argument files to `esptool.py` as follows:

```
python esptool.py --chip esp32 write_flash @build/flash_project_args
```

Alternatively, it is possible to manually copy the parameters from the argument file and pass them on the command line.

The build directory also contains a generated file `flasher_args.json` which contains project flash information, in JSON format. This file is used by `idf.py` and can also be used by other tools which need information about the project build.

### 4.5.15 Building the Bootloader

The bootloader is a special “subproject” inside `/components/bootloader/subproject`. It has its own project `CMakeLists.txt` file and builds separate `.ELF` and `.BIN` files to the main project. However it shares its configuration and build directory with the main project.

The subproject is inserted as an external project from the top-level project, by the file `/components/bootloader/project_include.cmake`. The main build process runs CMake for the subproject, which includes discovering components (a subset of the main components) and generating a bootloader-specific config (derived from the main `sdkconfig`).

### 4.5.16 Writing Pure CMake Components

The ESP-IDF build system “wraps” CMake with the concept of “components”, and helper functions to automatically integrate these components into a project build.

However, underneath the concept of “components” is a full CMake build system. It is also possible to make a component which is pure CMake.

Here is an example minimal “pure CMake” component CMakeLists file for a component named `json`:

```
add_library(json STATIC
  cJSON/cJSON.c
  cJSON/cJSON_Utils.c)

target_include_directories(json PUBLIC cJSON)
```

- This is actually an equivalent declaration to the IDF `json` component [/components/json/CMakeLists.txt](#).
- This file is quite simple as there are not a lot of source files. For components with a large number of files, the globbing behaviour of ESP-IDF’s component logic can make the component CMakeLists style simpler.)
- Any time a component adds a library target with the component name, the ESP-IDF build system will automatically add this to the build, expose public include directories, etc. If a component wants to add a library target with a different name, dependencies will need to be added manually via CMake commands.

### 4.5.17 Using Third-Party CMake Projects with Components

CMake is used for a lot of open-source C and C++ projects —code that users can tap into for their applications. One of the benefits of having a CMake build system is the ability to import these third-party projects, sometimes even without modification! This allows for users to be able to get functionality that may not yet be provided by a component, or use another library for the same functionality.

Importing a library might look like this for a hypothetical library `foo` to be used in the `main` component:

```
# Register the component
idf_component_register(...)

# Set values of hypothetical variables that control the build of `foo`
set(FOO_BUILD_STATIC OFF)
set(FOO_BUILD_TESTS OFF)

# Create and import the library targets
add_subdirectory(foo)

# Publicly link `foo` to `main` component
target_link_libraries(main PUBLIC foo)
```

For an actual example, take a look at [build\\_system/cmake/import\\_lib](#). Take note that what needs to be done in order to import the library may vary. It is recommended to read up on the library’s documentation for instructions on how to import it from other projects. Studying the library’s CMakeLists.txt and build structure can also be helpful.

It is also possible to wrap a third-party library to be used as a component in this manner. For example, the `mbedtls` component is a wrapper for Espressif’s fork of `mbedtls`. See its [component CMakeLists.txt](#).

The CMake variable `ESP_PLATFORM` is set to 1 whenever the ESP-IDF build system is being used. Tests such as `if (ESP_PLATFORM)` can be used in generic CMake code if special IDF-specific logic is required.

#### Using ESP-IDF components from external libraries

The above example assumes that the external library `foo` (or `tinyclib` in the case of the `import_lib` example) doesn’t need to use any ESP-IDF APIs apart from common APIs such as `libc`, `libstdc++`, etc. If the external library needs to use APIs provided by other ESP-IDF components, this needs to be specified in the external CMakeLists.txt file by adding a dependency on the library target `idf::<componentname>`.

For example, in the `foo/CMakeLists.txt` file:

```
add_library(foo bar.c fizz.cpp buzz.cpp)

if(ESP_PLATFORM)
    # On ESP-IDF, bar.c needs to include esp_flash.h from the spi_flash component
    target_link_libraries(foo PRIVATE idf::spi_flash)
endif()
```

### 4.5.18 Using Prebuilt Libraries with Components

Another possibility is that you have a prebuilt static library (`.a` file), built by some other build process.

The ESP-IDF build system provides a utility function `add_prebuilt_library` for users to be able to easily import and use prebuilt libraries:

```
add_prebuilt_library(target_name lib_path [REQUIRES req1 req2 ...] [PRIV_REQUIRES_
↳req1 req2 ...])
```

where:

- `target_name`- name that can be used to reference the imported library, such as when linking to other targets
- `lib_path`- path to prebuilt library; may be an absolute or relative path to the component directory

Optional arguments `REQUIRES` and `PRIV_REQUIRES` specify dependency on other components. These have the same meaning as the arguments for `idf_component_register`.

Take note that the prebuilt library must have been compiled for the same target as the consuming project. Configuration relevant to the prebuilt library must also match. If not paid attention to, these two factors may contribute to subtle bugs in the app.

For an example, take a look at [build\\_system/cmake/import\\_prebuilt](#).

### 4.5.19 Using ESP-IDF in Custom CMake Projects

ESP-IDF provides a template CMake project for easily creating an application. However, in some instances the user might already have an existing CMake project or may want to create a custom one. In these cases it is desirable to be able to consume IDF components as libraries to be linked to the user's targets (libraries/ executables).

It is possible to do so by using the *build system APIs provided* by `tools/cmake/idf.cmake`. For example:

```
cmake_minimum_required(VERSION 3.16)
project(my_custom_app C)

# Include CMake file that provides ESP-IDF CMake build system APIs.
include(${ENV{IDF_PATH}/tools/cmake/idf.cmake)

# Include ESP-IDF components in the build, may be thought as an equivalent of
# add_subdirectory() but with some additional processing and magic for ESP-IDF.
↳build
# specific build processes.
idf_build_process(esp32)

# Create the project executable and plainly link the newlib component to it using
# its alias, idf::newlib.
add_executable(${CMAKE_PROJECT_NAME}.elf main.c)
target_link_libraries(${CMAKE_PROJECT_NAME}.elf idf::newlib)

# Let the build system know what the project executable is to attach more targets,
↳dependencies, etc.
idf_build_executable(${CMAKE_PROJECT_NAME}.elf)
```

The example in [build\\_system/cmake/idf\\_as\\_lib](#) demonstrates the creation of an application equivalent to [hello world application](#) using a custom CMake project.

## 4.5.20 ESP-IDF CMake Build System API

### idf-build-commands

```
idf_build_get_property(var property [GENERATOR_EXPRESSION])
```

Retrieve a *build property* *property* and store it in *var* accessible from the current scope. Specifying *GENERATOR\_EXPRESSION* will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.

```
idf_build_set_property(property val [APPEND])
```

Set a *build property* *property* with value *val*. Specifying *APPEND* will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

```
idf_build_component(component_dir)
```

Present a directory *component\_dir* that contains a component to the build system. Relative paths are converted to absolute paths with respect to current directory. All calls to this command must be performed before *idf\_build\_process*.

This command does not guarantee that the component will be processed during build (see the *COMPONENTS* argument description for *idf\_build\_process*)

```
idf_build_process(target
    [PROJECT_DIR project_dir]
    [PROJECT_VER project_ver]
    [PROJECT_NAME project_name]
    [SDKCONFIG sdkconfig]
    [SDKCONFIG_DEFAULTS sdkconfig_defaults]
    [BUILD_DIR build_dir]
    [COMPONENTS component1 component2 ...])
```

Performs the bulk of the behind-the-scenes magic for including ESP-IDF components such as component configuration, libraries creation, dependency expansion and resolution. Among these functions, perhaps the most important from a user's perspective is the libraries creation by calling each component's *idf\_component\_register*. This command creates the libraries for each component, which are accessible using aliases in the form *idf::component\_name*. These aliases can be used to link the components to the user's own targets, either libraries or executables.

The call requires the target chip to be specified with *target* argument. Optional arguments for the call include:

- **PROJECT\_DIR** - directory of the project; defaults to **CMAKE\_SOURCE\_DIR**
- **PROJECT\_NAME** - name of the project; defaults to **CMAKE\_PROJECT\_NAME**
- **PROJECT\_VER** - version/revision of the project; defaults to "1"
- **SDKCONFIG** - output path of generated *sdkconfig* file; defaults to **PROJECT\_DIR/sdkconfig** or **CMAKE\_SOURCE\_DIR/sdkconfig** depending if **PROJECT\_DIR** is set
- **SDKCONFIG\_DEFAULTS** - list of files containing default config to use in the build (list must contain full paths); defaults to empty. For each value *filename* in the list, the config from file *filename.target*, if it exists, is also loaded.
- **BUILD\_DIR** - directory to place ESP-IDF build-related artifacts, such as generated binaries, text files, components; defaults to **CMAKE\_BINARY\_DIR**
- **COMPONENTS** - select components to process among the components known by the build system (added via *idf\_build\_component*). This argument is used to trim the build. Other components are automatically added if they are required in the dependency chain, i.e. the public and private requirements of the components in this list are automatically added, and in turn the public and private requirements of those requirements, so on and so forth. If not specified, all components known to the build system are processed.

```
idf_build_executable(executable)
```

Specify the executable *executable* for ESP-IDF build. This attaches additional targets such as dependencies related to flashing, generating additional binary files, etc. Should be called after `idf_build_process`.

```
idf_build_get_config(var config [GENERATOR_EXPRESSION])
```

Get the value of the specified config. Much like build properties, specifying *GENERATOR\_EXPRESSION* will retrieve the generator expression string for that config, instead of the actual value, which can be used with CMake commands that support generator expressions. Actual config values are only known after call to `idf_build_process`, however.

### idf-build-properties

These are properties that describe the build. Values of build properties can be retrieved by using the build command `idf_build_get_property`. For example, to get the Python interpreter used for the build:

```
idf_build_get_property(python PYTHON)
message(STATUS "The Python interpreter is: ${python}")
```

- `BUILD_DIR` - build directory; set from `idf_build_process BUILD_DIR` argument
- `BUILD_COMPONENTS` - list of components included in the build; set by `idf_build_process`
- `BUILD_COMPONENT_ALIASES` - list of library alias of components included in the build; set by `idf_build_process`
- `C_COMPILE_OPTIONS` - compile options applied to all components' C source files
- `COMPILE_OPTIONS` - compile options applied to all components' source files, regardless of it being C or C++
- `COMPILE_DEFINITIONS` - compile definitions applied to all component source files
- `CXX_COMPILE_OPTIONS` - compile options applied to all components' C++ source files
- `EXECUTABLE` - project executable; set by call to `idf_build_executable`
- `EXECUTABLE_NAME` - name of project executable without extension; set by call to `idf_build_executable`
- `EXECUTABLE_DIR` - path containing the output executable
- `IDF_COMPONENT_MANAGER` - the component manager is enabled by default, but if this property is set to 0 it was disabled by the `IDF_COMPONENT_MANAGER` environment variable
- `IDF_PATH` - ESP-IDF path; set from `IDF_PATH` environment variable, if not, inferred from the location of `idf.cmake`
- `IDF_TARGET` - target chip for the build; set from the required target argument for `idf_build_process`
- `IDF_VER` - ESP-IDF version; set from either a version file or the Git revision of the `IDF_PATH` repository
- `INCLUDE_DIRECTORIES` - include directories for all component source files
- `KCONFIGS` - list of Kconfig files found in components in build; set by `idf_build_process`
- `KCONFIG_PROJBUILDS` - list of Kconfig.projbuild files found in components in build; set by `idf_build_process`
- `PROJECT_NAME` - name of the project; set from `idf_build_process PROJECT_NAME` argument
- `PROJECT_DIR` - directory of the project; set from `idf_build_process PROJECT_DIR` argument
- `PROJECT_VER` - version of the project; set from `idf_build_process PROJECT_VER` argument
- `PYTHON` - Python interpreter used for the build; set from `PYTHON` environment variable if available, if not "python" is used
- `SDKCONFIG` - full path to output config file; set from `idf_build_process SDKCONFIG` argument
- `SDKCONFIG_DEFAULTS` - list of files containing default config to use in the build; set from `idf_build_process SDKCONFIG_DEFAULTS` argument
- `SDKCONFIG_HEADER` - full path to C/C++ header file containing component configuration; set by `idf_build_process`
- `SDKCONFIG_CMAKE` - full path to CMake file containing component configuration; set by `idf_build_process`
- `SDKCONFIG_JSON` - full path to JSON file containing component configuration; set by `idf_build_process`

- `SDKCONFIG_JSON_MENUS` - full path to JSON file containing config menus; set by `idf_build_process`

### idf-component-commands

```
idf_component_get_property(var component property [GENERATOR_EXPRESSION])
```

Retrieve a specified *component*'s *component property*, *property* and store it in *var* accessible from the current scope. Specifying *GENERATOR\_EXPRESSION* will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.

```
idf_component_set_property(component property val [APPEND])
```

Set a specified *component*'s *component property*, *property* with value *val*. Specifying *APPEND* will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

```
idf_component_register([[SRCS src1 src2 ...] | [[SRC_DIRS dir1 dir2 ...] [EXCLUDE_
→SRCS src1 src2 ...]]
                        [INCLUDE_DIRS dir1 dir2 ...]
                        [PRIV_INCLUDE_DIRS dir1 dir2 ...]
                        [REQUIRES component1 component2 ...]
                        [PRIV_REQUIRES component1 component2 ...]
                        [LDFRAGMENTS ldfragment1 ldfragment2 ...]
                        [REQUIRED_IDF_TARGETS target1 target2 ...]
                        [EMBED_FILES file1 file2 ...]
                        [EMBED_TXTFILES file1 file2 ...]
                        [KCONFIG kconfig]
                        [KCONFIG_PROJBUILD kconfig_projbuild]
                        [WHOLE_ARCHIVE])
```

Register a component to the build system. Much like the `project()` CMake command, this should be called from the component's `CMakeLists.txt` directly (not through a function or macro) and is recommended to be called before any other command. Here are some guidelines on what commands can **not** be called before `idf_component_register`:

- commands that are not valid in CMake script mode
- custom commands defined in `project_include.cmake`
- build system API commands except `idf_build_get_property`; although consider whether the property may not have been set yet

Commands that set and operate on variables are generally okay to call before `idf_component_register`.

The arguments for `idf_component_register` include:

- `SRCS` - component source files used for creating a static library for the component; if not specified, component is treated as a config-only component and an interface library is created instead.
- `SRC_DIRS`, `EXCLUDE_SRCS` - used to glob source files (`.c`, `.cpp`, `.S`) by specifying directories, instead of specifying source files manually via `SRCS`. Note that this is subject to the *limitations of globbing in CMake*. Source files specified in `EXCLUDE_SRCS` are removed from the globbed files.
- `INCLUDE_DIRS` - paths, relative to the component directory, which will be added to the include search path for all other components which require the current component
- `PRIV_INCLUDE_DIRS` - directory paths, must be relative to the component directory, which will be added to the include search path for this component's source files only
- `REQUIRES` - public component requirements for the component
- `PRIV_REQUIRES` - private component requirements for the component; ignored on config-only components
- `LDFRAGMENTS` - component linker fragment files
- `REQUIRED_IDF_TARGETS` - specify the only target the component supports
- `KCONFIG` - override the default Kconfig file
- `KCONFIG_PROJBUILD` - override the default Kconfig.projbuild file

- `WHOLE_ARCHIVE` - if specified, the component library is surrounded by `-Wl,--whole-archive,-Wl,--no-whole-archive` when linked. This has the same effect as setting `WHOLE_ARCHIVE` component property.

The following are used for *embedding data into the component*, and is considered as source files when determining if a component is config-only. This means that even if the component does not specify source files, a static library is still created internally for the component if it specifies either:

- `EMBED_FILES` - binary files to be embedded in the component
- `EMBED_TXTFILES` - text files to be embedded in the component

### idf-component-properties

These are properties that describe a component. Values of component properties can be retrieved by using the build command `idf_component_get_property`. For example, to get the directory of the `freertos` component:

```
idf_component_get_property(dir freertos COMPONENT_DIR)
message(STATUS "The 'freertos' component directory is: ${dir}")
```

- `COMPONENT_ALIAS` - alias for `COMPONENT_LIB` used for linking the component to external targets; set by `idf_build_component` and alias library itself is created by `idf_component_register`
- `COMPONENT_DIR` - component directory; set by `idf_build_component`
- `COMPONENT_OVERRIDEN_DIR` - contains the directory of the original component if *this component overrides another component*
- `COMPONENT_LIB` - name for created component static/interface library; set by `idf_build_component` and library itself is created by `idf_component_register`
- `COMPONENT_NAME` - name of the component; set by `idf_build_component` based on the component directory name
- `COMPONENT_TYPE` - type of the component, whether `LIBRARY` or `CONFIG_ONLY`. A component is of type `LIBRARY` if it specifies source files or embeds a file
- `EMBED_FILES` - list of files to embed in component; set from `idf_component_register` `EMBED_FILES` argument
- `EMBED_TXTFILES` - list of text files to embed in component; set from `idf_component_register` `EMBED_TXTFILES` argument
- `INCLUDE_DIRS` - list of component include directories; set from `idf_component_register` `INCLUDE_DIRS` argument
- `KCONFIG` - component Kconfig file; set by `idf_build_component`
- `KCONFIG_PROJBUILD` - component Kconfig.projbuild; set by `idf_build_component`
- `LDFRAGMENTS` - list of component linker fragment files; set from `idf_component_register` `LDFRAGMENTS` argument
- `MANAGED_PRIV_REQUIRES` - list of private component dependencies added by the IDF component manager from dependencies in `idf_component.yml` manifest file
- `MANAGED_REQUIRES` - list of public component dependencies added by the IDF component manager from dependencies in `idf_component.yml` manifest file
- `PRIV_INCLUDE_DIRS` - list of component private include directories; set from `idf_component_register` `PRIV_INCLUDE_DIRS` on components of type `LIBRARY`
- `PRIV_REQUIRES` - list of private component dependencies; set from value of `idf_component_register` `PRIV_REQUIRES` argument and dependencies in `idf_component.yml` manifest file
- `REQUIRED_IDF_TARGETS` - list of targets the component supports; set from `idf_component_register` `EMBED_TXTFILES` argument
- `REQUIRES` - list of public component dependencies; set from value of `idf_component_register` `REQUIRES` argument and dependencies in `idf_component.yml` manifest file
- `SRCS` - list of component source files; set from `SRCS` or `SRC_DIRS/EXCLUDE_SRCS` argument of `idf_component_register`
- `WHOLE_ARCHIVE` - if this property is set to `TRUE` (or any boolean “true” CMake value: `1`, `ON`, `YES`, `Y`), the component library is surrounded by `-Wl,--whole-archive,-Wl,--no-whole-archive` when linked. This can be used to force the linker to include every object file into the executable, even if the object file doesn't resolve any references from the rest of the application. This is commonly used when a component

contains plugins or modules which rely on link-time registration. This property is `FALSE` by default. It can be set to `TRUE` from the component `CMakeLists.txt` file.

### 4.5.21 File Globbing & Incremental Builds

The preferred way to include source files in an ESP-IDF component is to list them manually via `SRCS` argument to `idf_component_register`:

```
idf_component_register(SRCS library/a.c library/b.c platform/platform.c
                      ...)
```

This preference reflects the [CMake best practice](#) of manually listing source files. This could, however, be inconvenient when there are lots of source files to add to the build. The ESP-IDF build system provides an alternative way for specifying source files using `SRC_DIRS`:

```
idf_component_register(SRC_DIRS library platform
                      ...)
```

This uses globbing behind the scenes to find source files in the specified directories. Be aware, however, that if a new source file is added and this method is used, then CMake won't know to automatically re-run and this file won't be added to the build.

The trade-off is acceptable when you're adding the file yourself, because you can trigger a clean build or run `idf.py reconfigure` to manually re-run CMake. However, the problem gets harder when you share your project with others who may check out a new version using a source control tool like Git...

For components which are part of ESP-IDF, we use a third party Git CMake integration module ([/tools/cmake/third\\_party/GetGitRevisionDescription.cmake](#)) which automatically re-runs CMake any time the repository commit changes. This means if you check out a new ESP-IDF version, CMake will automatically re-run.

For project components (not part of ESP-IDF), there are a few different options:

- If keeping your project file in Git, ESP-IDF will automatically track the Git revision and re-run CMake if the revision changes.
- If some components are kept in a third git repository (not the project repository or ESP-IDF repository), you can add a call to the `git_describe` function in a component `CMakeLists` file in order to automatically trigger re-runs of CMake when the Git revision changes.
- If not using Git, remember to manually run `idf.py reconfigure` whenever a source file may change.
- To avoid this problem entirely, use `SRCS` argument to `idf_component_register` to list all source files in project components.

The best option will depend on your particular project and its users.

### 4.5.22 Build System Metadata

For integration into IDEs and other build systems, when CMake runs the build process generates a number of metadata files in the `build/` directory. To regenerate these files, run `cmake` or `idf.py reconfigure` (or any other `idf.py build` command).

- `compile_commands.json` is a standard format JSON file which describes every source file which is compiled in the project. A CMake feature generates this file, and many IDEs know how to parse it.
- `project_description.json` contains some general information about the ESP-IDF project, configured paths, etc.
- `flasher_args.json` contains `esptool.py` arguments to flash the project's binary files. There are also `flash_*_args` files which can be used directly with `esptool.py`. See [Flash arguments](#).
- `CMakeCache.txt` is the CMake cache file which contains other information about the CMake process, toolchain, etc.
- `config/sdkconfig.json` is a JSON-formatted version of the project configuration values.

- `config/kconfig_menus.json` is a JSON-formatted version of the menus shown in `menuconfig`, for use in external IDE UIs.

### JSON Configuration Server

A tool called `confserver.py` is provided to allow IDEs to easily integrate with the configuration system logic. `confserver.py` is designed to run in the background and interact with a calling process by reading and writing JSON over process stdin & stdout.

You can run `confserver.py` from a project via `idf.py confserver` or `ninja confserver`, or a similar target triggered from a different build generator.

For more information about `confserver.py`, see [tools/kconfig\\_new/README.md](https://github.com/espressif/esp-idf/blob/master/tools/kconfig_new/README.md).

## 4.5.23 Build System Internals

### Build Scripts

The listfiles for the ESP-IDF build system reside in `/tools/cmake`. The modules which implement core build system functionality are as follows:

- `build.cmake` - Build related commands i.e. build initialization, retrieving/setting build properties, build processing.
- `component.cmake` - Component related commands i.e. adding components, retrieving/setting component properties, registering components.
- `kconfig.cmake` - Generation of configuration files (`sdkconfig`, `sdkconfig.h`, `sdkconfig.cmake`, etc.) from Kconfig files.
- `ldgen.cmake` - Generation of final linker script from linker fragment files.
- `target.cmake` - Setting build target and toolchain file.
- `utilities.cmake` - Miscellaneous helper commands.

Aside from these files, there are two other important CMake scripts in `/tools/cmake`:

- `idf.cmake` - Sets up the build and includes the core modules listed above. Included in CMake projects in order to access ESP-IDF build system functionality.
- `project.cmake` - Includes `idf.cmake` and provides a custom `project()` command that takes care of all the heavy lifting of building an executable. Included in the top-level `CMakeLists.txt` of standard ESP-IDF projects.

The rest of the files in `/tools/cmake` are support or third-party scripts used in the build process.

### Build Process

This section describes the standard ESP-IDF application build process. The build process can be broken down roughly into four phases:

Fig. 36: ESP-IDF Build System Process

**Initialization** This phase sets up necessary parameters for the build.

- **Upon inclusion of `idf.cmake` in `project.cmake`, the following steps are performed:**
  - Set `IDF_PATH` from environment variable or inferred from path to `project.cmake` included in the top-level `CMakeLists.txt`.
  - Add `/tools/cmake` to `CMAKE_MODULE_PATH` and include core modules plus the various helper/third-party scripts.
  - Set build tools/executables such as default Python interpreter.
  - Get ESP-IDF git revision and store as `IDF_VER`.
  - Set global build specifications i.e. compile options, compile definitions, include directories for all components in the build.
  - Add components in `components` to the build.
- **The initial part of the custom `project()` command performs the following steps:**
  - Set `IDF_TARGET` from environment variable or CMake cache and the corresponding `CMAKE_TOOLCHAIN_FILE` to be used.
  - Add components in `EXTRA_COMPONENT_DIRS` to the build.
  - Prepare arguments for calling command `idf_build_process()` from variables such as `COMPONENTS/EXCLUDE_COMPONENTS`, `SDKCONFIG`, `SDKCONFIG_DEFAULTS`.

The call to `idf_build_process()` command marks the end of this phase.

### Enumeration

This phase builds a final list of components to be processed in the build, and is performed in the first half of `idf_build_process()`.

- Retrieve each component's public and private requirements. A child process is created which executes each component's `CMakeLists.txt` in script mode. The values of `idf_component_register` `REQUIRES` and `PRIV_REQUIRES` argument is returned to the parent build process. This is called early expansion. The variable `CMAKE_BUILD_EARLY_EXPANSION` is defined during this step.
- Recursively include components based on public and private requirements.

### Processing

This phase processes the components in the build, and is the second half of `idf_build_process()`.

- Load project configuration from `sdkconfig` file and generate an `sdkconfig.cmake` and `sdkconfig.h` header. These define configuration variables/macros that are accessible from the build scripts and C/C++ source/header files, respectively.
- Include each component's `project_include.cmake`.
- Add each component as a subdirectory, processing its `CMakeLists.txt`. The component `CMakeLists.txt` calls the registration command, `idf_component_register` which adds source files, include directories, creates component library, links dependencies, etc.

### Finalization

This phase is everything after `idf_build_process()`.

- Create executable and link the component libraries to it.
- Generate project metadata files such as `project_description.json` and display relevant information about the project built.

Browse </tools/cmake/project.cmake> for more details.

## 4.5.24 Migrating from ESP-IDF GNU Make System

Some aspects of the CMake-based ESP-IDF build system are very similar to the older GNU Make-based system. The developer needs to provide values the include directories, source files etc. There is a syntactical difference, however,

as the developer needs to pass these as arguments to the registration command, `idf_component_register`.

### Automatic Conversion Tool

An automatic project conversion tool is available in `tools/cmake/convert_to_cmake.py` in ESP-IDF v4.x releases. The script was removed in v5.0 because of its `make` build system dependency.

### No Longer Available in CMake

Some features are significantly different or removed in the CMake-based system. The following variables no longer exist in the CMake-based build system:

- `COMPONENT_BUILD_DIR`: Use `CMAKE_CURRENT_BINARY_DIR` instead.
- `COMPONENT_LIBRARY`: Defaulted to `$(COMPONENT_NAME).a`, but the library name could be overridden by the component. The name of the component library can no longer be overridden by the component.
- `CC`, `LD`, `AR`, `OBJCOPY`: Full paths to each tool from the `gcc xtensa` cross-toolchain. Use `CMAKE_C_COMPILER`, `CMAKE_C_LINK_EXECUTABLE`, `CMAKE_OBJCOPY`, etc instead. [Full list here](#).
- `HOSTCC`, `HOSTLD`, `HOSTAR`: Full names of each tool from the host native toolchain. These are no longer provided, external projects should detect any required host toolchain manually.
- `COMPONENT_ADD_LDFLAGS`: Used to override linker flags. Use the CMake [target\\_link\\_libraries](#) command instead.
- `COMPONENT_ADD_LINKER_DEPS`: List of files that linking should depend on. [target\\_link\\_libraries](#) will usually infer these dependencies automatically. For linker scripts, use the provided custom CMake function `target_linker_scripts`.
- `COMPONENT_SUBMODULES`: No longer used, the build system will automatically enumerate all submodules in the ESP-IDF repository.
- `COMPONENT_EXTRA_INCLUDES`: Used to be an alternative to `COMPONENT_PRIV_INCLUDEDIRS` for absolute paths. Use `COMPONENT_PRIV_INCLUDE_DIRS` argument to `idf_component_register` for all cases now (can be relative or absolute).
- `COMPONENT_OBJS`: Previously, component sources could be specified as a list of object files. Now they can be specified as a list of source files via `SRC` argument to `idf_component_register`.
- `COMPONENT_OBJEXCLUDE`: Has been replaced with `EXCLUDE_SRCS` argument to `idf_component_register`. Specify source files (as absolute paths or relative to component directory), instead.
- `COMPONENT_EXTRA_CLEAN`: Set property `ADDITIONAL_CLEAN_FILES` instead but note [CMake has some restrictions around this functionality](#).
- `COMPONENT_OWNBUILDTARGET` & `COMPONENT_OWNCLEANTARGET`: Use CMake [ExternalProject](#) instead. See [Fully Overriding The Component Build Process](#) for full details.
- `COMPONENT_CONFIG_ONLY`: Call `idf_component_register` without any arguments instead. See [Configuration-Only Components](#).
- `CFLAGS`, `CPPFLAGS`, `CXXFLAGS`: Use equivalent CMake commands instead. See [Controlling Component Compilation](#).

### No Default Values

Unlike in the legacy Make-based build system, the following have no default values:

- Source directories (`COMPONENT_SRCDIRS` variable in Make, `SRC_DIRS` argument to `idf_component_register` in CMake)
- Include directories (`COMPONENT_ADD_INCLUDEDIRS` variable in Make, `INCLUDE_DIRS` argument to `idf_component_register` in CMake)

### No Longer Necessary

- In the legacy Make-based build system, it is required to also set `COMPONENT_SRCDIRS` if `COMPONENT_SRCS` is set. In CMake, the equivalent is not necessary i.e. specifying `SRC_DIRS` to

`idf_component_register` if `SRCS` is also specified (in fact, `SRCS` is ignored if `SRC_DIRS` is specified).

### Flashing from make

`make flash` and similar targets still work to build and flash. However, project `sdkconfig` no longer specifies serial port and baud rate. Environment variables can be used to override these. See [Flashing with ninja or make](#) for more details.

## 4.6 Core Dump

### 4.6.1 Overview

ESP-IDF provides support to generate core dumps on unrecoverable software errors. This useful technique allows post-mortem analysis of software state at the moment of failure. Upon the crash system enters panic state, prints some information and halts or reboots depending configuration. User can choose to generate core dump in order to analyse the reason of failure on PC later on. Core dump contains snapshots of all tasks in the system at the moment of failure. Snapshots include tasks control blocks (TCB) and stacks. So it is possible to find out what task, at what instruction (line of code) and what callstack of that task lead to the crash. It is also possible dumping variables content on demand if previously attributed accordingly. ESP-IDF provides special script `espcoredump.py` to help users to retrieve and analyse core dumps. This tool provides two commands for core dumps analysis:

- `info_corefile` - prints crashed task's registers, callstack, list of available tasks in the system, memory regions and contents of memory stored in core dump (TCBs and stacks)
- `dbg_corefile` - creates core dump ELF file and runs GDB debug session with this file. User can examine memory, variables and tasks states manually. Note that since not all memory is saved in core dump only values of variables allocated on stack will be meaningful

For more information about core dump internals see the - [Core dump internals](#)

### 4.6.2 Configurations

There are a number of core dump related configuration options which user can choose in project configuration menu (`idf.py menuconfig`).

#### Core dump data destination (Components -> Core dump -> Data destination)

- Save core dump to Flash (Flash)
- Print core dump to UART (UART)
- Disable core dump generation (None)

#### Core dump data format (Components -> Core dump -> Core dump data format)

- ELF format (Executable and Linkable Format file for core dump)
- Binary format (Basic binary format for core dump)

The ELF format contains extended features and allow to save more information about broken tasks and crashed software but it requires more space in the flash memory. This format of core dump is recommended for new software designs and is flexible enough to extend saved information for future revisions.

The Binary format is kept for compatibility reasons, it uses less space in the memory to keep data and provides better performance.

#### Core dump data integrity check (Components -> Core dump -> Core dump data integrity check)

- Use CRC32 for core dump integrity verification

**Maximum number of tasks snapshots in core dump (Components -> Core dump -> Maximum number of tasks)**

**Delay before core dump is printed to UART (Components -> Core dump -> Delay before print to UART)**

The value is in ms.

**Handling of UART core dumps in IDF Monitor (Components -> Core dump -> Delay before print to UART)**

The value is base64 encoded.

- Decode and show summary (info\_corefile)
- Don't decode

**Reserved stack size (Components -> Core dump -> Reserved stack size)**

Size of the memory to be reserved for core dump stack. If 0 core dump process will run on the stack of crashed task/ISR, otherwise special stack will be allocated. To ensure that core dump itself will not overflow task/ISR stack set this to the value above 800.

### 4.6.3 Save core dump to flash

When this option is selected core dumps are saved to special partition on flash. When using default partition table files which are provided with ESP-IDF it automatically allocates necessary space on flash. But if user wants to use its own layout file together with core dump feature it should define separate partition for core dump as it is shown below:

```
# Name, Type, SubType, Offset, Size
# Note: if you have increased the bootloader size, make sure to update the offsets.
↳to avoid overlap
nvs, data, nvs, 0x9000, 0x6000
phy_init, data, phy, 0xf000, 0x1000
factory, app, factory, 0x10000, 1M
coredump, data, coredump,, 64K
```

There are no special requirements for partition name. It can be chosen according to the user application needs, but partition type should be 'data' and sub-type should be 'coredump'. Also when choosing partition size note that core dump data structure introduces constant overhead of 20 bytes and per-task overhead of 12 bytes. This overhead does not include size of TCB and stack for every task. So partition size should be at least 20 + max tasks number x (12 + TCB size + max task stack size) bytes.

The example of generic command to analyze core dump from flash is:

```
espcoredump.py -p </path/to/serial/port> info_corefile </path/to/program/elf/file>
```

or

```
espcoredump.py -p </path/to/serial/port> dbg_corefile </path/to/program/elf/file>
```

### 4.6.4 Print core dump to UART

When this option is selected base64-encoded core dumps are printed on UART upon system panic. In this case user should save core dump text body to some file manually and then run the following command:

```
espcoredump.py --chip esp32c3 info_corefile -t b64 -c </path/to/saved/base64/text>
↳</path/to/program/elf/file>
```

or

```
espcoredump.py --chip esp32c3 dbg_corefile -t b64 -c </path/to/saved/base64/text>
↳</path/to/program/elf/file>
```

Base64-encoded body of core dump will be between the following header and footer:

```
===== CORE DUMP START =====  
<body of base64-encoded core dump, save it to file on disk>  
===== CORE DUMP END =====
```

The `CORE DUMP START` and `CORE DUMP END` lines must not be included in core dump text file.

### 4.6.5 ROM Functions in Backtraces

It is possible situation that at the moment of crash some tasks or/and crashed task itself have one or more ROM functions in their callstacks. Since ROM is not part of the program ELF it will be impossible for GDB to parse such callstacks, because it tries to analyse functions' prologues to accomplish that. In that case callstack printing will be broken with error message at the first ROM function. To overcome this issue, you can use the [ROM ELF](#) provided by Espressif. You can find the esp32c3's corresponding ROM ELF file from the list of released archives. The ROM ELF file can then be passed to `espcoredump.py`. More details about ROM ELFs can be found [here](#).

### 4.6.6 Dumping variables on demand

Sometimes you want to read the last value of a variable to understand the root cause of a crash. Core dump supports retrieving variable data over GDB by attributing special notations declared variables.

#### Supported notations and RAM regions

- `COREDUMP_DRAM_ATTR` places variable into DRAM area which will be included into dump.
- `COREDUMP_RTC_ATTR` places variable into RTC area which will be included into dump.
- `COREDUMP_RTC_FAST_ATTR` places variable into RTC\_FAST area which will be included into dump.

#### Example

1. In *Project Configuration Menu*, enable *COREDUMP TO FLASH*, then save and exit.
2. In your project, create a global variable in DRAM area as such as:

```
// uint8_t global_var;  
COREDUMP_DRAM_ATTR uint8_t global_var;
```

3. In main application, set the variable to any value and `assert(0)` to cause a crash.

```
global_var = 25;  
assert(0);
```

4. Build, flash and run the application on a target device and wait for the dumping information.
5. Run the command below to start core dumping in GDB, where `PORT` is the device USB port:

```
espcoredump.py -p PORT dbg_corefile <path/to/elf>
```

6. In GDB shell, type `p global_var` to get the variable content:

```
(gdb) p global_var  
$1 = 25 '\031'
```

### 4.6.7 Running `espcoredump.py`

Generic command syntax: `espcoredump.py [options] command [args]`

### Script Options

- chip** {*auto,esp32,esp32s2,esp32s3,esp32c2,esp32c3*} Target chip type. Default value is “auto”
- port** *PORT*, **-p** *PORT* Serial port device. Either “chip” or “port” need to be specified to determine the port when you have multi-target connected at the same time.
- baud** *BAUD*, **-b** *BAUD* Serial port baud rate used when flashing/reading
- gdb-timeout-sec** *GDB\_TIMEOUT\_SEC* Overwrite the default internal delay for gdb responses

**Commands** **dbg\_corefile** Starts GDB debugging session with specified corefile

**info\_corefile** Print core dump info from file

### Command Arguments

- debug** *DEBUG*, **-d** *DEBUG* Log level (0..3)
- gdb** *GDB*, **-g** *GDB* Path to gdb
- core** *CORE*, **-c** *CORE* Path to core dump file (if skipped core dump will be read from flash)
- core-format** {*b64,elf,raw*}, **-t** {*b64,elf,raw*} File specified with “-c” is an ELF ( “elf” ), raw (raw) or base64-encoded (b64) binary
- off** *OFF*, **-o** *OFF* Offset of coredump partition in flash (type “idf.py partition-table” to see).
- save-core** *SAVE\_CORE*, **-s** *SAVE\_CORE* Save core to file. Otherwise temporary core file will be deleted. Does not work with “-c”
- rom-elf** *ROM\_ELF*, **-r** *ROM\_ELF* Path to ROM ELF file. Will use “<target>\_rom.elf” if not specified
- print-mem**, **-m** Print memory dump. Only valid when info\_corefile.
- <prog>** Path to program ELF file.

### Related Documents

**Anatomy of core dump image** Core dump component can be configured to use old legacy binary format or the new ELF one. The ELF format is recommended for new designs. It provides more information about the CPU and memory state of a program at the moment when panic handler is entered. The memory state embeds a snapshot of all tasks mapped in the memory space of the program. The CPU state contains register values when the core dump has been generated. Core dump file uses a subset of the ELF structures to register these information. Loadable ELF segments are used for the memory state of the process while ELF notes (ELF.PT\_NOTE) are used for process metadata (pid, registers, signal, ...). Especially, the CPU status is stored in a note with a special name and type (CORE, NT\_PRSTATUS type).

Here is an overview of coredump layout:

Note: The format of image file showed on the above pictures represents current version of image and can be changed in future releases.

**Overview of implementation** The figure below describes some basic aspects related to implementation of core dump:

Note: The diagram above hide some details and represents current implementation of the core dump and can be changed later.

## 4.7 Deep Sleep Wake Stubs

ESP32-C3 supports running a “deep sleep wake stub” when coming out of deep sleep. This function runs immediately as soon as the chip wakes up - before any normal initialisation, bootloader, or ESP-IDF code has run. After the wake stub runs, the SoC can go back to sleep or continue to start ESP-IDF normally.

Deep sleep wake stub code is loaded into “RTC Fast Memory” and any data which it uses must also be loaded into RTC memory. RTC memory regions hold their contents during deep sleep.

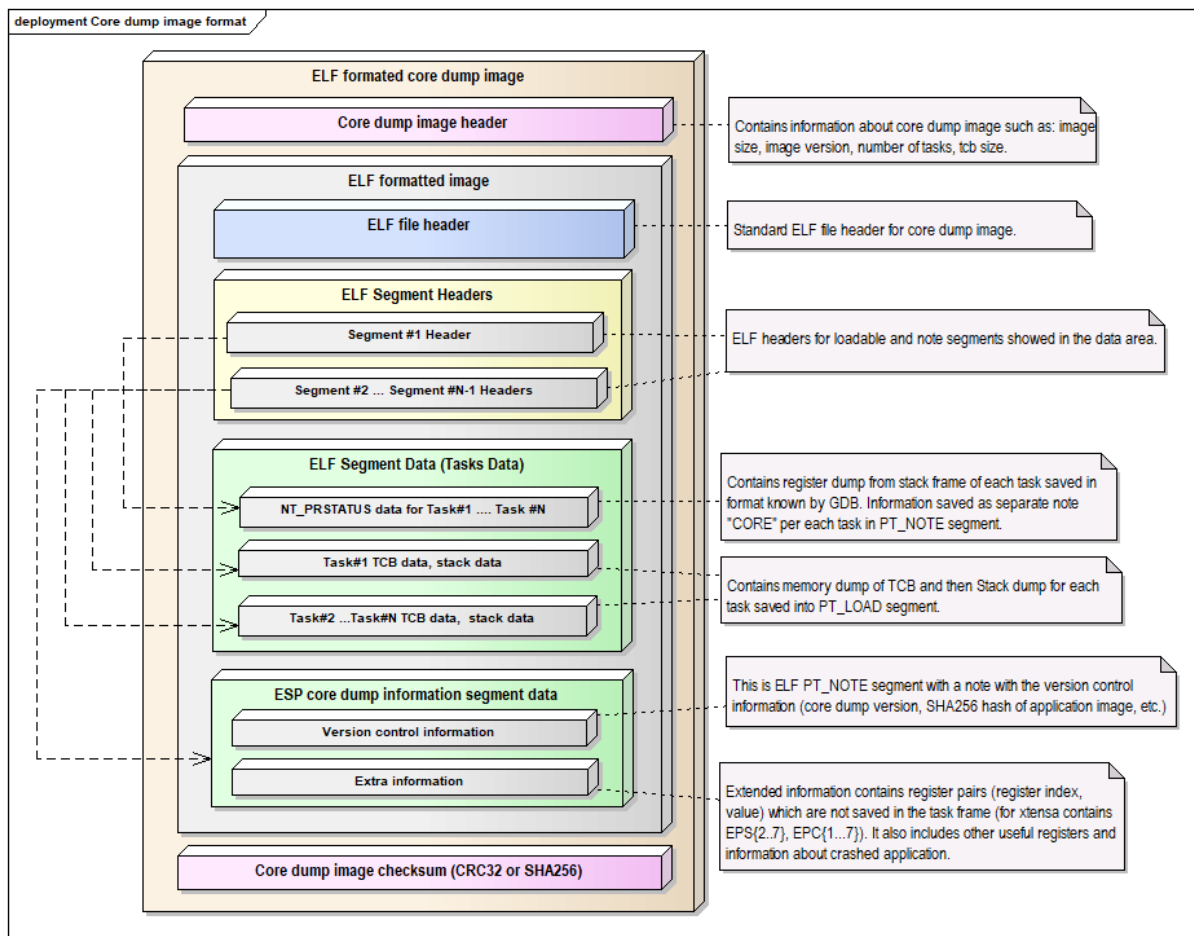

Fig. 37: Core dump ELF image format

Fig. 38: Core dump binary image format

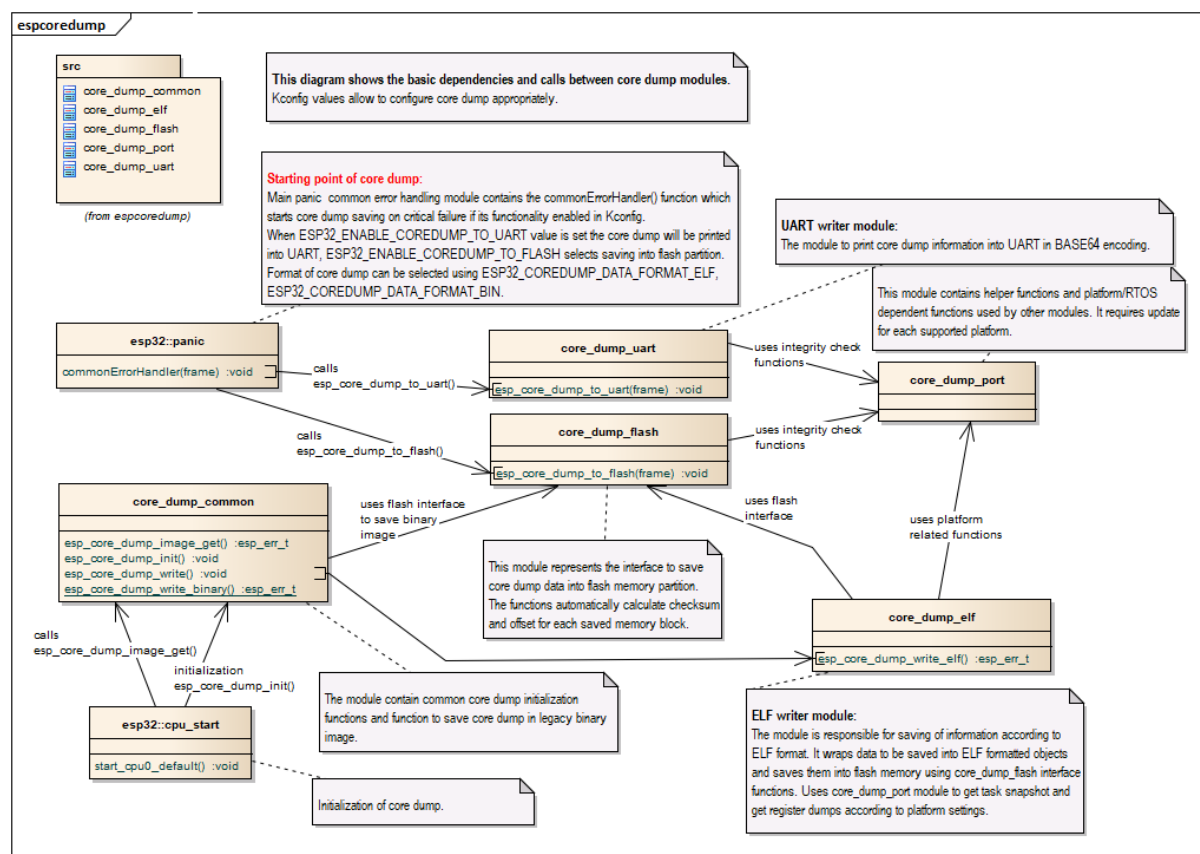

Fig. 39: Core dump implementation overview

## 4.7.1 Rules for Wake Stubs

Wake stub code must be carefully written:

- As the SoC has freshly woken from sleep, most of the peripherals are in reset states. The SPI flash is unmapped.
- The wake stub code can only call functions implemented in ROM or loaded into RTC Fast Memory (see below.)
- The wake stub code can only access data loaded in RTC memory. All other RAM will be uninitialized and have random contents. The wake stub can use other RAM for temporary storage, but the contents will be overwritten when the SoC goes back to sleep or starts ESP-IDF.
- RTC memory must include any read-only data (.rodata) used by the stub.
- Data in RTC memory is initialised whenever the SoC restarts, except when waking from deep sleep. When waking from deep sleep, the values which were present before going to sleep are kept.
- Wake stub code is a part of the main esp-idf app. During normal running of esp-idf, functions can call the wake stub functions or access RTC memory. It is as if these were regular parts of the app.

## 4.7.2 Implementing A Stub

The wake stub in esp-idf is called `esp_wake_deep_sleep()`. This function runs whenever the SoC wakes from deep sleep. There is a default version of this function provided in esp-idf, but the default function is weak-linked so if your app contains a function named `esp_wake_deep_sleep()` then this will override the default.

If supplying a custom wake stub, the first thing it does should be to call `esp_default_wake_deep_sleep()`.

It is not necessary to implement `esp_wake_deep_sleep()` in your app in order to use deep sleep. It is only necessary if you want to have special behaviour immediately on wake.

If you want to swap between different deep sleep stubs at runtime, it is also possible to do this by calling the `esp_set_deep_sleep_wake_stub()` function. This is not necessary if you only use the default `esp_wake_deep_sleep()` function.

All of these functions are declared in the `esp_sleep.h` header under `components/esp32c3`.

### 4.7.3 Loading Code Into RTC Memory

Wake stub code must be resident in RTC Fast Memory. This can be done in one of two ways.

The first way is to use the `RTC_IRAM_ATTR` attribute to place a function into RTC memory:

```
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    // Add additional functionality here
}
```

The second way is to place the function into any source file whose name starts with `rtc_wake_stub`. Files names `rtc_wake_stub*` have their contents automatically put into RTC memory by the linker.

The first way is simpler for very short and simple code, or for source files where you want to mix “normal” and “RTC” code. The second way is simpler when you want to write longer pieces of code for RTC memory.

### 4.7.4 Loading Data Into RTC Memory

Data used by stub code must be resident in RTC memory.

Specifying this data can be done in one of two ways:

The first way is to use the `RTC_DATA_ATTR` and `RTC_RODATA_ATTR` to specify any data (writeable or read-only, respectively) which should be loaded into RTC memory:

```
RTC_DATA_ATTR int wake_count;

void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    static RTC_RODATA_ATTR const char fmt_str[] = "Wake count %d\n";
    esp_rom_printf(fmt_str, wake_count++);
}
```

The attributes `RTC_FAST_ATTR` and `RTC_SLOW_ATTR` can be used to specify data that will be force placed into `RTC_FAST` and `RTC_SLOW` memory respectively, but for ESP32-C3 there is only RTC fast memory, so both attributes will map to this region.

Unfortunately, any string constants used in this way must be declared as arrays and marked with `RTC_RODATA_ATTR`, as shown in the example above.

The second way is to place the data into any source file whose name starts with `rtc_wake_stub`.

For example, the equivalent example in `rtc_wake_stub_counter.c`:

```
int wake_count;

void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    esp_rom_printf("Wake count %d\n", wake_count++);
}
```

The second way is a better option if you need to use strings, or write other more complex code.

To reduce wake-up time use the `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` Kconfig option, see more information in [Fast boot from Deep Sleep](#).

## 4.7.5 CRC Check For Wake Stubs

During deep sleep, all RTC Fast memory areas will be validated with CRC. When ESP32-C3 wakes up from deep sleep, the RTC fast memory will be validated with CRC again. If the validation passes, the wake stubs code will be executed. Otherwise, the normal initialization, bootloader and esp-idf codes will be executed.

---

**Note:** When the `CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP` option is enabled, all the RTC fast memory except the wake stubs area is added to the heap.

---

## 4.7.6 Example

ESP-IDF provides an example to show how to implement the Deep-sleep wake stub.

- [system/deep\\_sleep\\_wake\\_stub](#)

## 4.8 Error Handling

### 4.8.1 Overview

Identifying and handling run-time errors is important for developing robust applications. There can be multiple kinds of run-time errors:

- Recoverable errors:
  - Errors indicated by functions through return values (error codes)
  - C++ exceptions, thrown using `throw` keyword
- Unrecoverable (fatal) errors:
  - Failed assertions (using `assert` macro and equivalent methods, see [Assertions](#)) and `abort()` calls.
  - CPU exceptions: access to protected regions of memory, illegal instruction, etc.
  - System level checks: watchdog timeout, cache access error, stack overflow, stack smashing, heap corruption, etc.

This guide explains ESP-IDF error handling mechanisms related to recoverable errors, and provides some common error handling patterns.

For instructions on diagnosing unrecoverable errors, see [Fatal Errors](#).

### 4.8.2 Error codes

The majority of ESP-IDF-specific functions use `esp_err_t` type to return error codes. `esp_err_t` is a signed integer type. Success (no error) is indicated with `ESP_OK` code, which is defined as zero.

Various ESP-IDF header files define possible error codes using preprocessor defines. Usually these defines start with `ESP_ERR_` prefix. Common error codes for generic failures (out of memory, timeout, invalid argument, etc.) are defined in `esp_err.h` file. Various components in ESP-IDF may define additional error codes for specific situations.

For the complete list of error codes, see [Error Code Reference](#).

### 4.8.3 Converting error codes to error messages

For each error code defined in ESP-IDF components, `esp_err_t` value can be converted to an error code name using `esp_err_to_name()` or `esp_err_to_name_r()` functions. For example, passing `0x101` to `esp_err_to_name()` will return “ESP\_ERR\_NO\_MEM” string. Such strings can be used in log output to make it easier to understand which error has happened.

Additionally, `esp_err_to_name_r()` function will attempt to interpret the error code as a [standard POSIX error code](#), if no matching `ESP_ERR_` value is found. This is done using `strerror_r` function. POSIX error codes (such as `ENOENT`, `ENOMEM`) are defined in `errno.h` and are typically obtained from `errno` variable. In ESP-IDF this variable is thread-local: multiple FreeRTOS tasks have their own copies of `errno`. Functions which set `errno` only modify its value for the task they run in.

This feature is enabled by default, but can be disabled to reduce application binary size. See [CONFIG\\_ESP\\_ERR\\_TO\\_NAME\\_LOOKUP](#). When this feature is disabled, `esp_err_to_name()` and `esp_err_to_name_r()` are still defined and can be called. In this case, `esp_err_to_name()` will return `UNKNOWN_ERROR`, and `esp_err_to_name_r()` will return `Unknown error 0xXXXX(YYYYY)`, where `0xXXXX` and `YYYYY` are the hexadecimal and decimal representations of the error code, respectively.

### 4.8.4 ESP\_ERROR\_CHECK macro

`ESP_ERROR_CHECK` macro serves similar purpose as `assert`, except that it checks `esp_err_t` value rather than a `bool` condition. If the argument of `ESP_ERROR_CHECK` is not equal `ESP_OK`, then an error message is printed on the console, and `abort()` is called.

Error message will typically look like this:

```
ESP_ERROR_CHECK failed: esp_err_t 0x107 (ESP_ERR_TIMEOUT) at 0x400d1fdf
file: "/Users/user/esp/example/main/main.c" line 20
func: app_main
expression: sdmmc_card_init(host, &card)

Backtrace: 0x40086e7c:0x3ffb4ff0 0x40087328:0x3ffb5010 0x400d1fdf:0x3ffb5030_
↳0x400d0816:0x3ffb5050
```

**Note:** If `IDF_MONITOR` is used, addresses in the backtrace will be converted to file names and line numbers.

- The first line mentions the error code as a hexadecimal value, and the identifier used for this error in source code. The latter depends on `CONFIG_ESP_ERR_TO_NAME_LOOKUP` option being set. Address in the program where error has occurred is printed as well.
- Subsequent lines show the location in the program where `ESP_ERROR_CHECK` macro was called, and the expression which was passed to the macro as an argument.
- Finally, backtrace is printed. This is part of panic handler output common to all fatal errors. See [Fatal Errors](#) for more information about the backtrace.

### 4.8.5 ESP\_ERROR\_CHECK\_WITHOUT\_ABORT macro

`ESP_ERROR_CHECK_WITHOUT_ABORT` macro serves similar purpose as `ESP_ERROR_CHECK`, except that it won't call `abort()`.

### 4.8.6 ESP\_RETURN\_ON\_ERROR macro

`ESP_RETURN_ON_ERROR` macro checks the error code, if the error code is not equal `ESP_OK`, it prints the message and returns.

### 4.8.7 ESP\_GOTO\_ON\_ERROR macro

`ESP_GOTO_ON_ERROR` macro checks the error code, if the error code is not equal `ESP_OK`, it prints the message, sets the local variable `ret` to the code, and then exits by jumping to `goto_tag`.

### 4.8.8 ESP\_RETURN\_ON\_FALSE macro

`ESP_RETURN_ON_FALSE` macro checks the condition, if the condition is not equal `true`, it prints the message and returns with the supplied `err_code`.

### 4.8.9 ESP\_GOTO\_ON\_FALSE macro

`ESP_GOTO_ON_FALSE` macro checks the condition, if the condition is not equal `true`, it prints the message, sets the local variable `ret` to the supplied `err_code`, and then exits by jumping to `goto_tag`.

### 4.8.10 CHECK MACROS Examples

Some examples:

```
static const char* TAG = "Test";

esp_err_t test_func(void)
{
    esp_err_t ret = ESP_OK;

    ESP_ERROR_CHECK(x); // err message_
    ↪printed if `x` is not `ESP_OK`, and then `abort()`.
    ESP_ERROR_CHECK_WITHOUT_ABORT(x); // err message_
    ↪printed if `x` is not `ESP_OK`, without `abort()`.
    ESP_RETURN_ON_ERROR(x, TAG, "fail reason 1"); // err message_
    ↪printed if `x` is not `ESP_OK`, and then function returns with code `x`.
    ESP_GOTO_ON_ERROR(x, err, TAG, "fail reason 2"); // err message_
    ↪printed if `x` is not `ESP_OK`, `ret` is set to `x`, and then jumps to `err`.
    ESP_RETURN_ON_FALSE(a, err_code, TAG, "fail reason 3"); // err message_
    ↪printed if `a` is not `true`, and then function returns with code `err_code`.
    ESP_GOTO_ON_FALSE(a, err_code, err, TAG, "fail reason 4"); // err message_
    ↪printed if `a` is not `true`, `ret` is set to `err_code`, and then jumps to_
    ↪`err`.

err:
    // clean up
    return ret;
}
```

**Note:** If the option `CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT` in Kconfig is enabled, the err message will be discarded, while the other action works as is.

The `ESP_RETURN_XX` and `ESP_GOTO_XX` macros can't be called from ISR. While there are `xx_ISR` versions for each of them, e.g., `ESP_RETURN_ON_ERROR_ISR`, these macros could be used in ISR.

### 4.8.11 Error handling patterns

1. Attempt to recover. Depending on the situation, we may try the following methods:
  - retry the call after some time;
  - attempt to de-initialize the driver and re-initialize it again;

- fix the error condition using an out-of-band mechanism (e.g reset an external peripheral which is not responding).

Example:

```
esp_err_t err;
do {
    err = sdio_slave_send_queue(addr, len, arg, timeout);
    // keep retrying while the sending queue is full
} while (err == ESP_ERR_TIMEOUT);
if (err != ESP_OK) {
    // handle other errors
}
```

2. Propagate the error to the caller. In some middleware components this means that a function must exit with the same error code, making sure any resource allocations are rolled back.

Example:

```
sdmmc_card_t* card = calloc(1, sizeof(sdmmc_card_t));
if (card == NULL) {
    return ESP_ERR_NO_MEM;
}
esp_err_t err = sdmmc_card_init(host, &card);
if (err != ESP_OK) {
    // Clean up
    free(card);
    // Propagate the error to the upper layer (e.g. to notify the user).
    // Alternatively, application can define and return custom error code.
    return err;
}
```

3. Convert into unrecoverable error, for example using `ESP_ERROR_CHECK`. See [ESP\\_ERROR\\_CHECK macro](#) section for details.

Terminating the application in case of an error is usually undesirable behavior for middleware components, but is sometimes acceptable at application level.

Many ESP-IDF examples use `ESP_ERROR_CHECK` to handle errors from various APIs. This is not the best practice for applications, and is done to make example code more concise.

Example:

```
ESP_ERROR_CHECK(spi_bus_initialize(host, bus_config, dma_chan));
```

## 4.8.12 C++ Exceptions

Support for C++ Exceptions in ESP-IDF is disabled by default, but can be enabled using `CONFIG_COMPILER_CXX_EXCEPTIONS` option.

Enabling exception handling normally increases application binary size by a few KB. Additionally it may be necessary to reserve some amount of RAM for exception emergency pool. Memory from this pool will be used if it is not possible to allocate exception object from the heap. Amount of memory in the emergency pool can be set using `CONFIG_COMPILER_CXX_EXCEPTIONS_EMG_POOL_SIZE` variable.

If an exception is thrown, but there is no `catch` block, the program will be terminated by `abort` function, and backtrace will be printed. See [Fatal Errors](#) for more information about backtraces.

See [cxx/exceptions](#) for an example of C++ exception handling.

## 4.9 ESP-WIFI-MESH

This guide provides information regarding the ESP-WIFI-MESH protocol. Please see the [ESP-WIFI-MESH API Reference](#) for more information about API usage.

## 4.9.1 Overview

ESP-WIFI-MESH is a networking protocol built atop the Wi-Fi protocol. ESP-WIFI-MESH allows numerous devices (henceforth referred to as nodes) spread over a large physical area (both indoors and outdoors) to be interconnected under a single WLAN (Wireless Local-Area Network). ESP-WIFI-MESH is self-organizing and self-healing meaning the network can be built and maintained autonomously.

The ESP-WIFI-MESH guide is split into the following sections:

1. *Introduction*
2. *ESP-WIFI-MESH Concepts*
3. *Building a Network*
4. *Managing a Network*
5. *Data Transmission*
6. *Channel Switching*
7. *Performance*
8. *Further Notes*

## 4.9.2 Introduction

Fig. 40: Traditional Wi-Fi Network Architecture

A traditional infrastructure Wi-Fi network is a point-to-multipoint network where a single central node known as the access point (AP) is directly connected to all other nodes known as stations. The AP is responsible for arbitrating and forwarding transmissions between the stations. Some APs also relay transmissions to/from an external IP network via a router. Traditional infrastructure Wi-Fi networks suffer the disadvantage of limited coverage area due to the requirement that every station must be in range to directly connect with the AP. Furthermore, traditional Wi-Fi networks are susceptible to overloading as the maximum number of stations permitted in the network is limited by the capacity of the AP.

ESP-WIFI-MESH differs from traditional infrastructure Wi-Fi networks in that nodes are not required to connect to a central node. Instead, nodes are permitted to connect with neighboring nodes. Nodes are mutually responsible for relaying each others transmissions. This allows an ESP-WIFI-MESH network to have much greater coverage area as nodes can still achieve interconnectivity without needing to be in range of the central node. Likewise, ESP-WIFI-MESH is also less susceptible to overloading as the number of nodes permitted on the network is no longer limited by a single central node.

Fig. 41: ESP-WIFI-MESH Network Architecture

### 4.9.3 ESP-WIFI-MESH Concepts

#### Terminology

Term	Description
Node	Any device that <b>is</b> or <b>can be</b> part of an ESP-WIFI-MESH network
Root Node	The top node in the network
Child Node	A node X is a child node when it is connected to another node Y where the connection makes node X more distant from the root node than node Y (in terms of number of connections).
Parent Node	The converse notion of a child node
Descendant Node	Any node reachable by repeated proceeding from parent to child
Sibling Nodes	Nodes that share the same parent node
Connection	A traditional Wi-Fi association between an AP and a station. A node in ESP-WIFI-MESH will use its station interface to associate with the softAP interface of another node, thus forming a connection. The connection process includes the authentication and association processes in Wi-Fi.
Upstream Connection	The connection from a node to its parent node
Downstream Connection	The connection from a node to one of its child nodes
Wireless Hop	The portion of the path between source and destination nodes that corresponds to a single wireless connection. A data packet that traverses a single connection is known as <b>single-hop</b> whereas traversing multiple connections is known as <b>multi-hop</b> .
Subnetwork	A subnetwork is subdivision of an ESP-WIFI-MESH network which consists of a node and all of its descendant nodes. Therefore the subnetwork of the root node consists of all nodes in an ESP-WIFI-MESH network.
MAC Address	Media Access Control Address used to uniquely identify each node or router within an ESP-WIFI-MESH network.
DS	Distribution System (External IP Network)

#### Tree Topology

ESP-WIFI-MESH is built atop the infrastructure Wi-Fi protocol and can be thought of as a networking protocol that combines many individual Wi-Fi networks into a single WLAN. In Wi-Fi, stations are limited to a single connection

with an AP (upstream connection) at any time, whilst an AP can be simultaneously connected to multiple stations (downstream connections). However ESP-WIFI-MESH allows nodes to simultaneously act as a station and an AP. Therefore a node in ESP-WIFI-MESH can have **multiple downstream connections using its softAP interface**, whilst simultaneously having a **single upstream connection using its station interface**. This naturally results in a tree network topology with a parent-child hierarchy consisting of multiple layers.

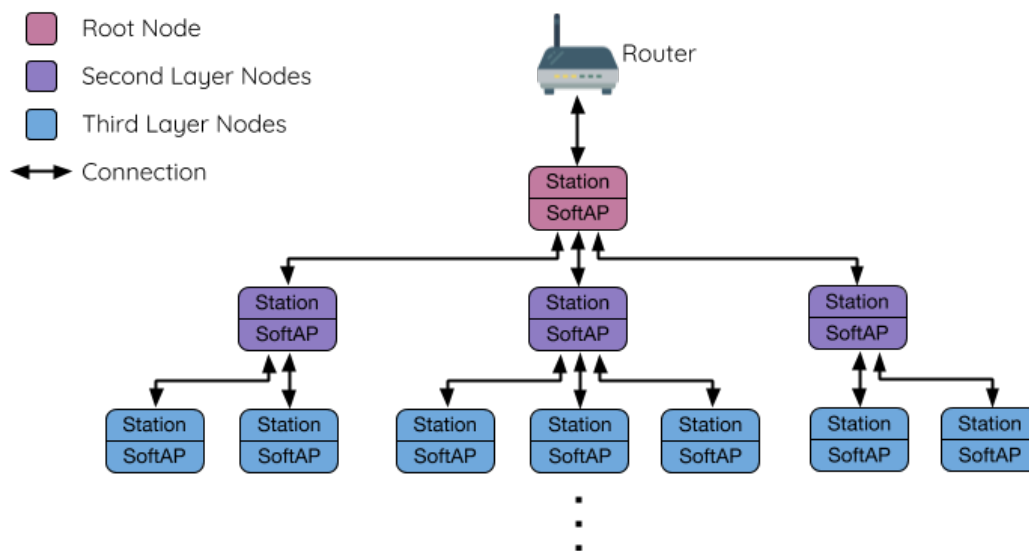

Fig. 42: ESP-WIFI-MESH Tree Topology

ESP-WIFI-MESH is a multiple hop (multi-hop) network meaning nodes can transmit packets to other nodes in the network through one or more wireless hops. Therefore, nodes in ESP-WIFI-MESH not only transmit their own packets, but simultaneously serve as relays for other nodes. Provided that a path exists between any two nodes on the physical layer (via one or more wireless hops), any pair of nodes within an ESP-WIFI-MESH network can communicate.

---

**Note:** The size (total number of nodes) in an ESP-WIFI-MESH network is dependent on the maximum number of layers permitted in the network, and the maximum number of downstream connections each node can have. Both of these variables can be configured to limit the size of the network.

---

### Node Types

**Root Node:** The root node is the top node in the network and serves as the only interface between the ESP-WIFI-MESH network and an external IP network. The root node is connected to a conventional Wi-Fi router and relays packets to/from the external IP network to nodes within the ESP-WIFI-MESH network. **There can only be one root node within an ESP-WIFI-MESH network** and the root node's upstream connection may only be with the router. Referring to the diagram above, node A is the root node of the network.

**Leaf Nodes:** A leaf node is a node that is not permitted to have any child nodes (no downstream connections). Therefore a leaf node can only transmit or receive its own packets, but cannot forward the packets of other nodes. If a node is situated on the network's maximum permitted layer, it will be assigned as a leaf node. This prevents the node from forming any downstream connections thus ensuring the network does not add an extra layer. Some nodes without a softAP interface (station only) will also be assigned as leaf nodes due to the requirement of a softAP interface for any downstream connections. Referring to the diagram above, nodes L/M/N are situated on the networks maximum permitted layer hence have been assigned as leaf nodes .

**Intermediate Parent Nodes:** Connected nodes that are neither the root node or a leaf node are intermediate parent nodes. An intermediate parent node must have a single upstream connection (a single parent node), but can have zero to multiple downstream connections (zero to multiple child nodes). Therefore an intermediate parent node

Fig. 43: ESP-WIFI-MESH Node Types

can transmit and receive packets, but also forward packets sent from its upstream and downstream connections. Referring to the diagram above, nodes B to J are intermediate parent nodes. **Intermediate parent nodes without downstream connections such as nodes E/F/G/I/J are not equivalent to leaf nodes** as they are still permitted to form downstream connections in the future.

**Idle Nodes:** Nodes that have yet to join the network are assigned as idle nodes. Idle nodes will attempt to form an upstream connection with an intermediate parent node or attempt to become the root node under the correct circumstances (see [Automatic Root Node Selection](#)). Referring to the diagram above, nodes K and O are idle nodes.

### Beacon Frames & RSSI Thresholding

Every node in ESP-WIFI-MESH that is able to form downstream connections (i.e. has a softAP interface) will periodically transmit Wi-Fi beacon frames. A node uses beacon frames to allow other nodes to detect its presence and know of its status. Idle nodes will listen for beacon frames to generate a list of potential parent nodes, one of which the idle node will form an upstream connection with. ESP-WIFI-MESH uses the Vendor Information Element to store metadata such as:

- Node Type (Root, Intermediate Parent, Leaf, Idle)
- Current layer of Node
- Maximum number of layers permitted in the network
- Current number of child nodes
- Maximum number of downstream connections to accept

The signal strength of a potential upstream connection is represented by RSSI (Received Signal Strength Indication) of the beacon frames of the potential parent node. To prevent nodes from forming a weak upstream connection, ESP-WIFI-MESH implements an RSSI threshold mechanism for beacon frames. If a node detects a beacon frame with an RSSI below a preconfigured threshold, the transmitting node will be disregarded when forming an upstream connection.

**Panel A** of the illustration above demonstrates how the RSSI threshold affects the number of parent node candidates an idle node has.

Fig. 44: Effects of RSSI Thresholding

**Panel B** of the illustration above demonstrates how an RF shielding object can lower the RSSI of a potential parent node. Due to the RF shielding object, the area in which the RSSI of node X is above the threshold is significantly reduced. This causes the idle node to disregard node X even though node X is physically adjacent. The idle node will instead form an upstream connection with the physically distant node Y due to a stronger RSSI.

**Note:** Nodes technically still receive all beacon frames on the MAC layer. The RSSI threshold is an ESP-WIFI-MESH feature that simply filters out all received beacon frames that are below the preconfigured threshold.

### Preferred Parent Node

When an idle node has multiple parent nodes candidates (potential parent nodes), the idle node will form an upstream connection with the **preferred parent node**. The preferred parent node is determined based on the following criteria:

- Which layer the parent node candidate is situated on
- The number of downstream connections (child nodes) the parent node candidate currently has

The selection of the preferred parent node will always prioritize the parent node candidate on the shallowest layer of the network (including the root node). This helps minimize the total number of layers in an ESP-WIFI-MESH network when upstream connections are formed. For example, given a second layer node and a third layer node, the second layer node will always be preferred.

If there are multiple parent node candidates within the same layer, the parent node candidate with the least child nodes will be preferred. This criteria has the effect of balancing the number of downstream connections amongst nodes of the same layer.

**Panel A** of the illustration above demonstrates an example of how the idle node G selects a preferred parent node given the five parent node candidates B/C/D/E/F. Nodes on the shallowest layer are preferred, hence nodes B/C are prioritized since they are second layer nodes whereas nodes D/E/F are on the third layer. Node C is selected as the preferred parent node due it having fewer downstream connections (fewer child nodes) compared to node B.

**Panel B** of the illustration above demonstrates the case where the root node is within range of the idle node G. In other words, the root node's beacon frames are above the RSSI threshold when received by node G. The root node is always the shallowest node in an ESP-WIFI-MESH network hence is always the preferred parent node given multiple parent node candidates.

Fig. 45: Preferred Parent Node Selection

**Note:** Users may also define their own algorithm for selecting a preferred parent node, or force a node to only connect with a specific parent node (see the [Mesh Manual Networking Example](#)).

### Routing Tables

Each node within an ESP-WIFI-MESH network will maintain its individual routing table used to correctly route ESP-WIFI-MESH packets (see [ESP-WIFI-MESH Packet](#)) to the correct destination node. The routing table of a particular node will **consist of the MAC addresses of all nodes within the particular node's subnetwork** (including the MAC address of the particular node itself). Each routing table is internally partitioned into multiple subtables with each subtable corresponding to the subnetwork of each child node.

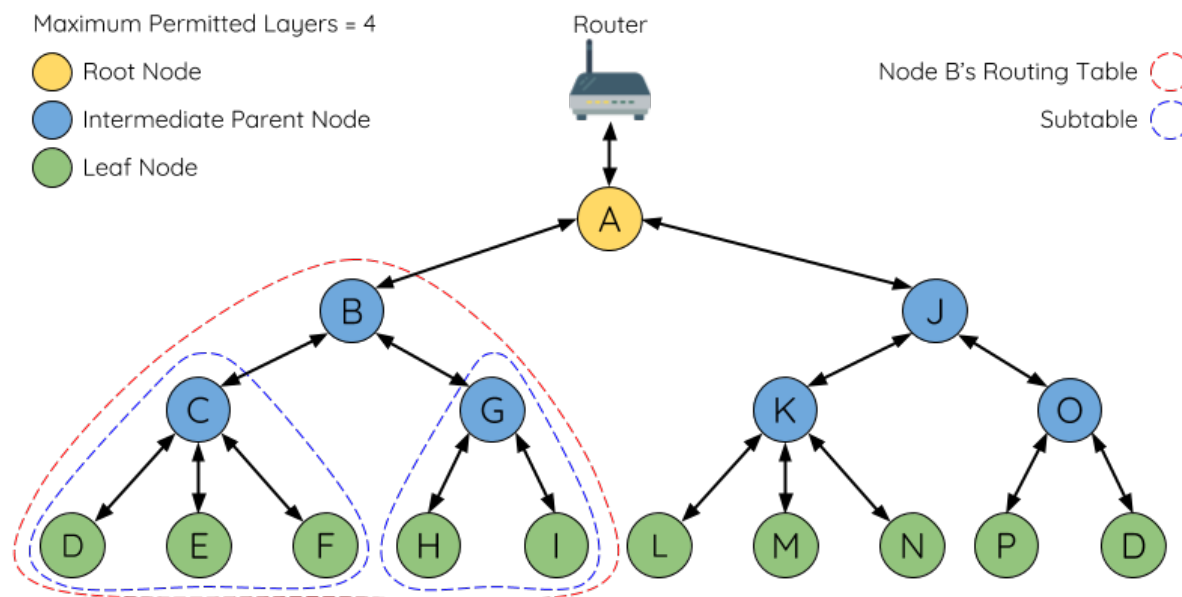

Fig. 46: ESP-WIFI-MESH Routing Tables Example

Using the diagram above as an example, the routing table of node B would consist of the MAC addresses of nodes B to I (i.e. equivalent to the subnetwork of node B). Node B's routing table is internally partitioned into two subtables containing nodes C to F and nodes G to I (i.e. equivalent to the subnetworks of nodes C and G respectively).

**ESP-WIFI-MESH utilizes routing tables to determine whether an ESP-WIFI-MESH packet should be forwarded upstream or downstream based on the following rules.**

1. If the packet's destination MAC address is within the current node's routing table and is not the current node, select the subtable that contains the destination MAC address and forward the data packet downstream to the child node corresponding to the subtable.
2. If the destination MAC address is not within the current node's routing table, forward the data packet upstream to the current node's parent node. Doing so repeatedly will result in the packet arriving at the root node where the routing table should contain all nodes within the network.

**Note:** Users can call `esp_mesh_get_routing_table()` to obtain a node's routing table, or `esp_mesh_get_routing_table_size()` to obtain the size of a node's routing table. `esp_mesh_get_subnet_nodes_list()` can be used to obtain the corresponding subtable of a specific child node. Likewise `esp_mesh_get_subnet_nodes_num()` can be used to obtain the size of the subtable.

## 4.9.4 Building a Network

### General Process

**Warning:** Before the ESP-WIFI-MESH network building process can begin, certain parts of the configuration must be uniform across each node in the network (see `mesh_cfg_t`). Each node must be configured with **the same Mesh Network ID, router configuration, and softAP configuration.**

An ESP-WIFI-MESH network building process involves selecting a root node, then forming downstream connections layer by layer until all nodes have joined the network. The exact layout of the network can be dependent on factors such as root node selection, parent node selection, and asynchronous power-on reset. However, the ESP-WIFI-MESH network building process can be generalized into the following steps:

Fig. 47: ESP-WIFI-MESH Network Building Process

**1. Root Node Selection** The root node can be designated during configuration (see section on *User Designated Root Node*), or dynamically elected based on the signal strength between each node and the router (see *Automatic Root Node Selection*). Once selected, the root node will connect with the router and begin allowing downstream connections to form. Referring to the figure above, node A is selected to be the root node hence node A forms an upstream connection with the router.

**2. Second Layer Formation** Once the root node has connected to the router, idle nodes in range of the root node will begin connecting with the root node thereby forming the second layer of the network. Once connected, the second layer nodes become intermediate parent nodes (assuming maximum permitted layers > 2) hence the next layer to form. Referring to the figure above, nodes B to D are in range of the root node. Therefore nodes B to D form upstream connections with the root node and become intermediate parent nodes.

**3. Formation of remaining layers** The remaining idle nodes will connect with intermediate parent nodes within range thereby forming a new layer in the network. Once connected, the idle nodes become intermediate parent node or leaf nodes depending on the network's maximum permitted layers. This step is repeated until there are no more idle nodes within the network or until the maximum permitted layer of the network has been reached. Referring to the figure above, nodes E/F/G connect with nodes B/C/D respectively and become intermediate parent nodes themselves.

**4. Limiting Tree Depth** To prevent the network from exceeding the maximum permitted number of layers, nodes on the maximum layer will automatically become leaf nodes once connected. This prevents any other idle node from connecting with the leaf node thereby preventing a new layer from forming. However if an idle node has no other potential parent node, it will remain idle indefinitely. Referring to the figure above, the network's maximum permitted layers is set to four. Therefore when node H connects, it becomes a leaf node to prevent any downstream connections from forming.

### Automatic Root Node Selection

The automatic selection of a root node involves an election process amongst all idle nodes based on their signal strengths with the router. Each idle node will transmit their MAC addresses and router RSSI values via Wi-Fi beacon frames. **The MAC address is used to uniquely identify each node in the network** whilst the **router RSSI** is used to indicate a node's signal strength with reference to the router.

Each node will then simultaneously scan for the beacon frames from other idle nodes. If a node detects a beacon frame with a stronger router RSSI, the node will begin transmitting the contents of that beacon frame (i.e. voting for the node with the stronger router RSSI). The process of transmission and scanning will repeat for a preconfigured minimum number of iterations (10 iterations by default) and result in the beacon frame with the strongest router RSSI being propagated throughout the network.

After all iterations, each node will individually check for its **vote percentage** (number of votes/number of nodes participating in election) to determine if it should become the root node. **If a node has a vote percentage larger than a preconfigured threshold (90% by default), the node will become a root node.**

The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is automatically selected.

1. On power-on reset, each node begins transmitting beacon frames consisting of their own MAC addresses and their router RSSIs.
2. Over multiple iterations of transmission and scanning, the beacon frame with the strongest router RSSI is propagated throughout the network. Node C has the strongest router RSSI (-10 dB) hence its beacon frame is propagated throughout the network. All nodes participating in the election vote for node C thus giving node C a vote percentage of 100%. Therefore node C becomes a root node and connects with the router.
3. Once Node C has connected with the router, nodes A/B/D/E connect with node C as it is the preferred parent node (i.e. the shallowest node). Nodes A/B/D/E form the second layer of the network.
4. Node F and G connect with nodes D and E respectively and the network building process is complete.

Fig. 48: Root Node Election Example

**Note:** The minimum number of iterations for the election process can be configured using `esp_mesh_set_attempts()`. Users should adjust the number of iterations based on the number of nodes within the network (i.e. the larger the network the larger number of scan iterations required).

**Warning:** **Vote percentage threshold** can also be configured using `esp_mesh_set_vote_percentage()`. Setting a low vote percentage threshold **can result in two or more nodes becoming root nodes** within the same ESP-WIFI-MESH network leading to the building of multiple networks. If such is the case, ESP-WIFI-MESH has internal mechanisms to autonomously resolve the **root node conflict**. The networks of the multiple root nodes will be combined into a single network with a single root node. However, root node conflicts where two or more root nodes have the same router SSID but different router BSSID are not handled.

### User Designated Root Node

The root node can also be designated by user which will entail the designated root node to directly connect with the router and forgo the election process. When a root node is designated, all other nodes within the network must also forgo the election process to prevent the occurrence of a root node conflict. The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is designated by the user.

1. Node A is designated the root node by the user therefore directly connects with the router. All other nodes forgo the election process.
2. Nodes C/D connect with node A as their preferred parent node. Both nodes form the second layer of the network.
3. Likewise, nodes B/E connect with node C, and node F connects with node D. Nodes B/E/F form the third layer of the network.
4. Node G connects with node E, forming the fourth layer of the network. However the maximum permitted number of layers in this network is configured as four, therefore node G becomes a leaf node to prevent any new layers from forming.

Fig. 49: Root Node Designation Example (Root Node = A, Max Layers = 4)

**Note:** When designating a root node, the root node should call `esp_mesh_set_parent()` in order to directly connect with the router. Likewise, all other nodes should call `esp_mesh_fix_root()` to forgo the election process.

### Parent Node Selection

By default, ESP-WIFI-MESH is self organizing meaning that each node will autonomously select which potential parent node to form an upstream connection with. The autonomously selected parent node is known as the preferred parent node. The criteria used for selecting the preferred parent node is designed to reduce the number of layers in the ESP-WIFI-MESH network and to balance the number of downstream connections between potential parent nodes (see section on [Preferred Parent Node](#)).

However ESP-WIFI-MESH also allows users to disable self-organizing behavior which will allow users to define their own criteria for parent node selection, or to configure nodes to have designated parent nodes (see the [Mesh Manual Networking Example](#)).

### Asynchronous Power-on Reset

ESP-WIFI-MESH network building can be affected by the order in which nodes power-on. If certain nodes within the network power-on asynchronously (i.e. separated by several minutes), **the final structure of the network could differ from the ideal case where all nodes are powered on synchronously**. Nodes that are delayed in powering on will adhere to the following rules:

**Rule 1:** If a root node already exists in the network, the delayed node will not attempt to elect a new root node, even if it has a stronger RSSI with the router. The delayed node will instead join the network like any other idle node by connecting with a preferred parent node. If the delayed node is the designated root node, all other nodes in the network will remain idle until the delayed node powers-on.

**Rule 2:** If a delayed node forms an upstream connection and becomes an intermediate parent node, it may also become the new preferred parent of other nodes (i.e. being a shallower node). This will cause the other nodes to switch their upstream connections to connect with the delayed node (see [Parent Node Switching](#)).

**Rule 3:** If an idle node has a designated parent node which is delayed in powering-on, the idle node will not attempt to form any upstream connections in the absence of its designated parent node. The idle node will remain idle indefinitely until its designated parent node powers-on.

The following example demonstrates the effects of asynchronous power-on with regards to network building.

Fig. 50: Network Building with Asynchronous Power On Example

1. Nodes A/C/D/F/G/H are powered-on synchronously and begin the root node election process by broadcasting their MAC addresses and router RSSIs. Node A is elected as the root node as it has the strongest RSSI.

2. Once node A becomes the root node, the remaining nodes begin forming upstream connections layer by layer with their preferred parent nodes. The result is a network with five layers.

3. Node B/E are delayed in powering-on but neither attempt to become the root node even though they have stronger router RSSIs (-20 dB and -10 dB) compared to node A. Instead both delayed nodes form upstream connections with their preferred parent nodes A and C respectively. Both nodes B/E become intermediate parent nodes after connecting.

4. Nodes D/G switch their upstream connections as node B is the new preferred parent node due to it being on a shallower layer (second layer node). Due to the switch, the resultant network has three layers instead of the original five layers.

**Synchronous Power-On:** Had all nodes powered-on synchronously, node E would have become the root node as it has the strongest router RSSI (-10 dB). This would result in a significantly different network layout compared to the network formed under the conditions of asynchronous power-on. **However the synchronous power-on network layout can still be reached if the user manually switches the root node** (see [esp\\_mesh\\_waive\\_root\(\)](#)).

**Note:** Differences in parent node selection caused by asynchronous power-on are autonomously corrected for to some extent in ESP-WIFI-MESH (see [Parent Node Switching](#)).

## Loop-back Avoidance, Detection, and Handling

A loop-back is the situation where a particular node forms an upstream connection with one of its descendant nodes (a node within the particular node's subnetwork). This results in a circular connection path thereby breaking the tree topology. ESP-WIFI-MESH prevents loop-back during parent selection by excluding nodes already present in the selecting node's routing table (see [Routing Tables](#)) thus prevents a particular node from attempting to connect to any node within its subnetwork.

In the event that a loop-back occurs, ESP-WIFI-MESH utilizes a path verification mechanism and energy transfer mechanism to detect the loop-back occurrence. The parent node of the upstream connection that caused the loop-back will then inform the child node of the loop-back and initiate a disconnection.

### 4.9.5 Managing a Network

**ESP-WIFI-MESH is a self healing network meaning it can detect and correct for failures in network routing.**

Failures occur when a parent node with one or more child nodes breaks down, or when the connection between a parent node and its child nodes becomes unstable. Child nodes in ESP-WIFI-MESH will autonomously select a new parent node and form an upstream connection with it to maintain network interconnectivity. ESP-WIFI-MESH can handle both Root Node Failures and Intermediate Parent Node Failures.

#### Root Node Failure

If the root node breaks down, the nodes connected with it (second layer nodes) will promptly detect the failure of the root node. The second layer nodes will initially attempt to reconnect with the root node. However after multiple failed attempts, the second layer nodes will initialize a new round of root node election. **The second layer node with the strongest router RSSI will be elected as the new root node** whilst the remaining second layer nodes will form an upstream connection with the new root node (or a neighboring parent node if not in range).

If the root node and multiple downstream layers simultaneously break down (e.g. root node, second layer, and third layer), the shallowest layer that is still functioning will initialize the root node election. The following example illustrates an example of self healing from a root node break down.

Fig. 51: Self Healing From Root Node Failure

1. Node C is the root node of the network. Nodes A/B/D/E are second layer nodes connected to node C.
2. Node C breaks down. After multiple failed attempts to reconnect, the second layer nodes begin the election process by broadcasting their router RSSIs. Node B has the strongest router RSSI.
3. Node B is elected as the root node and begins accepting downstream connections. The remaining second layer nodes A/D/E form upstream connections with node B thus the network is healed and can continue operating normally.

---

**Note:** If a designated root node breaks down, the remaining nodes **will not autonomously attempt to elect a new root node** as an election process will never be attempted whilst a designated root node is used.

---

### Intermediate Parent Node Failure

If an intermediate parent node breaks down, the disconnected child nodes will initially attempt to reconnect with the parent node. After multiple failed attempts to reconnect, each child node will begin to scan for potential parent nodes (see *Beacon Frames & RSSI Thresholding*).

If other potential parent nodes are available, each child node will individually select a new preferred parent node (see *Preferred Parent Node*) and form an upstream connection with it. If there are no other potential parent nodes for a particular child node, it will remain idle indefinitely.

The following diagram illustrates an example of self healing from an Intermediate Parent Node break down.

Fig. 52: Self Healing From Intermediate Parent Node Failure

1. The following branch of the network consists of nodes A to G.
2. Node C breaks down. Nodes F/G detect the break down and attempt to reconnect with node C. After multiple failed attempts to reconnect, nodes F/G begin to select a new preferred parent node.
3. Node G is out of range from any other parent node hence remains idle for the time being. Node F is in range of nodes B/E, however node B is selected as it is the shallower node. Node F becomes an intermediate parent node after connecting with Node B thus node G can connect with node F. The network is healed, however the network routing as been affected and an extra layer has been added.

---

**Note:** If a child node has a designated parent node that breaks down, the child node will make no attempt to connect with a new parent node. The child node will remain idle indefinitely.

---

### Root Node Switching

ESP-WIFI-MESH does not automatically switch the root node unless the root node breaks down. Even if the root node's router RSSI degrades to the point of disconnection, the root node will remain unchanged. Root node switching is the act of explicitly starting a new election such that a node with a stronger router RSSI will be elected as the new root node. This can be a useful method of adapting to degrading root node performance.

To trigger a root node switch, the current root node must explicitly call `esp_mesh_waive_root()` to trigger a new election. The current root node will signal all nodes within the network to begin transmitting and scanning for beacon frames (see *Automatic Root Node Selection*) **whilst remaining connected to the network (i.e. not idle)**. If

another node receives more votes than the current root node, a root node switch will be initiated. **The root node will remain unchanged otherwise.**

A newly elected root node sends a **switch request** to the current root node which in turn will respond with an acknowledgment signifying both nodes are ready to switch. Once the acknowledgment is received, the newly elected root node will disconnect from its parent and promptly form an upstream connection with the router thereby becoming the new root node of the network. The previous root node will disconnect from the router **whilst maintaining all of its downstream connections** and enter the idle state. The previous root node will then begin scanning for potential parent nodes and selecting a preferred parent.

The following diagram illustrates an example of a root node switch.

Fig. 53: Root Node Switch Example

1. Node C is the current root node but has degraded signal strength with the router (-85db). The node C triggers a new election and all nodes begin transmitting and scanning for beacon frames **whilst still being connected**.

2. After multiple rounds of transmission and scanning, node B is elected as the new root node. Node B sends node C a **switch request** and node C responds with an acknowledgment.

3. Node B disconnects from its parent and connects with the router becoming the network's new root node. Node C disconnects from the router, enters the idle state, and begins scanning for and selecting a new preferred parent node. **Node C maintains all its downstream connections throughout this process.**

4. Node C selects node B as its preferred parent node, forms an upstream connection, and becomes a second layer node. The network layout is similar after the switch as node C still maintains the same subnetwork. However each node in node C's subnetwork has been placed one layer deeper as a result of the switch. *Parent Node Switching* may adjust the network layout afterwards if any nodes have a new preferred parent node as a result of the root node switch.

**Note:** Root node switching must require an election hence is only supported when using a self-organized ESP-WIFI-MESH network. In other words, root node switching cannot occur if a designated root node is used.

### Parent Node Switching

Parent Node Switching entails a child node switching its upstream connection to another parent node of a shallower layer. **Parent Node Switching occurs autonomously** meaning that a child node will change its upstream connection

automatically if a potential parent node of a shallower layer becomes available (i.e. due to a *Asynchronous Power-on Reset*).

All potential parent nodes periodically transmit beacon frames (see *Beacon Frames & RSSI Thresholding*) allowing for a child node to scan for the availability of a shallower parent node. Due to parent node switching, a self-organized ESP-WIFI-MESH network can dynamically adjust its network layout to ensure each connection has a good RSSI and that the number of layers in the network is minimized.

## 4.9.6 Data Transmission

### ESP-WIFI-MESH Packet

ESP-WIFI-MESH network data transmissions use ESP-WIFI-MESH packets. ESP-WIFI-MESH packets are **entirely contained within the frame body of a Wi-Fi data frame**. A multi-hop data transmission in an ESP-WIFI-MESH network will involve a single ESP-WIFI-MESH packet being carried over each wireless hop by a different Wi-Fi data frame.

The following diagram shows the structure of an ESP-WIFI-MESH packet and its relation with a Wi-Fi data frame.

Fig. 54: ESP-WIFI-MESH Packet

**The header** of an ESP-WIFI-MESH packet contains the MAC addresses of the source and destination nodes. The options field contains information pertaining to the special types of ESP-WIFI-MESH packets such as a group transmission or a packet originating from the external IP network (see *MESH\_OPT\_SEND\_GROUP* and *MESH\_OPT\_RECV\_DS\_ADDR*).

**The payload** of an ESP-WIFI-MESH packet contains the actual application data. This data can be raw binary data, or encoded under an application layer protocol such as HTTP, MQTT, and JSON (see *mesh\_proto\_t*).

---

**Note:** When sending an ESP-WIFI-MESH packet to the external IP network, the destination address field of the header will contain the IP address and port of the target server rather than the MAC address of a node (see *mesh\_addr\_t*). Furthermore the root node will handle the formation of the outgoing TCP/IP packet.

---

### Group Control & Multicasting

Multicasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to multiple nodes within the network. Multicasting in ESP-WIFI-MESH can be achieved by either specifying a list of target nodes, or specifying a preconfigured group of nodes. Both methods of multicasting are called via *esp\_mesh\_send()*.

To multicast by specifying a list of target nodes, users must first set the ESP-WIFI-MESH packet's destination address to the **Multicast-Group Address** (`01:00:5E:xx:xx:xx`). This signifies that the ESP-WIFI-MESH packet is a multicast packet with a group of addresses, and that the address should be obtained from the header options. Users must then list the MAC addresses of the target nodes as options (see *mesh\_opt\_t* and *MESH\_OPT\_SEND\_GROUP*). This method of multicasting requires no prior setup but can incur a large amount of overhead data as each target node's MAC address must be listed in the options field of the header.

Multicasting by group allows a ESP-WIFI-MESH packet to be transmitted to a preconfigured group of nodes. Each grouping is identified by a unique ID, and a node can be placed into a group via `esp_mesh_set_group_id()`. Multicasting to a group involves setting the destination address of the ESP-WIFI-MESH packet to the target group ID. Furthermore, the `MESH_DATA_GROUP` flag must set. Using groups to multicast incurs less overhead, but requires nodes to previously added into groups.

---

**Note:** During a multicast, all nodes within the network still receive the ESP-WIFI-MESH packet on the MAC layer. However, nodes not included in the MAC address list or the target group will simply filter out the packet.

---

## Broadcasting

Broadcasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to all nodes within the network. Each node essentially forwards a broadcast packet to all of its upstream and downstream connections such that the packet propagates throughout the network as quickly as possible. However, ESP-WIFI-MESH utilizes the following methods to avoid wasting bandwidth during a broadcast.

1. When an intermediate parent node receives a broadcast packet from its parent, it will forward the packet to each of its child nodes whilst storing a copy of the packet for itself.
2. When an intermediate parent node is the source node of the broadcast, it will transmit the broadcast packet upstream to its parent node and downstream to each of its child nodes.
3. When an intermediate parent node receives a broadcast packet from one of its child nodes, it will forward the packet to its parent node and each of its remaining child nodes whilst storing a copy of the packet for itself.
4. When a leaf node is the source node of a broadcast, it will directly transmit the packet to its parent node.
5. When the root node is the source node of a broadcast, the root node will transmit the packet to all of its child nodes.
6. When the root node receives a broadcast packet from one of its child nodes, it will forward the packet to each of its remaining child nodes whilst storing a copy of the packet for itself.
7. When a node receives a broadcast packet with a source address matching its own MAC address, the node will discard the broadcast packet.
8. When an intermediate parent node receives a broadcast packet from its parent node which was originally transmitted from one of its child nodes, it will discard the broadcast packet

## Upstream Flow Control

ESP-WIFI-MESH relies on parent nodes to control the upstream data flow of their immediate child nodes. To prevent a parent node's message buffer from overflowing due to an overload of upstream transmissions, a parent node will allocate a quota for upstream transmissions known as a **receiving window** for each of its child nodes. **Each child node must apply for a receiving window before it is permitted to transmit upstream.** The size of a receiving window can be dynamically adjusted. An upstream transmission from a child node to the parent node consists of the following steps:

1. Before each transmission, the child node sends a window request to its parent node. The window request consists of a sequence number which corresponds to the child node's data packet that is pending transmission.
2. The parent node receives the window request and compares the sequence number with the sequence number of the previous packet sent by the child node. The comparison is used to calculate the size of the receiving window which is transmitted back to the child node.
3. The child node transmits the data packet in accordance with the window size specified by the parent node. If the child node depletes its receiving window, it must obtain another receiving window by sending a request before it is permitted to continue transmitting.

**Note:** ESP-WIFI-MESH does not support any downstream flow control.

**Warning:** Due to *Parent Node Switching*, packet loss may occur during upstream transmissions.

Due to the fact that the root node acts as the sole interface to an external IP network, it is critical that downstream nodes are aware of the root node's connection status with the external IP network. Failing to do so can lead to nodes attempting to pass data upstream to the root node whilst it is disconnected from the IP network. This results in unnecessary transmissions and packet loss. ESP-WIFI-MESH address this issue by providing a mechanism to stabilize the throughput of outgoing data based on the connection status between the root node and the external IP network. The root node can broadcast its external IP network connection status to all other nodes by calling `esp_mesh_post_toDS_state()`.

### Bi-Directional Data Stream

The following diagram illustrates the various network layers involved in an ESP-WIFI-MESH Bidirectional Data Stream.

Fig. 55: ESP-WIFI-MESH Bidirectional Data Stream

Due to the use of *Routing Tables*, **ESP-WIFI-MESH is able to handle pack forwarding entirely on the mesh layer**. A TCP/IP layer is only required on the root node when it transmits/receives a packet to/from an external IP network.

### 4.9.7 Channel Switching

#### Background

In traditional Wi-Fi networks, **channels** are predetermined frequency ranges. In an infrastructure basic service set (BSS), the serving AP and its connected stations must be on the same operating channels (1 to 14) in which beacons are transmitted. Physically adjacent BSS (Basic Service Sets) operating on the same channel can lead to interference and degraded performance.

In order to allow a BSS adapt to changing physical layer conditions and maintain performance, Wi-Fi contains mechanisms for **network channel switching**. A network channel switch is an attempt to move a BSS to a new operating channel whilst minimizing disruption to the BSS during this process. However it should be recognized that a channel switch may be unsuccessful in moving all stations to the new operating channel.

In an infrastructure Wi-Fi network, network channel switches are triggered by the AP with the aim of having the AP and all connected stations synchronously switch to a new channel. Network channel switching is implemented

by embedding a **Channel Switch Announcement (CSA)** element within the AP's periodically transmitted beacon frames. The CSA element is used to advertise to all connected stations regarding an upcoming network channel switch and will be included in multiple beacon frames up until the switch occurs.

A CSA element contains information regarding the **New Channel Number** and a **Channel Switch Count** which indicates the number of beacon frame intervals (TBTTs) remaining until the network channel switch occurs. Therefore, the Channel Switch Count is decremented every beacon frame and allows connected stations to synchronize their channel switch with the AP.

### ESP-WIFI-MESH Network Channel Switching

ESP-WIFI-MESH Network Channel Switching also utilize beacon frames that contain a CSA element. However, being a multi-hop network makes the switching process in ESP-WIFI-MESH is more complex due to the fact that a beacon frame might not be able to reach all nodes within the network (i.e. in a single hop). Therefore, an ESP-WIFI-MESH network relies on nodes to forward the CSA element so that it is propagated throughout the network.

When an intermediate parent node with one or more child nodes receives a beacon frame containing a CSA, the node will forward the CSA element by including the element in its next transmitted beacon frame (i.e. with the same **New Channel Number** and **Channel Switch Count**). Given that all nodes within an ESP-WIFI-MESH network receive the same CSA, the nodes can synchronize their channel switches using the Channel Switch Count, albeit with a short delay due to CSA element forwarding.

An ESP-WIFI-MESH network channel switch can be triggered by either the router or the root node.

**Root Node Triggered** A root node triggered channel switch can only occur when the ESP-WIFI-MESH network is not connected to a router. By calling `esp_mesh_switch_channel()`, the root node will set an initial Channel Switch Count value and begin including a CSA element in its beacon frames. Each CSA element is then received by second layer nodes, and forwarded downstream in their own beacon frames.

**Router Triggered** When an ESP-WIFI-MESH network is connected to a router, the entire network must use the same channel as the router. Therefore, **the root node will not be permitted to trigger a channel switch when it is connected to a router.**

When the root node receives beacon frame containing a CSA element from the router, **the root node will set Channel Switch Count value in the CSA element to a custom value before forwarding it downstream via beacon frames.** It will also decrement the Channel Switch Count of subsequent CSA elements relative to the custom value. This custom value can be based on factors such as the number of network layers, the current number of nodes etc.

The setting the Channel Switch Count value to a custom value is due to the fact that the ESP-WIFI-MESH network and its router may have a different and varying beacon intervals. Therefore, the Channel Switch Count value provided by the router is irrelevant to an ESP-WIFI-MESH network. By using a custom value, nodes within the ESP-WIFI-MESH network are able to switch channels synchronously relative to the ESP-WIFI-MESH network's beacon interval. However, this will also result in the ESP-WIFI-MESH network's channel switch being unsynchronized with the channel switch of the router and its connected stations.

### Impact of Network Channel Switching

- **Due to the ESP-WIFI-MESH network channel switch being unsynchronized with the router's channel switch, there will be:**
  - The ESP-WIFI-MESH network's channel switch time is dependent on the ESP-WIFI-MESH network's beacon interval and the root node's custom Channel Switch Count value.
  - The channel discrepancy prevents any data exchange between the root node and the router during that ESP-WIFI-MESH network's switch.
  - In the ESP-WIFI-MESH network, the root node and intermediate parent nodes will request their connected child nodes to stop transmissions until the channel switch takes place by setting the **Channel Switch Mode** field in the CSA element to 1.

- Frequent router triggered network channel switches can degrade the ESP-WIFI-MESH network's performance. Note that this can be caused by the ESP-WIFI-MESH network itself (e.g. due to wireless medium contention with ESP-WIFI-MESH network). If this is the case, users should disable the automatic channel switching on the router and use a specified channel instead.
- **When there is a temporary channel discrepancy, the root node remains technically connected to the router.**
  - Disconnection occurs after the root node fails to receive any beacon frames or probe responses from the router over a fixed number of router beacon intervals.
  - Upon disconnection, the root node will automatically re-scan all channels for the presence of a router.
- **If the root node is unable to receive any of the router's CSA beacon frames (e.g. due to short switch time given by the router).**
  - After the router switches channels, the root node will no longer be able to receive the router's beacon frames and probe responses and result in a disconnection after a fixed number of beacon intervals.
  - The root node will re-scan all channels for the router after disconnection.
  - The root node will maintain downstream connections throughout this process.

---

**Note:** Although ESP-WIFI-MESH network channel switching aims to move all nodes within the network to a new operating channel, it should be recognized that a channel switch might not successfully move all nodes (e.g. due to reasons such as node failures).

---

### Channel and Router Switching Configuration

ESP-WIFI-MESH allows for autonomous channel switching to be enabled/disabled via configuration. Likewise, autonomous router switching (i.e. when a root node autonomously connects to another router) can also be enabled/disabled by configuration. Autonomous channel switching and router switching is dependent on the following configuration parameters and run-time conditions.

**Allow Channel Switch:** This parameter is set via the `allow_channel_switch` field of the `mesh_cfg_t` structure and permits an ESP-WIFI-MESH network to dynamically switch channels when set.

**Preset Channel:** An ESP-WIFI-MESH network can have a preset channel by setting the `channel` field of the `mesh_cfg_t` structure to the desired channel number. If this field is unset, the `allow_channel_switch` parameter is overridden such that channel switches are always permitted.

**Allow Router Switch:** This parameter is set via the `allow_router_switch` field of the `mesh_router_t` and permits an ESP-WIFI-MESH to dynamically switch to a different router when set.

**Preset Router BSSID:** An ESP-WIFI-MESH network can have a preset router by setting the `bssid` field of the `mesh_router_t` structure to the BSSID of the desired router. If this field is unset, the `allow_router_switch` parameter is overridden such that router switches are always permitted.

**Root Node Present:** The presence of a root node will can also affect whether or a channel or router switch is permitted.

The following table illustrates how the different combinations of parameters/conditions affect whether channel switching and/or router switching is permitted. Note that X represents a “don't care” for the parameter.

Preset Channel	Allow Channel Switch	Preset Router BSSID	Allow Router Switch	Root Node Present	Permitted Switches?
N	X	N	X	X	Channel and Router
N	X	Y	N	X	Channel Only
N	X	Y	Y	X	Channel and Router
Y	Y	N	X	X	Channel and Router
Y	N	N	X	N	Router Only
Y	N	N	X	Y	Channel and Router
Y	Y	Y	N	X	Channel Only
Y	N	Y	N	N	N
Y	N	Y	N	Y	Channel Only
Y	Y	Y	Y	X	Channel and Router
Y	N	Y	Y	N	Router Only
Y	N	Y	Y	Y	Channel and Router

### 4.9.8 Performance

The performance of an ESP-WIFI-MESH network can be evaluated based on multiple metrics such as the following:

**Network Building Time:** The amount of time taken to build an ESP-WIFI-MESH network from scratch.

**Healing Time:** The amount of time taken for the network to detect a node break down and carry out appropriate actions to heal the network (such as generating a new root node or forming new connections).

**Per-hop latency:** The latency of data transmission over one wireless hop. In other words, the time taken to transmit a data packet from a parent node to a child node or vice versa.

**Network Node Capacity:** The total number of nodes the ESP-WIFI-MESH network can simultaneously support. This number is determined by the maximum number of downstream connections a node can accept and the maximum number of layers permissible in the network.

The following table lists the common performance figures of an ESP-WIFI-MESH network:

- Network Building Time: < 60 seconds
- **Healing time:**
  - Root node break down: < 10 seconds
  - Child node break down: < 5 seconds
- Per-hop latency: 10 to 30 milliseconds

**Note:** The following test conditions were used to generate the performance figures above.

- Number of test devices: **100**
- Maximum Downstream Connections to Accept: **6**
- Maximum Permissible Layers: **6**

**Note:** Throughput depends on packet error rate and hop count.

**Note:** The throughput of root node's access to the external IP network is directly affected by the number of nodes in the ESP-WIFI-MESH network and the bandwidth of the router.

**Note:** The performance figures can vary greatly between installations based on network configuration and operating environment.

---

## 4.9.9 Further Notes

- Data transmission uses Wi-Fi WPA2-PSK encryption
- Mesh networking IE uses AES encryption

Router and internet icon made by [Smashicons](https://www.flaticon.com) from [www.flaticon.com](https://www.flaticon.com)

## 4.10 Event Handling

Several ESP-IDF components use *events* to inform application about state changes, such as connection or disconnection. This document gives an overview of these event mechanisms.

### 4.10.1 Wi-Fi, Ethernet, and IP Events

Before the introduction of *esp\_event library*, events from Wi-Fi driver, Ethernet driver, and TCP/IP stack were dispatched using the so-called *legacy event loop*. The following sections explain each of the methods.

#### esp\_event Library Event Loop

esp\_event library is designed to supersede the legacy event loop for the purposes of event handling in ESP-IDF. In the legacy event loop, all possible event types and event data structures had to be defined in `system_event_id_t` enumeration and `system_event_info_t` union, which made it impossible to send custom events to the event loop, and use the event loop for other kinds of events (e.g. Mesh). Legacy event loop also supported only one event handler function, therefore application components could not handle some of Wi-Fi or IP events themselves, and required application to forward these events from its event handler function.

See *esp\_event library API reference* for general information on using this library. Wi-Fi, Ethernet, and IP events are sent to the *default event loop* provided by this library.

#### Legacy Event Loop

This event loop implementation is started using `esp_event_loop_init()` function. Application typically supplies an *event handler*, a function with the following signature:

```
esp_err_t event_handler(void *ctx, system_event_t *event)
{
}
```

Both the pointer to event handler function, and an arbitrary context pointer are passed to `esp_event_loop_init()`.

When Wi-Fi, Ethernet, or IP stack generate an event, this event is sent to a high-priority *event* task via a queue. Application-provided event handler function is called in the context of this task. Event task stack size and event queue size can be adjusted using `CONFIG_ESP_SYSTEM_EVENT_TASK_STACK_SIZE` and `CONFIG_ESP_SYSTEM_EVENT_QUEUE_SIZE` options, respectively.

Event handler receives a pointer to the event structure (`system_event_t`) which describes current event. This structure follows a *tagged union* pattern: `event_id` member indicates the type of event, and `event_info` member is a union of description structures. Application event handler will typically use `switch(event->event_id)` to handle different kinds of events.

If application event handler needs to relay the event to some other task, it is important to note that event pointer passed to the event handler is a pointer to temporary structure. To pass the event to another task, application has to make a copy of the entire structure.

### Event IDs and Corresponding Data Structures

Event ID (legacy event ID)	Event data structure
<b>Wi-Fi</b>	
WIFI_EVENT_WIFI_READY (SYSTEM_EVENT_WIFI_READY)	n/a
WIFI_EVENT_SCAN_DONE (SYSTEM_EVENT_SCAN_DONE)	<a href="#">wifi_event_sta_scan_done_t</a>

#### 4.10.2 Mesh Events

ESP-WIFI-MESH uses a system similar to the [Legacy Event Loop](#) to deliver events to the application. See [System Events](#) for details.

### 4.10.3 Bluetooth Events

Various modules of the Bluetooth stack deliver events to applications via dedicated callback functions. Callback functions receive the event type (enumerated value) and event data (union of structures for each event type). The following list gives the registration API name, event enumeration type, and event parameters type.

- BLE GAP: `esp_ble_gap_register_callback()`, `esp_gap_ble_cb_event_t`, `esp_ble_gap_cb_param_t`.
- BT GAP: `esp_bt_gap_register_callback()`, `esp_bt_gap_cb_event_t`, `esp_bt_gap_cb_param_t`.
- GATT: `esp_ble_gattc_register_callback()`, `esp_ble_gattc_cb_event_t`, `esp_ble_gattc_cb_param_t`.
- GATTS: `esp_ble_gatts_register_callback()`, `esp_ble_gatts_cb_event_t`, `esp_ble_gatts_cb_param_t`.
- SPP: `esp_spp_register_callback()`, `esp_spp_cb_event_t`, `esp_spp_cb_param_t`.
- Blufi: `esp_blufi_register_callbacks()`, `esp_blufi_cb_event_t`, `esp_blufi_cb_param_t`.
- A2DP: `esp_a2d_register_callback()`, `esp_a2d_cb_event_t`, `esp_a2d_cb_param_t`.
- AVRC: `esp_avrc_ct_register_callback()`, `esp_avrc_ct_cb_event_t`, `esp_avrc_ct_cb_param_t`.
- HFP Client: `esp_hf_client_register_callback()`, `esp_hf_client_cb_event_t`, `esp_hf_client_cb_param_t`.
- HFP AG: `esp_bt_hf_register_callback()`, `esp_hf_cb_event_t`, `esp_hf_cb_param_t`.

## 4.11 Fatal Errors

### 4.11.1 Overview

In certain situations, execution of the program can not be continued in a well defined way. In ESP-IDF, these situations include:

- CPU Exceptions: Illegal Instruction, Load/Store Alignment Error, Load/Store Prohibited error.
- System level checks and safeguards:
  - *Interrupt watchdog* timeout
  - *Task watchdog* timeout (only fatal if `CONFIG_ESP_TASK_WDT_PANIC` is set)
  - Cache access error
  - Memory protection fault
  - Brownout detection event
  - Stack overflow
  - Stack smashing protection check
  - Heap integrity check
  - Undefined behavior sanitizer (UBSAN) checks
- Failed assertions, via `assert`, `configASSERT` and similar macros.

This guide explains the procedure used in ESP-IDF for handling these errors, and provides suggestions on troubleshooting the errors.

### 4.11.2 Panic Handler

Every error cause listed in the *Overview* will be handled by the *panic handler*.

The panic handler will start by printing the cause of the error to the console. For CPU exceptions, the message will be similar to

Guru Meditation Error: Core 0 panic'ed (Illegal instruction). Exception `↳` was unhandled.

For some of the system level checks (interrupt watchdog, cache access error), the message will be similar to

Guru Meditation Error: Core 0 panic'ed (Cache error). Exception was `↳` unhandled.

In all cases, the error cause will be printed in parentheses. See *Guru Meditation Errors* for a list of possible error causes.

Subsequent behavior of the panic handler can be set using `CONFIG_ESP_SYSTEM_PANIC` configuration choice. The available options are:

- Print registers and reboot (`CONFIG_ESP_SYSTEM_PANIC_PRINT_REBOOT`) —default option. This will print register values at the point of the exception, print the backtrace, and restart the chip.
- Print registers and halt (`CONFIG_ESP_SYSTEM_PANIC_PRINT_HALT`) Similar to the above option, but halt instead of rebooting. External reset is required to restart the program.
- Silent reboot (`CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT`) Don't print registers or backtrace, restart the chip immediately.
- Invoke GDB Stub (`CONFIG_ESP_SYSTEM_PANIC_GDBSTUB`) Start GDB server which can communicate with GDB over console UART port. This option will only provide read-only debugging or post-mortem debugging. See *GDB Stub* for more details.
- Invoke dynamic GDB Stub (`ESP_SYSTEM_GDBSTUB_RUNTIME`) Start GDB server which can communicate with GDB over console UART port. This option allows the user to debug a program at run time and set break points, alter the execution, etc. See *GDB Stub* for more details.

The behavior of the panic handler is affected by two other configuration options.

- If `CONFIG_ESP_DEBUG_OCDAWARE` is enabled (which is the default), the panic handler will detect whether a JTAG debugger is connected. If it is, execution will be halted and control will be passed to the debugger. In this case, registers and backtrace are not dumped to the console, and GDBStub / Core Dump functions are not used.
- If the *Core Dump* feature is enabled, then the system state (task stacks and registers) will be dumped to either Flash or UART, for later analysis.
- If `CONFIG_ESP_PANIC_HANDLER_IRAM` is disabled (disabled by default), the panic handler code is placed in flash memory, not IRAM. This means that if ESP-IDF crashes while flash cache is disabled, the panic handler will automatically re-enable flash cache before running GDB Stub or Core Dump. This adds some minor risk, if the flash cache status is also corrupted during the crash. If this option is enabled, the panic handler code (including required UART functions) is placed in IRAM, and hence will decrease the usable memory space in SRAM. But this may be necessary to debug some complex issues with crashes while flash cache is disabled (for example, when writing to SPI flash) or when flash cache is corrupted when an exception is triggered.

The following diagram illustrates the panic handler behavior:

### 4.11.3 Register Dump and Backtrace

Unless the `CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT` option is enabled, the panic handler prints some of the CPU registers, and the backtrace, to the console

```
Core 0 register dump:

MHARTID : 0x00000000

```

Moreover, the *IDF Monitor* is also capable of generating and printing a backtrace thanks to the stack dump provided by the board in the panic handler. The output looks like this:

```

Backtrace:

0x42006686 in bar (ptr=ptr@entry=0x0) at ../main/hello_world_main.c:18
18      *ptr = 0x42424242;
#0  0x42006686 in bar (ptr=ptr@entry=0x0) at ../main/hello_world_main.c:18
#1  0x42006692 in foo () at ../main/hello_world_main.c:22
#2  0x420066ac in app_main () at ../main/hello_world_main.c:28
#3  0x42015ece in main_task (args=<optimized out>) at /Users/user/esp/components/
↳freertos/port/port_common.c:142
#4  0x403859b8 in vPortEnterCritical () at /Users/user/esp/components/freertos/
↳port/riscv/port.c:130
#5  0x00000000 in ?? ()
Backtrace stopped: frame did not save the PC

```

While the backtrace above is very handy, it requires the user to use *IDF Monitor*. Thus, in order to generate and print a backtrace while using another monitor program, it is possible to activate `CONFIG_ESP_SYSTEM_USE_EH_FRAME` option from the menuconfig.

This option will let the compiler generate DWARF information for each function of the project. Then, when a CPU exception occurs, the panic handler will parse these data and determine the backtrace of the task that failed. The output looks like this:

```
Backtrace: 0x42009e9a:0x3fc92120 0x42009ea6:0x3fc92120 0x42009ec2:0x3fc92130
↳0x42024620:0x3fc92150 0x40387d7c:0x3fc92160 0xffffffff:0x3fc92170
```

These PC : SP pairs represent the PC (Program Counter) and SP (Stack Pointer) for each stack frame of the current task.

The main benefit of the `CONFIG_ESP_SYSTEM_USE_EH_FRAME` option is that the backtrace is generated by the board itself (without the need for *IDF Monitor*). However, the option's drawback is that it results in an increase of the compiled binary's size (ranging from 20% to 100% increase in size). Furthermore, this option causes debug information to be included within the compiled binary. Therefore, users are strongly advised not to enable this option in mass/final production builds.

To find the location where a fatal error has happened, look at the lines which follow the "Backtrace" line. Fatal error location is the top line, and subsequent lines show the call stack.

#### 4.11.4 GDB Stub

If the `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` option is enabled, the panic handler will not reset the chip when a fatal error happens. Instead, it will start a GDB remote protocol server, commonly referred to as GDB Stub. When this happens, a GDB instance running on the host computer can be instructed to connect to the ESP32-C3 UART port.

If *IDF Monitor* is used, GDB is started automatically when a GDB Stub prompt is detected on the UART. The output looks like this:

```
Entering gdb stub now.
$T0b#e6GNU gdb (crosstool-NG crosstool-ng-1.22.0-80-gff1f415) 7.10
Copyright (C) 2015 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law. Type "show copying"
and "show warranty" for details.
This GDB was configured as "--host=x86_64-build_apple-darwin16.3.0 --
↳target=riscv32-esp-elf".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
<http://www.gnu.org/software/gdb/bugs/>.
Find the GDB manual and other documentation resources online at:
<http://www.gnu.org/software/gdb/documentation/>.
For help, type "help".
Type "apropos word" to search for commands related to "word"...
Reading symbols from /Users/user/esp/example/build/example.elf...done.
Remote debugging using /dev/cu.usbserial-31301
0x400e1b41 in app_main ()
    at /Users/user/esp/example/main/main.cpp:36
36      *((int*) 0) = 0;
(gdb)
```

The GDB prompt can be used to inspect CPU registers, local and static variables, and arbitrary locations in memory. It is not possible to set breakpoints, change the PC, or continue execution. To reset the program, exit GDB and perform an external reset: Ctrl-T Ctrl-R in *IDF Monitor*, or using the external reset button on the development board.

### 4.11.5 RTC Watchdog Timeout

The RTC watchdog is used in the startup code to keep track of execution time and it also helps to prevent a lock-up caused by an unstable power source. It is enabled by default (see [CONFIG\\_BOOTLOADER\\_WDT\\_ENABLE](#)). If the execution time is exceeded, the RTC watchdog will restart the system. In this case, the ROM bootloader will print a message with the `RTC Watchdog Timeout` reason for the reboot.

```
rst:0x10 (RTCWDT_RTC_RST)
```

The RTC watchdog covers the execution time from the first stage bootloader (ROM bootloader) to application startup. It is initially set in the ROM bootloader, then configured in the bootloader with the [CONFIG\\_BOOTLOADER\\_WDT\\_TIME\\_MS](#) option (9000 ms by default). During the application initialization stage, it is reconfigured because the source of the slow clock may have changed, and finally disabled right before the `app_main()` call. There is an option [CONFIG\\_BOOTLOADER\\_WDT\\_DISABLE\\_IN\\_USER\\_CODE](#) which prevents the RTC watchdog from being disabled before `app_main`. Instead, the RTC watchdog remains active and must be fed periodically in your application's code.

### 4.11.6 Guru Meditation Errors

This section explains the meaning of different error causes, printed in parens after the `Guru Meditation Error: Core panic'ed` message.

---

**Note:** See the [Guru Meditation Wikipedia article](#) for historical origins of “Guru Meditation” .

---

#### Illegal instruction

This CPU exception indicates that the instruction which was executed was not a valid instruction. Most common reasons for this error include:

- FreeRTOS task function has returned. In FreeRTOS, if a task function needs to terminate, it should call `vTaskDelete()` and delete itself, instead of returning.
- Failure to read next instruction from SPI flash. This usually happens if:
  - Application has reconfigured the SPI flash pins as some other function (GPIO, UART, etc.). Consult the Hardware Design Guidelines and the datasheet for the chip or module for details about the SPI flash pins.
  - Some external device has accidentally been connected to the SPI flash pins, and has interfered with communication between ESP32-C3 and SPI flash.
- In C++ code, exiting from a non-void function without returning a value is considered to be an undefined behavior. When optimizations are enabled, the compiler will often omit the epilogue in such functions. This most often results in an Illegal instruction exception. By default, ESP-IDF build system enables `-Werror=return-type` which means that missing return statements are treated as compile time errors. However if the application project disables compiler warnings, this issue might go undetected and the Illegal instruction exception will occur at run time.

#### Instruction address misaligned

This CPU exception indicates that the address of the instruction to execute is not 2-byte aligned.

#### Instruction access fault, Load access fault, Store access fault

This CPU exception happens when application attempts to execute, read from or write to an invalid memory location. The address which was written/read is found in `MTVAL` register in the register dump. If this address is zero, it usually means that application attempted to dereference a NULL pointer. If this address is close to zero, it usually means that application attempted to access member of a structure, but the pointer to the structure was NULL. If this address is

something else (garbage value, not in `0x3fxxxxxx - 0x6xxxxxx` range), it likely means that the pointer used to access the data was either not initialized or was corrupted.

### Breakpoint

This CPU exception happens when the instruction `EBREAK` is executed.

### Load address misaligned, Store address misaligned

Application has attempted to read or write memory location, and address alignment did not match load/store size. For example, 32-bit load can only be done from 4-byte aligned address, and 16-bit load can only be done from a 2-byte aligned address.

### Interrupt wdt timeout on CPU0 / CPU1

Indicates that an interrupt watchdog timeout has occurred. See [Watchdogs](#) for more information.

### Cache error

In some situations, ESP-IDF will temporarily disable access to external SPI Flash and SPI RAM via caches. For example, this happens when `spi_flash` APIs are used to read/write/erase/mmap regions of SPI Flash. In these situations, tasks are suspended, and interrupt handlers not registered with `ESP_INTR_FLAG_IRAM` are disabled. Make sure that any interrupt handlers registered with this flag have all the code and data in IRAM/DRAM. Refer to the [SPI flash API documentation](#) for more details.

### Memory protection fault

ESP32-C3 Permission Control feature is used in ESP-IDF to prevent the following types of memory access:

- writing to instruction RAM after the program is loaded
- executing code from data RAM (areas used for heap and static `.data` and `.bss`)

Such operations are not necessary for most programs. Prohibiting such operations typically makes software vulnerabilities harder to exploit. Applications which rely on dynamic loading or self-modifying code may disable this protection using `CONFIG_ESP_SYSTEM_MEMPROT_FEATURE` Kconfig option.

When the fault occurs, the panic handler reports the address of the fault and the type of memory access that caused it.

## 4.11.7 Other Fatal Errors

### Brownout

ESP32-C3 has a built-in brownout detector, which is enabled by default. The brownout detector can trigger a system reset if the supply voltage goes below a safe level. The brownout detector can be configured using `CONFIG_ESP_BROWNOUT_DET` and `CONFIG_ESP_BROWNOUT_DET_LVL_SEL` options.

When the brownout detector triggers, the following message is printed:

```
Brownout detector was triggered
```

The chip is reset after the message is printed.

Note that if the supply voltage is dropping at a fast rate, only part of the message may be seen on the console.

## Corrupt Heap

ESP-IDF's heap implementation contains a number of run-time checks of the heap structure. Additional checks ( "Heap Poisoning" ) can be enabled in menuconfig. If one of the checks fails, a message similar to the following will be printed:

```
CORRUPT HEAP: Bad tail at 0x3ffe270a. Expected 0xbaad5678 got 0xbaac5678
assertion "head != NULL" failed: file "/Users/user/esp/esp-idf/components/heap/
↳multi_heap_poisoning.c", line 201, function: multi_heap_free
abort() was called at PC 0x400dca43 on core 0
```

Consult [Heap Memory Debugging](#) documentation for further information.

## Stack Smashing

Stack smashing protection (based on GCC `-fstack-protector*` flags) can be enabled in ESP-IDF using `CONFIG_COMPILER_STACK_CHECK_MODE` option. If stack smashing is detected, message similar to the following will be printed:

```
Stack smashing protect failure!

abort() was called at PC 0x400d2138 on core 0

Backtrace: 0x4008e6c0:0x3ffc1780 0x4008e8b7:0x3ffc17a0 0x400d2138:0x3ffc17c0
↳0x400e79d5:0x3ffc17e0 0x400e79a7:0x3ffc1840 0x400e79df:0x3ffc18a0
↳0x400e2235:0x3ffc18c0 0x400e1916:0x3ffc18f0 0x400e19cd:0x3ffc1910
↳0x400e1a11:0x3ffc1930 0x400e1bb2:0x3ffc1950 0x400d2c44:0x3ffc1a80
0
```

The backtrace should point to the function where stack smashing has occurred. Check the function code for unbounded access to local arrays.

## Undefined behavior sanitizer (UBSAN) checks

Undefined behavior sanitizer (UBSAN) is a compiler feature which adds run-time checks for potentially incorrect operations, such as:

- overflows (multiplication overflow, signed integer overflow)
- shift base or exponent errors (e.g. shift by more than 32 bits)
- integer conversion errors

See [GCC documentation](#) of `-fsanitize=undefined` option for the complete list of supported checks.

**Enabling UBSAN** UBSAN is disabled by default. It can be enabled at file, component, or project level by adding the `-fsanitize=undefined` compiler option in the build system.

When enabling UBSAN for code which uses the SOC hardware register header files (`soc/xxx_reg.h`), it is recommended to disable shift-base sanitizer using `-fno-sanitize=shift-base` option. This is due to the fact that ESP-IDF register header files currently contain patterns which cause false positives for this specific sanitizer option.

To enable UBSAN at project level, add the following code at the end of the project's `CMakeLists.txt` file:

```
idf_build_set_property (COMPILE_OPTIONS "-fsanitize=undefined" "-fno-sanitize=shift-
↳base" APPEND)
```

Alternatively, pass these options through the `EXTRA_CFLAGS` and `EXTRA_CXXFLAGS` environment variables.

Enabling UBSAN results in significant increase of code and data size. Most applications, except for the trivial ones, will not fit into the available RAM of the microcontroller when UBSAN is enabled for the whole application. Therefore it is recommended that UBSAN is instead enabled for specific components under test.

To enable UBSAN for a specific component (`component_name`) from the project's `CMakeLists.txt` file, add the following code at the end of the file:

```
idf_component_get_property(lib component_name COMPONENT_LIB)
target_compile_options(${lib} PRIVATE "-fsanitize=undefined" "-fno-sanitize=shift-
↪base")
```

---

**Note:** See the build system documentation for more information about [build properties](#) and [component properties](#).

---

To enable UBSAN for a specific component (`component_name`) from `CMakeLists.txt` of the same component, add the following at the end of the file:

```
target_compile_options(${COMPONENT_LIB} PRIVATE "-fsanitize=undefined" "-fno-
↪sanitize=shift-base")
```

**UBSAN output** When UBSAN detects an error, a message and the backtrace are printed, for example:

```
Undefined behavior of type out_of_bounds
Backtrace:0x4008b383:0x3ffcd8b0 0x4008c791:0x3ffcd8d0 0x4008c587:0x3ffcd8f0_
↪0x4008c6be:0x3ffcd950 0x400db74f:0x3ffcd970 0x400db99c:0x3ffcd9a0
```

When using *IDF Monitor*, the backtrace will be decoded to function names and source code locations, pointing to the location where the issue has happened (here it is `main.c:128`):

```
0x4008b383: panic_abort at /path/to/esp-idf/components/esp_system/panic.c:367
0x4008c791: esp_system_abort at /path/to/esp-idf/components/esp_system/system_api.
↪c:106
0x4008c587: __ubsan_default_handler at /path/to/esp-idf/components/esp_system/
↪ubsan.c:152
0x4008c6be: __ubsan_handle_out_of_bounds at /path/to/esp-idf/components/esp_system/
↪ubsan.c:223
0x400db74f: test_ub at main.c:128
0x400db99c: app_main at main.c:56 (discriminator 1)
```

The types of errors reported by UBSAN can be as follows:

Name	Meaning
<code>type_mismatch</code> , <code>type_mismatch_v1</code>	Incorrect pointer value: null, unaligned, not compatible with the given type.
<code>add_overflow</code> , <code>sub_overflow</code> , <code>mul_overflow</code> , <code>negate_overflow</code>	Integer overflow during addition, subtraction, multiplication, negation.
<code>divrem_overflow</code>	Integer division by 0 or <code>INT_MIN</code> .
<code>shift_out_of_bounds</code>	Overflow in left or right shift operators.
<code>out_of_bounds</code>	Access outside of bounds of an array.
<code>unreachable</code>	Unreachable code executed.
<code>missing_return</code>	Non-void function has reached its end without returning a value (C++ only).
<code>vla_bound_not_positive</code>	Size of variable length array is not positive.
<code>load_invalid_value</code>	Value of <code>bool</code> or <code>enum</code> (C++ only) variable is invalid (out of bounds).
<code>nonnull_arg</code>	Null argument passed to a function which is declared with a <code>nonnull</code> attribute.
<code>nonnull_return</code>	Null value returned from a function which is declared with <code>returns_nonnull</code> attribute.
<code>builtin_unreachable</code>	<code>__builtin_unreachable</code> function called.
<code>pointer_overflow</code>	Overflow in pointer arithmetic.

## 4.12 Flash Encryption

This is a quick start guide to ESP32-C3's flash encryption feature. Using application code as an example, it demonstrates how to test and verify flash encryption operations during development and production.

### 4.12.1 Introduction

Flash encryption is intended for encrypting the contents of the ESP32-C3's off-chip flash memory. Once this feature is enabled, firmware is flashed as plaintext, and then the data is encrypted in place on the first boot. As a result, physical readout of flash will not be sufficient to recover most flash contents.

With flash encryption enabled, the following types of data are encrypted by default:

- Firmware bootloader
- Partition Table
- All “app” type partitions

Other types of data can be encrypted conditionally:

- Any partition marked with the `encrypted` flag in the partition table. For details, see [Encrypted Partition Flag](#).
- Secure Boot bootloader digest if Secure Boot is enabled (see below).

---

**Important:** For production use, flash encryption should be enabled in the “Release” mode only.

---

---

**Important:** Enabling flash encryption limits the options for further updates of ESP32-C3. Before using this feature, read the document and make sure to understand the implications.

---

### 4.12.2 Relevant eFuses

The flash encryption operation is controlled by various eFuses available on ESP32-C3. The list of eFuses and their descriptions is given in the table below. The names in eFuse column are also used by `espefuse.py` tool. For usage in the eFuse API, modify the name by adding `ESP_EFUSE_`, for example: `esp_efuse_read_field_bit(ESP_EFUSE_DISABLE_DL_ENCRYPT)`.

Table 20: eFuses Used in Flash Encryption

eFuse	Description	Bit Depth
BLOCK_KEYN	AES key storage. N is between 0 and 5.	256 bit key block
KEY_PURPOSE_N	Control the purpose of eFuse block BLOCK_KEYN, where N is between 0 and 5. For flash encryption, the only valid value is 4 for XTS_AES_128_KEY.	4
DIS_DOWNLOAD_MANUAL_ENCRYPT	If set, disable flash encryption when in download boot-modes.	1
SPI_BOOT_CRYPT_CNT	Enable encryption and decryption, when an SPI boot mode is set. Feature is enabled if 1 or 3 bits are set in the eFuse, disabled otherwise.	3

#### Note:

- R/W access control is available for all the eFuse bits listed in the table above.
- The default value of these bits is 0 after manufacturing.

Read and write access to eFuse bits is controlled by appropriate fields in the registers `WR_DIS` and `RD_DIS`. For more information on ESP32-C3 eFuses, see *eFuse manager*. To change protection bits of eFuse field using `espefuse.py`, use these two commands: `read_protect_efuse` and `write_protect_efuse`. Example `espefuse.py write_protect_efuse DISABLE_DL_ENCRYPT`.

### 4.12.3 Flash Encryption Process

Assuming that the eFuse values are in their default states and the firmware bootloader is compiled to support flash encryption, the flash encryption process executes as shown below:

1. On the first power-on reset, all data in flash is un-encrypted (plaintext). The ROM bootloader loads the firmware bootloader.
2. Firmware bootloader reads the `SPI_BOOT_CRYPT_CNT` eFuse value (0b000). Since the value is 0 (even number of bits set), it configures and enables the flash encryption block. For more information on the flash encryption block, see [ESP32-C3 Technical Reference Manual](#).
3. Firmware bootloader uses RNG (random) module to generate an 256 bit key and then writes it into `BLOCK_KEYN` eFuse. The software also updates the `KEY_PURPOSE_N` for the block where the key is stored. The key cannot be accessed via software as the write and read protection bits for `BLOCK_KEYN` eFuse are set. `KEY_PURPOSE_N` field is write-protected as well. The flash encryption is completely conducted by hardware, and the key cannot be accessed via software.
4. Flash encryption block encrypts the flash contents - the firmware bootloader, applications and partitions marked as encrypted. Encrypting in-place can take time, up to a minute for large partitions.
5. Firmware bootloader sets the first available bit in `SPI_BOOT_CRYPT_CNT` (0b001) to mark the flash contents as encrypted. Odd number of bits is set.
6. For *Development Mode*, the firmware bootloader allows the UART bootloader to re-flash encrypted binaries. Also, the `SPI_BOOT_CRYPT_CNT` eFuse bits are NOT write-protected. In addition, the firmware bootloader by default sets the eFuse bits `DIS_DOWNLOAD_ICACHE`, `DIS_PAD_JTAG`, `DIS_USB_JTAG` and `DIS_LEGACY_SPI_BOOT`.
7. For *Release Mode*, the firmware bootloader sets all the eFuse bits set under development mode as well as `DIS_DOWNLOAD_MANUAL_ENCRYPT`. It also write-protects the `SPI_BOOT_CRYPT_CNT` eFuse bits. To modify this behavior, see *Enabling UART Bootloader Encryption/Decryption*.

8. The device is then rebooted to start executing the encrypted image. The firmware bootloader calls the flash decryption block to decrypt the flash contents and then loads the decrypted contents into IRAM.

During the development stage, there is a frequent need to program different plaintext flash images and test the flash encryption process. This requires that Firmware Download mode is able to load new plaintext images as many times as it might be needed. However, during manufacturing or production stages, Firmware Download mode should not be allowed to access flash contents for security reasons.

Hence, two different flash encryption configurations were created: for development and for production. For details on these configurations, see Section [Flash Encryption Configuration](#).

#### 4.12.4 Flash Encryption Configuration

The following flash encryption modes are available:

- *Development Mode* - recommended for use only during development. In this mode, it is still possible to flash new plaintext firmware to the device, and the bootloader will transparently encrypt this firmware using the key stored in hardware. This allows, indirectly, to read out the plaintext of the firmware in flash.
- *Release Mode* - recommended for manufacturing and production. In this mode, flashing plaintext firmware to the device without knowing the encryption key is no longer possible.

This section provides information on the mentioned flash encryption modes and step by step instructions on how to use them.

##### Development Mode

During development, you can encrypt flash using either an ESP32-C3 generated key or external host-generated key.

**Using ESP32-C3 Generated Key** Development mode allows you to download multiple plaintext images using Firmware Download mode.

To test flash encryption process, take the following steps:

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in [Relevant eFuses](#).

See how to check [ESP32-C3 Flash Encryption Status](#).

2. In [Project Configuration Menu](#), do the following:

- *Enable flash encryption on boot*.
- *Select encryption mode* (**Development mode** by default).
- *Select UART ROM download mode* (**enabled** by default).
- *Select the appropriate bootloader log verbosity*.
- Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See [Bootloader Size](#).

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

---

**Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

---

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-C3 will reset. On the next boot, the

firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

A sample output of the first ESP32-C3 boot after enabling flash encryption is given below:

```

This is esp32c3 chip with 1 CPU core(s), WiFi/BLE, silicon revision 0, 2MB_
↳external flash
FLASH_CRYPT_CNT eFuse value is 1
Flash encryption feature is enabled in DEVELOPMENT mode

```

At this stage, if you need to update and re-flash binaries, see [Re-flashing Updated Partitions](#).

**Using Host Generated Key** It is possible to pre-generate a flash encryption key on the host computer and burn it into the eFuse. This allows you to pre-encrypt data on the host and flash already encrypted data without needing a plaintext flash update. This feature can be used in both [Development Mode](#) and [Release Mode](#). Without a pre-generated key, data is flashed in plaintext and then ESP32-C3 encrypts the data in-place.

---

**Note:** This option is not recommended for production, unless a separate key is generated for each individual device.

---

To use a host generated key, take the following steps:

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in [Relevant eFuses](#).

See how to check [ESP32-C3 Flash Encryption Status](#).

2. Generate a random key by running:

```
espsecure.py generate_flash_encryption_key my_flash_encryption_key.bin
```

3. **Before the first encrypted boot**, burn the key into your device's eFuse using the command below. This action can be done **only once**.

```
espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin XTS_
↳AES_128_KEY
```

where BLOCK is a free keyblock between BLOCK\_KEY0 and BLOCK\_KEY5.

If the key is not burned and the device is started after enabling flash encryption, the ESP32-C3 will generate a random key that software cannot access or modify.

4. In [Project Configuration Menu](#), do the following:
  - [Enable flash encryption on boot](#)

- [Select encryption mode](#) (**Development mode** by default)
- [Select the appropriate bootloader log verbosity](#)
- Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See [Bootloader Size](#).

5. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

---

**Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

---

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-C3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

If using Development Mode, then the easiest way to update and re-flash binaries is [Re-flashing Updated Partitions](#).

If using Release Mode, then it is possible to pre-encrypt the binaries on the host and then flash them as ciphertext. See [Manually Encrypting Files](#).

**Re-flashing Updated Partitions** If you update your application code (done in plaintext) and want to re-flash it, you will need to encrypt it before flashing. To encrypt the application and flash it in one step, run:

```
idf.py encrypted-app-flash monitor
```

If all partitions needs to be updated in encrypted format, run:

```
idf.py encrypted-flash monitor
```

## Release Mode

In Release mode, UART bootloader cannot perform flash encryption operations. New plaintext images can ONLY be downloaded using the over-the-air (OTA) scheme which will encrypt the plaintext image before writing to flash.

To use this mode, take the following steps:

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in [Relevant eFuses](#).

See how to check [ESP32-C3 Flash Encryption Status](#).

2. In [Project Configuration Menu](#), do the following:

- [Enable flash encryption on boot](#)
- [Select Release mode](#) (Note that once Release mode is selected, the `EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT` eFuse bit will be burned to disable flash encryption hardware in ROM Download Mode.)
- [Select UART ROM download mode](#) (*Permanently switch to Secure mode (recommended)*). This is the default option, and is recommended. It is also possible to change this configuration setting to permanently disable UART ROM download mode, if this mode is not needed.
- [Select the appropriate bootloader log verbosity](#)
- Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See [Bootloader Size](#).

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

---

**Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

---

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-C3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

Once the flash encryption is enabled in Release mode, the bootloader will write-protect the `SPI_BOOT_CRYPT_CNT` eFuse.

For subsequent plaintext field updates, use [OTA scheme](#).

---

**Note:** If you have pre-generated the flash encryption key and stored a copy, and the UART download mode is not permanently disabled via `CONFIG_SECURE_UART_ROM_DL_MODE`, then it is possible to update the flash locally by pre-encrypting the files and then flashing the ciphertext. See [Manually Encrypting Files](#).

---

## Best Practices

When using Flash Encryption in production:

- Do not reuse the same flash encryption key between multiple devices. This means that an attacker who copies encrypted data from one device cannot transfer it to a second device.
- The UART ROM Download Mode should be disabled entirely if it is not needed, or permanently set to “Secure Download Mode” otherwise. Secure Download Mode permanently limits the available commands to updating SPI config, changing baud rate, basic flash write, and returning a summary of the currently enabled security features with the `get_security_info` command. The default behaviour is to set Secure Download Mode on first boot in Release mode. To disable Download Mode entirely, select `CONFIG_SECURE_UART_ROM_DL_MODE` to “Permanently disable ROM Download Mode (recommended)” or call `esp_efuse_disable_rom_download_mode()` at runtime.
- Enable [Secure Boot](#) as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

### 4.12.5 Possible Failures

Once flash encryption is enabled, the `SPI_BOOT_CRYPT_CNT` eFuse value will have an odd number of bits set. It means that all the partitions marked with the encryption flag are expected to contain encrypted ciphertext. Below are the three typical failure cases if the ESP32-C3 is erroneously loaded with plaintext data:

1. If the bootloader partition is re-flashed with a **plaintext firmware bootloader image**, the ROM bootloader will fail to load the firmware bootloader resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
invalid header: 0xb414f76b
invalid header: 0xb414f76b
```

(continues on next page)

(continued from previous page)

```
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
```

---

**Note:** The value of invalid header will be different for every application.

---

---

**Note:** This error also appears if the flash contents are erased or corrupted.

---

2. If the firmware bootloader is encrypted, but the partition table is re-flashed with a **plaintext partition table image**, the bootloader will fail to read the partition table resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00

load:0x40078000,len:19168
load:0x40080400,len:6664
entry 0x40080764
I (60) boot: ESP-IDF v4.0-dev-763-g2c55fae6c-dirty 2nd stage bootloader
I (60) boot: compile time 19:15:54
I (62) boot: Enabling RNG early entropy source...
I (67) boot: SPI Speed      : 40MHz
I (72) boot: SPI Mode      : DIO
I (76) boot: SPI Flash Size : 4MB
E (80) flash_parts: partition 0 invalid magic number 0x94f6
E (86) boot: Failed to verify partition table
E (91) boot: load partition table error!
```

3. If the bootloader and partition table are encrypted, but the application is re-flashed with a **plaintext application image**, the bootloader will fail to load the application resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00
mode:DIO, clock div:2
load:0x3fff0018,len:4
load:0x3fff001c,len:8452
load:0x40078000,len:13616
load:0x40080400,len:6664
entry 0x40080764
I (56) boot: ESP-IDF v4.0-dev-850-gc4447462d-dirty 2nd stage bootloader
I (56) boot: compile time 15:37:14
I (58) boot: Enabling RNG early entropy source...
I (64) boot: SPI Speed      : 40MHz
I (68) boot: SPI Mode      : DIO
I (72) boot: SPI Flash Size : 4MB
I (76) boot: Partition Table:
I (79) boot: ## Label                Usage                Type ST Offset   Length
I (87) boot:  0 nvs                    WiFi data            01 02 0000a000 00006000

E (132) boot: Factory app partition is not bootable
E (138) boot: No bootable app partitions in the partition table
```

### 4.12.6 ESP32-C3 Flash Encryption Status

1. Ensure that you have an ESP32-C3 device with default flash encryption eFuse settings as shown in [Relevant eFuses](#).

To check if flash encryption on your ESP32-C3 device is enabled, do one of the following:

- flash the application example [security/flash\\_encryption](#) onto your device. This application prints the `SPI_BOOT_CRYPT_CNT` eFuse value and if flash encryption is enabled or disabled.
- [Find the serial port name](#) under which your ESP32-C3 device is connected, replace `PORT` with your port name in the following command, and run it:

```
espefuse.py -p PORT summary
```

### 4.12.7 Reading and Writing Data in Encrypted Flash

ESP32-C3 application code can check if flash encryption is currently enabled by calling [`esp\_flash\_encryption\_enabled\(\)`](#). Also, a device can identify the flash encryption mode by calling [`esp\_get\_flash\_encryption\_mode\(\)`](#).

Once flash encryption is enabled, be more careful with accessing flash contents from code.

#### Scope of Flash Encryption

Whenever the `SPI_BOOT_CRYPT_CNT` eFuse is set to a value with an odd number of bits, all flash content accessed via the MMU's flash cache is transparently decrypted. It includes:

- Executable application code in flash (IROM).
- All read-only data stored in flash (DROM).
- Any data accessed via [`spi\_flash\_mmap\(\)`](#).
- The firmware bootloader image when it is read by the ROM bootloader.

---

**Important:** The MMU flash cache unconditionally decrypts all existing data. Data which is stored unencrypted in flash memory will also be “transparently decrypted” via the flash cache and will appear to software as random garbage.

---

#### Reading from Encrypted Flash

To read data without using a flash cache MMU mapping, you can use the partition read function [`esp\_partition\_read\(\)`](#). This function will only decrypt data when it is read from an encrypted partition. Data read from unencrypted partitions will not be decrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also use the following SPI flash API functions:

- [`esp\_flash\_read\(\)`](#) to read raw (encrypted) data which will not be decrypted
- [`esp\_flash\_read\_encrypted\(\)`](#) to read and decrypt data

Data stored using the Non-Volatile Storage (NVS) API is always stored and read decrypted from the perspective of flash encryption. It is up to the library to provide encryption feature if required. Refer to [NVS Encryption](#) for more details.

### Writing to Encrypted Flash

It is recommended to use the partition write function `esp_partition_write()`. This function will only encrypt data when it is written to an encrypted partition. Data written to unencrypted partitions will not be encrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also pre-encrypt and write data using the function `esp_flash_write_encrypted()`

Also, the following ROM function exist but not supported in esp-idf applications:

- `esp_rom_spiflash_write_encrypted` pre-encrypts and writes data to flash
- `SPIWrite` writes unencrypted data to flash

Since data is encrypted in blocks, the minimum write size for encrypted data is 16 bytes and the alignment is also 16 bytes.

## 4.12.8 Updating Encrypted Flash

### OTA Updates

OTA updates to encrypted partitions will automatically write encrypted data if the function `esp_partition_write()` is used.

Before building the application image for OTA updating of an already encrypted device, enable the option [Enable flash encryption on boot](#) in project configuration menu.

For general information about ESP-IDF OTA updates, please refer to [OTA](#)

### Updating Encrypted Flash via Serial

Flashing an encrypted device via serial bootloader requires that the serial bootloader download interface has not been permanently disabled via eFuse.

In Development Mode, the recommended method is [Re-flashing Updated Partitions](#).

In Release Mode, if a copy of the same key stored in eFuse is available on the host then it's possible to pre-encrypt files on the host and then flash them. See [Manually Encrypting Files](#).

## 4.12.9 Disabling Flash Encryption

If flash encryption was enabled accidentally, flashing of plaintext data will soft-brick the ESP32-C3. The device will reboot continuously, printing the error `flash read err, 1000 or invalid header: 0xXXXXXX`.

For flash encryption in Development mode, encryption can be disabled by burning the `SPI_BOOT_CRYPT_CNT` eFuse. It can only be done one time per chip by taking the following steps:

1. In [Project Configuration Menu](#), disable [Enable flash encryption on boot](#), then save and exit.
2. Open project configuration menu again and **double-check** that you have disabled this option! If this option is left enabled, the bootloader will immediately re-enable encryption when it boots.
3. With flash encryption disabled, build and flash the new bootloader and application by running `idf.py flash`.
4. Use `espefuse.py` (in `components/esptool_py/esptool`) to disable the `SPI_BOOT_CRYPT_CNT` by running:

```
espefuse.py burn_efuse SPI_BOOT_CRYPT_CNT
```

Reset the ESP32-C3. Flash encryption will be disabled, and the bootloader will boot as usual.

#### 4.12.10 Key Points About Flash Encryption

- Flash memory contents is encrypted using XTS-AES-128. The flash encryption key is 256 bits and stored in one `BLOCK_KEYN` eFuse internal to the chip and, by default, is protected from software access.
- Flash access is transparent via the flash cache mapping feature of ESP32-C3 - any flash regions which are mapped to the address space will be transparently decrypted when read.  
Some data partitions might need to remain unencrypted for ease of access or might require the use of flash-friendly update algorithms which are ineffective if the data is encrypted. NVS partitions for non-volatile storage cannot be encrypted since the NVS library is not directly compatible with flash encryption. For details, refer to [NVS Encryption](#).
- If flash encryption might be used in future, the programmer must keep it in mind and take certain precautions when writing code that [uses encrypted flash](#).
- If secure boot is enabled, re-flashing the bootloader of an encrypted device requires a “Re-flashable” secure boot digest (see [Flash Encryption and Secure Boot](#)).

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See [Bootloader Size](#).

---

**Important:** Do not interrupt power to the ESP32-C3 while the first boot encryption pass is running. If power is interrupted, the flash contents will be corrupted and will require flashing with unencrypted data again. In this case, re-flashing will not count towards the flashing limit.

---

#### 4.12.11 Limitations of Flash Encryption

Flash encryption protects firmware against unauthorised readout and modification. It is important to understand the limitations of the flash encryption feature:

- Flash encryption is only as strong as the key. For this reason, we recommend keys are generated on the device during first boot (default behaviour). If generating keys off-device, ensure proper procedure is followed and don't share the same key between all production devices.
- Not all data is stored encrypted. If storing data on flash, check if the method you are using (library, API, etc.) supports flash encryption.
- Flash encryption does not prevent an attacker from understanding the high-level layout of the flash. This is because the same AES key is used for every pair of adjacent 16 byte AES blocks. When these adjacent 16 byte blocks contain identical content (such as empty or padding areas), these blocks will encrypt to produce matching pairs of encrypted blocks. This may allow an attacker to make high-level comparisons between encrypted devices (i.e. to tell if two devices are probably running the same firmware version).
- Flash encryption alone may not prevent an attacker from modifying the firmware of the device. To prevent unauthorised firmware from running on the device, use flash encryption in combination with [Secure Boot](#).

#### 4.12.12 Flash Encryption and Secure Boot

It is recommended to use flash encryption in combination with Secure Boot. However, if Secure Boot is enabled, additional restrictions apply to device re-flashing:

- [OTA Updates](#) are not restricted, provided that the new app is signed correctly with the Secure Boot signing key.

#### 4.12.13 Advanced Features

The following section covers advanced features of flash encryption.

## Encrypted Partition Flag

Some partitions are encrypted by default. Other partitions can be marked in the partition table description as requiring encryption by adding the flag `encrypted` to the partitions' flag field. As a result, data in these marked partitions will be treated as encrypted in the same manner as an app partition.

```
# Name, Type, SubType, Offset, Size, Flags
nvs, data, nvs, 0x9000, 0x6000
phy_init, data, phy, 0xf000, 0x1000
factory, app, factory, 0x10000, 1M
secret_data, 0x40, 0x01, 0x20000, 256K, encrypted
```

For details on partition table description, see [partition table](#).

Further information about encryption of partitions:

- Default partition tables do not include any encrypted data partitions.
- With flash encryption enabled, the `app` partition is always treated as encrypted and does not require marking.
- If flash encryption is not enabled, the flag “encrypted” has no effect.
- You can also consider protecting `phy_init` data from physical access, readout, or modification, by marking the optional `phy` partition with the flag `encrypted`.
- The `nvs` partition cannot be encrypted, because the NVS library is not directly compatible with flash encryption.

## Enabling UART Bootloader Encryption/Decryption

On the first boot, the flash encryption process burns by default the following eFuses:

- `DIS_DOWNLOAD_MANUAL_ENCRYPT` which disables flash encryption operation when running in UART bootloader boot mode.
- `DIS_DOWNLOAD_ICACHE` which disables the entire MMU flash cache when running in UART bootloader mode.
- `DIS_PAD_JTAG` and `DIS_USB_JTAG` which disables JTAG.
- `DIS_DIRECT_BOOT` (old name `DIS_LEGACY_SPI_BOOT`) which disables direct boot mode

However, before the first boot you can choose to keep any of these features enabled by burning only selected eFuses and write-protect the rest of eFuses with unset value 0. For example:

```
espfuse.py --port PORT burn_efuse DIS_DOWNLOAD_MANUAL_ENCRYPT
espfuse.py --port PORT write_protect_efuse DIS_DOWNLOAD_MANUAL_ENCRYPT
```

---

**Note:** Set all appropriate bits before write-protecting!

Write protection of all the three eFuses is controlled by one bit. It means that write-protecting one eFuse bit will inevitably write-protect all unset eFuse bits.

---

Write protecting these eFuses to keep them unset is not currently very useful, as `esptool.py` does not support reading encrypted flash.

## JTAG Debugging

By default, when Flash Encryption is enabled (in either Development or Release mode) then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables flash encryption.

See [JTAG with Flash Encryption or Secure Boot](#) for more information about using JTAG Debugging with Flash Encryption.

## Manually Encrypting Files

Manually encrypting or decrypting files requires the flash encryption key to be pre-burned in eFuse (see [Using Host Generated Key](#)) and a copy to be kept on the host. If the flash encryption is configured in Development Mode then it's not necessary to keep a copy of the key or follow these steps, the simpler [Re-flashing Updated Partitions](#) steps can be used.

The key file should be a single raw binary file (example: `key.bin`).

For example, these are the steps to encrypt the file `build/my-app.bin` to flash at offset `0x10000`. Run `espsecure.py` as follows:

```
espsecure.py encrypt_flash_data --aes_xts --keyfile /path/to/key.bin --address_
↳0x10000 --output my-app-ciphertext.bin build/my-app.bin
```

The file `my-app-ciphertext.bin` can then be flashed to offset `0x10000` using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds.

---

**Note:** If the flashed ciphertext file is not recognized by the ESP32-C3 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset.

---

The command `espsecure.py decrypt_flash_data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

### 4.12.14 Technical Details

The following sections provide some reference information about the operation of flash encryption.

#### Flash Encryption Algorithm

- ESP32-C3 use the XTS-AES block cipher mode with 256 bit size for flash encryption.
- XTS-AES is a block cipher mode specifically designed for disc encryption and addresses the weaknesses other potential modes (e.g. AES-CTR) have for this use case. A detailed description of the XTS-AES algorithm can be found in [IEEE Std 1619-2007](#).
- The flash encryption key is stored in one `BLOCK_KEYN` eFuse and, by default, is protected from further writes or software readout.
- To see the full flash encryption algorithm implemented in Python, refer to the `_flash_encryption_operation()` function in the `espsecure.py` source code.

## 4.13 Hardware Abstraction

ESP-IDF provides a group of APIs for hardware abstraction. These APIs allow you to control peripherals at different levels of abstraction, giving you more flexibility compared to using only the ESP-IDF drivers to interact with hardware. ESP-IDF Hardware abstraction is likely to be useful for writing high-performance bare-metal drivers, or for attempting to port an ESP chip to another platform.

This guide is split into the following sections:

1. [Architecture](#)
2. [LL \(Low Level\) Layer](#)
3. [HAL \(Hardware Abstraction Layer\)](#)

**Warning:** Hardware abstraction API (excluding the driver and `xxx_types.h`) should be considered an experimental feature, thus cannot be considered public API. The hardware abstraction API does not adhere to the API name changing restrictions of ESP-IDF's versioning scheme. In other words, it is possible that Hardware Abstraction API may change in between non-major release versions.

**Note:** Although this document mainly focuses on hardware abstraction of peripherals, e.g., UART, SPI, I2C, certain layers of hardware abstraction extend to other aspects of hardware as well, e.g., some of the CPU's features are partially abstracted.

---

### 4.13.1 Architecture

Hardware abstraction in ESP-IDF is comprised of the following layers, ordered from low level of abstraction that is closer to hardware, to high level of abstraction that is further away from hardware.

- Low Level (LL) Layer
- Hardware Abstraction Layer (HAL)
- Driver Layers

The LL Layer, and HAL are entirely contained within the `hal` component. Each layer is dependent on the layer below it, i.e., driver depends on HAL, HAL depends on LL, LL depends on the register header files.

For a particular peripheral `xxx`, its hardware abstraction generally consists of the header files described in the table below. Files that are **Target Specific** have a separate implementation for each target, i.e., a separate copy for each chip. However, the `#include` directive is still target-independent, i.e., is the same for different targets, as the build system automatically includes the correct version of the header and source files.

Table 21: Hardware Abstraction Header Files

Include Directive	Target Specific	Description
<code>#include 'soc/xxx_caps.h'</code>	Y	This header contains a list of C macros specifying the various capabilities of the ESP32-C3's peripheral <code>xxx</code> . Hardware capabilities of a peripheral include things such as the number of channels, DMA support, hardware FIFO/buffer lengths, etc.
<code>#include "soc/xxx_struct.h"</code> <code>#include "soc/xxx_reg.h"</code>	Y	The two headers contain a representation of a peripheral's registers in C structure and C macro format respectively, allowing you to operate a peripheral at the register level via either of these two header files.
<code>#include "soc/xxx_pins.h"</code>	Y	If certain signals of a peripheral are mapped to a particular pin of the ESP32-C3, their mappings are defined in this header as C macros.
<code>#include "soc/xxx_periph.h"</code>	N	This header is mainly used as a convenience header file to automatically include <code>xxx_caps.h</code> , <code>xxx_struct.h</code> , and <code>xxx_reg.h</code> .
<code>#include "hal/xxx_types.h"</code>	N	This header contains type definitions and macros that are shared among the LL, HAL, and driver layers. Moreover, it is considered public API thus can be included by the application level. The shared types and definitions usually related to non-implementation specific concepts such as the following: <ul style="list-style-type: none"> <li>• Protocol-related types/macros such as frames, modes, common bus speeds, etc.</li> <li>• Features/characteristics of an <code>xxx</code> peripheral that are likely to be present on any implementation (implementation-independent) such as channels, operating modes, signal amplification or attenuation intensities, etc.</li> </ul>
<code>#include "hal/xxx_ll.h"</code>	Y	This header contains the Low Level (LL) Layer of hardware abstraction. LL Layer API are primarily used to abstract away register operations into readable functions.
<code>#include "hal/xxx_hal.h"</code>	Y	The Hardware Abstraction Layer (HAL) is used to abstract away peripheral operation steps into functions (e.g., reading a buffer, starting a transmission, handling an event, etc). The HAL is built on top of the LL Layer.
<code>#include "driver/xxx.h"</code>	N	The driver layer is the highest level of ESP-IDF's hardware abstraction. Driver layer API are meant to be called from ESP-IDF applications, and internally utilize OS primitives. Thus, driver layer API are event-driven, and can be used in a multi-threaded environment.

### 4.13.2 LL (Low Level) Layer

The primary purpose of the LL Layer is to abstract away register field access into more easily understandable functions. LL functions essentially translate various in/out arguments into the register fields of a peripheral in the form of get/set functions. All the necessary bit shifting, masking, offsetting, and endianness of the register fields should be handled by the LL functions.

```
//Inside xxx_ll.h

static inline void xxx_ll_set_baud_rate(xxx_dev_t *hw,
                                       xxx_ll_clk_src_t clock_source,
                                       uint32_t baud_rate) {
    uint32_t src_clk_freq = (source_clk == XXX_SCLK_APB) ? APB_CLK_FREQ : REF_CLK_
↪FREQ;
    uint32_t clock_divider = src_clk_freq / baud;
    // Set clock select field
    hw->clk_div_reg.divider = clock_divider >> 4;
    // Set clock divider field
```

(continues on next page)

(continued from previous page)

```

hw->config.clk_sel = (source_clk == XXX_SCLK_APB) ? 0 : 1;
}

static inline uint32_t xxx_ll_get_rx_byte_count(xxx_dev_t *hw) {
    return hw->status_reg.rx_cnt;
}

```

The code snippet above illustrates typical LL functions for a peripheral `xxx`. LL functions typically have the following characteristics:

- All LL functions are defined as `static inline` so that there is minimal overhead when calling these functions due to compiler optimization. These functions are not guaranteed to be inlined by the compiler, so any LL function that is called when the cache is disabled (e.g., from an IRAM ISR context) should be marked with `__attribute__((always_inline))`.
- The first argument should be a pointer to a `xxx_dev_t` type. The `xxx_dev_t` type is a structure representing the peripheral's registers, thus the first argument is always a pointer to the starting address of the peripheral's registers. Note that in some cases where the peripheral has multiple channels with identical register layouts, `xxx_dev_t *hw` may point to the registers of a particular channel instead.
- LL functions should be short, and in most cases are deterministic. In other words, in the worst case, runtime of the LL function can be determined at compile time. Thus, any loops in LL functions should be finite bounded; however, there are currently a few exceptions to this rule.
- LL functions are not thread-safe, it is the responsibility of the upper layers (driver layer) to ensure that registers or register fields are not accessed concurrently.

### 4.13.3 HAL (Hardware Abstraction Layer)

The HAL layer models the operational process of a peripheral as a set of general steps, where each step has an associated function. For each step, the details of a peripheral's register implementation (i.e., which registers need to be set/read) are hidden (abstracted away) by the HAL. By modeling peripheral operation as a set of functional steps, any minor hardware implementation differences of the peripheral between different targets or chip versions can be abstracted away by the HAL (i.e., handled transparently). In other words, the HAL API for a particular peripheral remains mostly the same across multiple targets/chip versions.

The following HAL function examples are selected from the Watchdog Timer HAL as each function maps to one of the steps in a WDT's operation life cycle, thus illustrating how a HAL abstracts a peripheral's operation into functional steps.

```

// Initialize one of the WDTs
void wdt_hal_init(wdt_hal_context_t *hal, wdt_inst_t wdt_inst, uint32_t prescaler,
↳ bool enable_intr);

// Configure a particular timeout stage of the WDT
void wdt_hal_config_stage(wdt_hal_context_t *hal, wdt_stage_t stage, uint32_t
↳ timeout, wdt_stage_action_t behavior);

// Start the WDT
void wdt_hal_enable(wdt_hal_context_t *hal);

// Feed (i.e., reset) the WDT
void wdt_hal_feed(wdt_hal_context_t *hal);

// Handle a WDT timeout
void wdt_hal_handle_intr(wdt_hal_context_t *hal);

// Stop the WDT
void wdt_hal_disable(wdt_hal_context_t *hal);

// De-initialize the WDT
void wdt_hal_deinit(wdt_hal_context_t *hal);

```

HAL functions generally have the following characteristics:

- The first argument to a HAL function has the `xxx_hal_context_t *` type. The HAL context type is used to store information about a particular instance of the peripheral (i.e., the context instance). A HAL context is initialized by the `xxx_hal_init()` function and can store information such as the following:
  - The channel number of this instance
  - Pointer to the peripheral's (or channel's) registers (i.e., a `xxx_dev_t *` type)
  - Information about an ongoing transaction (e.g., pointer to DMA descriptor list in use)
  - Some configuration values for the instance (e.g., channel configurations)
  - Variables to maintain state information regarding the instance (e.g., a flag to indicate if the instance is waiting for transaction to complete)
- HAL functions should not contain any OS primitives such as queues, semaphores, mutexes, etc. All synchronization/concurrency should be handled at higher layers (e.g., the driver).
- Some peripherals may have steps that cannot be further abstracted by the HAL, thus end up being a direct wrapper (or macro) for an LL function.
- Some HAL functions may be placed in IRAM thus may carry an `IRAM_ATTR` or be placed in a separate `xxx_hal_iram.c` source file.

## 4.14 JTAG Debugging

This document provides a guide to installing OpenOCD for ESP32-C3 and debugging using GDB. The document is structured as follows:

**Introduction** Introduction to the purpose of this guide.

**How it Works?** Description how ESP32-C3, JTAG interface, OpenOCD and GDB are interconnected and working together to enable debugging of ESP32-C3.

**Selecting JTAG Adapter** What are the criteria and options to select JTAG adapter hardware.

**Setup of OpenOCD** Procedure to install OpenOCD and verify that it is installed.

**Configuring ESP32-C3 Target** Configuration of OpenOCD software and setting up of JTAG adapter hardware, which together make up the debugging target.

**Launching Debugger** Steps to start up a debug session with GDB from *Eclipse* and from *Command Line*.

**Debugging Examples** If you are not familiar with GDB, check this section for debugging examples provided from *Eclipse* as well as from *Command Line*.

**Building OpenOCD from Sources** Procedure to build OpenOCD from sources for *Windows*, *Linux* and *macOS* operating systems.

**Tips and Quirks** This section provides collection of tips and quirks related to JTAG debugging of ESP32-C3 with OpenOCD and GDB.

### 4.14.1 Introduction

Espressif has ported OpenOCD to support the ESP32-C3 processor and the multi-core FreeRTOS (which is the foundation of most ESP32-C3 apps). Additionally, some extra tools have been written to provide extra features that OpenOCD does not support natively.

This document provides a guide to installing OpenOCD for ESP32-C3 and debugging using GDB under Linux, Windows and macOS. Except for OS specific installation procedures, the s/w user interface and use procedures are the same across all supported operating systems.

---

**Note:** Screenshots presented in this document have been made for Eclipse Neon 3 running on Ubuntu 16.04 LTS. There may be some small differences in what a particular user interface looks like, depending on whether you are using Windows, macOS or Linux and / or a different release of Eclipse.

---

### 4.14.2 How it Works?

The key software and hardware components that perform debugging of ESP32-C3 with OpenOCD over JTAG (Joint Test Action Group) interface is presented in the diagram below under the “Debugging With JTAG” label. These components include riscv32-esp-elf-gdb debugger, OpenOCD on chip debugger, and the JTAG adapter connected to ESP32-C3 target.

Fig. 57: JTAG debugging - overview diagram

Likewise, the “Application Loading and Monitoring” label indicates the key software and hardware components that allow an application to be compiled, built, and flashed to ESP32-C3, as well as to provide means to monitor diagnostic messages from ESP32-C3.

“Debugging With JTAG” and “Application Loading and Monitoring” is integrated under the [Eclipse IDE](#) in order to provide a quick and easy transition between writing/compiling/loading/debugging code. The Eclipse IDE (and the integrated debugging software) is available for Windows, Linux and macOS platforms. Depending on user preferences, both the debugger and `idf.py build` can also be used directly from terminal/command line, instead of Eclipse.

The connection from PC to ESP32-C3 is done effectively with a single USB cable. This is made possible by the ESP32-C3 chip itself, which provides two USB channels, one for JTAG and the other for the USB terminal connection. The USB cable should be connected to the D+/D- USB pins of ESP32-C3 and not to the serial Rx/D/TxD through a USB-to-UART chip. The proper connection is explained later in subsection [Configuring ESP32-C3 Target](#).

---

**Note:** Debugging through the USB interface implemented in ESP32-C3 requires to have a chip with revision 0.3 or newer. Please use other debugging options (e.g. with ESP-Prog) for chip revisions 0.1 and 0.2. The easiest way to determine the chip revision is to look for the `boot: chip revision: v0.3` message at the beginning of the boot log. See [SoC errata](#) for more details.

---

### 4.14.3 Selecting JTAG Adapter

The quickest and most convenient way to start with JTAG debugging is through a USB cable connected to the D+/D- USB pins of ESP32-C3. No need for an external JTAG adapter and extra wiring / cable to connect JTAG to ESP32-C3.

If you decide to use separate JTAG adapter, look for one that is compatible with both the voltage levels on the ESP32-C3 as well as with the OpenOCD software. The JTAG port on the ESP32-C3 is an industry-standard JTAG port

which lacks (and does not need) the TRST pin. The JTAG I/O pins all are powered from the VDD\_3P3\_RTC pin (which normally would be powered by a 3.3 V rail) so the JTAG adapter needs to be able to work with JTAG pins in that voltage range.

On the software side, OpenOCD supports a fair amount of JTAG adapters. See <https://openocd.org/doc/html/Debug-Adapter-Hardware.html> for an (unfortunately slightly incomplete) list of the adapters OpenOCD works with. This page lists SWD-compatible adapters as well; take note that the ESP32-C3 does not support SWD. JTAG adapters that are hardcoded to a specific product line, e.g. ST-LINK debugging adapters for STM32 families, will not work.

The minimal signalling to get a working JTAG connection are TDI, TDO, TCK, TMS and GND. Some JTAG debuggers also need a connection from the ESP32-C3 power line to a line called e.g. Vtar to set the working voltage. SRST can optionally be connected to the CH\_PD of the ESP32-C3, although for now, support in OpenOCD for that line is pretty minimal.

[ESP-Prog](#) is an example for using an external board for debugging by connecting it to the JTAG pins of ESP32-C3.

#### 4.14.4 Setup of OpenOCD

If you have already set up ESP-IDF with CMake build system according to the [Getting Started Guide](#), then OpenOCD is already installed. After [setting up the environment](#) in your terminal, you should be able to run OpenOCD. Check this by executing the following command:

```
openocd --version
```

The output should be as follows (although the version may be more recent than listed here):

```
Open On-Chip Debugger v0.10.0-esp32-20190708 (2019-07-08-11:04)
Licensed under GNU GPL v2
For bug reports, read
  https://openocd.org/doc/doxygen/bugs.html
```

You may also verify that OpenOCD knows where its configuration scripts are located by printing the value of OPENOCD\_SCRIPTS environment variable, by typing `echo $OPENOCD_SCRIPTS` (for Linux and macOS) or `echo %OPENOCD_SCRIPTS%` (for Windows). If a valid path is printed, then OpenOCD is set up correctly.

If any of these steps do not work, please go back to the [setting up the tools](#) section of the Getting Started Guide.

---

**Note:** It is also possible to build OpenOCD from source. Please refer to [Building OpenOCD from Sources](#) section for details.

---

#### 4.14.5 Configuring ESP32-C3 Target

Once OpenOCD is installed, you can proceed to configuring the ESP32-C3 target (i.e ESP32-C3 board with JTAG interface). Configuring the target is split into the following three steps:

- [Configure and connect JTAG interface](#)
- [Run OpenOCD](#)
- [Upload application for debugging](#)

##### Configure and connect JTAG interface

This step depends on the JTAG and ESP32-C3 board you are using (see the two cases described below).

**Configure ESP32-C3 built-in JTAG Interface** ESP32-C3 has a built-in JTAG circuitry and can be debugged without any additional chip. Only an USB cable connected to the D+/D- pins is necessary. The necessary connections are shown in the following section.

## Configure Hardware

Table 22: ESP32-C3 pins and USB signals

ESP32-C3 Pin	USB Signal
GPIO18	D-
GPIO19	D+
5V	V_BUS
GND	Ground

Please verify that the ESP32-C3 pins used for USB communication are not connected to some other HW that may disturb the JTAG operation.

**Configure USB Drivers** JTAG communication should work on all supported platforms. Windows users might get `LIBUSB_ERROR_NOT_FOUND` errors. Please use version 2.8 (or newer) of the [ESP-IDF Tools Installer](#) and select the driver “Espressif - WinUSB support for JTAG (ESP32-C3/S3)” in order to resolve this issue. If you don’t want to re-run the installer then the same can be achieved with `idf-env` by running the following command from PowerShell:

```
Invoke-WebRequest 'https://dl.espressif.com/dl/idf-env/idf-env.exe' -OutFile .\idf-
↪env.exe; .\idf-env.exe driver install --espressif
```

### Configure Other JTAG Interfaces

For guidance about which JTAG interface to select when using OpenOCD with ESP32-C3, refer to the section [Selecting JTAG Adapter](#). Then follow the configuration steps below to get it working.

**Configure eFuses** By default, ESP32-C3 JTAG interface is connected to the [built-in USB\\_SERIAL\\_JTAG peripheral](#). To use an external JTAG adapter instead, you need to switch the JTAG interface to the GPIO pins. This can be done by burning eFuses using `espefuse.py` tool.

Burning `DIS_USB_JTAG` eFuse will permanently disable the connection between `USB_SERIAL_JTAG` and the JTAG port of the CPU. JTAG interface can then be connected to GPIO4-GPIO7. Note that USB CDC functionality of `USB_SERIAL_JTAG` will still be usable, i.e., flashing and monitoring over USB CDC will still work.

**Warning:** Burning eFuses is an irreversible operation, so please consider the above option before starting the process.

### Configure Hardware

1. Identify all pins/signals on JTAG interface and ESP32-C3 board that should be connected to establish communication.

Table 23: ESP32-C3 pins and JTAG signals

ESP32-C3 Pin	JTAG Signal
MTDO / GPIO7	TDO
MTDI / GPIO5	TDI
MTCK / GPIO6	TCK
MTMS / GPIO4	TMS

2. Verify if ESP32-C3 pins used for JTAG communication are not connected to some other hardware that may disturb JTAG operation.
3. Connect identified pin/signals of ESP32-C3 and JTAG interface.

**Configure Drivers** You may need to install driver software to make JTAG work with computer. Refer to documentation of your JTAG adapter for related details.

**Connect** Connect JTAG interface to the computer. Power on ESP32-C3 and JTAG interface boards. Check if the JTAG interface is visible on the computer.

To carry on with debugging environment setup, proceed to section [Run OpenOCD](#).

### Run OpenOCD

Once target is configured and connected to computer, you are ready to launch OpenOCD.

Open a terminal and set it up for using the ESP-IDF as described in the [setting up the environment](#) section of the Getting Started Guide. Then run OpenOCD (this command works on Windows, Linux, and macOS):

```
openocd -f board/esp32c3-builtin.cfg
```

---

**Note:** The files provided after `-f` above are specific for ESP32-C3 through built-in USB connection. You may need to provide different files depending on the hardware that is used. For guidance see [Configuration of OpenOCD for specific target](#).

For example, `board/esp32c3-ftdi.cfg` can be used for a custom board with an FT2232H or FT232H chip used for JTAG connection, or with ESP-Prog.

---

You should now see similar output (this log is for ESP32-C3 through built-in USB connection):

```
user-name@computer-name:~/esp/esp-idf$ openocd -f board/esp32c3-builtin.cfg
Open On-Chip Debugger v0.10.0-esp32-20201202-26-g05a036c2 (2021-03-15-17:18)
Licensed under GNU GPL v2
For bug reports, read
  https://openocd.org/doc/doxygen/bugs.html
Info : only one transport option; autoselect 'jtag'
Warn : Transport "jtag" was already selected
force hard breakpoints
Info : Listening on port 6666 for tcl connections
Info : Listening on port 4444 for telnet connections
Info : esp_usb_jtag: Device found. Base speed 40000KHz, div range 1 to 255

Info : Listening on port 3333 for gdb connections
```

- If there is an error indicating permission problems, please see section on “Permissions delegation” in the OpenOCD README file located in the `~/esp/openocd-esp32` directory.
- In case there is an error in finding the configuration files, e.g. `Can't find board/esp32c3-builtin.cfg`, check if the `OPENOCD_SCRIPTS` environment variable is set correctly. This variable is used by OpenOCD to look for the files specified after the `-f` option. See [Setup of OpenOCD](#) section for details. Also check if the file is indeed under the provided path.
- If you see JTAG errors (e.g., `...all ones` or `...all zeroes`), please check your JTAG connections, whether other signals are connected to JTAG besides ESP32-C3's pins, and see if everything is powered on correctly.

### Upload application for debugging

Build and upload your application to ESP32-C3 as usual, see [Step 5. First Steps on ESP-IDF](#).

Another option is to write application image to flash using OpenOCD via JTAG with commands like this:

```
openocd -f board/esp32c3-builtin.cfg -c "program_esp filename.bin 0x10000 verify_  
↪exit"
```

OpenOCD flashing command `program_esp` has the following format:

```
program_esp <image_file> <offset> [verify] [reset] [exit]
```

- `image_file` - Path to program image file.
- `offset` - Offset in flash bank to write image.
- `verify` - Optional. Verify flash contents after writing.
- `reset` - Optional. Reset target after programing.
- `exit` - Optional. Finally exit OpenOCD.
- `compress` - Optional. Compress image file before programming.
- `encrypt` - Optional. Encrypt binary before writing to flash. Same functionality with `idf.py encrypted-flash`
- `no_clock_boost` - Optional. Disable setting target clock frequency to its maximum possible value before programming. Clock boost is enabled by default.
- `restore_clock` - Optional. Restore clock frequency to its initial value after programming. Disabled by default.

You are now ready to start application debugging. Follow the steps described in the section below.

### 4.14.6 Launching Debugger

The toolchain for ESP32-C3 features GNU Debugger, in short GDB. It is available with other toolchain programs under filename: `riscv32-esp-elf-gdb`. GDB can be called and operated directly from command line in a terminal. Another option is to call it from within IDE (like Eclipse, Visual Studio Code, etc.) and operate indirectly with help of GUI instead of typing commands in a terminal.

Both options of using debugger are discussed under links below.

- [Eclipse](#)
- [Command Line](#)

It is recommended to first check if debugger works from [Command Line](#) and then move to using [Eclipse](#).

### 4.14.7 Debugging Examples

This section is intended for users not familiar with GDB. It presents example debugging session from [Eclipse](#) using simple application available under [get-started/blink](#) and covers the following debugging actions:

1. [Navigating through the code, call stack and threads](#)
2. [Setting and clearing breakpoints](#)
3. [Halting the target manually](#)
4. [Stepping through the code](#)
5. [Checking and setting memory](#)
6. [Watching and setting program variables](#)
7. [Setting conditional breakpoints](#)

Similar debugging actions are provided using GDB from [Command Line](#).

Before proceeding to examples, set up your ESP32-C3 target and load it with [get-started/blink](#).

### 4.14.8 Building OpenOCD from Sources

Please refer to separate documents listed below, that describe build process.

## Building OpenOCD from Sources for Windows

**Note:** This document outlines how to build a binary of OpenOCD from its source files instead of downloading the pre-built binary. For a quick setup, users can download a pre-built binary of OpenOCD from [Espressif GitHub](#) instead of compiling it themselves (see [Setup of OpenOCD](#) for more details).

---

**Note:** All code snippets in this document are assumed to be running in an MSYS2 shell with the MINGW32 subsystem.

---

**Install Dependencies** Install packages that are required to compile OpenOCD:

```
pacman -S --noconfirm --needed autoconf automake git make \  
mingw-w64-i686-gcc \  
mingw-w64-i686-toolchain \  
mingw-w64-i686-libtool \  
mingw-w64-i686-pkg-config \  
mingw-w64-cross-winpthreads-git \  
p7zip
```

**Download Sources of OpenOCD** The sources for the ESP32-C3-enabled variant of OpenOCD are available from Espressif's GitHub under <https://github.com/espressif/openocd-esp32>. These source files can be pulled via Git using the following commands:

```
cd ~/esp  
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in ~/esp/openocd-esp32 directory.

**Downloading libusb** The libusb library is also required when building OpenOCD. The following commands will download a particular release of libusb and uncompress it to the current directory.

```
wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z  
7z x -olibusb ./libusb-1.0.22.7z
```

We now need to export the following variables such that the libusb library gets linked into the OpenOCD build.

```
export CPPFLAGS="$CPPFLAGS -I${PWD}/libusb/include/libusb-1.0"  
export LDFLAGS="$LDFLAGS -L${PWD}/libusb/MinGW32/.libs/dll"
```

**Build OpenOCD** The following commands will configure OpenOCD then build it.

```
cd ~/esp/openocd-esp32  
export CPPFLAGS="$CPPFLAGS -D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="  
↪$CFLAGS -Wno-error"  
./bootstrap  
./configure --disable-doxxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --  
↪build=i686-w64-mingw32 --host=i686-w64-mingw32  
make  
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src  
cp /opt/i686-w64-mingw32/bin/libwinpthread-1.dll ./src
```

Once the build is completed, the OpenOCD binary will be placed in `~/esp/openocd-esp32/src/`.

You can then optionally call `make install`. This will copy the OpenOCD binary to a user specified location.

- This location can be specified when OpenOCD is configured, or by setting `export DESTDIR="/custom/install/dir"` before calling `make install`.
- If you have an existing OpenOCD (from e.g. another development platform), you may want to skip this call as your existing OpenOCD may get overwritten.

---

**Note:**

- Should an error occur, resolve it and try again until the command `make` works.
  - If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
  - If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
  - If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
  - For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.Windows`.
  - Don't forget to copy `libusb-1.0.dll` and `libwinpthread-1.dll` into `OOCD_INSTALLDIR/bin` from `~/esp/openocd-esp32/src`.
- 

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src` directory.

**Full Listing** For greater convenience, all of commands called throughout the OpenOCD build process have been listed in the code snippet below. Users can copy this code snippet into a shell script then execute it:

```
pacman -S --noconfirm --needed autoconf automake git make mingw-w64-i686-gcc mingw-w64-i686-toolchain mingw-w64-i686-libtool mingw-w64-i686-pkg-config mingw-w64-cross-winpthreads-git p7zip
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git

wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z
export CPPFLAGS="$CPPFLAGS -I${PWD}/libusb/include/libusb-1.0"; export LDFLAGS="$LDFLAGS -L${PWD}/libusb/MinGW32/.libs/dll"

export CPPFLAGS="$CPPFLAGS -D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="$CFLAGS -Wno-error"
cd ~/esp/openocd-esp32
./bootstrap
./configure --disable-doxxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --build=i686-w64-mingw32 --host=i686-w64-mingw32
make
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src
cp /opt/i686-w64-mingw32/bin/libwinpthread-1.dll ./src

# # optional
# export DESTDIR="$PWD"
# make install
# cp ./src/libusb-1.0.dll $DESTDIR/mingw32/bin
# cp ./src/libwinpthread-1.dll $DESTDIR/mingw32/bin
```

**Next Steps** To carry on with debugging environment setup, proceed to section [Configuring ESP32-C3 Target](#).

## Building OpenOCD from Sources for Linux

The following instructions are alternative to downloading binary OpenOCD from [Espressif GitHub](#). To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section *Setup of OpenOCD*.

**Download Sources of OpenOCD** The sources for the ESP32-C3-enabled variant of OpenOCD are available from Espressif GitHub under <https://github.com/espressif/openocd-esp32>. To download the sources, use the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in `~/esp/openocd-esp32` directory.

**Install Dependencies** Install packages that are required to compile OpenOCD.

---

**Note:** Install the following packages one by one, check if installation was successful and then proceed to the next package. Resolve reported problems before moving to the next step.

---

```
sudo apt-get install make
sudo apt-get install libtool
sudo apt-get install pkg-config
sudo apt-get install autoconf
sudo apt-get install automake
sudo apt-get install texinfo
sudo apt-get install libusb-1.0
```

---

**Note:**

- Version of pkg-config should be 0.2.3 or above.
  - Version of autoconf should be 2.6.4 or above.
  - Version of automake should be 1.9 or above.
  - When using USB-Blaster, ASIX Presto, OpenJTAG and FT2232 as adapters, drivers libFTDI and FTD2XX need to be downloaded and installed.
  - When using CMSIS-DAP, HIDAPI is needed.
- 

**Build OpenOCD** Proceed with configuring and building OpenOCD:

```
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g. another development platform), as it may get overwritten.

---

**Note:**

- Should an error occur, resolve it and try again until the command `make` works.
- If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.

- If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
  - For details concerning compiling OpenOCD, please refer to `openocd-esp32/README`.
- 

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/openocd-esp32/bin` directory.

**Next Steps** To carry on with debugging environment setup, proceed to section [Configuring ESP32-C3 Target](#).

### Building OpenOCD from Sources for MacOS

The following instructions are alternative to downloading binary OpenOCD from [Espressif GitHub](#). To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section [Setup of OpenOCD](#).

**Download Sources of OpenOCD** The sources for the ESP32-C3-enabled variant of OpenOCD are available from Espressif GitHub under <https://github.com/espressif/openocd-esp32>. To download the sources, use the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in `~/esp/openocd-esp32` directory.

**Install Dependencies** Install packages that are required to compile OpenOCD using Homebrew:

```
brew install automake libtool libusb wget gcc@4.9 pkg-config
```

**Build OpenOCD** Proceed with configuring and building OpenOCD:

```
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g. another development platform), as it may get overwritten.

---

**Note:**

- Should an error occur, resolve it and try again until the command `make` works.
  - If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
  - If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
  - If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
  - For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.OSX`.
- 

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src/openocd` directory.

**Next Steps** To carry on with debugging environment setup, proceed to section [Configuring ESP32-C3 Target](#).

The examples of invoking OpenOCD in this document assume using pre-built binary distribution described in section [Setup of OpenOCD](#).

To use binaries build locally from sources, change the path to OpenOCD executable to `src/openocd` and set the `OPENOCD_SCRIPTS` environment variable so that OpenOCD can find the configuration files. For Linux and macOS:

```
cd ~/esp/openocd-esp32
export OPENOCD_SCRIPTS=$PWD/tcl
```

For Windows:

```
cd %USERPROFILE%\esp\openocd-esp32
set "OPENOCD_SCRIPTS=%CD%\tcl"
```

Example of invoking OpenOCD build locally from sources, for Linux and macOS:

```
src/openocd -f board/esp32c3-builtin.cfg
```

and Windows:

```
src\openocd -f board/esp32c3-builtin.cfg
```

## 4.14.9 Tips and Quirks

This section provides collection of links to all tips and quirks referred to from various parts of this guide.

### Tips and Quirks

This section provides collection of all tips and quirks referred to from various parts of this guide.

**Breakpoints and watchpoints available** ESP32-C3 debugger supports 8 hardware implemented breakpoints and 64 software ones. Hardware breakpoints are implemented by ESP32-C3 chip's logic and can be set anywhere in the code: either in flash or IRAM program's regions. Additionally there are 2 types of software breakpoints implemented by OpenOCD: flash (up to 32) and IRAM (up to 32) breakpoints. Currently GDB can not set software breakpoints in flash. So until this limitation is removed those breakpoints have to be emulated by OpenOCD as hardware ones (see [below](#) for details). ESP32-C3 also supports 8 watchpoints, so 8 variables can be watched for change or read by the GDB command `watch myVariable`. Note that menuconfig option [CONFIG\\_FREERTOS\\_WATCHPOINT\\_END\\_OF\\_STACK](#) uses the last watchpoint and will not provide expected results, if you also try to use it within OpenOCD / GDB. See menuconfig's help for detailed description.

**What else should I know about breakpoints?** Emulating part of hardware breakpoints using software flash ones means that the GDB command `hb myFunction` which is invoked for function in flash will use pure hardware breakpoint if it is available otherwise one of the 32 software flash breakpoints is used. The same rule applies to `b myFunction`-like commands. In this case GDB will decide what type of breakpoint to set itself. If `myFunction` is resided in writable region (IRAM) software IRAM breakpoint will be used otherwise hardware or software flash breakpoint is used as it is done for `hb` command.

**Flash Mappings vs SW Flash Breakpoints** In order to set/clear software breakpoints in flash, OpenOCD needs to know their flash addresses. To accomplish conversion from the ESP32-C3 address space to the flash one, OpenOCD uses mappings of program's code regions resided in flash. Those mappings are kept in the image header which is prepended to program binary data (code and data segments) and is specific to every application image written to the flash. So to support software flash breakpoints OpenOCD should know where application image under debugging is

resided in the flash. By default OpenOCD reads partition table at 0x8000 and uses mappings from the first found application image, but there can be the cases when it will not work, e.g. partition table is not at standard flash location or even there can be multiple images: one factory and two OTA and you may want to debug any of them. To cover all possible debugging scenarios OpenOCD supports special command which can be used to set arbitrary location of application image to debug. The command has the following format:

```
esp appimage_offset <offset>
```

Offset should be in hex format. To reset to the default behaviour you can specify `-1` as offset.

---

**Note:** Since GDB requests memory map from OpenOCD only once when connecting to it, this command should be specified in one of the TCL configuration files, or passed to OpenOCD via its command line. In the latter case command line should look like below:

```
openocd -f board/esp32c3-builtin.cfg -c "init; halt; esp appimage_offset 0x210000"
```

Another option is to execute that command via OpenOCD telnet session and then connect GDB, but it seems to be less handy.

---

**Why stepping with “next” does not bypass subroutine calls?** When stepping through the code with `next` command, GDB is internally setting a breakpoint ahead in the code to bypass the subroutine calls. If all 8 breakpoints are already set, this functionality will not work. If this is the case, delete breakpoints to have one “spare”. With all breakpoints already used, stepping through the code with `next` command will work as like with `step` command and debugger will step inside subroutine calls.

**Support options for OpenOCD at compile time** ESP-IDF has some support options for OpenOCD debugging which can be set at compile time:

- `CONFIG_ESP_DEBUG_OCDAWARE` is enabled by default. If a panic or unhandled exception is thrown and a JTAG debugger is connected (ie OpenOCD is running), ESP-IDF will break into the debugger.
- `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` (disabled by default) sets watchpoint index 1 (the second of two) at the end of any task stack. This is the most accurate way to debug task stack overflows. Click the link for more details.

Please see the [project configuration menu](#) menu for more details on setting compile-time options.

**FreeRTOS support** OpenOCD has explicit support for the ESP-IDF FreeRTOS. GDB can see FreeRTOS tasks as threads. Viewing them all can be done using the GDB `i threads` command, changing to a certain task is done with `thread n`, with `n` being the number of the thread. FreeRTOS detection can be disabled in target’s configuration. For more details see [Configuration of OpenOCD for specific target](#).

**Optimize JTAG speed** In order to achieve higher data rates and minimize number of dropped packets it is recommended to optimize setting of JTAG clock frequency, so it is at maximum and still provides stable operation of JTAG. To do so use the following tips.

1. The upper limit of JTAG clock frequency is 20 MHz if CPU runs at 80 MHz, or 26 MHz if CPU runs at 160 MHz or 240 MHz.
2. Depending on particular JTAG adapter and the length of connecting cables, you may need to reduce JTAG frequency below 20 / 26 MHz.
3. In particular reduce frequency, if you get DSR/DIR errors (and they do not relate to OpenOCD trying to read from a memory range without physical memory being present there).
4. ESP-WROVER-KIT operates stable at 20 / 26 MHz.

**What is the meaning of debugger’s startup commands?** On startup, debugger is issuing sequence of commands to reset the chip and halt it at specific line of code. This sequence (shown below) is user defined to pick up at most convenient / appropriate line and start debugging.

- `set remote hardware-watchpoint-limit 8` —Restrict GDB to using available hardware watchpoints supported by the chip, 8 for ESP32-C3. For more information see <https://sourceware.org/gdb/onlinedocs/gdb/Remote-Configuration.html>.
- `mon reset halt` —reset the chip and keep the CPUs halted
- `flushregs` —monitor (`mon`) command can not inform GDB that the target state has changed. GDB will assume that whatever stack the target had before `mon reset halt` will still be valid. In fact, after reset the target state will change, and executing `flushregs` is a way to force GDB to get new state from the target.
- `thb app_main` —insert a temporary hardware breakpoint at `app_main`, put here another function name if required
- `c` —resume the program. It will then stop at breakpoint inserted at `app_main`.

**Configuration of OpenOCD for specific target** There are several kinds of OpenOCD configuration files (\*.cfg). All configuration files are located in subdirectories of `share/openocd/scripts` directory of OpenOCD distribution (or `tcl/scripts` directory of the source repository). For the purposes of this guide, the most important ones are `board`, `interface` and `target`.

- `interface` configuration files describe the JTAG adapter. Examples of JTAG adapters are ESP-Prog and J-Link.
- `target` configuration files describe specific chips, or in some cases, modules.
- `board` configuration files are provided for development boards with a built-in JTAG adapter. Such files include an `interface` configuration file to choose the adapter, and `target` configuration file to choose the chip/module.

The following configuration files are available for ESP32-C3:

Table 24: OpenOCD configuration files for ESP32-C3

Name	Description
<code>board/esp32c3-builtin.cfg</code>	Board configuration file for ESP32-C3 through built-in USB, includes target and adapter configuration.
<code>board/esp32c3-ftdi.cfg</code>	Board configuration file for ESP32-C3 debug through an ESP-Prog compatible FTDI, includes target and adapter configuration.
<code>target/esp32c3.cfg</code>	ESP32-C3 target configuration file. Can be used together with one of the <code>interface/</code> configuration files.
<code>interface/esp_usb_jtag.cfg</code>	JTAG adapter configuration file for ESP32-C3.
<code>interface/ftdi/esp32_devkitj_v1.cfg</code>	JTAG adapter configuration file for ESP-Prog boards.

If you are using one of the boards which have a pre-defined configuration file, you only need to pass one `-f` argument to OpenOCD, specifying that file.

If you are using a board not listed here, you need to specify both the interface configuration file and target configuration file.

**Custom configuration files** OpenOCD configuration files are written in TCL, and include a variety of choices for customization and scripting. This can be useful for non-standard debugging situations. Please refer to [OpenOCD Manual](#) for the TCL scripting reference.

**OpenOCD configuration variables** The following variables can be optionally set before including the ESP-specific target configuration file. This can be done either in a custom configuration file, or from the command line.

The syntax for setting a variable in TCL is:

```
set VARIABLE_NAME value
```

To set a variable from the command line (replace the name of .cfg file with the correct file for your board):

```
openocd -c 'set VARIABLE_NAME value' -f board/esp-xxxxx-kit.cfg
```

It is important to set the variable before including the ESP-specific configuration file, otherwise the variable will not have effect. You can set multiple variables by repeating the `-c` option.

Table 25: Common ESP-related OpenOCD variables

Variable	Description
ESP_RTOS	Set to <code>none</code> to disable RTOS support. In this case, thread list will not be available in GDB. Can be useful when debugging FreeRTOS itself, and stepping through the scheduler code.
ESP_FLASH_SIZE	Set to <code>0</code> to disable Flash breakpoints support.
ESP_SEMIHOST_BASEDIR	Set to the path (on the host) which will be the default directory for semihosting functions.
ESP_ONLYCPU	For multi-core targets, can be set to <code>1</code> to only enable single core debugging.

**How debugger resets ESP32-C3?** The board can be reset by entering `mon reset` or `mon reset halt` into GDB.

**Do not use JTAG pins for something else** Operation of JTAG may be disturbed, if some other h/w is connected to JTAG pins besides ESP32-C3 module and JTAG adapter. ESP32-C3 JTAG is using the following pins:

Table 26: ESP32-C3 pins and JTAG signals

ESP32-C3 Pin	JTAG Signal
MTDO / GPIO7	TDO
MTDI / GPIO5	TDI
MTCK / GPIO6	TCK
MTMS / GPIO4	TMS

JTAG communication will likely fail, if configuration of JTAG pins is changed by user application. If OpenOCD initializes correctly (detects the two Tensilica cores), but loses sync and spews out a lot of DTR/DIR errors when the program is ran, it is likely that the application reconfigures the JTAG pins to something else, or the user forgot to connect Vtar to a JTAG adapter that needed it.

Below is an excerpt from series of errors reported by GDB after the application stepped into the code that reconfigured MTDO pin to be an input:

```
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates target still busy!
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated.
↳an exception!
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated.
↳an overrun!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates target still busy!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated.
↳an exception!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated.
↳an overrun!
```

**JTAG with Flash Encryption or Secure Boot** By default, enabling Flash Encryption and/or Secure Boot will disable JTAG debugging. On first boot, the bootloader will burn an eFuse bit to permanently disable JTAG at the same time it enables the other features.

The project configuration option `CONFIG_SECURE_BOOT_ALLOW_JTAG` will keep JTAG enabled at this time, removing all physical security but allowing debugging. (Although the name suggests Secure Boot, this option can be applied even when only Flash Encryption is enabled).

However, OpenOCD may attempt to automatically read and write the flash in order to set *software breakpoints*. This has two problems:

- Software breakpoints are incompatible with Flash Encryption, OpenOCD currently has no support for encrypting or decrypting flash contents.
- If Secure Boot is enabled, setting a software breakpoint will change the digest of a signed app and make the signature invalid. This means if a software breakpoint is set and then a reset occurs, the signature verification will fail on boot.

To disable software breakpoints while using JTAG, add an extra argument `-c 'set ESP_FLASH_SIZE 0'` to the start of the OpenOCD command line, see *OpenOCD configuration variables*.

---

**Note:** For the same reason, the ESP-IDF app may fail bootloader verification of app signatures, when this option is enabled and a software breakpoint is set.

---

**Reporting issues with OpenOCD / GDB** In case you encounter a problem with OpenOCD or GDB programs itself and do not find a solution searching available resources on the web, open an issue in the OpenOCD issue tracker under <https://github.com/espressif/openocd-esp32/issues>.

1. In issue report provide details of your configuration:
  - a. JTAG adapter type, and the chip/module being debugged.
  - b. Release of ESP-IDF used to compile and load application that is being debugged.
  - c. Details of OS used for debugging.
  - d. Is OS running natively on a PC or on a virtual machine?
2. Create a simple example that is representative to observed issue. Describe steps how to reproduce it. In such an example debugging should not be affected by non-deterministic behaviour introduced by the Wi-Fi stack, so problems will likely be easier to reproduce, if encountered once.
3. Prepare logs from debugging session by adding additional parameters to start up commands.  
OpenOCD:

```
openocd -l openocd_log.txt -d3 -f board/esp32c3-builtin.cfg
```

Logging to a file this way will prevent information displayed on the terminal. This may be a good thing taken amount of information provided, when increased debug level `-d3` is set. If you still like to see the log on the screen, then use another command instead:

```
openocd -d3 -f board/esp32c3-builtin.cfg 2>&1 | tee openocd.log
```

Debugger:

```
riscv32-esp-elf-gdb -ex "set remotelogfile gdb_log.txt" <all other options>
```

Optionally add command `remotelogfile gdb_log.txt` to the `gdbinit` file.

4. Attach both `openocd_log.txt` and `gdb_log.txt` files to your issue report.

## 4.14.10 Related Documents

### Using Debugger

This section covers configuration and running debugger using several methods:

- from *Eclipse*
- from *Command Line*
- using *idf.py debug targets*

## Eclipse

**Note:** It is recommended to first check if debugger works using *idf.py debug targets* or from *Command Line* and then move to using Eclipse.

Debugging functionality is provided out of box in standard Eclipse installation. Another option is to use pluggins like “GDB Hardware Debugging” plugin. We have found this plugin quite convenient and decided to use throughout this guide.

To begin with, install “GDB Hardware Debugging” plugin by opening Eclipse and going to *Help > Install New Software*.

Once installation is complete, configure debugging session following steps below. Please note that some of configuration parameters are generic and some are project specific. This will be shown below by configuring debugging for “blink” example project. If not done already, add this project to Eclipse workspace following guidance in [Eclipse Plugin](#). The source of [get-started/blink](#) application is available in [examples](#) directory of ESP-IDF repository.

1. In Eclipse go to *Run > Debug Configuration*. A new window will open. In the window’s left pane double click “GDB Hardware Debugging” (or select “GDB Hardware Debugging” and press the “New” button) to create a new configuration.
2. In a form that will show up on the right, enter the “Name:” of this configuration, e.g. “Blink checking” .
3. On the “Main” tab below, under “Project:” , press “Browse” button and select the “blink” project.
4. In next line “C/C++ Application:” press “Browse” button and select “blink.elf” file. If “blink.elf” is not there, then likely this project has not been build yet. See [Eclipse Plugin](#) how to do it.
5. Finally, under “Build (if required) before launching” click “Disable auto build” .  
A sample window with settings entered in points 1 - 5 is shown below.

Fig. 58: Configuration of GDB Hardware Debugging - Main tab

6. Click “Debugger” tab. In field “GDB Command” enter `riscv32-esp-elf-gdb` to invoke debugger.
7. Change default configuration of “Remote host” by entering `3333` under the “Port number” .  
Configuration entered in points 6 and 7 is shown on the following picture.

Fig. 59: Configuration of GDB Hardware Debugging - Debugger tab

8. The last tab to that requires changing of default configuration is “Startup”. Under “Initialization Commands” uncheck “Reset and Delay (seconds)” and “Halt”. Then, in entry field below, enter the following lines:

```
mon reset halt
flushregs
set remote hardware-watchpoint-limit 2
```

**Note:** If you want to update image in the flash automatically before starting new debug session add the following lines of commands at the beginning of “Initialization Commands” textbox:

```
mon reset halt
mon program_esp ${workspace_loc:blink/build/blink.bin} 0x10000 verify
```

For description of `program_esp` command see [Upload application for debugging](#).

9. Under “Load Image and Symbols” uncheck “Load image” option.
10. Further down on the same tab, establish an initial breakpoint to halt CPUs after they are reset by debugger. The plugin will set this breakpoint at the beginning of the function entered under “Set break point at:”. Checkout this option and enter `app_main` in provided field.
11. Checkout “Resume” option. This will make the program to resume after `mon reset halt` is invoked per point 8. The program will then stop at breakpoint inserted at `app_main`. Configuration described in points 8 - 11 is shown below.

Fig. 60: Configuration of GDB Hardware Debugging - Startup tab

If the “Startup” sequence looks convoluted and respective “Initialization Commands” are not clear to you, check [What is the meaning of debugger’s startup commands?](#) for additional explanation.

- If you previously completed *Configuring ESP32-C3 Target* steps described above, so the target is running and ready to talk to debugger, go right to debugging by pressing “Debug” button. Otherwise press “Apply” to save changes, go back to *Configuring ESP32-C3 Target* and return here to start debugging.

Once all 1 - 12 configuration steps are satisfied, the new Eclipse perspective called “Debug” will open as shown on example picture below.

Fig. 61: Debug Perspective in Eclipse

If you are not quite sure how to use GDB, check *Eclipse* example debugging session in section *Debugging Examples*.

### Command Line

- Begin with completing steps described under *Configuring ESP32-C3 Target*. This is prerequisite to start a debugging session.
- Open a new terminal session and go to directory that contains project for debugging, e.g.

```
cd ~/esp/blink
```

- When launching a debugger, you will need to provide couple of configuration parameters and commands. Instead of entering them one by one in command line, create a configuration file and name it `gdbinit`:

```
target remote :3333
set remote hardware-watchpoint-limit 2
mon reset halt
flushregs
thb app_main
c
```

Save this file in current directory.

For more details what's inside `gdbinit` file, see *What is the meaning of debugger's startup commands?*

4. Now you are ready to launch GDB. Type the following in terminal:

```
riscv32-esp-elf-gdb -x gdbinit build/blink.elf
```

5. If previous steps have been done correctly, you will see a similar log concluded with (gdb) prompt:

```
user-name@computer-name:~/esp/blink$ riscv32-esp-elf-gdb -x gdbinit build/
↳blink.elf
GNU gdb (crosstool-NG crosstool-ng-1.22.0-61-gab8375a) 7.10

Temporary breakpoint 1, app_main () at /home/user-name/esp/blink/main/./blink.
↳c:43
43      xTaskCreate(&blink_task, "blink_task", 512, NULL, 5, NULL);
(gdb)
```

Note the third line from bottom that shows debugger halting at breakpoint established in `gdbinit` file at function `app_main()`. Since the processor is halted, the LED should not be blinking. If this is what you see as well, you are ready to start debugging.

If you are not quite sure how to use GDB, check [Command Line](#) example debugging session in section [Debugging Examples](#).

**idf.py debug targets** It is also possible to execute the described debugging tools conveniently from `idf.py`. These commands are supported:

1. `idf.py openocd`  
Runs OpenOCD in a console with configuration defined in the environment or via command line. It uses default script directory defined as `OPENOCD_SCRIPTS` environmental variable, which is automatically added from an Export script (`export.sh` or `export.bat`). It is possible to override the script location using command line argument `--openocd-scripts`.  
As for the JTAG configuration of the current board, please use the environmental variable `OPENOCD_COMMANDS` or `--openocd-commands` command line argument. If none of the above is defined, OpenOCD is started with `-f board/esp32c3-builtin.cfg` board definition.
2. `idf.py gdb`  
Starts the gdb the same way as the *Command Line*, but generates the initial gdb scripts referring to the current project elf file.
3. `idf.py gdbtui`  
The same as 2, but starts the gdb with `tui` argument allowing very simple source code view.
4. `idf.py gdbgui`  
Starts `gdbgui` debugger frontend enabling out-of-the-box debugging in a browser window. Please run the install script with the `--enable-gdbgui` argument in order to make this option supported, e.g. `install.sh --enable-gdbgui`.  
It is possible to combine these debugging actions on a single command line allowing convenient setup of blocking and non-blocking actions in one step. `idf.py` implements a simple logic to move the background actions (such as `openocd`) to the beginning and the interactive ones (such as `gdb`, `monitor`) to the end of the action list. An example of a very useful combination is:

```
idf.py openocd gdbgui monitor
```

The above command runs OpenOCD in the background, starts `gdbgui` to open a browser window with active debugger frontend and opens a serial monitor in the active console.

## Debugging Examples

This section describes debugging with GDB from *Eclipse* as well as from *Command Line*.

**Eclipse** Verify if your target is ready and loaded with `get-started/blink` example. Configure and start debugger following steps in section *Eclipse*. Pick up where target was left by debugger, i.e. having the application halted at breakpoint established at `app_main()`.

### Examples in this section

1. *Navigating through the code, call stack and threads*
2. *Setting and clearing breakpoints*
3. *Halting the target manually*
4. *Stepping through the code*
5. *Checking and setting memory*
6. *Watching and setting program variables*
7. *Setting conditional breakpoints*

**Navigating through the code, call stack and threads** When the target is halted, debugger shows the list of threads in “Debug” window. The line of code where program halted is highlighted in another window below, as shown on the following picture. The LED stops blinking.

Specific thread where the program halted is expanded showing the call stack. It represents function calls that lead up to the highlighted line of code, where the target halted. The first line of call stack under Thread #1 contains the last called function `app_main()`, that in turn was called from function `main_task()` shown in a line below. Each

Fig. 62: Debug Perspective in Eclipse

Fig. 63: Target halted during debugging

line of the stack also contains the file name and line number where the function was called. By clicking / highlighting the stack entries, in window below, you will see contents of this file.

By expanding threads you can navigate throughout the application. Expand Thread #5 that contains much longer call stack. You will see there, besides function calls, numbers like `0x4000000c`. They represent addresses of binary code not provided in source form.

Fig. 64: Navigate through the call stack

In another window on right, you can see the disassembled machine code no matter if your project provides it in source or only the binary form.

Go back to the `app_main()` in Thread #1 to familiar code of `blink.c` file that will be examined in more details in the following examples. Debugger makes it easy to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

**Setting and clearing breakpoints** When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers / peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let's establish two breakpoints when the state of LED changes. Basing on code listing above, this happens at lines 33 and 36. To do so, hold the "Control" on the keyboard and double click on number 33 in file `blink.c` file. A dialog will open where you can confirm your selection by pressing "OK" button. If you do not like to see the dialog just double click the line number. Set another breakpoint in line 36.

Information how many breakpoints are set and where is shown in window "Breakpoints" on top right. Click "Show Breakpoints Supported by Selected Target" to refresh this list. Besides the two just set breakpoints the list may contain temporary breakpoint at function `app_main()` established at debugger start. As maximum two breakpoints are allowed (see [Breakpoints and watchpoints available](#)), you need to delete it, or debugging will fail.

Fig. 65: Setting a breakpoint

Fig. 66: Three breakpoints are set / maximum two are allowed

If you now click “Resume” (click `blink_task()` under “Tread #8”, if “Resume” button is grayed out), the processor will run and halt at a breakpoint. Clicking “Resume” another time will make it run again, halt on second breakpoint, and so on.

You will be also able to see that LED is changing the state after each click to “Resume” program execution.

Read more about breakpoints under [Breakpoints and watchpoints available](#) and [What else should I know about breakpoints?](#)

**Halting the target manually** When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any break points defined. In such case, to go back to debugging mode, you can break program execution manually by pressing “Suspend” button.

To check it, delete all breakpoints and click “Resume”. Then click “Suspend”. Application will be halted at some random point and LED will stop blinking. Debugger will expand tread and highlight the line of code where application halted.

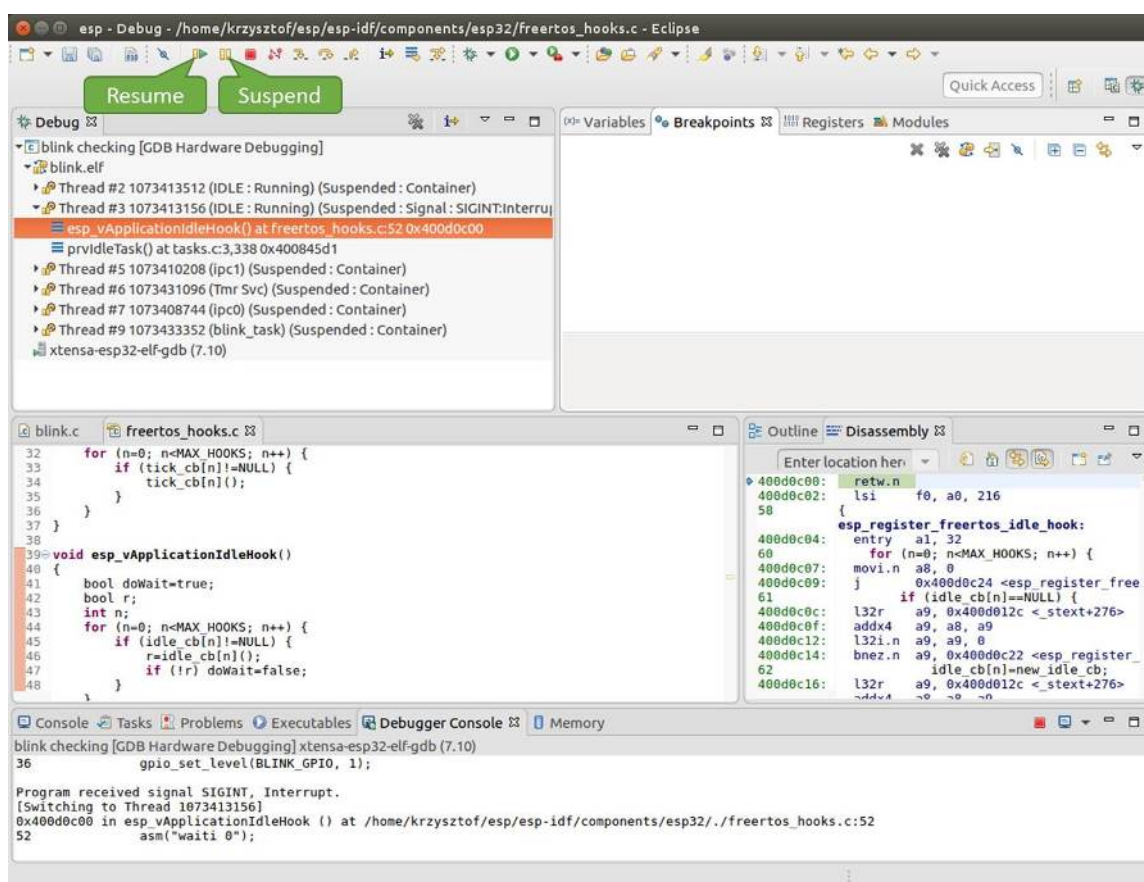

Fig. 67: Target halted manually

In particular case above, the application has been halted in line 52 of code in file `freertos_hooks.c`. Now you can resume it again by pressing “Resume” button or do some debugging as discussed below.

**Stepping through the code** It is also possible to step through the code using “Step Into (F5)” and “Step Over (F6)” commands. The difference is that “Step Into (F5)” is entering inside subroutines calls, while “Step Over (F6)” steps over the call, treating it as a single source line.

Before being able to demonstrate this functionality, using information discussed in previous paragraph, make sure that you have only one breakpoint defined at line 36 of `blink.c`.

Resume program by entering pressing F8 and let it halt. Now press “Step Over (F6)”, one by one couple of times, to see how debugger is stepping one program line at a time.

Fig. 68: Stepping through the code with “Step Over (F6)”

If you press “Step Into (F5)” instead, then debugger will step inside subroutine calls.

Fig. 69: Stepping through the code with “Step Into (F5)”

In this particular case debugger stepped inside `gpio_set_level(BLINK_GPIO, 0)` and effectively moved to `gpio.c` driver code.

See *Why stepping with “next” does not bypass subroutine calls?* for potential limitation of using `next` command.

**Checking and setting memory** To display or set contents of memory use “Memory” tab at the bottom of “Debug” perspective.

With the “Memory” tab, we will read from and write to the memory location `0x3FF44004` labeled as `GPIO_OUT_REG` used to set and clear individual GPIO’s.

For more information, see *ESP32-C3 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO\_MUX)* [PDF].

Being in the same `blink.c` project as before, set two breakpoints right after `gpio_set_level` instruction. Click “Memory” tab and then “Add Memory Monitor” button. Enter `0x3FF44004` in provided dialog.

Now resume program by pressing F8 and observe “Monitor” tab.

You should see one bit being flipped over at memory location `0x3FF44004` (and LED changing the state) each time F8 is pressed.

To set memory use the same “Monitor” tab and the same memory location. Type in alternate bit pattern as previously observed. Immediately after pressing enter you will see LED changing the state.

**Watching and setting program variables** A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file `blink.c` by adding a declaration of

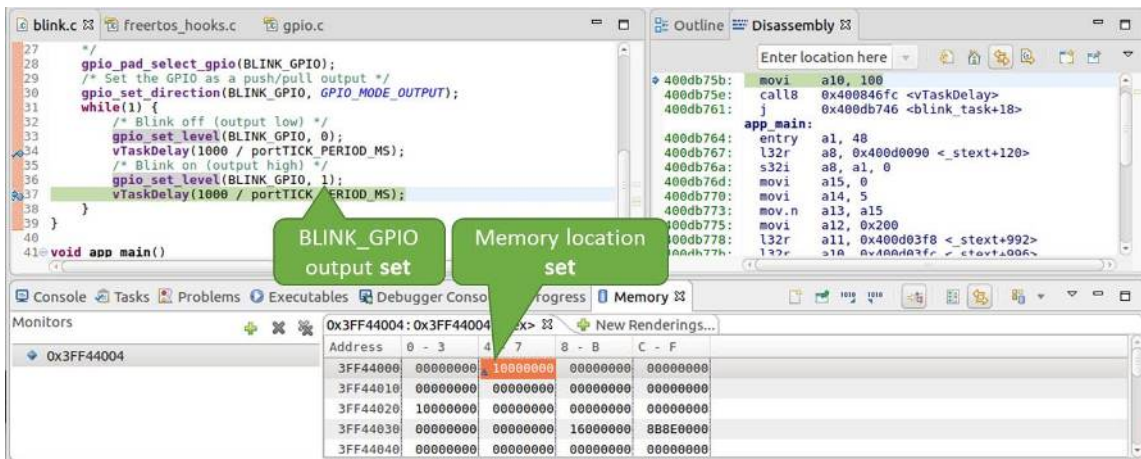

Fig. 70: Observing memory location 0x3FF44004 changing one bit to “ON”

Fig. 71: Observing memory location 0x3FF44004 changing one bit to “OFF”

a global variable `int i` above definition of function `blink_task`. Then add `i++` inside `while(1)` of this function to get `i` incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter a breakpoint in the line where you put `i++`.

In next step, in the window with “Breakpoints”, click the “Expressions” tab. If this tab is not visible, then add it by going to the top menu `Window > Show View > Expressions`. Then click “Add new expression” and enter `i`.

Resume program execution by pressing `F8`. Each time the program is halted you will see `i` value being incremented.

Fig. 72: Watching program variable “i”

To modify `i` enter a new number in “Value” column. After pressing “Resume (`F8`)” the program will keep incrementing `i` starting from the new entered number.

**Setting conditional breakpoints** Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Right click on the breakpoint to open a context menu and select “Breakpoint Properties”. Change the selection under “Type:” to “Hardware” and enter a “Condition:” like `i == 2`.

If current value of `i` is less than 2 (change it if required) and program is resumed, it will blink LED in a loop until condition `i == 2` gets true and then finally halt.

**Command Line** Verify if your target is ready and loaded with [get-started/blink](#) example. Configure and start debugger following steps in section [Command Line](#). Pick up where target was left by debugger, i.e. having the application halted at breakpoint established at `app_main()`:

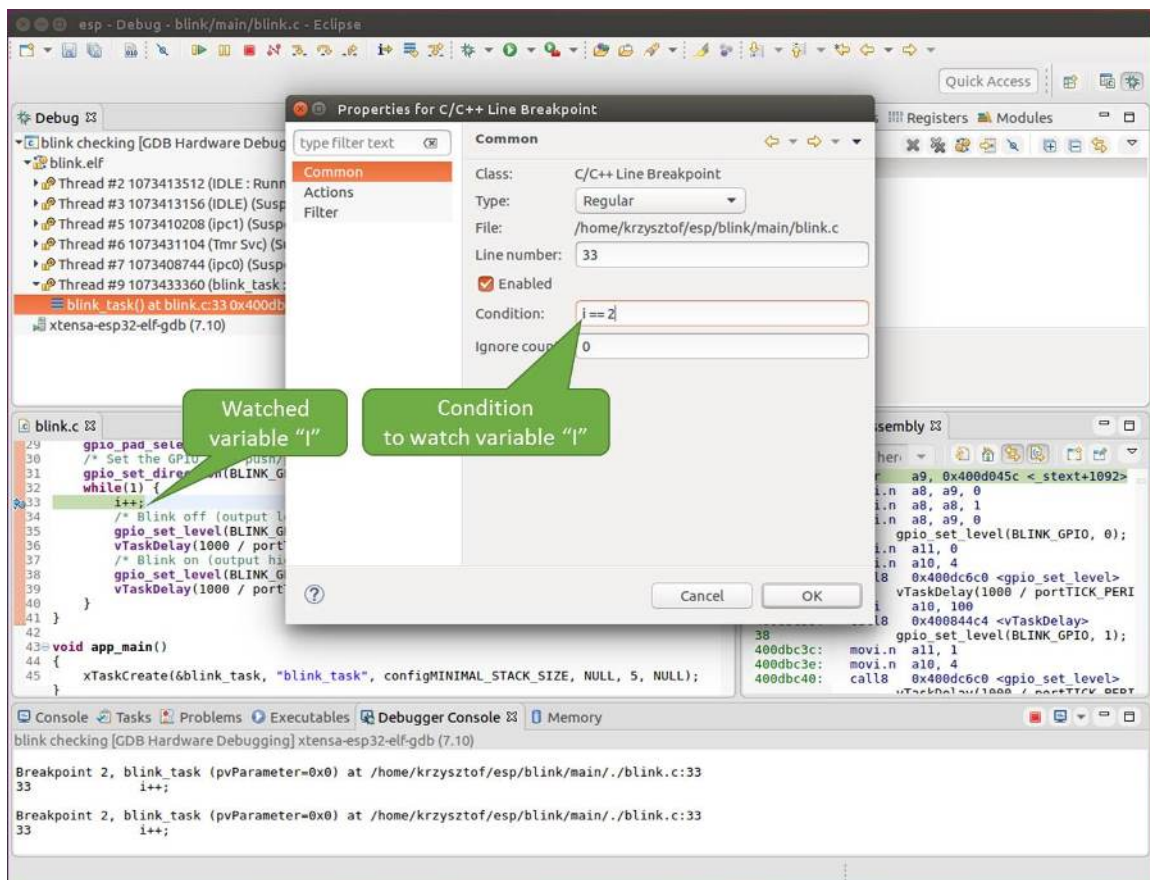

Fig. 73: Setting a conditional breakpoint

```
Temporary breakpoint 1, app_main () at /home/user-name/esp/blink/main/./blink.c:43
43     xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5, &
↳NULL);
(gdb)
```

### Examples in this section

1. *Navigating through the code, call stack and threads*
2. *Setting and clearing breakpoints*
3. *Halting and resuming the application*
4. *Stepping through the code*
5. *Checking and setting memory*
6. *Watching and setting program variables*
7. *Setting conditional breakpoints*

**Navigating through the code, call stack and threads** When you see the (gdb) prompt, the application is halted. LED should not be blinking.

To find out where exactly the code is halted, enter `l` or `list`, and debugger will show couple of lines of code around the halt point (line 43 of code in file `blink.c`)

```
(gdb) l
38     }
39 }
40
41 void app_main()
42 {
43     xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5, &
↳NULL);
44 }
(gdb)
```

Check how code listing works by entering, e.g. `l 30, 40` to see particular range of lines of code.

You can use `bt` or `backtrace` to see what function calls lead up to this code:

```
(gdb) bt
#0 app_main () at /home/user-name/esp/blink/main/./blink.c:43
#1 0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/
↳esp32c3/./cpu_start.c:339
(gdb)
```

Line #0 of output provides the last function call before the application halted, i.e. `app_main ()` we have listed previously. The `app_main ()` was in turn called by function `main_task` from line 339 of code located in file `cpu_start.c`.

To get to the context of `main_task` in file `cpu_start.c`, enter `frame N`, where `N = 1`, because the `main_task` is listed under #1):

```
(gdb) frame 1
#1 0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/
↳esp32c3/./cpu_start.c:339
339     app_main();
(gdb)
```

Enter `l` and this will reveal the piece of code that called `app_main ()` (in line 339):

```
(gdb) l
334     ;
335 }
```

(continues on next page)

(continued from previous page)

```

336 #endif
337     //Enable allocation in region where the startup stacks were located.
338     heap_caps_enable_nonos_stack_heaps();
339     app_main();
340     vTaskDelete(NULL);
341 }
342
(gdb)

```

By listing some lines before, you will see the function name `main_task` we have been looking for:

```

(gdb) l 326, 341
326 static void main_task(void* args)
327 {
328     // Now that the application is about to start, disable boot watchdogs
329     REG_CLR_BIT(TIMG_WDTCONFIG0_REG(0), TIMG_WDT_FLASHBOOT_MOD_EN_S);
330     REG_CLR_BIT(RTC_CNTL_WDTCONFIG0_REG, RTC_CNTL_WDT_FLASHBOOT_MOD_EN);
331 #if !CONFIG_FREERTOS_UNICORE
332     // Wait for FreeRTOS initialization to finish on APP CPU, before replacing
↳ its startup stack
333     while (port_xSchedulerRunning[1] == 0) {
334         ;
335     }
336 #endif
337     //Enable allocation in region where the startup stacks were located.
338     heap_caps_enable_nonos_stack_heaps();
339     app_main();
340     vTaskDelete(NULL);
341 }
(gdb)

```

To see the other code, enter `i threads`. This will show the list of threads running on target:

```

(gdb) i threads
Id   Target Id           Frame
  8   Thread 1073411336 (dport) 0x400d0848 in dport_access_init_core (arg=
↳ <optimized out>)
    at /home/user-name/esp/esp-idf/components/esp32c3/./dport_access.c:170
  7   Thread 1073408744 (ipc0) xQueueGenericReceive (xQueue=0x3ffae694,
↳ pvBuffer=0x0, xTicksToWait=1644638200,
    xJustPeeking=0) at /home/user-name/esp/esp-idf/components/freertos/./queue.
↳ c:1452
  6   Thread 1073431096 (Tmr Svc) prvTimerTask (pvParameters=0x0)
    at /home/user-name/esp/esp-idf/components/freertos/./timers.c:445
  5   Thread 1073410208 (ipc1 : Running) 0x4000bfea in ?? ()
  4   Thread 1073432224 (dport) dport_access_init_core (arg=0x0)
    at /home/user-name/esp/esp-idf/components/esp32c3/./dport_access.c:150
  3   Thread 1073413156 (IDLE) prvIdleTask (pvParameters=0x0)
    at /home/user-name/esp/esp-idf/components/freertos/./tasks.c:3282
  2   Thread 1073413512 (IDLE) prvIdleTask (pvParameters=0x0)
    at /home/user-name/esp/esp-idf/components/freertos/./tasks.c:3282
* 1   Thread 1073411772 (main : Running) app_main () at /home/user-name/esp/blink/
↳ main/./blink.c:43
(gdb)

```

The thread list shows the last function calls per each thread together with the name of C source file if available.

You can navigate to specific thread by entering `thread N`, where `N` is the thread Id. To see how it works go to thread thread 5:

```
(gdb) thread 5
```

(continues on next page)

(continued from previous page)

```
[Switching to thread 5 (Thread 1073410208)]
#0 0x4000bfea in ?? ()
(gdb)
```

Then check the backtrace:

```
(gdb) bt
#0 0x4000bfea in ?? ()
#1 0x40083a85 in vPortCPUReleaseMutex (mux=<optimized out>) at /home/user-name/
↳esp/esp-idf/components/freertos/./port.c:415
#2 0x40083fc8 in vTaskSwitchContext () at /home/user-name/esp/esp-idf/components/
↳freertos/./tasks.c:2846
#3 0x4008532b in _frxt_dispatch ()
#4 0x4008395c in xPortStartScheduler () at /home/user-name/esp/esp-idf/components/
↳freertos/./port.c:222
#5 0x4000000c in ?? ()
#6 0x4000000c in ?? ()
#7 0x4000000c in ?? ()
#8 0x4000000c in ?? ()
(gdb)
```

As you see, the backtrace may contain several entries. This will let you check what exact sequence of function calls lead to the code where the target halted. Question marks ?? instead of a function name indicate that application is available only in binary format, without any source file in C language. The value like 0x4000bfea is the memory address of the function call.

Using `bt`, `i threads`, `thread N` and `list` commands we are now able to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

**Setting and clearing breakpoints** When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers / peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let's establish two breakpoints when the state of LED changes. Basing on code listing above this happens at lines 33 and 36. Breakpoints may be established using command `break M` where `M` is the code line number:

```
(gdb) break 33
Breakpoint 2 at 0x400db6f6: file /home/user-name/esp/blink/main/./blink.c, line 33.
(gdb) break 36
Breakpoint 3 at 0x400db704: file /home/user-name/esp/blink/main/./blink.c, line 36.
```

If you now enter `c`, the processor will run and halt at a breakpoint. Entering `c` another time will make it run again, halt on second breakpoint, and so on:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F6 (active) APP_CPU: PC=0x400D10D8

Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↳blink.c:33
33         gpio_set_level(BLINK_GPIO, 0);
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F8 (active) APP_CPU: PC=0x400D10D8
Target halted. PRO_CPU: PC=0x400DB704 (active) APP_CPU: PC=0x400D10D8

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↳blink.c:36
36         gpio_set_level(BLINK_GPIO, 1);
```

(continues on next page)

```
(gdb)
```

You will be also able to see that LED is changing the state only if you resume program execution by entering `c`.

To examine how many breakpoints are set and where, use command `info break`:

```
(gdb) info break
Num      Type          Disp Enb Address      What
2        breakpoint    keep y  0x400db6f6 in blink_task at /home/user-name/esp/
↳blink/main/./blink.c:33
    breakpoint already hit 1 time
3        breakpoint    keep y  0x400db704 in blink_task at /home/user-name/esp/
↳blink/main/./blink.c:36
    breakpoint already hit 1 time
(gdb)
```

Please note that breakpoint numbers (listed under `Num`) start with 2. This is because first breakpoint has been already established at function `app_main()` by running command `thb app_main` on debugger launch. As it was a temporary breakpoint, it has been automatically deleted and now is not listed anymore.

To remove breakpoints enter `delete N` command (in short `d N`), where `N` is the breakpoint number:

```
(gdb) delete 1
No breakpoint number 1.
(gdb) delete 2
(gdb)
```

Read more about breakpoints under *Breakpoints and watchpoints available* and *What else should I know about breakpoints?*

**Halting and resuming the application** When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any break points defined. In such case, to go back to debugging mode, you can break program execution manually by entering `Ctrl+C`.

To check it delete all breakpoints and enter `c` to resume application. Then enter `Ctrl+C`. Application will be halted at some random point and LED will stop blinking. Debugger will print the following:

```
(gdb) c
Continuing.
^CTarget halted. PRO_CPU: PC=0x400D0C00          APP_CPU: PC=0x400D0C00 (active)
[New Thread 1073433352]

Program received signal SIGINT, Interrupt.
[Switching to Thread 1073413512]
0x400d0c00 in esp_vApplicationIdleHook () at /home/user-name/esp/esp-idf/
↳components/esp32c3/./freertos_hooks.c:52
52          asm("waiti 0");
(gdb)
```

In particular case above, the application has been halted in line 52 of code in file `freertos_hooks.c`. Now you can resume it again by enter `c` or do some debugging as discussed below.

---

**Note:** In MSYS2 shell `Ctrl+C` does not halt the target but exists debugger. To resolve this issue consider debugging with *Eclipse* or check a workaround under [http://www.mingw.org/wiki/Workaround\\_for\\_GDB\\_Ctrl\\_C\\_Interrupt](http://www.mingw.org/wiki/Workaround_for_GDB_Ctrl_C_Interrupt).

---

**Stepping through the code** It is also possible to step through the code using `step` and `next` commands (in short `s` and `n`). The difference is that `step` is entering inside subroutines calls, while `next` steps over the call, treating it as a single source line.

To demonstrate this functionality, using command `break` and `delete` discussed in previous paragraph, make sure that you have only one breakpoint defined at line 36 of `blink.c`:

```
(gdb) info break
Num      Type           Disp Enb Address      What
3        breakpoint      keep y  0x400db704 in blink_task at /home/user-name/esp/
↳blink/main/./blink.c:36
        breakpoint already hit 1 time
(gdb)
```

Resume program by entering `c` and let it halt:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB754 (active)    APP_CPU: PC=0x400D1128

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↳blink.c:36
36          gpio_set_level(BLINK_GPIO, 1);
(gdb)
```

Then enter `n` couple of times to see how debugger is stepping one program line at a time:

```
(gdb) n
Target halted. PRO_CPU: PC=0x400DB756 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB758 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DC04C (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB75B (active)    APP_CPU: PC=0x400D1128
37          vTaskDelay(1000 / portTICK_PERIOD_MS);
(gdb) n
Target halted. PRO_CPU: PC=0x400DB75E (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400846FC (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB761 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB746 (active)    APP_CPU: PC=0x400D1128
33          gpio_set_level(BLINK_GPIO, 0);
(gdb)
```

If you enter `s` instead, then debugger will step inside subroutine calls:

```
(gdb) s
Target halted. PRO_CPU: PC=0x400DB748 (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB74B (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DC04C (active)    APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DC04F (active)    APP_CPU: PC=0x400D1128
gpio_set_level (gpio_num=GPIO_NUM_4, level=0) at /home/user-name/esp/esp-idf/
↳components/driver/./gpio.c:183
183      GPIO_CHECK(GPIO_IS_VALID_OUTPUT_GPIO(gpio_num), "GPIO output gpio_num error
↳", ESP_ERR_INVALID_ARG);
(gdb)
```

In this particular case debugger stepped inside `gpio_set_level(BLINK_GPIO, 0)` and effectively moved to `gpio.c` driver code.

See [Why stepping with “next” does not bypass subroutine calls?](#) for potential limitation of using `next` command.

**Checking and setting memory** Displaying the contents of memory is done with command `x`. With additional parameters you may vary the format and count of memory locations displayed. Run `help x` to see more details. Companion command to `x` is `set` that let you write values to the memory.

We will demonstrate how `x` and `set` work by reading from and writing to the memory location `0x3FF44004` labeled as `GPIO_OUT_REG` used to set and clear individual GPIO's.

For more information, see *ESP32-C3 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO\_MUX)* [PDF].

Being in the same `blink.c` project as before, set two breakpoints right after `gpio_set_level` instruction. Enter two times `c` to get to the break point followed by `x /1wx 0x3FF44004` to display contents of `GPIO_OUT_REG` memory location:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB75E (active)   APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB74E (active)   APP_CPU: PC=0x400D1128

Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↳blink.c:34
34         vTaskDelay(1000 / portTICK_PERIOD_MS);
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000000
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB751 (active)   APP_CPU: PC=0x400D1128
Target halted. PRO_CPU: PC=0x400DB75B (active)   APP_CPU: PC=0x400D1128

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
↳blink.c:37
37         vTaskDelay(1000 / portTICK_PERIOD_MS);
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000010
(gdb)
```

If you are blinking LED connected to GPIO4, then you should see fourth bit being flipped each time the LED changes the state:

```
0x3ff44004: 0x00000000
...
0x3ff44004: 0x00000010
```

Now, when the LED is off, that corresponds to `0x3ff44004: 0x00000000` being displayed, try using `set` command to set this bit by writing `0x00000010` to the same memory location:

```
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000000
(gdb) set {unsigned int}0x3FF44004=0x000010
```

You should see the LED to turn on immediately after entering `set {unsigned int}0x3FF44004=0x000010` command.

**Watching and setting program variables** A common debugging task is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file `blink.c` by adding a declaration of a global variable `int i` above definition of function `blink_task`. Then add `i++` inside `while(1)` of this function to get `i` incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter the command `watch i`:

```
(gdb) watch i
Hardware watchpoint 2: i
(gdb)
```

This will insert so called “watchpoint” in each place of code where variable `i` is being modified. Now enter `continue` to resume the application and observe it being halted:

```
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB751 (active)   APP_CPU: PC=0x400D0811
[New Thread 1073432196]

Program received signal SIGTRAP, Trace/breakpoint trap.
[Switching to Thread 1073432196]
0x400db751 in blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/.
↳blink.c:33
33         i++;
(gdb)
```

Resume application couple more times so `i` gets incremented. Now you can enter `print i` (in short `p i`) to check the current value of `i`:

```
(gdb) p i
$1 = 3
(gdb)
```

To modify the value of `i` use `set` command as below (you can then print it out to check if it has been indeed changed):

```
(gdb) set var i = 0
(gdb) p i
$3 = 0
(gdb)
```

You may have up to two watchpoints, see [Breakpoints and watchpoints available](#).

**Setting conditional breakpoints** Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Delete existing breakpoints and try this:

```
(gdb) break blink.c:34 if (i == 2)
Breakpoint 3 at 0x400db753: file /home/user-name/esp/blink/main/.blink.c, line 34.
(gdb)
```

Above command sets conditional breakpoint to halt program execution in line 34 of `blink.c` if `i == 2`.

If current value of `i` is less than 2 and program is resumed, it will blink LED in a loop until condition `i == 2` gets true and then finally halt:

```
(gdb) set var i = 0
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB755 (active)   APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB753 (active)   APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB755 (active)   APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB753 (active)   APP_CPU: PC=0x400D112C

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/.
↳blink.c:34
34         gpio_set_level(BLINK_GPIO, 0);
(gdb)
```

**Obtaining help on commands** Commands presented so far should provide a very basic and intended to let you quickly get started with JTAG debugging. Check help what are the other commands at your disposal. To obtain help on syntax and functionality of a particular command, being at the `(gdb)` prompt type `help` and command name:

```
(gdb) help next
Step program, proceeding through subroutine calls.
Usage: next [N]
Unlike "step", if the current source line calls a subroutine,
this command does not enter the subroutine, but instead steps over
the call, in effect treating it as a single source line.
(gdb)
```

By typing just `help`, you will get top level list of command classes, to aid you drilling down to more details. Optionally refer to available GDB cheat sheets, for instance <https://darkdust.net/files/GDB%20Cheat%20Sheet.pdf>. Good to have as a reference (even if not all commands are applicable in an embedded environment).

**Ending debugger session** To quit debugger enter `q`:

```
(gdb) q
A debugging session is active.

    Inferior 1 [Remote target] will be detached.

Quit anyway? (y or n) y
Detaching from program: /home/user-name/esp/blink/build/blink.elf, Remote target
Ending remote debugging.
user-name@computer-name:~/esp/blink$
```

## 4.15 Linker Script Generation

### 4.15.1 Overview

There are several *memory regions* where code and data can be placed. Code and read-only data are placed by default in flash, writable data in RAM, etc. However, it is sometimes necessary to change these default placements.

For example, it may be necessary to place:

- critical code in RAM for performance reasons.
- executable code in IRAM so that it can be ran while cache is disabled.
- code in RTC memory for use in a wake stub.

With the linker script generation mechanism, it is possible to specify these placements at the component level within ESP-IDF. The component presents information on how it would like to place its symbols, objects or the entire archive. During build, the information presented by the components are collected, parsed and processed; and the placement rules generated is used to link the app.

### 4.15.2 Quick Start

This section presents a guide for quickly placing code/data to RAM and RTC memory - placements ESP-IDF provides out-of-the-box.

For this guide, suppose we have the following:

```

components
├── my_component
│   ├── CMakeLists.txt
│   ├── Kconfig
│   ├── src/
│   │   ├── my_src1.c
│   │   ├── my_src2.c
│   │   └── my_src3.c
│   └── my_linker_fragment_file.lf

```

- a component named `my_component` that is archived as library `libmy_component.a` during build
- three source files archived under the library, `my_src1.c`, `my_src2.c` and `my_src3.c` which are compiled as `my_src1.o`, `my_src2.o` and `my_src3.o`, respectively
- under `my_src1.o`, the function `my_function1` is defined; under `my_src2.o`, the function `my_function2` is defined
- there is bool-type config `PERFORMANCE_MODE` (y/n) and int type config `PERFORMANCE_LEVEL` (with range 0-3) in `my_component`'s `Kconfig`

### Creating and Specifying a Linker Fragment File

Before anything else, a linker fragment file needs to be created. A linker fragment file is simply a text file with a `.lf` extension upon which the desired placements will be written. After creating the file, it is then necessary to present it to the build system. The instructions for the build systems supported by ESP-IDF are as follows:

In the component's `CMakeLists.txt` file, specify argument `LDFRAGMENTS` in the `idf_component_register` call. The value of `LDFRAGMENTS` can either be an absolute path or a relative path from the component directory to the created linker fragment file.

```

# file paths relative to CMakeLists.txt
idf_component_register(...)
    LDFRAGMENTS "path/to/linker_fragment_file.lf" "path/to/
↳another_linker_fragment_file.lf"
    ...
)

```

### Specifying placements

It is possible to specify placements at the following levels of granularity:

- object file (`.obj` or `.o` files)
- symbol (function/variable)
- archive (`.a` files)

**Placing object files** Suppose the entirety of `my_src1.o` is performance-critical, so it is desirable to place it in RAM. On the other hand, the entirety of `my_src2.o` contains symbols needed coming out of deep sleep, so it needs to be put under RTC memory.

In the linker fragment file, we can write:

```

[mapping:my_component]
archive: libmy_component.a
entries:
    my_src1 (noflash)      # places all my_src1 code/read-only data under IRAM/DRAM
    my_src2 (rtc)         # places all my_src2 code/ data and read-only data under
↳RTC fast memory/RTC slow memory

```

What happens to `my_src3.o`? Since it is not specified, default placements are used for `my_src3.o`. More on default placements [here](#).

**Placing symbols** Continuing our example, suppose that among functions defined under `object1.o`, only `my_function1` is performance-critical; and under `object2.o`, only `my_function2` needs to execute after the chip comes out of deep sleep. This could be accomplished by writing:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    my_src1:my_function1 (noflash)
    my_src2:my_function2 (rtc)
```

The default placements are used for the rest of the functions in `my_src1.o` and `my_src2.o` and the entire `object3.o`. Something similar can be achieved for placing data by writing the variable name instead of the function name, like so:

```
my_src1:my_variable (noflash)
```

**Warning:** There are *limitations* in placing code/data at symbol granularity. In order to ensure proper placements, an alternative would be to group relevant code and data into source files, and *use object-granularity placements*.

**Placing entire archive** In this example, suppose that the entire component archive needs to be placed in RAM. This can be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    * (noflash)
```

Similarly, this places the entire component in RTC memory:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    * (rtc)
```

**Configuration-dependent placements** Suppose that the entire component library should only have special placement when a certain condition is true; for example, when `CONFIG_PERFORMANCE_MODE == y`. This could be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    if PERFORMANCE_MODE = y:
        * (noflash)
    else:
        * (default)
```

For a more complex config-dependent placement, suppose the following requirements: when `CONFIG_PERFORMANCE_LEVEL == 1`, only `object1.o` is put in RAM; when `CONFIG_PERFORMANCE_LEVEL == 2`, `object1.o` and `object2.o`; and when `CONFIG_PERFORMANCE_LEVEL == 3` all object files under the archive are to be put into RAM. When these three are false however, put entire library in RTC memory. This scenario is a bit contrived, but, it can be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    if PERFORMANCE_LEVEL = 1:
```

(continues on next page)

(continued from previous page)

```
my_src1 (noflash)
elif PERFORMANCE_LEVEL = 2:
    my_src1 (noflash)
    my_src2 (noflash)
elif PERFORMANCE_LEVEL = 3:
    my_src1 (noflash)
    my_src2 (noflash)
    my_src3 (noflash)
else:
    * (rtc)
```

Nesting condition-checking is also possible. The following is equivalent to the snippet above:

```
[mapping:my_component]
archive: libmy_component.a
entries:
    if PERFORMANCE_LEVEL <= 3 && PERFORMANCE_LEVEL > 0:
        if PERFORMANCE_LEVEL >= 1:
            object1 (noflash)
            if PERFORMANCE_LEVEL >= 2:
                object2 (noflash)
                if PERFORMANCE_LEVEL >= 3:
                    object2 (noflash)
        else:
            * (rtc)
```

### The ‘default’ placements

Up until this point, the term ‘default placements’ has been mentioned as fallback placements when the placement rules `rtc` and `noflash` are not specified. It is important to note that the tokens `noflash` or `rtc` are not merely keywords, but are actually entities called fragments, specifically *schemes*.

In the same manner as `rtc` and `noflash` are schemes, there exists a `default` scheme which defines what the default placement rules should be. As the name suggests, it is where code and data are usually placed, i.e. code/constants is placed in flash, variables placed in RAM, etc. More on the default scheme [here](#).

---

**Note:** For an example of an ESP-IDF component using the linker script generation mechanism, see [freertos/CMakeLists.txt](#). `freertos` uses this to place its object files to the instruction RAM for performance reasons.

---

This marks the end of the quick start guide. The following text discusses the internals of the mechanism in a little bit more detail. The following sections should be helpful in creating custom placements or modifying default behavior.

### 4.15.3 Linker Script Generation Internals

Linking is the last step in the process of turning C/C++ source files into an executable. It is performed by the toolchain’s linker, and accepts linker scripts which specify code/data placements, among other things. With the linker script generation mechanism, this process is no different, except that the linker script passed to the linker is dynamically generated from: (1) the collected *linker fragment files* and (2) *linker script template*.

---

**Note:** The tool that implements the linker script generation mechanism lives under `tools/ldgen`.

---

## Linker Fragment Files

As mentioned in the quick start guide, fragment files are simple text files with the `.lf` extension containing the desired placements. This is a simplified description of what fragment files contain, however. What fragment files actually contain are ‘fragments’. Fragments are entities which contain pieces of information which, when put together, form placement rules that tell where to place sections of object files in the output binary. There are three types of fragments: *sections*, *scheme* and *mapping*.

**Grammar** The three fragment types share a common grammar:

```
[type:name]
key: value
key:
  value
  value
  value
  ...
```

- **type:** Corresponds to the fragment type, can either be *sections*, *scheme* or *mapping*.
- **name:** The name of the fragment, should be unique for the specified fragment type.
- **key, value:** Contents of the fragment; each fragment type may support different keys and different grammars for the key values.
  - For *sections* and *scheme*, the only supported key is *entries*
  - For *mappings*, both *archive* and *entries* are supported.

---

**Note:** In cases where multiple fragments of the same type and name are encountered, an exception is thrown.

---

---

**Note:** The only valid characters for fragment names and keys are alphanumeric characters and underscore.

---

## Condition Checking

Condition checking enable the linker script generation to be configuration-aware. Depending on whether expressions involving configuration values are true or not, a particular set of values for a key can be used. The evaluation uses `eval_string` from `kconfiglib` package and adheres to its required syntax and limitations. Supported operators are as follows:

- **comparison**
  - `LessThan <`
  - `LessThanOrEqualTo <=`
  - `MoreThan >`
  - `MoreThanOrEqualTo >=`
  - `Equal =`
  - `NotEqual !=`
- **logical**
  - `Or ||`
  - `And &&`
  - `Negation !`
- **grouping**
  - `Parenthesis ()`

Condition checking behaves as you would expect an `if...elseif/elif...else` block in other languages. Condition-checking is possible for both key values and entire fragments. The two sample fragments below are equivalent:

```
# Value for keys is dependent on config
[type:name]
key_1:
```

(continues on next page)

(continued from previous page)

```

    if CONDITION = y:
        value_1
    else:
        value_2
key_2:
    if CONDITION = y:
        value_a
    else:
        value_b

```

```

# Entire fragment definition is dependent on config
if CONDITION = y:
    [type:name]
    key_1:
        value_1
    key_2:
        value_a
else:
    [type:name]
    key_1:
        value_2
    key_2:
        value_b

```

**Comments**

Comment in linker fragment files begin with #. Like in other languages, comment are used to provide helpful descriptions and documentation and are ignored during processing.

**Types Sections**

Sections fragments defines a list of object file sections that the GCC compiler emits. It may be a default section (e.g. `.text`, `.data`) or it may be user defined section through the `__attribute__` keyword.

The use of an optional '+' indicates the inclusion of the section in the list, as well as sections that start with it. This is the preferred method over listing both explicitly.

```

[sections:name]
entries:
    .section+
    .section
    ...

```

**Example:**

```

# Non-preferred
[sections:text]
entries:
    .text
    .text.*
    .literal
    .literal.*

# Preferred, equivalent to the one above
[sections:text]
entries:
    .text+           # means .text and .text.*
    .literal+       # means .literal and .literal.*

```

**Scheme**

Scheme fragments define what `target` a sections fragment is assigned to.

```
[scheme:name]
entries:
  sections -> target
  sections -> target
  ...
```

**Example:**

```
[scheme:noflash]
entries:
  text -> iram0_text      # the entries under the sections fragment named_
↔text will go to iram0_text
  rodata -> dram0_data   # the entries under the sections fragment named_
↔rodata will go to dram0_data
```

**The default scheme**

There exists a special scheme with the name `default`. This scheme is special because catch-all placement rules are generated from its entries. This means that, if one of its entries is `text -> flash_text`, the placement rule will be generated for the target `flash_text`.

```
*(.literal .literal.* .text .text.*)
```

These catch-all rules then effectively serve as fallback rules for those whose mappings were not specified.

The `default` scheme is defined in [esp\\_system/app.lf](#). The `noflash` and `rtc` scheme fragments which are built-in schemes referenced in the quick start guide are also defined in this file.

**Mapping**

Mapping fragments define what scheme fragment to use for mappable entities, i.e. object files, function names, variable names, archives.

```
[mapping:name]
archive: archive          # output archive file name, as built (i.e. libxxx.
↔a)
entries:
  object:symbol (scheme)  # symbol granularity
  object (scheme)        # object granularity
  * (scheme)              # archive granularity
```

There are three levels of placement granularity:

- **symbol:** The object file name and symbol name are specified. The symbol name can be a function name or a variable name.
- **object:** Only the object file name is specified.
- **archive:** `*` is specified, which is a short-hand for all the object files under the archive.

To know what an entry means, let us expand a sample object-granularity placement:

```
object (scheme)
```

Then expanding the scheme fragment from its entries definitions, we have:

```
object (sections -> target,
  sections -> target,
  ...)
```

Expanding the sections fragment with its entries definition:

```
object (.section,      # given this object file
  .section,          # put its sections listed here at this
  ... -> target,     # target
```

(continues on next page)

```
.section,
.section,      # same should be done for these sections
... -> target,

...           # and so on
```

Example:

```
[mapping:map]
archive: libfreertos.a
entries:
    * (noflash)
```

Aside from the entity and scheme, flags can also be specified in an entry. The following flags are supported (note: <> = argument name, [] = optional):

1. ALIGN(<alignment>[, pre, post])  
Align the placement by the amount specified in `alignment`. Generates
2. SORT([<sort\_by\_first>, <sort\_by\_second>])  
Emits `SORT_BY_NAME`, `SORT_BY_ALIGNMENT`, `SORT_BY_INIT_PRIORITY` or `SORT` in the input section description.  
Possible values for `sort_by_first` and `sort_by_second` are: `name`, `alignment`, `init_priority`.  
If both `sort_by_first` and `sort_by_second` are not specified, the input sections are sorted by name. If both are specified, then the nested sorting follows the same rules discussed in <https://sourceware.org/binutils/docs/ld/Input-Section-Wildcards.html>.
3. KEEP()  
Prevent the linker from discarding the placement by surrounding the input section description with `KEEP` command. See <https://sourceware.org/binutils/docs/ld/Input-Section-Keep.html> for more details.

#### 4.SURROUND(<name>)

Generate symbols before and after the placement. The generated symbols follow the naming `_<name>_start` and `_<name>_end`. For example, if `name == sym1`,

When adding flags, the specific `section -> target` in the scheme needs to be specified. For multiple `section -> target`, use a comma as a separator. For example,

```
# Notes:
# A. semicolon after entity-scheme
# B. comma before section2 -> target2
# C. section1 -> target1 and section2 -> target2 should be defined in entries of _
↪scheme1
entity1 (scheme1);
    section1 -> target1 KEEP() ALIGN(4, pre, post),
    section2 -> target2 SURROUND(sym) ALIGN(4, post) SORT()
```

Putting it all together, the following mapping fragment, for example,

```
[mapping:name]
archive: lib1.a
entries:
    obj1 (noflash);
    rodata -> dram0_data KEEP() SORT() ALIGN(8) SURROUND(my_sym)
```

generates an output on the linker script:

```

. = ALIGN(8)
_my_sym_start = ABSOLUTE(.)
KEEP(lib1.a:obj1.*( SORT(.rodata) SORT(.rodata.*) ))
_my_sym_end = ABSOLUTE(.)

```

Note that `ALIGN` and `SURROUND`, as mentioned in the flag descriptions, are order sensitive. Therefore, if for the same mapping fragment these two are switched, the following is generated instead:

```

_my_sym_start = ABSOLUTE(.)
. = ALIGN(8)
KEEP(lib1.a:obj1.*( SORT(.rodata) SORT(.rodata.*) ))
_my_sym_end = ABSOLUTE(.)

```

**On Symbol-Granularity Placements** Symbol granularity placements is possible due to compiler flags `-ffunction-sections` and `-ffdata-sections`. ESP-IDF compiles with these flags by default. If the user opts to remove these flags, then the symbol-granularity placements will not work. Furthermore, even with the presence of these flags, there are still other limitations to keep in mind due to the dependence on the compiler's emitted output sections.

For example, with `-ffunction-sections`, separate sections are emitted for each function; with section names predictably constructed i.e. `.text.{func_name}` and `.literal.{func_name}`. This is not the case for string literals within the function, as they go to pooled or generated section names.

With `-ffdata-sections`, for global scope data the compiler predictably emits either `.data.{var_name}`, `.rodata.{var_name}` or `.bss.{var_name}`; and so Type I mapping entry works for these. However, this is not the case for static data declared in function scope, as the generated section name is a result of mangling the variable name with some other information.

### Linker Script Template

The linker script template is the skeleton in which the generated placement rules are put into. It is an otherwise ordinary linker script, with a specific marker syntax that indicates where the generated placement rules are placed.

To reference the placement rules collected under a `target` token, the following syntax is used:

```
mapping[target]
```

Example:

The example below is an excerpt from a possible linker script template. It defines an output section `.iram0.text`, and inside is a marker referencing the target `iram0_text`.

```

.iram0.text :
{
    /* Code marked as running out of IRAM */
    _iram_text_start = ABSOLUTE(.);

    /* Marker referencing iram0_text */
    mapping[iram0_text]

    _iram_text_end = ABSOLUTE(.);
} > iram0_0_seg

```

Suppose the generator collected the fragment definitions below:

```

[sections:text]
.text+
.literal+

```

(continues on next page)

```
[sections:iram]
  .iram1+

[scheme:default]
entries:
  text -> flash_text
  iram -> iram0_text

[scheme:noflash]
entries:
  text -> iram0_text

[mapping:freertos]
archive: libfreertos.a
entries:
  * (noflash)
```

Then the corresponding excerpt from the generated linker script will be as follows:

```
.iram0.text :
{
  /* Code marked as running out of IRAM */
  _iram_text_start = ABSOLUTE(.);

  /* Placement rules generated from the processed fragments, placed where the
  ↪marker was in the template */
  *(.iram1 .iram1.*)
  *libfreertos.a:(.literal .text .literal.* .text.*)

  _iram_text_end = ABSOLUTE(.);
} > iram0_0_seg
```

```
*libfreertos.a:(.literal .text .literal.* .text.*)
```

Rule generated from the entry `* (noflash)` of the `freertos` mapping fragment. All `text` sections of all object files under the archive `libfreertos.a` will be collected under the target `iram0_text` (as per the `noflash` scheme) and placed wherever in the template `iram0_text` is referenced by a marker.

```
*(.iram1 .iram1.*)
```

Rule generated from the default scheme entry `iram -> iram0_text`. Since the default scheme specifies an `iram -> iram0_text` entry, it too is placed wherever `iram0_text` is referenced by a marker. Since it is a rule generated from the default scheme, it comes first among all other rules collected under the same target name.

The linker script template currently used is [esp\\_system/ld/esp32c3/sections.ld.in](#); the generated output script `sections.ld` is put under its build directory.

### Migrate to ESP-IDF v5.0 Linker Script Fragment Files Grammar

The old grammar supported in ESP-IDF v3.x would be dropped in ESP-IDF v5.0. Here are a few notes on how to migrate properly:

1. Now indentation is enforced and improperly indented fragment files would generate a runtime parse exception. This was not enforced in the old version but previous documentation and examples demonstrate properly indented grammar.
2. Migrate the old condition entry to the `if...elif...else` structure for conditionals. You can refer to the [earlier chapter](#) for detailed grammar.
3. mapping fragments now requires a name like other fragment types.

## 4.16 lwIP

ESP-IDF uses the open source [lwIP lightweight TCP/IP stack](#). The ESP-IDF version of lwIP ([esp-lwip](#)) has some modifications and additions compared to the upstream project.

### 4.16.1 Supported APIs

ESP-IDF supports the following lwIP TCP/IP stack functions:

- [BSD Sockets API](#)
- [Netconn API](#) is enabled but not officially supported for ESP-IDF applications

#### Adapted APIs

**Warning:** When using any lwIP API (other than [BSD Sockets API](#)), please make sure that it is thread safe. To check if a given API call is safe, enable [CONFIG\\_LWIP\\_CHECK\\_THREAD\\_SAFETY](#) and run the application. This way lwIP asserts the TCP/IP core functionality to be correctly accessed; the execution aborts if it is not locked properly or accessed from the correct task ([lwIP FreeRTOS Task](#)). The general recommendation is to use [ESP-NETIF](#) component to interact with lwIP.

Some common lwIP “app” APIs are supported indirectly by ESP-IDF:

- DHCP Server & Client are supported indirectly via the [ESP-NETIF](#) functionality
- Domain Name System (DNS) is supported in lwIP; DNS servers could be assigned automatically when acquiring a DHCP address, or manually configured using the [ESP-NETIF](#) API.

---

**Note:** DNS server configuration in lwIP is global, not interface-specific. If you are using multiple network interfaces with distinct DNS servers, exercise caution to prevent inadvertent overwrites of one interface’s DNS settings when acquiring a DHCP lease from another interface.

---

- Simple Network Time Protocol (SNTP) is supported via the [lwip/include/apps/sntp/sntp.h](#) [lwip/lwip/src/include/lwip/apps/sntp.h](#) functions (see also [SNTP Time Synchronization](#))
- ICMP Ping is supported using a variation on the lwIP ping API. See [ICMP Echo](#).
- NetBIOS lookup is available using the standard lwIP API. [protocols/http\\_server/restful\\_server](#) has an option to demonstrate using NetBIOS to look up a host on the LAN.
- mDNS uses a different implementation to the lwIP default mDNS (see [mDNS Service](#)), but lwIP can look up mDNS hosts using standard APIs such as `gethostbyname()` and the convention `hostname.local`, provided the [CONFIG\\_LWIP\\_DNS\\_SUPPORT\\_MDNS\\_QUERIES](#) setting is enabled.

### 4.16.2 BSD Sockets API

The BSD Sockets API is a common cross-platform TCP/IP sockets API that originated in the Berkeley Standard Distribution of UNIX but is now standardized in a section of the POSIX specification. BSD Sockets are sometimes called POSIX Sockets or Berkeley Sockets.

As implemented in ESP-IDF, lwIP supports all of the common usages of the BSD Sockets API.

#### References

A wide range of BSD Sockets reference material is available, including:

- [Single UNIX Specification BSD Sockets page](#)
- [Berkeley Sockets Wikipedia page](#)

## Examples

A number of ESP-IDF examples show how to use the BSD Sockets APIs:

- [protocols/sockets/tcp\\_server](#)
- [protocols/sockets/tcp\\_client](#)
- [protocols/sockets/udp\\_server](#)
- [protocols/sockets/udp\\_client](#)
- [protocols/sockets/udp\\_multicast](#)
- [protocols/http\\_request](#) (Note: this is a simplified example of using a TCP socket to send an HTTP request. The *ESP HTTP Client* is a much better option for sending HTTP requests.)

## Supported functions

The following BSD socket API functions are supported. For full details see [lwip/lwip/src/include/lwip/sockets.h](#).

- `socket()`
- `bind()`
- `accept()`
- `shutdown()`
- `getpeername()`
- `getsockopt()` & `setsockopt()` (see [Socket Options](#))
- `close()` (via [Virtual filesystem component](#))
- `read()`, `readv()`, `write()`, `writew()` (via [Virtual filesystem component](#))
- `recv()`, `recvmsg()`, `recvfrom()`
- `send()`, `sendmsg()`, `sendto()`
- `select()` (via [Virtual filesystem component](#))
- `poll()` (Note: on ESP-IDF, `poll()` is implemented by calling `select` internally, so using `select()` directly is recommended if a choice of methods is available.)
- `fcntl()` (see [fcntl](#))

Non-standard functions:

- `ioctl()` (see [ioctls](#))

---

**Note:** Some lwIP application sample code uses prefixed versions of BSD APIs, for example `lwip_socket()` instead of the standard `socket()`. Both forms can be used with ESP-IDF, but using standard names is recommended.

---

## Socket Error Handling

BSD Socket error handling code is very important for robust socket applications. Normally the socket error handling involves the following aspects:

- Detecting the error.
- Getting the error reason code.
- Handle the error according to the reason code.

In lwIP, we have two different scenarios of handling socket errors:

- Socket API returns an error. For more information, see [Socket API Errors](#).
- `select(int maxfdp1, fd_set *readset, fd_set *writerset, fd_set *exceptset, struct timeval *timeout)` has exception descriptor indicating that the socket has an error. For more information, see [select\(\) Errors](#).

## Socket API Errors

### The error detection

- We can know that the socket API fails according to its return value.

#### Get the error reason code

- When socket API fails, the return value doesn't contain the failure reason and the application can get the error reason code by accessing `errno`. Different values indicate different meanings. For more information, see [<Socket Error Reason Code>](#).

Example:

```
int err;
int sockfd;

if (sockfd = socket(AF_INET, SOCK_STREAM, 0) < 0) {
    // the error code is obtained from errno
    err = errno;
    return err;
}
```

### select() Errors

#### The error detection

- Socket error when `select()` has exception descriptor

#### Get the error reason code

- If the `select` indicates that the socket fails, we can't get the error reason code by accessing `errno`, instead we should call `getsockopt()` to get the failure reason code. Because `select()` has exception descriptor, the error code will not be given to `errno`.

---

**Note:** `getsockopt` function prototype `int getsockopt(int s, int level, int optname, void *optval, socklen_t *optlen)`. Its function is to get the current value of the option of any type, any state socket, and store the result in `optval`. For example, when you get the error code on a socket, you can get it by `getsockopt(sockfd, SOL_SOCKET, SO_ERROR, &err, &optlen)`.

---

Example:

```
int err;

if (select(sockfd + 1, NULL, NULL, &exfds, &tval) <= 0) {
    err = errno;
    return err;
} else {
    if (FD_ISSET(sockfd, &exfds)) {
        // select() exception set using getsockopt()
        int optlen = sizeof(int);
        getsockopt(sockfd, SOL_SOCKET, SO_ERROR, &err, &optlen);
        return err;
    }
}
```

**Socket Error Reason Code** Below is a list of common error codes. For more detailed list of standard POSIX/C error codes, please see [newlib errno.h](#) and the platform-specific extensions [newlib/platform\\_include/errno.h](#)

Error code	Description
ECONNREFUSED	Connection refused
EADDRINUSE	Address already in use
ECONNABORTED	Software caused connection abort
ENETUNREACH	Network is unreachable
ENETDOWN	Network interface is not configured
ETIMEDOUT	Connection timed out
EHOSTDOWN	Host is down
EHOSTUNREACH	Host is unreachable
EINPROGRESS	Connection already in progress
EALREADY	Socket already connected
EDESTADDRREQ	Destination address required
EPROTONOSUPPORT	Unknown protocol

### Socket Options

The `getsockopt()` and `setsockopt()` functions allow getting/setting per-socket options.

Not all standard socket options are supported by lwIP in ESP-IDF. The following socket options are supported:

**Common options** Used with level argument `SOL_SOCKET`.

- `SO_REUSEADDR` (available if `CONFIG_LWIP_SO_REUSE` is set, behavior can be customized by setting `CONFIG_LWIP_SO_REUSE_RXTOALL`)
- `SO_KEEPALIVE`
- `SO_BROADCAST`
- `SO_ACCEPTCONN`
- `SO_RCVBUF` (available if `CONFIG_LWIP_SO_RCVBUF` is set)
- `SO_SNDTIMEO` / `SO_RCVTIMEO`
- `SO_ERROR` (this option is only used with `select()`, see [Socket Error Handling](#))
- `SO_TYPE`
- `SO_NO_CHECK` (for UDP sockets only)

**IP options** Used with level argument `IPPROTO_IP`.

- `IP_TOS`
- `IP_TTL`
- `IP_PKTINFO` (available if `CONFIG_LWIP_NETBUF_RECVINFO` is set)

For multicast UDP sockets:

- `IP_MULTICAST_IF`
- `IP_MULTICAST_LOOP`
- `IP_MULTICAST_TTL`
- `IP_ADD_MEMBERSHIP`
- `IP_DROP_MEMBERSHIP`

**TCP options** TCP sockets only. Used with level argument `IPPROTO_TCP`.

- `TCP_NODELAY`

Options relating to TCP keepalive probes:

- `TCP_KEEPALIVE` (int value, TCP keepalive period in milliseconds)
- `TCP_KEEPIDLE` (same as `TCP_KEEPALIVE`, but the value is in seconds)
- `TCP_KEEPINTVL` (int value, interval between keepalive probes in seconds)
- `TCP_KEEPCNT` (int value, number of keepalive probes before timing out)

**IPv6 options** IPv6 sockets only. Used with level argument `IPPROTO_IPV6`

- `IPV6_CHECKSUM`
- `IPV6_V6ONLY`

For multicast IPv6 UDP sockets:

- `IPV6_JOIN_GROUP / IPV6_ADD_MEMBERSHIP`
- `IPV6_LEAVE_GROUP / IPV6_DROP_MEMBERSHIP`
- `IPV6_MULTICAST_IF`
- `IPV6_MULTICAST_HOPS`
- `IPV6_MULTICAST_LOOP`

## **fcntl**

The `fcntl()` function is a standard API for manipulating options related to a file descriptor. In ESP-IDF, the *Virtual filesystem component* layer is used to implement this function.

When the file descriptor is a socket, only the following `fcntl()` values are supported:

- `O_NONBLOCK` to set/clear non-blocking I/O mode. Also supports `O_NDELAY`, which is identical to `O_NONBLOCK`.
- `O_RDONLY`, `O_WRONLY`, `O_RDWR` flags for different read/write modes. These can read via `F_GETFL` only, they cannot be set using `F_SETFL`. A TCP socket will return a different mode depending on whether the connection has been closed at either end or is still open at both ends. UDP sockets always return `O_RDWR`.

## **ioctl**

The `ioctl()` function provides a semi-standard way to access some internal features of the TCP/IP stack. In ESP-IDF, the *Virtual filesystem component* layer is used to implement this function.

When the file descriptor is a socket, only the following `ioctl()` values are supported:

- `FIONREAD` returns the number of bytes of pending data already received in the socket's network buffer.
- `FIONBIO` is an alternative way to set/clear non-blocking I/O status for a socket, equivalent to `fcntl(fd, F_SETFL, O_NONBLOCK, ...)`.

### **4.16.3 Netconn API**

lwIP supports two lower level APIs as well as the BSD Sockets API: the Netconn API and the Raw API.

The lwIP Raw API is designed for single threaded devices and is not supported in ESP-IDF.

The Netconn API is used to implement the BSD Sockets API inside lwIP, and it can also be called directly from ESP-IDF apps. This API has lower resource usage than the BSD Sockets API, in particular it can send and receive data without needing to first copy it into internal lwIP buffers.

---

**Important:** Espressif does not test the Netconn API in ESP-IDF. As such, this functionality is *enabled but not supported*. Some functionality may only work correctly when used from the BSD Sockets API.

---

For more information about the Netconn API, consult [lwip/lwip/src/include/lwip/api.h](#) and [this wiki page which is part of the unofficial lwIP Application Developers Manual](#).

### **4.16.4 lwIP FreeRTOS Task**

lwIP creates a dedicated TCP/IP FreeRTOS task to handle socket API requests from other tasks.

A number of configuration items are available to modify the task and the queues ( “mailboxes” ) used to send data to/from the TCP/IP task:

- [CONFIG\\_LWIP\\_TCPIP\\_RECVMBOX\\_SIZE](#)
- [CONFIG\\_LWIP\\_TCPIP\\_TASK\\_STACK\\_SIZE](#)
- [CONFIG\\_LWIP\\_TCPIP\\_TASK\\_AFFINITY](#)

### 4.16.5 IPv6 Support

Both IPv4 and IPv6 are supported as dual stack and enabled by default (IPv6 may be disabled if it's not needed, see [Minimum RAM usage](#)). IPv6 support is limited to *Stateless Autoconfiguration* only, *Stateful configuration* is not supported in ESP-IDF (not in upstream lwip). IPv6 Address configuration is defined by means of these protocols or services:

- **SLAAC** IPv6 Stateless Address Autoconfiguration (RFC-2462)
- **DHCPv6** Dynamic Host Configuration Protocol for IPv6 (RFC-8415)

None of these two types of address configuration is enabled by default, so the device uses only Link Local addresses or statically defined addresses.

#### Stateless Autoconfiguration Process

To enable address autoconfiguration using Router Advertisement protocol please enable:

- [CONFIG\\_LWIP\\_IPV6\\_AUTOCONFIG](#)

This configuration option enables IPv6 autoconfiguration for all network interfaces (in contrast to the upstream lwIP, where the autoconfiguration needs to be explicitly enabled for each netif with `netif->ip6_autoconfig_enabled=1`

#### DHCPv6

DHCPv6 in lwIP is very simple and support only stateless configuration. It could be enabled using:

- [CONFIG\\_LWIP\\_IPV6\\_DHCP6](#)

Since the DHCPv6 works only in its stateless configuration, the *Stateless Autoconfiguration Process* has to be enabled, too, by means of [CONFIG\\_LWIP\\_IPV6\\_AUTOCONFIG](#). Moreover, the DHCPv6 needs to be explicitly enabled from the application code using

```
dhcp6_enable_stateless(netif);
```

#### DNS servers in IPv6 autoconfiguration

In order to autoconfigure DNS server(s), especially in IPv6 only networks, we have these two options

- Recursive domain name system –this belongs to the Neighbor Discovery Protocol (NDP), uses *Stateless Autoconfiguration Process*. Number of servers must be set [CONFIG\\_LWIP\\_IPV6\\_RDNSS\\_MAX\\_DNS\\_SERVERS](#), this is option is disabled (set to 0) by default.
- DHCPv6 stateless configuration –uses [DHCPv6](#) to configure DNS servers. Note that the this configuration assumes IPv6 Router Advertisement Flags (RFC-5175) to be set to
  - Managed Address Configuration Flag = 0
  - Other Configuration Flag = 1

### 4.16.6 esp-lwip custom modifications

#### Additions

The following code is added which is not present in the upstream lwIP release:

**Thread-safe sockets** It is possible to `close()` a socket from a different thread to the one that created it. The `close()` call will block until any function calls currently using that socket from other tasks have returned.

It is, however, not possible to delete a task while it is actively waiting on `select()` or `poll()` APIs. It is always necessary that these APIs exit before destroying the task, as this might corrupt internal structures and cause subsequent crashes of the lwIP. (These APIs allocate globally referenced callback pointers on stack, so that when the task gets destroyed before unrolling the stack, the lwIP would still hold pointers to the deleted stack)

**On demand timers** lwIP IGMP and MLD6 features both initialize a timer in order to trigger timeout events at certain times.

The default lwIP implementation is to have these timers enabled all the time, even if no timeout events are active. This increases CPU usage and power consumption when using automatic light sleep mode. `esp-lwip` default behaviour is to set each timer “on demand” so it is only enabled when an event is pending.

To return to the default lwIP behaviour (always-on timers), disable `CONFIG_LWIP_TIMERS_ONDEMAND`.

**Lwip timers API** When users are not using WiFi, these APIs provide users with the ability to turn off LwIP timer to reduce power consumption.

The following API functions are supported. For full details see [lwip/lwip/src/include/lwip/timeouts.h](http://lwip/lwip/src/include/lwip/timeouts.h).

- `sys_timeouts_init()`
- `sys_timeouts_deinit()`

### Additional Socket Options

- Some standard IPV4 and IPV6 multicast socket options are implemented (see *Socket Options*).
- Possible to set IPV6-only UDP and TCP sockets with `IPV6_V6ONLY` socket option (normal lwIP is TCP only).

### IP layer features

- IPV4 source based routing implementation is different.
- IPV4 mapped IPV6 addresses are supported.

**Customized lwIP hooks** The original lwIP supports implementing custom compile-time modifications via `LWIP_HOOK_FILENAME`. This file is already used by the IDF port layer, but IDF users could still include and implement any custom additions via a header file defined by the macro `ESP_IDF_LWIP_HOOK_FILENAME`. Here is an example of adding a custom hook file to the build process (the hook is called `my_hook.h` and located in the project's `main` folder):

```
idf_component_get_property(lwip lwip COMPONENT_LIB)
target_compile_options(${lwip} PRIVATE "-I${PROJECT_DIR}/main")
target_compile_definitions(${lwip} PRIVATE "-DESP_IDF_LWIP_HOOK_FILENAME=\"my_hook.
↪h\"")
```

**Customized lwIP Options From ESP-IDF Build System** The most common lwIP options are configurable through the component configuration menu. However, certain definitions need to be injected from the command line. The CMake function `target_compile_definitions()` can be employed to define macros, as illustrated below:

```
idf_component_get_property(lwip lwip COMPONENT_LIB)
target_compile_definitions(${lwip} PRIVATE "-DETHARP_SUPPORT_VLAN=1")
```

This approach may not work for function-like macros, as there is no guarantee that the definition will be accepted by all compilers, although it is supported in GCC. To address this limitation, the `add_definitions()` function can be utilized to define the macro for the entire project, for example: `add_definitions("-DFALLBACK_DNS_SERVER_ADDRESS(addr)=\"IP_ADDR4((addr), 8, 8, 8)\")`.

Alternatively, you can define your function-like macro in a header file which will be pre-included as an lwIP hook file, see [Customized lwIP hooks](#).

### Limitations

ESP-IDF additions to lwIP still suffer from the global DNS limitation, described in [Adapted APIs](#). To address this limitation from application code, the `FALLBACK_DNS_SERVER_ADDRESS()` macro can be utilized to define a global DNS fallback server accessible from all interfaces. Alternatively, you have the option to maintain per-interface DNS servers and reconfigure them whenever the default interface changes.

Calling `send()` or `sendto()` repeatedly on a UDP socket may eventually fail with `errno` equal to `ENOMEM`. This is a limitation of buffer sizes in the lower layer network interface drivers. If all driver transmit buffers are full then UDP transmission will fail. Applications sending a high volume of UDP datagrams who don't wish for any to be dropped by the sender should check for this error code and re-send the datagram after a short delay.

Increasing the number of TX buffers in the [Wi-Fi](#) project configuration may also help.

## 4.16.7 Performance Optimization

TCP/IP performance is a complex subject, and performance can be optimized towards multiple goals. The default settings of ESP-IDF are tuned for a compromise between throughput, latency, and moderate memory usage.

### Maximum throughput

Espressif tests ESP-IDF TCP/IP throughput using the [wifi/iperf](#) example in an RF sealed enclosure.

The [wifi/iperf/sdkconfig.defaults](#) file for the iperf example contains settings known to maximize TCP/IP throughput, usually at the expense of higher RAM usage. To get maximum TCP/IP throughput in an application at the expense of other factors then suggest applying settings from this file into the project `sdkconfig`.

---

**Important:** Suggest applying changes a few at a time and checking the performance each time with a particular application workload.

---

- If a lot of tasks are competing for CPU time on the system, consider that the lwIP task has configurable CPU affinity (`CONFIG_LWIP_TCPIP_TASK_AFFINITY`) and runs at fixed priority `ESP_TASK_TCPIP_PRIO` (18). Configure competing tasks to be pinned to a different core, or to run at a lower priority. See also [Built-In Task Priorities](#).
- If using `select()` function with socket arguments only, disabling `CONFIG_VFS_SUPPORT_SELECT` will make `select()` calls faster.
- If there is enough free IRAM, select `CONFIG_LWIP_IRAM_OPTIMIZATION` to improve TX/RX throughput

If using a Wi-Fi network interface, please also refer to [Wi-Fi Buffer Usage](#).

### Minimum latency

Except for increasing buffer sizes, most changes which increase throughput will also decrease latency by reducing the amount of CPU time spent in lwIP functions.

- For TCP sockets, lwIP supports setting the standard `TCP_NODELAY` flag to disable Nagle's algorithm.

## Minimum RAM usage

Most lwIP RAM usage is on-demand, as RAM is allocated from the heap as needed. Therefore, changing lwIP settings to reduce RAM usage may not change RAM usage at idle but can change it at peak.

- Reducing `CONFIG_LWIP_MAX_SOCKETS` reduces the maximum number of sockets in the system. This will also cause TCP sockets in the `WAIT_CLOSE` state to be closed and recycled more rapidly (if needed to open a new socket), further reducing peak RAM usage.
- Reducing `CONFIG_LWIP_TCPIP_RECVMBOX_SIZE`, `CONFIG_LWIP_TCP_RECVMBOX_SIZE` and `CONFIG_LWIP_UDP_RECVMBOX_SIZE` reduce memory usage at the expense of throughput, depending on usage.
- Reducing `CONFIG_LWIP_TCP_MSL`, `CONFIG_LWIP_TCP_FIN_WAIT_TIMEOUT` reduces the maximum segment lifetime in the system. This will also cause TCP sockets in the `TIME_WAIT`, `FIN_WAIT_2` state to be closed and recycled more rapidly
- Disable `CONFIG_LWIP_IPV6` can save about 39 KB for firmware size and 2KB RAM when system power up and 7KB RAM when TCPIP stack running. If there is no requirement for supporting IPV6 then it can be disabled to save flash and RAM footprint.

If using Wi-Fi, please also refer to [Wi-Fi Buffer Usage](#).

**Peak Buffer Usage** The peak heap memory that lwIP consumes is the **theoretically-maximum memory** that the lwIP driver consumes. Generally, the peak heap memory that lwIP consumes depends on:

- the memory required to create a UDP connection: `lwip_udp_conn`
- the memory required to create a TCP connection: `lwip_tcp_conn`
- the number of UDP connections that the application has: `lwip_udp_con_num`
- the number of TCP connections that the application has: `lwip_tcp_con_num`
- the TCP TX window size: `lwip_tcp_tx_win_size`
- the TCP RX window size: `lwip_tcp_rx_win_size`

**So, the peak heap memory that the LwIP consumes can be calculated with the following formula:**

$$\text{lwip\_dynamic\_peek\_memory} = (\text{lwip\_udp\_con\_num} * \text{lwip\_udp\_conn}) + (\text{lwip\_tcp\_con\_num} * (\text{lwip\_tcp\_tx\_win\_size} + \text{lwip\_tcp\_rx\_win\_size} + \text{lwip\_tcp\_conn}))$$

Some TCP-based applications need only one TCP connection. However, they may choose to close this TCP connection and create a new one when an error (such as a sending failure) occurs. This may result in multiple TCP connections existing in the system simultaneously, because it may take a long time for a TCP connection to close, according to the TCP state machine (refer to RFC793).

## 4.17 Memory Types

ESP32-C3 chip has multiple memory types and flexible memory mapping features. This section describes how ESP-IDF uses these features by default.

ESP-IDF distinguishes between instruction memory bus (IRAM, IROM, RTC FAST memory) and data memory bus (DRAM, DROM). Instruction memory is executable, and can only be read or written via 4-byte aligned words. Data memory is not executable and can be accessed via individual byte operations. For more information about the different memory buses consult the *ESP32-C3 Technical Reference Manual > System and Memory* [PDF].

### 4.17.1 DRAM (Data RAM)

Non-constant static data (`.data`) and zero-initialized data (`.bss`) is placed by the linker into Internal SRAM as data memory. The remaining space in this region is used for the runtime heap.

---

**Note:** The maximum statically allocated DRAM size is reduced by the *IRAM (Instruction RAM)* size of the compiled application. The available heap memory at runtime is reduced by the total static IROM and DRAM usage of the

application.

---

Constant data may also be placed into DRAM, for example if it is used in a non-flash-safe ISR (see explanation under [How to place code in IRAM](#)).

### “noinit” DRAM

The macro `__NOINIT_ATTR` can be used as attribute to place data into `.noinit` section. The values placed into this section will not be initialized at startup and should keep its value after software restart.

Example:

```
__NOINIT_ATTR uint32_t noinit_data;
```

## 4.17.2 IRAM (Instruction RAM)

---

**Note:** Any internal SRAM which is not used for Instruction RAM will be made available as *DRAM (Data RAM)* for static data and dynamic allocation (heap).

---

### When to place code in IRAM

Cases when parts of the application should be placed into IRAM:

- Interrupt handlers must be placed into IRAM if `ESP_INTR_FLAG_IRAM` is used when registering the interrupt handler. For more information, see [IRAM-Safe Interrupt Handlers](#).
- Some timing critical code may be placed into IRAM to reduce the penalty associated with loading the code from flash. ESP32-C3 reads code and data from flash via the MMU cache. In some cases, placing a function into IRAM may reduce delays caused by a cache miss and significantly improve that function's performance.

### How to place code in IRAM

Some code is automatically placed into the IRAM region using the linker script.

If some specific application code needs to be placed into IRAM, it can be done by using the [Linker Script Generation](#) feature and adding a linker script fragment file to your component that targets at the entire source files or functions with the `noflash` placement. See the [Linker Script Generation](#) docs for more information.

Alternatively, it's possible to specify IRAM placement in the source code using the `IRAM_ATTR` macro:

```
#include "esp_attr.h"

void IRAM_ATTR gpio_isr_handler(void* arg)
{
    // ...
}
```

There are some possible issues with placement in IRAM, that may cause problems with IRAM-safe interrupt handlers:

- Strings or constants inside an `IRAM_ATTR` function may not be placed in RAM automatically. It's possible to use `DRAM_ATTR` attributes to mark these, or using the linker script method will cause these to be automatically placed correctly.

```
void IRAM_ATTR gpio_isr_handler(void* arg)
{
    const static DRAM_ATTR uint8_t INDEX_DATA[] = { 45, 33, 12, 0 };
    const static char *MSG = DRAM_STR("I am a string stored in RAM");
}
```

Note that knowing which data should be marked with `DRAM_ATTR` can be hard, the compiler will sometimes recognize that a variable or expression is constant (even if it is not marked `const`) and optimize it into flash, unless it is marked with `DRAM_ATTR`.

- GCC optimizations that automatically generate jump tables or switch/case lookup tables place these tables in flash. IDF by default builds all files with `-fno-jump-tables -fno-tree-switch-conversion` flags to avoid this.

Jump table optimizations can be re-enabled for individual source files that don't need to be placed in IRAM. For instructions on how to add the `-fno-jump-tables -fno-tree-switch-conversion` options when compiling individual source files, see [Controlling Component Compilation](#).

### 4.17.3 IROM (code executed from flash)

If a function is not explicitly placed into *IRAM (Instruction RAM)* or RTC memory, it is placed into flash. As IRAM is limited, most of an application's binary code must be placed into IROM instead.

During *Application Startup Flow*, the bootloader (which runs from IRAM) configures the MMU flash cache to map the app's instruction code region to the instruction space. Flash accessed via the MMU is cached using some internal SRAM and accessing cached flash data is as fast as accessing other types of internal memory.

### 4.17.4 DROM (data stored in flash)

By default, constant data is placed by the linker into a region mapped to the MMU flash cache. This is the same as the *IROM (code executed from flash)* section, but is for read-only data not executable code.

The only constant data not placed into this memory type by default are literal constants which are embedded by the compiler into application code. These are placed as the surrounding function's executable instructions.

The `DRAM_ATTR` attribute can be used to force constants from DROM into the *DRAM (Data RAM)* section (see above).

### 4.17.5 RTC FAST memory

The same region of RTC FAST memory can be accessed as both instruction and data memory. Code which has to run after wake-up from deep sleep mode has to be placed into RTC memory. Please check detailed description in *deep sleep* documentation.

Remaining RTC FAST memory is added to the heap unless the option `CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP` is disabled. This memory can be used interchangeably with *DRAM (Data RAM)*, but is slightly slower to access.

### 4.17.6 DMA Capable Requirement

Most peripheral DMA controllers (e.g. SPI, sdmmc, etc.) have requirements that sending/receiving buffers should be placed in DRAM and word-aligned. We suggest to place DMA buffers in static variables rather than in the stack. Use macro `DMA_ATTR` to declare global/local static variables like:

```

DMA_ATTR uint8_t buffer[]="I want to send something";

void app_main()
{
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}

```

Or:

```

void app_main()
{
    DMA_ATTR static uint8_t buffer[] = "I want to send something";
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}

```

It is also possible to allocate DMA-capable memory buffers dynamically by using the `MALLOC_CAP_DMA` capabilities flag.

### 4.17.7 DMA Buffer in the stack

Placing DMA buffers in the stack is possible but discouraged. If doing so, pay attention to the following:

- Use macro `WORD_ALIGNED_ATTR` in functions before variables to place them in proper positions like:

```

void app_main()
{
    uint8_t stuff;
    WORD_ALIGNED_ATTR uint8_t buffer[] = "I want to send something"; //or_
    ↪the buffer will be placed right after stuff.
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}

```

## 4.18 OpenThread

**OpenThread** is an IP stack running on the 802.15.4 MAC layer which features mesh network and low power consumption.

### 4.18.1 Modes of the OpenThread stack

OpenThread can run under the following modes on Espressif chips:

#### Standalone Node

The full OpenThread stack and the application layer run on the same chip. This mode is available on chips with 15.4 radio such as ESP32-H2 and ESP32-C6.

#### Radio Co-Processor (RCP)

The chip is connected to another host running the OpenThread IP stack. It sends and receives 15.4 packets on behalf of the host. This mode is available on chips with 15.4 radio such as ESP32-H2 and ESP32-C6. The underlying transport between the chip and the host can be SPI or UART. For the sake of latency, we recommend using SPI as the underlying transport.

#### OpenThread Host

For chips without a 15.4 radio, it can be connected to an RCP and run OpenThread under host mode. This mode enables OpenThread on Wi-Fi chips such as ESP32, ESP32-S2, ESP32-S3, and ESP32-C3. The following diagram shows how devices work under different modes:

Fig. 74: OpenThread device modes

### 4.18.2 How to Write an OpenThread Application

The OpenThread `openthread/ot_cli` example is a good place to start at. It demonstrates basic OpenThread initialization and simple socket-based server and client.

#### Before OpenThread Initialization

- s1.1: The main task calls `esp_vfs_eventfd_register()` to initialize the eventfd virtual file system. The eventfd file system is used for task notification in the OpenThread driver.
- s1.2: The main task calls `nvs_flash_init()` to initialize the NVS where the Thread network data is stored.
- s1.3: **Optional.** The main task calls `esp_netif_init()` only when it wants to create the network interface for Thread.

- s1.4: The main task calls `esp_event_loop_create()` to create the system Event task and initialize an application event's callback function.

### OpenThread Stack Initialization

- s2.1: Call `esp_openthread_init()` to initialize the OpenThread stack.

### OpenThread Network Interface Initialization

The whole stage is **optional** and only required if the application wants to create the network interface for Thread.

- s3.1: Call `esp_netif_new()` with `ESP_NETIF_DEFAULT_OPENTHREAD` to create the interface.
- s3.2: Call `esp_openthread_netif_glue_init()` to create the OpenThread interface handlers.
- s3.3: Call `esp_netif_attach()` to attach the handlers to the interface.

### The OpenThread Main Loop

- s4.3: Call `esp_openthread_launch_mainloop()` to launch the OpenThread main loop. Note that this is a busy loop and does not return until the OpenThread stack is terminated.

### Calling OpenThread APIs

The OpenThread APIs are not thread-safe. When calling OpenThread APIs from other tasks, make sure to hold the lock with `esp_openthread_lock_acquire()` and release the lock with `esp_openthread_lock_release()` afterwards.

### Deinitialization

The following steps are required to deinitialize the OpenThread stack:

- Call `esp_netif_destroy()` and `esp_openthread_netif_glue_deinit()` to deinitialize the OpenThread network interface if you have created one.
- Call `esp_openthread_deinit()` to deinitialize the OpenThread stack.

## 4.18.3 The OpenThread Border Router

The OpenThread border router connects the Thread network with other IP networks. It provides IPv6 connectivity, service registration, and commission functionality.

To launch an OpenThread border router on an ESP chip, you need to connect an RCP to a Wi-Fi capable chip such as ESP32.

Calling `esp_openthread_border_router_init()` during the initialization launches all the border routing functionalities.

You may refer to the `openthread/ot_br` example and the README for further border router details.

## 4.19 Partition Tables

### 4.19.1 Overview

A single ESP32-C3's flash can contain multiple apps, as well as many different kinds of data (calibration data, filesystems, parameter storage, etc). For this reason a partition table is flashed to (*default offset*) 0x8000 in the flash.

Partition table length is 0xC00 bytes (maximum 95 partition table entries). An MD5 checksum, which is used for checking the integrity of the partition table, is appended after the table data.

Each entry in the partition table has a name (label), type (app, data, or something else), subtype and the offset in flash where the partition is loaded.

The simplest way to use the partition table is to open the project configuration menu (`idf.py menuconfig`) and choose one of the simple predefined partition tables under `CONFIG_PARTITION_TABLE_TYPE`:

- “Single factory app, no OTA”
- “Factory app, two OTA definitions”

In both cases the factory app is flashed at offset 0x10000. If you execute `idf.py partition-table` then it will print a summary of the partition table.

### 4.19.2 Built-in Partition Tables

Here is the summary printed for the “Single factory app, no OTA” configuration:

```
# ESP-IDF Partition Table
# Name, Type, SubType, Offset, Size, Flags
nvs, data, nvs, 0x9000, 0x6000,
phy_init, data, phy, 0xf000, 0x1000,
factory, app, factory, 0x10000, 1M,
```

- At a 0x10000 (64 KB) offset in the flash is the app labelled “factory” . The bootloader will run this app by default.
- There are also two data regions defined in the partition table for storing NVS library partition and PHY init data.

Here is the summary printed for the “Factory app, two OTA definitions” configuration:

```
# ESP-IDF Partition Table
# Name, Type, SubType, Offset, Size, Flags
nvs, data, nvs, 0x9000, 0x4000,
otadata, data, ota, 0xd000, 0x2000,
phy_init, data, phy, 0xf000, 0x1000,
factory, app, factory, 0x10000, 1M,
ota_0, app, ota_0, 0x110000, 1M,
ota_1, app, ota_1, 0x210000, 1M,
```

- There are now three app partition definitions. The type of the factory app (at 0x10000) and the next two “OTA” apps are all set to “app” , but their subtypes are different.
- There is also a new “otadata” slot, which holds the data for OTA updates. The bootloader consults this data in order to know which app to execute. If “ota data” is empty, it will execute the factory app.

### 4.19.3 Creating Custom Tables

If you choose “Custom partition table CSV” in menuconfig then you can also enter the name of a CSV file (in the project directory) to use for your partition table. The CSV file can describe any number of definitions for the table you need.

The CSV format is the same format as printed in the summaries shown above. However, not all fields are required in the CSV. For example, here is the “input” CSV for the OTA partition table:

#	Name,	Type,	SubType,	Offset,	Size,	Flags
	nvs,	data,	nvs,	0x9000,	0x4000	
	otadata,	data,	ota,	0xd000,	0x2000	
	phy_init,	data,	phy,	0xf000,	0x1000	
	factory,	app,	factory,	0x10000,	1M	
	ota_0,	app,	ota_0,	,	1M	
	ota_1,	app,	ota_1,	,	1M	
	nvs_key,	data,	nvs_keys,	,	0x1000	

- Whitespace between fields is ignored, and so is any line starting with # (comments).
- Each non-comment line in the CSV file is a partition definition.
- The “Offset” field for each partition is empty. The `gen_esp32part.py` tool fills in each blank offset, starting after the partition table and making sure each partition is aligned correctly.

### Name field

Name field can be any meaningful name. It is not significant to the ESP32-C3. Names longer than 16 characters will be truncated.

### Type field

Partition type field can be specified as `app` (0x00) or `data` (0x01). Or it can be a number 0-254 (or as hex 0x00-0xFE). Types 0x00-0x3F are reserved for ESP-IDF core functions.

If your app needs to store data in a format not already supported by ESP-IDF, then please add a custom partition type value in the range 0x40-0xFE.

See [`esp\_partition\_type\_t`](#) for the enum definitions for `app` and `data` partitions.

If writing in C++ then specifying a application-defined partition type requires casting an integer to [`esp\_partition\_type\_t`](#) in order to use it with the [partition API](#). For example:

```
static const esp_partition_type_t APP_PARTITION_TYPE_A = (esp_partition_type_t)0x40;
```

The ESP-IDF bootloader ignores any partition types other than `app` (0x00) and `data` (0x01).

### SubType

The 8-bit subtype field is specific to a given partition type. ESP-IDF currently only specifies the meaning of the subtype field for `app` and `data` partition types.

See enum [`esp\_partition\_subtype\_t`](#) for the full list of subtypes defined by ESP-IDF, including the following:

- When type is `app`, the subtype field can be specified as `factory` (0x00), `ota_0` (0x10) ... `ota_15` (0x1F) or `test` (0x20).
  - `factory` (0x00) is the default `app` partition. The bootloader will execute the `factory` app unless there it sees a partition of type `data/ota`, in which case it reads this partition to determine which OTA image to boot.
    - \* OTA never updates the `factory` partition.
    - \* If you want to conserve flash usage in an OTA project, you can remove the `factory` partition and use `ota_0` instead.
  - `ota_0` (0x10) ... `ota_15` (0x1F) are the OTA `app` slots. When *OTA* is in use, the OTA data partition configures which `app` slot the bootloader should boot. When using OTA, an application should have at least two OTA application slots (`ota_0` & `ota_1`). Refer to the [OTA documentation](#) for more details.
  - `test` (0x20) is a reserved subtype for `factory` test procedures. It will be used as the fallback boot partition if no other valid `app` partition is found. It is also possible to configure the bootloader to read a GPIO input during each boot, and boot this partition if the GPIO is held low, see [Boot from Test Firmware](#).

- When type is `data`, the subtype field can be specified as `ota` (0x00), `phy` (0x01), `nvs` (0x02), `nvs_keys` (0x04), or a range of other component-specific subtypes (see [subtype enum](#)).
  - `ota` (0) is the *OTA data partition* which stores information about the currently selected OTA app slot. This partition should be 0x2000 bytes in size. Refer to the [OTA documentation](#) for more details.
  - `phy` (1) is for storing PHY initialisation data. This allows PHY to be configured per-device, instead of in firmware.
    - \* In the default configuration, the phy partition is not used and PHY initialisation data is compiled into the app itself. As such, this partition can be removed from the partition table to save space.
    - \* To load PHY data from this partition, open the project configuration menu (`idf.py menuconfig`) and enable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION` option. You will also need to flash your devices with phy init data as the esp-idf build system does not do this automatically.
  - `nvs` (2) is for the *Non-Volatile Storage (NVS) API*.
    - \* NVS is used to store per-device PHY calibration data (different to initialisation data).
    - \* NVS is used to store WiFi data if the `esp_wifi_set_storage(WIFI_STORAGE_FLASH)` initialisation function is used.
    - \* The NVS API can also be used for other application data.
    - \* It is strongly recommended that you include an NVS partition of at least 0x3000 bytes in your project.
    - \* If using NVS API to store a lot of data, increase the NVS partition size from the default 0x6000 bytes.
  - `nvs_keys` (4) is for the NVS key partition. See *Non-Volatile Storage (NVS) API* for more details.
    - \* It is used to store NVS encryption keys when *NVS Encryption* feature is enabled.
    - \* The size of this partition should be 4096 bytes (minimum partition size).
  - There are other predefined data subtypes for data storage supported by ESP-IDF. These include *FAT filesystem* (`ESP_PARTITION_SUBTYPE_DATA_FAT`), *SPIFFS* (`ESP_PARTITION_SUBTYPE_DATA_SPIFFS`), etc. Other subtypes of `data` type are reserved for future ESP-IDF uses.
- If the partition type is any application-defined value (range 0x40-0xFE), then `subtype` field can be any value chosen by the application (range 0x00-0xFE). Note that when writing in C++, an application-defined subtype value requires casting to type `esp_partition_subtype_t` in order to use it with the *partition API*.

### Extra Partition SubTypes

A component can define a new partition subtype by setting the `EXTRA_PARTITION_SUBTYPES` property. This property is a CMake list, each entry of which is a comma separated string with `<type>`, `<subtype>`, `<value>` format. The build system uses this property to add extra subtypes and creates fields named `ESP_PARTITION_SUBTYPE_<type>_<subtype>` in `esp_partition_type_t`. The project can use this subtype to define partitions in the partitions table CSV file and use the new fields in `esp_partition_type_t`.

### Offset & Size

Partitions with blank offsets in the CSV file will start after the previous partition, or after the partition table in the case of the first partition.

Partitions of type `app` have to be placed at offsets aligned to 0x10000 (64K). If you leave the offset field blank, `gen_esp32part.py` will automatically align the partition. If you specify an unaligned offset for an app partition, the tool will return an error.

Sizes and offsets can be specified as decimal numbers, hex numbers with the prefix 0x, or size multipliers K or M (1024 and 1024\*1024 bytes).

If you want the partitions in the partition table to work relative to any placement (`CONFIG_PARTITION_TABLE_OFFSET`) of the table itself, leave the offset field (in CSV file) for all partitions blank. Similarly, if changing the partition table offset then be aware that all blank partition offsets may change to match, and that any fixed offsets may now collide with the partition table (causing an error).

## Flags

Only one flag is currently supported, `encrypted`. If this field is set to `encrypted`, this partition will be encrypted if *Flash Encryption* is enabled.

---

**Note:** `app` type partitions will always be encrypted, regardless of whether this flag is set or not.

---

### 4.19.4 Generating Binary Partition Table

The partition table which is flashed to the ESP32-C3 is in a binary format, not CSV. The tool `partition_table/gen_esp32part.py` is used to convert between CSV and binary formats.

If you configure the partition table CSV name in the project configuration (`idf.py menuconfig`) and then build the project or run `idf.py partition-table`, this conversion is done as part of the build process.

To convert CSV to Binary manually:

```
python gen_esp32part.py input_partitions.csv binary_partitions.bin
```

To convert binary format back to CSV manually:

```
python gen_esp32part.py binary_partitions.bin input_partitions.csv
```

To display the contents of a binary partition table on stdout (this is how the summaries displayed when running `idf.py partition-table` are generated:

```
python gen_esp32part.py binary_partitions.bin
```

### 4.19.5 Partition Size Checks

The ESP-IDF build system will automatically check if generated binaries fit in the available partition space, and will fail with an error if a binary is too large.

Currently these checks are performed for the following binaries:

- Bootloader binary must fit in space before partition table (see *Bootloader Size*).
- App binary should fit in at least one partition of type “app”. If the app binary doesn’t fit in any app partition, the build will fail. If it only fits in some of the app partitions, a warning is printed about this.

---

**Note:** Although the build process will fail if the size check returns an error, the binary files are still generated and can be flashed (although they may not work if they are too large for the available space.)

---

### MD5 checksum

The binary format of the partition table contains an MD5 checksum computed based on the partition table. This checksum is used for checking the integrity of the partition table during the boot.

The MD5 checksum generation can be disabled by the `--disable-md5sum` option of `gen_esp32part.py` or by the `CONFIG_PARTITION_TABLE_MD5` option.

### 4.19.6 Flashing the partition table

- `idf.py partition-table-flash`: will flash the partition table with `esptool.py`.
- `idf.py flash`: Will flash everything including the partition table.

A manual flashing command is also printed as part of `idf.py partition-table` output.

---

**Note:** Note that updating the partition table doesn't erase data that may have been stored according to the old partition table. You can use `idf.py erase-flash` (or `esptool.py erase_flash`) to erase the entire flash contents.

---

### 4.19.7 Partition Tool (`parttool.py`)

The component `partition_table` provides a tool `parttool.py` for performing partition-related operations on a target device. The following operations can be performed using the tool:

- reading a partition and saving the contents to a file (`read_partition`)
- writing the contents of a file to a partition (`write_partition`)
- erasing a partition (`erase_partition`)
- retrieving info such as name, offset, size and flag ( "encrypted" ) of a given partition (`get_partition_info`)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool's Python API and command-line interface, respectively.

#### Python API

Before anything else, make sure that the `parttool` module is imported.

```
import sys
import os

idf_path = os.environ["IDF_PATH"] # get value of IDF_PATH from environment
parttool_dir = os.path.join(idf_path, "components", "partition_table") # parttool.
↳py lives in $IDF_PATH/components/partition_table

sys.path.append(parttool_dir) # this enables Python to find parttool module
from parttool import * # import all names inside parttool module
```

The starting point for using the tool's Python API to do is create a `ParttoolTarget` object:

```
# Create a parttool.py target device connected on serial port /dev/ttyUSB1
target = ParttoolTarget("/dev/ttyUSB1")
```

The created object can now be used to perform operations on the target device:

```
# Erase partition with name 'storage'
target.erase_partition(PartitionName("storage"))

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin'
↳'
target.read_partition(PartitionType("data", "spiffs"), "spiffs.bin")

# Write to partition 'factory' the contents of a file named 'factory.bin'
target.write_partition(PartitionName("factory"), "factory.bin")

# Print the size of default boot partition
storage = target.get_partition_info(PARTITION_BOOT_DEFAULT)
print(storage.size)
```

The partition to operate on is specified using `PartitionName` or `PartitionType` or `PARTITION_BOOT_DEFAULT`. As the name implies, these can be used to refer to partitions of a particular name, type-subtype combination, or the default boot partition.

More information on the Python API is available in the docstrings for the tool.

## Command-line Interface

The command-line interface of *parttool.py* has the following structure:

```
parttool.py [command-args] [subcommand] [subcommand-args]
```

- `command-args` - These are arguments that are needed **for** executing the main `command` (`parttool.py`), mostly pertaining to the target device
- `subcommand` - This is the operation to be performed
- `subcommand-args` - These are arguments that are specific to the chosen operation

```
# Erase partition with name 'storage'
parttool.py --port "/dev/ttyUSB1" erase_partition --partition-name=storage

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin'
parttool.py --port "/dev/ttyUSB1" read_partition --partition-type=data --partition-
  subtype=spiffs --output "spiffs.bin"

# Write to partition 'factory' the contents of a file named 'factory.bin'
parttool.py --port "/dev/ttyUSB1" write_partition --partition-name=factory --input
  "factory.bin"

# Print the size of default boot partition
parttool.py --port "/dev/ttyUSB1" get_partition_info --partition-boot-default --
  info size
```

More information can be obtained by specifying `-help` as argument:

```
# Display possible subcommands and show main command argument descriptions
parttool.py --help

# Show descriptions for specific subcommand arguments
parttool.py [subcommand] --help
```

## 4.20 Performance

ESP-IDF ships with default settings that are designed for a trade-off between performance, resource usage, and available functionality.

These guides describe how to optimize a firmware application for a particular aspect of performance. Usually this involves some trade-off in terms of limiting available functions, or swapping one aspect of performance (such as execution speed) for another (such as RAM usage).

### 4.20.1 How to Optimize Performance

1. Decide what the performance-critical aspects of your application are (for example: a particular response time to a certain network operation, a particular startup time limit, particular peripheral data throughput, etc.).
2. Find a way to measure this performance (some methods are outlined in the guides below).
3. Modify the code and project configuration and compare the new measurement to the old measurement.
4. Repeat step 3 until the performance meets the requirements set out in step 1.

## 4.20.2 Guides

### Maximizing Execution Speed

**Overview** Optimizing execution speed is a key element of software performance. Code that executes faster can also have other positive effects, like reducing overall power consumption. However, improving execution speed may have trade-offs with other aspects of performance such as [Minimizing Binary Size](#).

**Choose What To Optimize** If a function in the application firmware is executed once per week in the background, it may not matter if that function takes 10 ms or 100 ms to execute. If a function is executed constantly at 10 Hz, it matters greatly if it takes 10 ms or 100 ms to execute.

Most application firmwares will only have a small set of functions which require optimal performance. Perhaps those functions are executed very often, or have to meet some application requirements for latency or throughput. Optimization efforts should be targeted at these particular functions.

**Measuring Performance** The first step to improving something is to measure it.

**Basic Performance Measurements** If measuring performance relative to an external interaction with the world, you may be able to measure this directly (for example see the examples [wifi/iperf](#) and [ethernet/iperf](#) for measuring general network performance, or you can use an oscilloscope or logic analyzer to measure timing of an interaction with a device peripheral.)

Otherwise, one way to measure performance is to augment the code to take timing measurements:

```
#include "esp_timer.h"

void measure_important_function(void) {
    const unsigned MEASUREMENTS = 5000;
    uint64_t start = esp_timer_get_time();

    for (int retries = 0; retries < MEASUREMENTS; retries++) {
        important_function(); // This is the thing you need to measure
    }

    uint64_t end = esp_timer_get_time();

    printf("%u iterations took %llu milliseconds (%llu microseconds per_
↪invocation)\n",
           MEASUREMENTS, (end - start)/1000, (end - start)/MEASUREMENTS);
}
```

Executing the target multiple times can help average out factors like RTOS context switches, overhead of measurements, etc.

- Using `esp_timer_get_time()` generates “wall clock” timestamps with microsecond precision, but has moderate overhead each time the timing functions are called.
- It’s also possible to use the standard Unix `gettimeofday()` and `utime()` functions, although the overhead is slightly higher.
- Otherwise, including `hal/cpu_hal.h` and calling the HAL function `cpu_hal_get_cycle_count()` will return the number of CPU cycles executed. This function has lower overhead than the others. It is good for measuring very short execution times with high precision.
- If making “microbenchmarks” (i.e. benchmarking only a very small routine of code that runs in less than 1-2 milliseconds) then flash cache performance can sometimes cause big variations in timing measurements depending on the binary. This happens because binary layout can cause different patterns of cache misses in a particular sequence of execution. If the test code is larger then this effect usually averages out. Executing a small function multiple times when benchmarking can help reduce the impact of flash cache misses. Alternatively, move this code to IRAM (see [Targeted Optimizations](#)).

**External Tracing** The *Application Level Tracing library* allows measuring code execution with minimal impact on the code itself.

**Tasks** If the option `CONFIG_FREERTOS_GENERATE_RUN_TIME_STATS` is enabled then the FreeRTOS API `vTaskGetRunTimeStats()` can be used to retrieve runtime information about the processor time used by each FreeRTOS task.

*SEGGER SystemView* is an excellent tool for visualizing task execution and looking for performance issues or improvements in the system as a whole.

**Improving Overall Speed** The following optimizations will improve the execution of nearly all code - including boot times, throughput, latency, etc:

- Set `CONFIG_ESPTOOLPY_FLASHMODE` to QIO or QOUT mode (Quad I/O). Both will almost double the speed at which code is loaded or executed from flash compared to the default DIO mode. QIO is slightly faster than QOUT if both are supported. Note that both the flash chip model and the electrical connections between the ESP32-C3 and the flash chip must support quad I/O modes or the SoC will not work correctly.
- Set `CONFIG_COMPILER_OPTIMIZATION` to “Optimize for performance (-O2)”. This may slightly increase binary size compared to the default setting, but will almost certainly increase performance of some code. Note that if your code contains C or C++ Undefined Behaviour then increasing the compiler optimization level may expose bugs that otherwise are not seen.
- Avoid using floating point arithmetic (`float`). On ESP32-C3 these calculations are emulated in software and are very slow. If possible then use fixed point representations, a different method of integer representation, or convert part of the calculation to be integer only before switching to floating point.
- Avoid using double precision floating point arithmetic (`double`). These calculations are emulated in software and are very slow. If possible then use an integer-based representation, or single-precision floating point.

**Reduce Logging Overhead** Although standard output is buffered, it’s possible for an application to be limited by the rate at which it can print data to log output once buffers are full. This is particularly relevant for startup time if a lot of output is logged, but can happen at other times as well. There are multiple ways to solve this problem:

- Reduce the volume of log output by lowering the app `CONFIG_LOG_DEFAULT_LEVEL` (the equivalent boot-loader setting is `CONFIG_BOOTLOADER_LOG_LEVEL`). This also reduces the binary size, and saves some CPU time spent on string formatting.
- Increase the speed of logging output by increasing the `CONFIG_ESP_CONSOLE_UART_BAUDRATE`

**Not Recommended** The following options will also increase execution speed, but are not recommended as they also reduce the debuggability of the firmware application and may increase the severity of any bugs.

- Set `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL` to disabled. This also reduces firmware binary size by a small amount. However, it may increase the severity of bugs in the firmware including security-related bugs. If necessary to do this to optimize a particular function, consider adding `#define NDEBUG` in the top of that single source file instead.

**Targeted Optimizations** The following changes will increase the speed of a chosen part of the firmware application:

- Move frequently executed code to IRAM. By default, all code in the app is executed from flash cache. This means that it’s possible for the CPU to have to wait on a “cache miss” while the next instructions are loaded from flash. Functions which are copied into IRAM are loaded once at boot time, and then will always execute at full speed.

IRAM is a limited resource, and using more IRAM may reduce available DRAM, so a strategic approach is needed when moving code to IRAM. See *IRAM (Instruction RAM)* for more information.

- Jump table optimizations can be re-enabled for individual source files that don't need to be placed in IRAM. For hot paths in large switch cases this will improve performance. For instructions on how to add the `-fjump-tables -fno-switch-conversion` options when compiling individual source files, see *Controlling Component Compilation*

**Improving Startup Time** In addition to the overall performance improvements shown above, the following options can be tweaked to specifically reduce startup time:

- Minimizing the `CONFIG_LOG_DEFAULT_LEVEL` and `CONFIG_BOOTLOADER_LOG_LEVEL` has a large impact on startup time. To enable more logging after the app starts up, set the `CONFIG_LOG_MAXIMUM_LEVEL` as well and then call `esp_log_level_set()` to restore higher level logs. The `system/startup_time` main function shows how to do this.
- If using deep sleep, setting `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` allows a faster wake from sleep. Note that if using Secure Boot this represents a security compromise, as Secure Boot validation will not be performed on wake.
- Setting `CONFIG_BOOTLOADER_SKIP_VALIDATE_ON_POWER_ON` will skip verifying the binary on every boot from power-on reset. How much time this saves depends on the binary size and the flash settings. Note that this setting carries some risk if the flash becomes corrupt unexpectedly. Read the help text of the *config item* for an explanation and recommendations if using this option.
- It's possible to save a small amount of time during boot by disabling RTC slow clock calibration. To do so, set `CONFIG_RTC_CLK_CAL_CYCLES` to 0. Any part of the firmware that uses RTC slow clock as a timing source will be less accurate as a result.

The example project `system/startup_time` is pre-configured to optimize startup time. The file `system/startup_time/sdkconfig.defaults` contain all of these settings. You can append these to the end of your project's own `sdkconfig` file to merge the settings, but please read the documentation for each setting first.

**Task Priorities** As ESP-IDF FreeRTOS is a real-time operating system, it's necessary to ensure that high throughput or low latency tasks are granted a high priority in order to run immediately. Priority is set when calling `xTaskCreate()` or `xTaskCreatePinnedToCore()` and can be changed at runtime by calling `vTaskPrioritySet()`.

It's also necessary to ensure that tasks yield CPU (by calling `vTaskDelay()`, `sleep()`, or by blocking on semaphores, queues, task notifications, etc) in order to not starve lower priority tasks and cause problems for the overall system. The *Task Watchdog Timer (TWDT)* provides a mechanism to automatically detect if task starvation happens, however note that a Task WDT timeout does not always indicate a problem (sometimes the correct operation of the firmware requires some long-running computation). In these cases tweaking the Task WDT timeout or even disabling the Task WDT may be necessary.

**Built-In Task Priorities** ESP-IDF starts a number of system tasks at fixed priority levels. Some are automatically started during the boot process, some are started only if the application firmware initializes a particular feature. To optimize performance, structure application task priorities so that they are not delayed by system tasks, while also not starving system tasks and impacting other functions of the system.

This may require splitting up a particular task. For example, perform a time-critical operation in a high priority task or an interrupt handler and do the non-time-critical part in a lower priority task.

Header `components/esp_system/include/esp_task.h` contains macros for the priority levels used for built-in ESP-IDF tasks system.

Common priorities are:

- *Main task that executes app\_main function* has minimum priority (1).
- *High Resolution Timer (ESP Timer)* system task to manage timer events and execute callbacks has high priority (22, `ESP_TASK_TIMER_PRI0`)

- FreeRTOS Timer Task to handle FreeRTOS timer callbacks is created when the scheduler initializes and has minimum task priority (1, *configurable*).
- *Event Handling* system task to manage the default system event loop and execute callbacks has high priority (20, `ESP_TASK_EVENT_PRI0`). This configuration is only used if the application calls `esp_event_loop_create_default()`, it's possible to call `esp_event_loop_create()` with a custom task configuration instead.
- *lwIP* TCP/IP task has high priority (18, `ESP_TASK_TCPIP_PRI0`).
- *Wi-Fi Driver* task has high priority (23).
- Wi-Fi wpa\_supplicant component may create dedicated tasks while the Wi-Fi Protected Setup (WPS), WPA2 EAP-TLS, Device Provisioning Protocol (DPP) or BSS Transition Management (BTM) features are in use. These tasks all have low priority (2).
- *Bluetooth Controller* task has high priority (23, `ESP_TASK_BT_CONTROLLER_PRI0`). The Bluetooth Controller needs to respond to requests with low latency, so it should always be close to the highest priority task in the system.
- *NimBLE Bluetooth Host* host task has high priority (21).
- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the priority is medium-high (15). This setting can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
- If using the *MQTT* component, it creates a task with default priority 5 (*configurable*, depends on `CONFIG_MQTT_USE_CUSTOM_CONFIG` (also configurable runtime by `task_prio` field in the `esp_mqtt_client_config_t`)).
- To see what is the task priority for mDNS service, please check [Performance Optimization](#).

**Choosing application task priorities** In general, it's not recommended to set task priorities higher than the built-in Wi-Fi/BT operations as starving them of CPU may make the system unstable. For very short timing-critical operations that don't use the network, use an ISR or a very restricted task (very short bursts of runtime only) at highest priority (24). Choosing priority 19 will allow lower layer Wi-Fi/BT functionality to run without delays, but still preempts the lwIP TCP/IP stack and other less time-critical internal functionality - this is the best option for time-critical tasks that don't perform network operations. Any task that does TCP/IP network operations should run at lower priority than the lwIP TCP/IP task (18) to avoid priority inversion issues.

---

**Note:** Task execution is always completely suspended when writing to the built-in SPI flash chip. Only *IRAM-Safe Interrupt Handlers* will continue executing.

---

**Improving Interrupt Performance** ESP-IDF supports dynamic *Interrupt allocation* with interrupt preemption. Each interrupt in the system has a priority, and higher priority interrupts will preempt lower priority ones.

Interrupt handlers will execute in preference to any task (provided the task is not inside a critical section). For this reason, it's important to minimize the amount of time spent executing in an interrupt handler.

To obtain the best performance for a particular interrupt handler:

- Assign more important interrupts a higher priority using a flag such as `ESP_INTR_FLAG_LEVEL2` or `ESP_INTR_FLAG_LEVEL3` when calling `esp_intr_alloc()`.
- If you're sure the entire interrupt handler can run from IRAM (see *IRAM-Safe Interrupt Handlers*) then set the `ESP_INTR_FLAG_IRAM` flag when calling `esp_intr_alloc()` to assign the interrupt. This prevents it being temporarily disabled if the application firmware writes to the internal SPI flash.
- Even if the interrupt handler is not IRAM safe, if it is going to be executed frequently then consider moving the handler function to IRAM anyhow. This minimizes the chance of a flash cache miss when the interrupt code is executed (see *Targeted Optimizations*). It's possible to do this without adding the `ESP_INTR_FLAG_IRAM` flag to mark the interrupt as IRAM-safe, if only part of the handler is guaranteed to be in IRAM.

### Improving Network Speed

- For Wi-Fi, see [How to Improve Wi-Fi Performance](#) and [Wi-Fi Buffer Usage](#)

- For lwIP TCP/IP (Wi-Fi and Ethernet), see [Performance Optimization](#)
- The `wifi/iperf` example contains a configuration that is heavily optimized for Wi-Fi TCP/IP throughput. Append the contents of the files `wifi/iperf/sdkconfig.defaults`, `wifi/iperf/sdkconfig.defaults.esp32c3` and `wifi/iperf/sdkconfig.ci.99` to your project `sdkconfig` file in order to add all of these options. Note that some of these options may have trade-offs in terms of reduced debuggability, increased firmware size, increased memory usage, or reduced performance of other features. To get the best result, read the documentation pages linked above and use this information to determine exactly which options are best suited for your app.

## Minimizing Binary Size

The ESP-IDF build system compiles all source files in the project and ESP-IDF, but only functions and variables that are actually referenced by the program are linked into the final binary. In some cases, it is necessary to reduce the total size of the firmware binary (for example, in order to fit it into the available flash partition size).

The first step to reducing the total firmware binary size is measuring what is causing the size to increase.

**Measuring Static Sizes** To optimize both firmware binary size and memory usage it's necessary to measure statically allocated RAM ( “data” , “bss” ), code ( “text” ) and read-only data ( “rodata” ) in your project.

Using the `idf.py` sub-commands `size`, `size-components` and `size-files` provides a summary of memory used by the project:

### Size Summary (`idf.py size`)

```
$ idf.py size
[...]
Total sizes:
DRAM .data size: 11584 bytes
DRAM .bss size: 19624 bytes
Used static DRAM: 0 bytes ( 0 available, nan% used)
Used static IRAM: 0 bytes ( 0 available, nan% used)
Used stat D/IRAM: 136276 bytes ( 519084 available, 20.8% used)
  Flash code: 630508 bytes
  Flash rodata: 177048 bytes
Total image size:~ 924208 bytes (.bin may be padded larger)
```

This output breaks down the size of all static memory regions in the firmware binary:

- `DRAM .data size` is statically allocated RAM that is assigned to non-zero values at startup. This uses RAM (DRAM) at runtime and also uses space in the binary file.
- `DRAM .bss size` is statically allocated RAM that is assigned zero at startup. This uses RAM (DRAM) at runtime but doesn't use any space in the binary file.
- `Used static DRAM`, `Used static IRAM` - these options are kept for compatibility with ESP32 target, and currently read 0.
- `Used stat D/IRAM` - This is total internal RAM usage, the sum of static DRAM `.data` + `.bss`, and also static *IRAM (Instruction RAM)* used by the application for executable code. The `available` size is the estimated amount of DRAM which will be available as heap memory at runtime (due to metadata overhead and implementation constraints, and heap allocations done by ESP-IDF during startup, the actual free heap at startup will be lower than this).
- `Flash code` is the total size of executable code executed from flash cache (*IROM*). This uses space in the binary file.
- `Flash rodata` is the total size of read-only data loaded from flash cache (*DROM*). This uses space in the binary file.
- `Total image size` is the estimated total binary file size, which is the total of all the used memory types except for `.bss`.

**Component Usage Summary (idf.py size-components)** The summary output provided by `idf.py size` does not give enough detail to find the main contributor to excessive binary size. To analyze in more detail, use `idf.py size-components`

```
$ idf.py size-components

The first lines of output from `idf.py size-components` are the same as `idf.py size`. After this a table is printed of “per-archive contributions to ELF file”. This means how much each static library archive has contributed to the final binary size.

Generally, one static library archive is built per component, although some are binary libraries included by a particular component (for example, `libnet80211.a` is included by `esp_wifi` component). There are also toolchain

libraries such as `libc.a` and `libgcc.a` listed here, these provide Standard C/C++ Library and toolchain built-in functionality.

If your project is simple and only has a “main” component, then all of the project’s code will be shown under `libmain.a`. If your project includes its own components (see [Build System](#)), then they will each be shown on a separate line.

The table is sorted in descending order of the total contribution to the binary size.

The columns are as follows:

- DRAM `.data` & `.bss` & other - `.data` and `.bss` are the same as for the totals shown above (static variables, these both reduce total available RAM at runtime but `.bss` doesn’t contribute to the binary file size). “other” is a column for any custom section types that also contribute to RAM size (usually this value is 0).
- IRAM - is the same as for the totals shown above (code linked to execute from IRAM, uses space in the binary file and also reduces DRAM available as heap at runtime).
- Flash code & rodata - these are the same as the totals above, IROM and DROM space accessed from flash cache that contribute to the binary size.

**Source File Usage Summary (`idf.py size-files`)** For even more detail, run `idf.py size-files` to get a summary of the contribution each object file has made to the final binary size. Each object file corresponds to a single source file.

```

[... additional lines removed ...]								

After the summary of total sizes, a table of “Per-file contributions to ELF file” is printed.

The columns are the same as shown above for `idy.py size-components`, but this time the granularity is the contribution of each individual object file to the binary size.

For example, we can see that the file `x509_cert_bundle.S.o` contributed 64212 bytes to the total firmware size, all as `.rodata` in flash. Therefore we can guess that this application is using the *ESP x509 Certificate Bundle* feature and not using this feature would save at least this many bytes from the firmware size.

Some of the object files are linked from binary libraries and therefore you won't find a corresponding source file. To locate which component a source file belongs to, it's generally possible to search in the ESP-IDF source tree or look in the *Linker Map File* for the full path.

**Comparing Two Binaries** If making some changes that affect binary size, it's possible to use an ESP-IDF tool to break down the exact differences in size.

This operation isn't part of `idf.py`, it's necessary to run the `idf-size.py` Python tool directly.

To do so, first locate the linker map file in the build directory. It will have the name `PROJECTNAME.map`. The `idf-size.py` tool performs its analysis based on the output of the linker map file.

To compare with another binary, you will also need its corresponding `.map` file saved from the build directory.

For example, to compare two builds: one with the default `CONFIG_COMPILER_OPTIMIZATION` setting “Debug (-Og)” configuration and one with “Optimize for size (-Os)” :

```
$ $IDF_PATH/tools/idf_size.py --diff build_Og/https_request.map build_Os/https_
↪request.map
<CURRENT> MAP file: build_Os/https_request.map
<REFERENCE> MAP file: build_Og/https_request.map
Difference is counted as <CURRENT> - <REFERENCE>, i.e. a positive number means_
↪that <CURRENT> is larger.
Total sizes of <CURRENT>:
↪<REFERENCE>      Difference
DRAM .data size:  14516 bytes
↪14956            -440
DRAM .bss size:   15792 bytes
↪15808           -16
Used static DRAM: 30308 bytes ( 150428 available, 16.8% used)
↪30764           -456 ( +456 available, +0 total)
Used static IRAM: 78498 bytes ( 52574 available, 59.9% used)
↪83918          -5420 ( +5420 available, +0 total)
    Flash code:   509183 bytes
↪559943         -50760
    Flash rodata: 170592 bytes
↪176736         -6144
Total image size:~ 772789 bytes (.bin may be padded larger)
↪835553         -62764
```

We can see from the “Difference” column that changing this one setting caused the whole binary to be over 60 KB smaller and over 5 KB more RAM is available.

It’s also possible to use the “diff” mode to output a table of component-level (static library archive) differences:

```
$ $IDF_PATH/tools/idf_size.py --archives --diff build_Og/https_request.map build_
↪Oshttps_request.map
```

Also at the individual source file level:

```
$ $IDF_PATH/tools/idf_size.py --files --diff build_Og/https_request.map build_
↪Oshttps_request.map
```

Other options (like writing the output to a file) are available, pass `--help` to see the full list.

**Showing Size When Linker Fails** If too much static memory is used, then the linker will fail with an error such as DRAM segment data does not fit, region ``iram0_0_seg'` overflowed by 44 bytes, or similar.

In these cases, `idf.py size` will not succeed either. However it is possible to run `idf_size.py` manually in order to view the *partial static memory usage* (the memory usage will miss the variables which could not be linked, so there still appears to be some free space.)

The map file argument is `<projectname>.map` in the build directory

```
$ $IDF_PATH/tools/idf_size.py build/project_name.map
```

It is also possible to view the equivalent of `size-components` or `size-files` output:

```
$ $IDF_PATH/tools/idf_size.py --archives build/project_name.map
$ $IDF_PATH/tools/idf_size.py --files build/project_name.map
```

**Linker Map File** *This is an advanced analysis method, but it can be very useful. Feel free to skip ahead to [:ref:reducing-overall-size](#) and possibly come back to this later.*

The `idf.py` size analysis tools all work by parsing the GNU binutils “linker map file”, which is a summary of everything the linker did when it created (“linked”) the final firmware binary file

Linker map files themselves are plain text files, so it’s possible to read them and find out exactly what the linker did. However, they are also very complex and long - often 100,000 or more lines!

The map file itself is broken into parts and each part has a heading. The parts are:

- `Archive member included to satisfy reference by file (symbol)`. This shows you: for each object file included in the link, what symbol (function or variable) was the linker searching for when it included that object file. If you’re wondering why some object file in particular was included in the binary, this part may give a clue. This part can be used in conjunction with the `Cross Reference Table` at the end of the file. Note that not every object file shown in this list ends up included in the final binary, some end up in the `Discarded input sections` list instead.
- `Allocating common symbols` - This is a list of (some) global variables along with their sizes. Common symbols have a particular meaning in ELF binary files, but ESP-IDF doesn’t make much use of them.
- `Discarded input sections` - These sections were read by the linker as part of an object file to be linked into the final binary, but then nothing else referred to them so they were discarded from the final binary. For ESP-IDF this list can be very long, as we compile each function and static variable to a unique section in order to minimize the final binary size (specifically ESP-IDF uses compiler options `-ffunction-sections` `-fdata-sections` and linker option `--gc-sections`). Items mentioned in this list *do not* contribute to the final binary.
- `Memory Configuration, Linker script and memory map` These two parts go together. Some of the output comes directly from the linker command line and the Linker Script, both provided by the [Build System](#). The linker script is partially generated from the ESP-IDF project using the [Linker Script Generation](#) feature.  
As the output of the `Linker script` and `memory map` part of the map unfolds, you can see each symbol (function or static variable) linked into the final binary along with its address (as a 16 digit hex number), its length (also in hex), and the library and object file it was linked from (which can be used to determine the component and the source file).  
Following all of the output sections that take up space in the final `.bin` file, the `memory map` also includes some sections in the ELF file that are only used for debugging (ELF sections `.debug_*`, etc.). These don’t contribute to the final binary size. You’ll notice the address of these symbols is a very low number (starting from `0x0000000000000000` and counting up).
- `Cross Reference Table`. This table shows for each symbol (function or static variable), the list of object file(s) that referred to it. If you’re wondering why a particular thing is included in the binary, this will help determine what included it.

---

**Note:** Unfortunately, the `Cross Reference Table` doesn’t only include symbols that made it into the final binary. It also includes symbols in discarded sections. Therefore, just because something is shown here doesn’t mean that it was included in the final binary - this needs to be checked separately.

---

---

**Note:** Linker map files are generated by the GNU binutils linker “ld”, not ESP-IDF. You can find additional information online about the linker map file format. This quick summary is written from the perspective of ESP-IDF build system in particular.

---

**Reducing Overall Size** The following configuration options will reduce the final binary size of almost any ESP-IDF project:

- Set `CONFIG_COMPILER_OPTIMIZATION` to “Optimize for size (-Os)”. In some cases, “Optimize for performance (-O2)” will also reduce the binary size compared to the default. Note that if your code contains C or C++ Undefined Behaviour then increasing the compiler optimization level may expose bugs that otherwise don’t happen.
- Reduce the compiled-in log output by lowering the app `CONFIG_LOG_DEFAULT_LEVEL`. If the `CONFIG_LOG_MAXIMUM_LEVEL` is changed from the default then this setting controls the binary size instead.

Reducing compiled-in logging reduces the number of strings in the binary, and also the code size of the calls to logging functions.

- Set the `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL` to “Silent”. This avoids compiling in a dedicated assertion string and source file name for each assert that may fail. It’s still possible to find the failed assert in the code by looking at the memory address where the assertion failed.
- Besides the `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL`, you can disable or silent the assertion for HAL component separately by setting `CONFIG_HAL_DEFAULT_ASSERTION_LEVEL`. It is to notice that ESP-IDF lowers HAL assertion level in bootloader to be silent even if `CONFIG_HAL_DEFAULT_ASSERTION_LEVEL` is set to full-assertion level. This is to reduce the bootloader size.
- Set `CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT`. This removes specific error messages for particular internal ESP-IDF error check macros. This may make it harder to debug some error conditions by reading the log output.
- If the binary needs to run on only certain revision(s) of ESP32-C3, increasing `CONFIG_ESP32C3_REV_MIN` to match can result in a reduced binary size. This is particularly true if setting ESP32-C3 minimum revision 3 and using Wi-Fi, as some functionality was moved to ROM code.
- Don’t enable `CONFIG_COMPILER_CXX_EXCEPTIONS`, `CONFIG_COMPILER_CXX_RTTI`, or set the `CONFIG_COMPILER_STACK_CHECK_MODE` to Overall. All of these options are already disabled by default, but they have a large impact on binary size.
- Disabling `CONFIG_ESP_ERR_TO_NAME_LOOKUP` will remove the lookup table to translate user-friendly names for error values (see *Error Handling*) in error logs, etc. This saves some binary size, but error values will be printed as integers only.
- Setting `CONFIG_ESP_SYSTEM_PANIC` to “Silent reboot” will save a small amount of binary size, however this is *only* recommended if no one will use UART output to debug the device.
- Set `CONFIG_COMPILER_SAVE_RESTORE_LIBCALLS` to reduce binary size by replacing inlined prologues/epilogues with library calls.
- If the application binary uses only one of the security versions of the protocomm component, then the support for others can be disabled to save some code size. The support can be disabled through `CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_0`, `CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_1` or `CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_2` respectively.

---

**Note:** In addition to the many configuration items shown here, there are a number of configuration options where changing the option from the default will increase binary size. These are not noted here. Where the increase is significant, this is usually noted in the configuration item help text.

---

**Targeted Optimizations** The following binary size optimizations apply to a particular component or a function:

#### Wi-Fi

- Disabling `CONFIG_ESP32_WIFI_ENABLE_WPA3_SAE` will save some Wi-Fi binary size if WPA3 support is not needed. (Note that WPA3 is mandatory for new Wi-Fi device certifications.)
- Disabling `CONFIG_ESP_WIFI_SOFTAP_SUPPORT` will save some Wi-Fi binary size if soft-AP support is not needed.
- Disabling `CONFIG_ESP_WIFI_ENTERPRISE_SUPPORT` will save some Wi-Fi binary size if enterprise support is not needed.

**Bluetooth NimBLE** If using *NimBLE Bluetooth Host* then the following modifications can reduce binary size:

- `CONFIG_BT_NIMBLE_MAX_CONNECTIONS` to 1 if only one BLE connection is needed.
- Disable either `CONFIG_BT_NIMBLE_ROLE_CENTRAL` or `CONFIG_BT_NIMBLE_ROLE_OBSERVER` if these roles are not needed.
- Reducing `CONFIG_BT_NIMBLE_LOG_LEVEL` can reduce binary size. Note that if the overall log level has been reduced as described above in *Reducing Overall Size* then this also reduces the NimBLE log level.

### lwIP IPv6

- Setting `CONFIG_LWIP_IPV6` to false will reduce the size of the lwIP TCP/IP stack, at the cost of only supporting IPv4.

---

**Note:** IPv6 is required by some components such as `coap` and `ASIO port`. These components will not be available if IPV6 is disabled.

---

**Newlib nano formatting** By default, ESP-IDF uses newlib “full” formatting for I/O (`printf`, `scanf`, etc.)

Enabling the config option `CONFIG_NEWLIB_NANO_FORMAT` will switch newlib to the “nano” formatting mode. This both smaller in code size and a large part of the implementation is compiled into the ESP32-C3 ROM, so it doesn't need to be included in the binary at all.

The exact difference in binary size depends on which features the firmware uses, but 25 KB ~ 50 KB is typical.

Enabling Nano formatting also reduces the stack usage of each function that calls `printf()` or another string formatting function, see [Reducing Stack Sizes](#).

“Nano” formatting doesn't support 64-bit integers, or C99 formatting features. For a full list of restrictions, search for `--enable-newlib-nano-formatted-io` in the [Newlib README file](#).

**mbedTLS features** Under *Component Config* -> *mbedTLS* there are multiple mbedTLS features which are enabled by default but can be disabled if not needed to save code size.

These include:

- `CONFIG_MBEDTLS_HAVE_TIME`
- `CONFIG_MBEDTLS_ECDSA_DETERMINISTIC`
- `CONFIG_MBEDTLS_SHA512_C`
- `CONFIG_MBEDTLS_SHA3_C`
- `CONFIG_MBEDTLS_CLIENT_SSL_SESSION_TICKETS`
- `CONFIG_MBEDTLS_SERVER_SSL_SESSION_TICKETS`
- `CONFIG_MBEDTLS_SSL_CONTEXT_SERIALIZATION`
- `CONFIG_MBEDTLS_SSL_ALPN`
- `CONFIG_MBEDTLS_SSL_RENEGOTIATION`
- `CONFIG_MBEDTLS_CCM_C`
- `CONFIG_MBEDTLS_GCM_C`
- `CONFIG_MBEDTLS_ECP_C` (Alternatively: Leave this option enabled but disable some of the elliptic curves listed in the sub-menu.)
- `CONFIG_MBEDTLS_ECP_NIST_OPTIM`
- `CONFIG_MBEDTLS_ECP_FIXED_POINT_OPTIM`
- Change `CONFIG_MBEDTLS_TLS_MODE` if both server & client functionalities are not needed
- Consider disabling some ciphersuites listed in the “TLS Key Exchange Methods” sub-menu (i.e. `CONFIG_MBEDTLS_KEY_EXCHANGE_RSA`)

The help text for each option has some more information.

---

**Important:** It is **strongly not recommended to disable all these mbedTLS options**. Only disable options where you understand the functionality and are certain that it is not needed in the application. In particular:

- Ensure that any TLS server(s) the device connects to can still be used. If the server is controlled by a third party or a cloud service, recommend ensuring that the firmware supports at least two of the supported cipher suites in case one is disabled in a future update.
- Ensure that any TLS client(s) that connect to the device can still connect with supported/recommended cipher suites. Note that future versions of client operating systems may remove support for some features, so it is recommended to enable multiple supported cipher suites or algorithms for redundancy.

If depending on third party clients or servers, always pay attention to announcements about future changes to supported TLS features. If not, the ESP32-C3 device may become inaccessible if support changes.

---

**Note:** Not every combination of mbedTLS compile-time config is tested in ESP-IDF. If you find a combination that fails to compile or function as expected, please report the details on GitHub.

---

**VFS** *Virtual filesystem* feature in ESP-IDF allows multiple filesystem drivers and file-like peripheral drivers to be accessed using standard I/O functions (`open`, `read`, `write`, etc.) and C library functions (`fopen`, `fread`, `fwrite`, etc.). When filesystem or file-like peripheral driver functionality is not used in the application this feature can be fully or partially disabled. VFS component provides the following configuration options:

- `CONFIG_VFS_SUPPORT_TERMIOS` — can be disabled if the application doesn't use `termios` family of functions. Currently, these functions are implemented only for UART VFS driver. Most applications can disable this option. Disabling this option reduces the code size by about 1.8 kB.
- `CONFIG_VFS_SUPPORT_SELECT` — can be disabled if the application doesn't use `select` function with file descriptors. Currently, only the UART and eventfd VFS drivers implement `select` support. Note that when this option is disabled, `select` can still be used for socket file descriptors. Disabling this option reduces the code size by about 2.7 kB.
- `CONFIG_VFS_SUPPORT_DIR` — can be disabled if the application doesn't use directory related functions, such as `readdir` (see the description of this option for the complete list). Applications which only open, read and write specific files and don't need to enumerate or create directories can disable this option, reducing the code size by 0.5 kB or more, depending on the filesystem drivers in use.
- `CONFIG_VFS_SUPPORT_IO` — can be disabled if the application doesn't use filesystems or file-like peripheral drivers. This disables all VFS functionality, including the three options mentioned above. When this option is disabled, `console` can't be used. Note that the application can still use standard I/O functions with socket file descriptors when this option is disabled. Compared to the default configuration, disabling this option reduces code size by about 9.4 kB.

**Bootloader Size** This document deals with the size of an ESP-IDF app binary only, and not the ESP-IDF *Second stage bootloader*.

For a discussion of ESP-IDF bootloader binary size, see *Bootloader Size*.

**IRAM Binary Size** If the IRAM section of a binary is too large, this issue can be resolved by reducing IRAM memory usage. See *Optimizing IRAM Usage*.

### Minimizing RAM Usage

In some cases, a firmware application's available RAM may run low or run out entirely. In these cases, it's necessary to tune the memory usage of the firmware application.

In general, firmware should aim to leave some “headroom” of free internal RAM in order to deal with extraordinary situations or changes in RAM usage in future updates.

**Background** Before optimizing ESP-IDF RAM usage, it's necessary to understand the basics of ESP32-C3 memory types, the difference between static and dynamic memory usage in C, and the way ESP-IDF uses stack and heap. This information can all be found in *Heap Memory Allocation*.

**Measuring Static Memory Usage** The `idf.py` tool can be used to generate reports about the static memory usage of an application. Refer to *the Binary Size chapter for more information*.

**Measuring Dynamic Memory Usage** ESP-IDF contains a range of heap APIs for measuring free heap at runtime. See [Heap Memory Debugging](#).

---

**Note:** In embedded systems, heap fragmentation can be a significant issue alongside total RAM usage. The heap measurement APIs provide ways to measure the “largest free block”. Monitoring this value along with the total number of free bytes can give a quick indication of whether heap fragmentation is becoming an issue.

---

### Reducing Static Memory Usage

- Reducing the static memory usage of the application increases the amount of RAM available for heap at runtime, and vice versa.
- Generally speaking, minimizing static memory usage requires monitoring the `.data` and `.bss` sizes. For tools to do this, see [Measuring Static Sizes](#).
- Internal ESP-IDF functions do not make heavy use of static RAM allocation in C. In many instances (including: Wi-Fi library, Bluetooth controller) “static” buffers are still allocated from heap, but the allocation is done once when the feature is initialized and will be freed if the feature is deinitialized. This is done in order to maximize the amount of free memory at different points in the application life-cycle.

To minimize static memory use:

- Declare structures, buffers, or other variables `const` whenever possible. Constant data can be stored in flash not RAM. This may require changing functions in the firmware to take `const *` arguments instead of mutable pointer arguments. These changes can also reduce the stack usage of some functions.
- If using Bluedroid, setting the option `CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY` will cause Bluedroid to allocate memory on initialization and free it on deinitialization. This doesn't necessarily reduce the peak memory usage, but changes it from static memory usage to runtime memory usage.
- If `Coredump` component is enabled, `ESP_COREDUMP_LOG` macros will use ~5KB internal memory to place strings into DRAM. By disabling `CONFIG_ESP_COREDUMP_LOGS` option, these logs are disabled and the memory is reclaimed.

**Reducing Stack Sizes** In FreeRTOS, task stacks are usually allocated from the heap. The stack size for each task is fixed (passed as an argument to `xTaskCreate()`). Each task can use up to its allocated stack size, but using more than this will cause an otherwise valid program to crash with a stack overflow or heap corruption.

Therefore, determining the optimum sizes of each task stack can substantially reduce RAM usage.

To determine optimum task stack sizes:

- Combine tasks. The best task stack size is 0 bytes, achieved by combining a task with another existing task. Anywhere that the firmware can be structured to perform multiple functions sequentially in a single task will increase free memory. In some cases, using a “worker task” pattern where jobs are serialized into a FreeRTOS queue (or similar) and then processed by generic worker tasks may help.
- Consolidate task functions. String formatting functions (like `printf`) are particularly heavy users of stack, so any task which doesn't ever call these can usually have its stack size reduced.
- Enabling [Newlib nano formatting](#) will reduce the stack usage of any task that calls `printf()` or other C string formatting functions.
- Avoid allocating large variables on the stack. In C, any large struct or array allocated as an “automatic” variable (i.e. default scope of a C declaration) will use space on the stack. Minimize the sizes of these, allocate them statically and/or see if you can save memory by allocating them from the heap only when they are needed.
- Avoid deep recursive function calls. Individual recursive function calls don't always add a lot of stack usage each time they are called, but if each function includes large stack-based variables then the overhead can get quite high.
- At runtime, call the function `uxTaskGetStackHighWaterMark()` with the handle of any task where you think there is unused stack memory. This function returns the minimum lifetime free stack memory in bytes. The easiest time to call this is from the task itself: call `uxTaskGetStackHighWaterMark(NULL)` to get the current task's high water mark after the time that the task has achieved its peak stack usage (i.e. if there is a main loop, execute the main loop a number of times with all possible states and

then call `uxTaskGetStackHighWaterMark()`. Often, it's possible to subtract almost the entire value returned here from the total stack size of a task, but allow some safety margin to account for unexpected small increases in stack usage at runtime.

- Call `uxTaskGetSystemState()` at runtime to get a summary of all tasks in the system. This includes their individual stack “high watermark” values.
- When debugger watchpoints are not being used, set the `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` option to trigger an immediate panic if a task writes the word at the end of its assigned stack. This is slightly more reliable than the default `CONFIG_FREERTOS_CHECK_STACKOVERFLOW` option of “Check using canary bytes”, because the panic happens immediately, not on the next RTOS context switch. Neither option is perfect, it's possible in some cases for stack pointer to skip the watchpoint or canary bytes and corrupt another region of RAM, instead.

**Internal Stack Sizes** ESP-IDF allocates a number of internal tasks for housekeeping purposes or operating system functions. Some are created during the startup process, and some are created at runtime when particular features are initialized.

The default stack sizes for these tasks are usually set conservatively high, to allow all common usage patterns. Many of the stack sizes are configurable, and it may be possible to reduce them to match the real runtime stack usage of the task.

---

**Important:** If internal task stack sizes are set too small, ESP-IDF will crash unpredictably. Even if the root cause is task stack overflow, this is not always clear when debugging. It is recommended that internal stack sizes are only reduced carefully (if at all), with close attention to “high water mark” free space under load. If reporting an issue that occurs when internal task stack sizes have been reduced, please always include this information and the specific configuration that is being used.

---

- *Main task that executes `app_main` function* has stack size `CONFIG_ESP_MAIN_TASK_STACK_SIZE`.
- *High Resolution Timer (ESP Timer) system task* which executes callbacks has stack size `CONFIG_ESP_TIMER_TASK_STACK_SIZE`.
- *FreeRTOS Timer Task* to handle FreeRTOS timer callbacks has stack size `CONFIG_FREERTOS_TIMER_TASK_STACK_DEPTH`.
- *Event Handling system task* to execute callbacks for the default system event loop has stack size `CONFIG_ESP_SYSTEM_EVENT_TASK_STACK_SIZE`.
- *lwIP TCP/IP task* has stack size `CONFIG_LWIP_TCPIP_TASK_STACK_SIZE`
- *Bluedroid Bluetooth Host* have task stack sizes `CONFIG_BT_BTC_TASK_STACK_SIZE`, `CONFIG_BT_BTU_TASK_STACK_SIZE`.
- *NimBLE Bluetooth Host* has task stack size `CONFIG_BT_NIMBLE_HOST_TASK_STACK_SIZE`
- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the task stack size is 4 KB. This setting can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
- FreeRTOS idle task stack size is configured by `CONFIG_FREERTOS_IDLE_TASK_STACKSIZE`.
- If using the `MQTT` component, it creates a task with stack size configured by `CONFIG_MQTT_TASK_STACK_SIZE`. MQTT stack size can also be configured using `task_stack` field of `esp_mqtt_client_config_t`.
- To see how to optimize RAM usage when using mDNS, please check [Performance Optimization](#).

---

**Note:** Aside from built-in system features such as esp-timer, if an ESP-IDF feature is not initialized by the firmware then no associated task is created. In those cases, the stack usage is zero and the stack size configuration for the task is not relevant.

---

**Reducing Heap Usage** For functions that assist in analyzing heap usage at runtime, see [Heap Memory Debugging](#).

Normally, optimizing heap usage consists of analyzing the usage and removing calls to `malloc()` that aren't being used, reducing the corresponding sizes, or freeing previously allocated buffers earlier.

There are some ESP-IDF configuration options that can reduce heap usage at runtime:

- lwIP documentation has a section to configure [Minimum RAM usage](#).
- [Wi-Fi Buffer Usage](#) describes options to either reduce numbers of “static” buffers or reduce the maximum number of “dynamic” buffers in use, in order to minimize memory usage at possible cost of performance. Note that “static” Wi-Fi buffers are still allocated from heap when Wi-Fi is initialized and will be freed if Wi-Fi is deinitialized.
- Several Mbed TLS configuration options can be used to reduce heap memory usage. See the [Mbed TLS](#) docs for details.

---

**Note:** There are other configuration options that will increase heap usage at runtime if changed from the defaults. These are not listed here, but the help text for the configuration item will mention if there is some memory impact.

---

**Optimizing IRAM Usage** The available DRAM at runtime (for heap usage) is also reduced by the static IRAM usage. Therefore, one way to increase available DRAM is to reduce IRAM usage.

If the app allocates more static IRAM than is available then the app will fail to build and linker errors such as section ``.iram0.text'` will not fit in region ``iram0_0_seg'`, IRAM0 segment data does not fit and region ``iram0_0_seg'` overflowed by 84 bytes will be seen. If this happens, it is necessary to find ways to reduce static IRAM usage in order to link the application.

To analyze the IRAM usage in the firmware binary, use [Measuring Static Sizes](#). If the firmware failed to link, steps to analyze are shown at [Showing Size When Linker Fails](#).

The following options will reduce IRAM usage of some ESP-IDF features:

- Enable [CONFIG\\_FREERTOS\\_PLACE\\_FUNCTIONS\\_INTO\\_FLASH](#). Provided these functions are not (incorrectly) used from ISRs, this option is safe to enable in all configurations.
- Enable [CONFIG\\_FREERTOS\\_PLACE\\_SNAPSHOT\\_FUNS\\_INTO\\_FLASH](#). Enabling this option will place snapshot-related functions, such as `vTaskGetSnapshot` or `uxTaskGetSnapshotAll`, in flash.
- Enable [CONFIG\\_RINGBUF\\_PLACE\\_FUNCTIONS\\_INTO\\_FLASH](#). Provided these functions are not (incorrectly) used from ISRs, this option is safe to enable in all configurations.
- Enable [CONFIG\\_RINGBUF\\_PLACE\\_ISR\\_FUNCTIONS\\_INTO\\_FLASH](#). This option is not safe to use if the ISR ringbuf functions are used from an IRAM interrupt context, e.g. if [CONFIG\\_UART\\_ISR\\_IN\\_IRAM](#) is enabled. For the IDF drivers where this is the case you will get an error at run-time when installing the driver in question.
- Disable Wi-Fi options [CONFIG\\_ESP32\\_WIFI\\_IRAM\\_OPT](#) and/or [CONFIG\\_ESP32\\_WIFI\\_RX\\_IRAM\\_OPT](#). Disabling these options will free available IRAM at the cost of Wi-Fi performance.
- [CONFIG\\_SPI\\_FLASH\\_ROM\\_IMPL](#) enabling this option will free some IRAM but will mean that `esp_flash` bugfixes and new flash chip support is not available.
- Disabling [CONFIG\\_ESP\\_EVENT\\_POST\\_FROM\\_IRAM\\_ISR](#) prevents posting `esp_event` events from [IRAM-Safe Interrupt Handlers](#) but will save some IRAM.
- Disabling [CONFIG\\_SPI\\_MASTER\\_ISR\\_IN\\_IRAM](#) prevents `spi_master` interrupts from being serviced while writing to flash, and may otherwise reduce `spi_master` performance, but will save some IRAM.
- Setting [CONFIG\\_HAL\\_DEFAULT\\_ASSERTION\\_LEVEL](#) to disable assertion for HAL component will save some IRAM especially for HAL code who calls `HAL_ASSERT` a lot and resides in IRAM.

**Flash Suspend Feature** When using ESP Flash APIs and other APIs based on the former (NVS, Partition APIs, etc.), the Cache will be disabled. During this period of time, any code executed must reside in internal RAM (see [Concurrency Constraints for flash on SPI1](#)). Hence, interrupt handlers that are not in internal RAM will not be executed.

To achieve this, ESP-IDF Drivers usually have the following two options: - an option to place the driver’s internal ISR handler in internal RAM - an option to place some control functions in internal RAM.

User ISR callbacks (and involved variables) have to be in internal RAM if they are also used in interrupt contexts.

Placing additional code into IRAM will exacerbate the IRAM usage. For this reason, there is [CONFIG\\_SPI\\_FLASH\\_AUTO\\_SUSPEND](#), which can alleviate the aforementioned kinds of IRAM usage. By enabling this feature, cache won't be disabled when ESP Flash and ESP-Flash-based APIs are used. Therefore, code and data in Flash can be executed or accessed normally, but with some minor delay. See [Flash Auto Suspend](#) for more details about this feature.

Regarding the flash suspend feature usage, and corresponding response time delay, please also see this example [system/flash\\_suspend](#).

---

**Note:** Moving frequently-called functions from IRAM to flash may increase their execution time.

---

---

**Note:** Other configuration options exist that will increase IRAM usage by moving some functionality into IRAM, usually for performance, but the default option is not to do this. These are not listed here. The IRAM size impact of enabling these options is usually noted in the configuration item help text.

---

## 4.21 RF calibration

ESP32-C3 supports three RF calibration methods during RF initialization:

1. Partial calibration
2. Full calibration
3. No calibration

### 4.21.1 Partial calibration

During RF initialization, the partial calibration method is used by default for RF calibration. It is done based on the full calibration data which is stored in the NVS. To use this method, please go to `menuconfig` and enable [CONFIG\\_ESP\\_PHY\\_CALIBRATION\\_AND\\_DATA\\_STORAGE](#).

### 4.21.2 Full calibration

Full calibration is triggered in the following conditions:

1. NVS does not exist.
2. The NVS partition to store calibration data is erased.
3. Hardware MAC address is changed.
4. PHY library version is changed.
5. The RF calibration data loaded from the NVS partition is broken.

It takes about 100ms more than partial calibration. If boot duration is not critical, it is suggested to use the full calibration method. To switch to the full calibration method, go to `menuconfig` and disable [CONFIG\\_ESP\\_PHY\\_CALIBRATION\\_AND\\_DATA\\_STORAGE](#). If you use the default method of RF calibration, there are two ways to add the function of triggering full calibration as a last-resort remedy.

1. Erase the NVS partition if you don't mind all of the data stored in the NVS partition is erased. That is indeed the easiest way.
2. Call API `esp_phy_erase_cal_data_in_nvs()` before initializing WiFi and BT/BLE based on some conditions (e.g. an option provided in some diagnostic mode). In this case, only phy namespace of the NVS partition is erased.

### 4.21.3 No calibration

No calibration method is only used when the device wakes up from deep sleep.

### 4.21.4 PHY initialization data

The PHY initialization data is used for RF calibration. There are two ways to get the PHY initialization data.

One is the default initialization data which is located in the header file `components/esp_phy/esp32c3/include/phy_init_data.h`.

It is embedded into the application binary after compiling and then stored into read-only memory (DROM). To use the default initialization data, please go to `menuconfig` and disable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION`.

Another is the initialization data which is stored in a partition. When using a custom partition table, make sure that PHY data partition is included (type: `data`, subtype: `phy`). With default partition table, this is done automatically. If initialization data is stored in a partition, it has to be flashed there, otherwise runtime error will occur. To switch to the initialization data stored in a partition, go to `menuconfig` and enable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION`.

### 4.21.5 API Reference

#### Header File

- `components/esp_phy/include/esp_phy_init.h`

#### Functions

const `esp_phy_init_data_t` \*`esp_phy_get_init_data` (void)

Get PHY init data.

If “Use a partition to store PHY init data” option is set in `menuconfig`, This function will load PHY init data from a partition. Otherwise, PHY init data will be compiled into the application itself, and this function will return a pointer to PHY init data located in read-only memory (DROM).

If “Use a partition to store PHY init data” option is enabled, this function may return NULL if the data loaded from flash is not valid.

---

**Note:** Call `esp_phy_release_init_data` to release the pointer obtained using this function after the call to `esp_wifi_init`.

---

**Returns** pointer to PHY init data structure

void `esp_phy_release_init_data` (const `esp_phy_init_data_t` \*data)

Release PHY init data.

**Parameters** `data` –pointer to PHY init data structure obtained from `esp_phy_get_init_data` function

`esp_err_t` `esp_phy_load_cal_data_from_nvs` (`esp_phy_calibration_data_t` \*out\_cal\_data)

Function called by `esp_phy_load_cal_and_init` to load PHY calibration data.

This is a convenience function which can be used to load PHY calibration data from NVS. Data can be stored to NVS using `esp_phy_store_cal_data_to_nvs` function.

If calibration data is not present in the NVS, or data is not valid (was obtained for a chip with a different MAC address, or obtained for a different version of software), this function will return an error.

**Parameters** `out_cal_data` –pointer to calibration data structure to be filled with loaded data.

**Returns** `ESP_OK` on success

*esp\_err\_t* **esp\_phy\_store\_cal\_data\_to\_nvs** (const *esp\_phy\_calibration\_data\_t* \*cal\_data)

Function called by `esp_phy_load_cal_and_init` to store PHY calibration data.

This is a convenience function which can be used to store PHY calibration data to the NVS. Calibration data is returned by `esp_phy_load_cal_and_init` function. Data saved using this function to the NVS can later be loaded using `esp_phy_store_cal_data_to_nvs` function.

**Parameters** `cal_data` –pointer to calibration data which has to be saved.

**Returns** `ESP_OK` on success

*esp\_err\_t* **esp\_phy\_erase\_cal\_data\_in\_nvs** (void)

Erase PHY calibration data which is stored in the NVS.

This is a function which can be used to trigger full calibration as a last-resort remedy if partial calibration is used. It can be called in the application based on some conditions (e.g. an option provided in some diagnostic mode).

**Returns** `ESP_OK` on success

**Returns** others on fail. Please refer to NVS API return value error number.

bool **esp\_phy\_is\_initialized** (void)

Get phy initialize status.

**Returns** return true if phy is already initialized.

void **esp\_phy\_enable** (void)

Enable PHY and RF module.

PHY and RF module should be enabled in order to use WiFi or BT. Now PHY and RF enabling job is done automatically when start WiFi or BT. Users should not call this API in their application.

void **esp\_phy\_disable** (void)

Disable PHY and RF module.

PHY module should be disabled in order to shutdown WiFi or BT. Now PHY and RF disabling job is done automatically when stop WiFi or BT. Users should not call this API in their application.

void **esp\_phy\_load\_cal\_and\_init** (void)

Load calibration data from NVS and initialize PHY and RF module.

void **esp\_phy\_modem\_init** (void)

Initialize backup memory for Phy power up/down.

void **esp\_phy\_modem\_deinit** (void)

Deinitialize backup memory for Phy power up/down Set `phy_init_flag` if all modems deinit on ESP32C3.

void **esp\_phy\_common\_clock\_enable** (void)

Enable WiFi/BT common clock.

void **esp\_phy\_common\_clock\_disable** (void)

Disable WiFi/BT common clock.

int64\_t **esp\_phy\_rf\_get\_on\_ts** (void)

Get the time stamp when PHY/RF was switched on.

**Returns** return 0 if PHY/RF is never switched on. Otherwise return time in microsecond since boot when phy/rf was last switched on

*esp\_err\_t* **esp\_phy\_update\_country\_info** (const char \*country)

Update the corresponding PHY init type according to the country code of Wi-Fi.

**Parameters** `country` –country code

**Returns** `ESP_OK` on success.

**Returns** `esp_err_t` code describing the error on fail

char \***get\_phy\_version\_str** (void)

Get PHY lib version.

**Returns** PHY lib version.

void **phy\_init\_param\_set** (uint8\_t param)

Set PHY init parameters.

**Parameters** **param** –is 1 means combo module

void **phy\_wifi\_enable\_set** (uint8\_t enable)

Wi-Fi RX enable.

**Parameters** **enable** –Whether to enable phy for wifi

## Structures

struct **esp\_phy\_init\_data\_t**

Structure holding PHY init parameters.

### Public Members

uint8\_t **params**[128]

opaque PHY initialization parameters

struct **esp\_phy\_calibration\_data\_t**

Opaque PHY calibration data.

### Public Members

uint8\_t **version**[4]

PHY version

uint8\_t **mac**[6]

The MAC address of the station

uint8\_t **opaque**[1894]

calibration data

## Enumerations

enum **esp\_phy\_calibration\_mode\_t**

PHY calibration mode.

*Values:*

enumerator **PHY\_RF\_CAL\_PARTIAL**

Do part of RF calibration. This should be used after power-on reset.

enumerator **PHY\_RF\_CAL\_NONE**

Don't do any RF calibration. This mode is only suggested to be used after deep sleep reset.

enumerator **PHY\_RF\_CAL\_FULL**

Do full RF calibration. Produces best results, but also consumes a lot of time and current. Suggested to be used once.

## 4.22 Secure Boot V2

---

**Important:** This document is about Secure Boot V2, supported on the following chips: ESP32 (ECO3 onwards), ESP32-S2, ESP32-S3, ESP32-C3 (ECO3 onwards), and ESP32-C2. Except for ESP32, it is the only supported Secure Boot scheme.

Secure Boot V2 uses RSA-PSS based app and bootloader verification. This document can also be used as a reference for signing apps using the RSA-PSS scheme without signing the bootloader.

---

Secure Boot V2 is available for ESP32-C3 from ECO3 onwards. To use these options in menuconfig, set [CONFIG\\_ESP32C3\\_REV\\_MIN](#) greater than or equal to *Rev 3*.

### 4.22.1 Background

Secure Boot protects a device from running any unauthorized (i.e., unsigned) code by checking that each piece of software that is being booted is signed. On an ESP32-C3, these pieces of software include the second stage bootloader and each application binary. Note that the first stage bootloader does not require signing as it is ROM code thus cannot be changed.

A new RSA based Secure Boot verification scheme (Secure Boot V2) has been introduced on the ESP32 (ECO3 onwards), ESP32-S2, ESP32-S3 and ESP32-C3 (ECO3 onwards).

The Secure Boot process on the ESP32-C3 involves the following steps:

1. When the first stage bootloader loads the second stage bootloader, the second stage bootloader's RSA-PSS signature is verified. If the verification is successful, the second stage bootloader is executed.
2. When the second stage bootloader loads a particular application image, the application's RSA-PSS signature is verified. If the verification is successful, the application image is executed.

### 4.22.2 Advantages

- The RSA-PSS public key is stored on the device. The corresponding RSA-PSS private key is kept at a secret place and is never accessed by the device.
- Up to three public keys can be generated and stored in the chip during manufacturing.
- ESP32-C3 provides the facility to permanently revoke individual public keys. This can be configured conservatively or aggressively.
- Conservatively - The old key is revoked after the bootloader and application have successfully migrated to a new key. Aggressively - The key is revoked as soon as verification with this key fails.
- Same image format and signature verification method is applied for applications and software bootloader.
- No secrets are stored on the device. Therefore, it is immune to passive side-channel attacks (timing or power analysis, etc.)

### 4.22.3 Secure Boot V2 Process

This is an overview of the Secure Boot V2 Process. Instructions how to enable Secure Boot are supplied in section [How To Enable Secure Boot V2](#).

Secure Boot V2 verifies the bootloader image and application binary images using a dedicated *signature block*. Each image has a separately generated signature block which is appended to the end of the image.

Up to 3 signature blocks can be appended to the bootloader or application image in ESP32-C3.

Each signature block contains a signature of the preceding image as well as the corresponding RSA-3072 public key. For more details about the format, refer to [Signature Block Format](#). A digest of the RSA-3072 public key is stored in the eFuse.

The application image is not only verified on every boot but also on each over the air (OTA) update. If the currently selected OTA app image cannot be verified, the bootloader will fall back and look for another correctly signed application image.

The Secure Boot V2 process follows these steps:

1. On startup, the ROM code checks the Secure Boot V2 bit in the eFuse. If Secure Boot is disabled, a normal boot will be executed. If Secure Boot is enabled, the boot will proceed according to the following steps.
2. The ROM code verifies the bootloader's signature block ([Verifying a Signature Block](#)). If this fails, the boot process will be aborted.
3. The ROM code verifies the bootloader image using the raw image data, its corresponding signature block(s), and the eFuse ([Verifying an Image](#)). If this fails, the boot process will be aborted.
4. The ROM code executes the bootloader.
5. The bootloader verifies the application image's signature block ([Verifying a Signature Block](#)). If this fails, the boot process will be aborted.
6. The bootloader verifies the application image using the raw image data, its corresponding signature blocks and the eFuse ([Verifying an Image](#)). If this fails, the boot process will be aborted. If the verification fails but another application image is found, the bootloader will then try to verify that other image using steps 5 to 7. This repeats until a valid image is found or no other images are found.
7. The bootloader executes the verified application image.

### 4.22.4 Signature Block Format

The signature block starts on a 4KB aligned boundary and has a flash sector of its own. The signature is calculated over all bytes in the image including the padding bytes ([Secure Padding](#)).

The content of each signature block is shown in the following table:

Table 27: Content of a Signature Block

Offset	Size (bytes)	Description
0	1	Magic byte
1	1	Version number byte (currently 0x02), 0x01 is for Secure Boot V1.
2	2	Padding bytes, Reserved. Should be zero.
4	32	SHA-256 hash of only the image content, not including the signature block.
36	384	RSA Public Modulus used for signature verification. (value 'n' in RFC8017).
420	4	RSA Public Exponent used for signature verification (value 'e' in RFC8017).
424	384	Pre-calculated R, derived from 'n'.
808	4	Pre-calculated M', derived from 'n'
812	384	RSA-PSS Signature result (section 8.1.1 of RFC8017) of image content, computed using following PSS parameters: SHA256 hash, MFG1 function, salt length 32 bytes, default trailer field (0xBC).
1196	4	CRC32 of the preceding 1196 bytes.
1200	16	Zero padding to length 1216 bytes.

---

**Note:** R and M' are used for hardware-assisted Montgomery Multiplication.

---

The remainder of the signature sector is erased flash (0xFF) which allows writing other signature blocks after previous signature block.

### 4.22.5 Secure Padding

In Secure Boot V2 scheme, the application image is padded to the flash MMU page size boundary to ensure that only verified contents are mapped in the internal address space. This is known as secure padding. Signature of the image is calculated after padding and then signature block (4KB) gets appended to the image.

- Default flash MMU page size is 64KB
- Secure padding is applied through the option `--secure-pad-v2` in the `elf2image` conversion using `esptool.py`

Following table explains the Secure Boot V2 signed image with secure padding and signature block appended:

Table 28: Contents of a signed application

Offset	Size (KB)	Description
0	580	Unsigned application size (as an example)
580	60	Secure padding (aligned to next 64KB boundary)
640	4	Signature block

---

**Note:** Please note that the application image always starts on the next flash MMU page size boundary (default 64KB) and hence the space left over after the signature block shown above can be utilized to store any other data partitions (e.g., `nvs`).

---

### 4.22.6 Verifying a Signature Block

A signature block is “valid” if the first byte is 0xe7 and a valid CRC32 is stored at offset 1196. Otherwise it's invalid.

### 4.22.7 Verifying an Image

An image is “verified” if the public key stored in any signature block is valid for this device, and if the stored signature is valid for the image data read from flash.

1. Compare the SHA-256 hash digest of the public key embedded in the bootloader's signature block with the digest(s) saved in the eFuses. If public key's hash doesn't match any of the hashes from the eFuses, the verification fails.
2. Generate the application image digest and match it with the image digest in the signature block. If the digests don't match, the verification fails.
3. Use the public key to verify the signature of the bootloader image, using RSA-PSS (section 8.1.2 of RFC8017) with the image digest calculated in step (2) for comparison.

### 4.22.8 Bootloader Size

Enabling Secure boot and/or flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

In the case when `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` is disabled, the bootloader is sector padded (4KB) using the `--pad-to-size` option in `elf2image` command of `esptool`.

### 4.22.9 eFuse usage

- `SECURE_BOOT_EN` - Enables Secure Boot protection on boot.
- `KEY_PURPOSE_X` - Set the purpose of the key block on ESP32-C3 by programming `SECURE_BOOT_DIGESTX` ( $X = 0, 1, 2$ ) into `KEY_PURPOSE_X` ( $X = 0, 1, 2, 3, 4, 5$ ). Example: If `KEY_PURPOSE_2` is set to `SECURE_BOOT_DIGEST1`, then `BLOCK_KEY2` will have the Secure Boot V2 public key digest. The write-protection bit must be set (this field does not have a read-protection bit).
- `BLOCK_KEYX` - The block contains the data corresponding to its purpose programmed in `KEY_PURPOSE_X`. Stores the SHA-256 digest of the public key. SHA-256 hash of public key modulus, exponent, pre-calculated  $R$  &  $M'$  values (represented as 776 bytes –offsets 36 to 812 - as per the *Signature Block Format*) is written to an eFuse key block. The write-protection bit must be set, but the read-protection bit must not.
- `KEY_REVOKEX` - The revocation bits corresponding to each of the 3 key block. Ex. Setting `KEY_REVOKE2` revokes the key block whose key purpose is `SECURE_BOOT_DIGEST2`.
- `SECURE_BOOT_AGGRESSIVE_REVOKE` - Enables aggressive revocation of keys. The key is revoked as soon as verification with this key fails.

To ensure no trusted keys can be added later by an attacker, each unused key digest slot should be revoked (`KEY_REVOKEX`). It will be checked during app startup in `esp_secure_boot_init_checks()` and fixed unless `CONFIG_SECURE_BOOT_ALLOW_UNUSED_DIGEST_SLOTS` is enabled.

The key(s) must be readable in order to give software access to it. If the key(s) is read-protected then the software reads the key(s) as all zeros and the signature verification process will fail, and the boot process will be aborted.

### 4.22.10 How To Enable Secure Boot V2

1. Open the *Project Configuration Menu*, in “Security features” set “Enable hardware Secure Boot in bootloader” to enable Secure Boot.
2. The “Secure Boot V2” option will be selected and the “App Signing Scheme” would be set to RSA by default.
3. Specify the path to Secure Boot signing key, relative to the project directory.
4. Select the desired UART ROM download mode in “UART ROM download mode” . By default, it is set to “Permanently switch to Secure mode” which is generally recommended. For production devices, the most secure option is to set it to “Permanently disabled” .
5. Set other menuconfig options (as desired). Then exit menuconfig and save your configuration.
6. The first time you run `idf.py build`, if the signing key is not found then an error message will be printed with a command to generate a signing key via `espsecure.py generate_signing_key`.

---

**Important:** A signing key generated this way will use the best random number source available to the OS and its Python installation (`/dev/urandom` on OSX/Linux and `CryptGenRandom()` on Windows). If this random number source is weak, then the private key will be weak.

---

---

**Important:** For production environments, we recommend generating the key pair using `openssl` or another industry standard encryption program. See *Generating Secure Boot Signing Key* for more details.

---

7. Run `idf.py bootloader` to build a Secure Boot enabled bootloader. The build output will include a prompt for a flashing command, using `esptool.py write_flash`.
8. When you're ready to flash the bootloader, run the specified command (you have to enter it yourself, this step is not performed by the build system) and then wait for flashing to complete.
9. Run `idf.py flash` to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 6.

---

**Note:** `idf.py flash` doesn't flash the bootloader if Secure Boot is enabled.

---

10. Reset the ESP32-C3 and it will boot the software bootloader you flashed. The software bootloader will enable Secure Boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32-C3 to verify that Secure Boot is enabled and no errors have occurred due to the build configuration.

---

**Note:** Secure boot won't be enabled until after a valid partition table and app image have been flashed. This is to prevent accidents before the system is fully configured.

---

---

**Note:** If the ESP32-C3 is reset or powered down during the first boot, it will start the process again on the next boot.

---

11. On subsequent boots, the Secure Boot hardware will verify the software bootloader has not changed and the software bootloader will verify the signed app image (using the validated public key portion of its appended signature block).

### 4.22.11 Restrictions after Secure Boot is enabled

- Any updated bootloader or app will need to be signed with a key matching the digest already stored in eFuse.
- After Secure Boot is enabled, no further eFuses can be read protected. (If *Flash Encryption* is enabled then the bootloader will ensure that any flash encryption key generated on first boot will already be read protected.) If `CONFIG_SECURE_BOOT_INSECURE` is enabled then this behavior can be disabled, but this is not recommended.

### 4.22.12 Generating Secure Boot Signing Key

The build system will prompt you with a command to generate a new signing key via `espsecure.py generate_signing_key`.

The `--version 2` parameter will generate the RSA 3072 private key for Secure Boot V2.

The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source, and using the best available RSA-PSS key generation utilities.

For example, to generate a signing key using the `openssl` command line:

```
` openssl genrsa -out my_secure_boot_signing_key.pem 3072 `
```

Remember that the strength of the Secure Boot system depends on keeping the signing key private.

### 4.22.13 Remote Signing of Images

### Signing using espsecure.py

For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default esp-idf Secure Boot configuration). The espsecure.py command line program can be used to sign app images & partition table data for Secure Boot, on a remote system.

To use remote signing, disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` and build the firmware. The private signing key does not need to be present on the build system.

After the app image and partition table are built, the build system will print signing steps using espsecure.py:

```
espsecure.py sign_data BINARY_FILE --version 2 --keyfile PRIVATE_SIGNING_KEY
```

The above command appends the image signature to the existing binary. You can use the `-output` argument to write the signed binary to a separate file:

```
espsecure.py sign_data --version 2 --keyfile PRIVATE_SIGNING_KEY --output SIGNED_  
↪BINARY_FILE BINARY_FILE
```

### Signing using Pre-calculated Signatures

If you have valid pre-calculated signatures generated for an image and their corresponding public keys, you can use these signatures to generate a signature sector and append it to the image. Note that the pre-calculated signature should be calculated over all bytes in the image including the secure-padding bytes.

In such cases, the firmware image should be built by disabling the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES`. This image will be secure-padded and to generate a signed binary use the following command:

```
espsecure.py sign_data --version 2 --pub-key PUBLIC_SIGNING_KEY --signature_  
↪SIGNATURE_FILE --output SIGNED_BINARY_FILE BINARY_FILE
```

The above command verifies the signature, generates a signature block (refer to *Signature Block Format*) and appends it to the binary file.

### Signing using an External Hardware Security Module (HSM)

For security reasons, you might also use an external Hardware Security Module (HSM) to store your private signing key, which cannot be accessed directly but has an interface to generate the signature of a binary file and its corresponding public key.

In such cases, disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` and build the firmware. This secure-padded image then can be used to supply the external HSM for generating a signature. Refer to [Signing using an External HSM](#) to generate a signed image.

---

**Note:** For all the above three remote signing workflows, the signed binary is written to the filename provided to the `--output` argument and the option `--append_signatures` allows us to append multiple signatures (up to 3) to the image.

---

## 4.22.14 Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all Secure Boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.

- Use Secure Boot in combination with *flash encryption* to prevent local readout of the flash contents.

#### 4.22.15 Key Management

- Between 1 and 3 RSA-3072 public key pairs (Keys #0, #1, #2) should be computed independently and stored separately.
- The KEY\_DIGEST eFuses should be write protected after being programmed.
- The unused KEY\_DIGEST slots must have their corresponding KEY\_REVOKE eFuse burned to permanently disable them. This must happen before the device leaves the factory.
- The eFuses can either be written by the software bootloader during first boot after enabling “Secure Boot V2” from menuconfig or can be done using *espfuse.py* which communicates with the serial bootloader program in ROM.
- The KEY\_DIGESTs should be numbered sequentially beginning at key digest #0. (i.e., if key digest #1 is used, key digest #0 should be used. If key digest #2 is used, key digest #0 & #1 must be used.)
- The software bootloader (non OTA upgradeable) is signed using at least one, possibly all three, private keys and flashed in the factory.
- Apps should only be signed with a single private key (the others being stored securely elsewhere), however they may be signed with multiple private keys if some are being revoked (see Key Revocation, below).

#### 4.22.16 Multiple Keys

- The bootloader should be signed with all the private key(s) that are needed for the life of the device, before it is flashed.
- The build system can sign with at most one private key, user has to run manual commands to append more signatures if necessary.
- **You can use the append functionality of `espsecure.py`, this command would also printed at the end of the Secure B**  
`espsecure.py sign_data -k secure_boot_signing_key2.pem -v 2 --append_signatures -o signed_bootloader.bin build/bootloader/bootloader.bin`
- While signing with multiple private keys, it is recommended that the private keys be signed independently, if possible on different servers and stored separately.
- **You can check the signatures attached to a binary using -** `espsecure.py signature_info_v2 datafile.bin`

#### 4.22.17 Key Revocation

- Keys are processed in a linear order. (key #0, key #1, key #2).
- Applications should be signed with only one key at a time, to minimize the exposure of unused private keys.
- The bootloader can be signed with multiple keys from the factory.

#### Conservative approach:

Assuming a trusted private key (N-1) has been compromised, to update to new key pair (N).

1. Server sends an OTA update with an application signed with the new private key (#N).
  2. The new OTA update is written to an unused OTA app partition.
  3. The new application's signature block is validated. The public keys are checked against the digests programmed in the eFuse & the application is verified using the verified public key.
  4. The active partition is set to the new OTA application's partition.
  5. Device resets, loads the bootloader (verified with key #N-1 and #N) which then boots new app (verified with key #N).
  6. The new app verifies bootloader and application with key #N (as a final check) and then runs code to revoke key #N-1 (sets KEY\_REVOKE eFuse bit).
  7. The API `esp_ota_revoke_secure_boot_public_key()` can be used to revoke the key #N-1.
- A similar approach can also be used to physically re-flash with a new key. For physical re-flashing, the bootloader content can also be changed at the same time.

**Aggressive approach:**

ROM code has an additional feature of revoking a public key digest if the signature verification fails.

To enable this feature, you need to burn `SECURE_BOOT_AGGRESSIVE_REVOKE` efuse or enable [CONFIG\\_SECURE\\_BOOT\\_ENABLE\\_AGGRESSIVE\\_KEY\\_REVOKE](#)

Key revocation is not applicable unless secure boot is successfully enabled. Also, a key is not revoked in case of invalid signature block or invalid image digest, it is only revoked in case the signature verification fails, i.e. revoke key only if failure in step 3 of [Verifying an Image](#)

Once a key is revoked, it can never be used for verifying a signature of an image. This feature provides strong resistance against physical attacks on the device. However, this could also brick the device permanently if all the keys are revoked because of signature verification failure.

### 4.22.18 Technical Details

The following sections contain low-level reference descriptions of various Secure Boot elements:

#### Manual Commands

Secure boot is integrated into the esp-idf build system, so `idf.py build` will sign an app image and `idf.py bootloader` will produce a signed bootloader if secure signed binaries on build is enabled.

However, it is possible to use the `espsecure.py` tool to make standalone signatures and digests.

To sign a binary image:

```
espsecure.py sign_data --version 2 --keyfile ./my_signing_key.pem --output ./image_
→signed.bin image-unsigned.bin
```

Keyfile is the PEM file containing an RSA-3072 private signing key.

### 4.22.19 Secure Boot & Flash Encryption

If Secure Boot is used without [Flash Encryption](#), it is possible to launch “time-of-check to time-of-use” attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both the features together.

### 4.22.20 Signed App Verification Without Hardware Secure Boot

The Secure Boot V2 signature of apps can be checked on OTA update, without enabling the hardware Secure Boot option. This option uses the same app signature scheme as Secure Boot V2, but unlike hardware Secure Boot it does not prevent an attacker who can write to flash from bypassing the signature protection.

This may be desirable in cases where the delay of Secure Boot verification on startup is unacceptable, and/or where the threat model does not include physical access or attackers writing to bootloader or app partitions in flash.

In this mode, the public key which is present in the signature block of the currently running app will be used to verify the signature of a newly updated app. (The signature on the running app isn't verified during the update process, it's assumed to be valid.) In this way the system creates a chain of trust from the running app to the newly updated app.

For this reason, it's essential that the initial app flashed to the device is also signed. A check is run on app startup and the app will abort if no signatures are found. This is to try and prevent a situation where no update is possible. The app should have only one valid signature block in the first position. Note again that, unlike hardware Secure Boot V2, the signature of the running app isn't verified on boot. The system only verifies a signature block in the first position and ignores any other appended signatures.

Although multiple trusted keys are supported when using hardware Secure Boot, only the first public key in the signature block is used to verify updates if signature checking without Secure Boot is configured. If multiple trusted public keys are required, it's necessary to enable the full Secure Boot feature instead.

---

**Note:** In general, it's recommended to use full hardware Secure Boot unless certain that this option is sufficient for application security needs.

---

### How To Enable Signed App Verification

1. Open *Project Configuration Menu* -> Security features
2. Ensure *App Signing Scheme* is *RSA*
3. Enable *CONFIG\_SECURE\_SIGNED\_APPS\_NO\_SECURE\_BOOT*
4. By default, “Sign binaries during build” will be enabled on selecting “Require signed app images” option, which will sign binary files as a part of build process. The file named in “Secure boot private signing key” will be used to sign the image.
5. If you disable “Sign binaries during build” option then all app binaries must be manually signed by following instructions in *Remote Signing of Images*.

<b>Warning:</b> It is very important that all apps flashed have been signed, either during the build or after the build.
--

## 4.22.21 Advanced Features

### JTAG Debugging

By default, when Secure Boot is enabled then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables Secure Boot.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

## 4.23 Thread Local Storage

### 4.23.1 Overview

Thread-local storage (TLS) is a mechanism by which variables are allocated such that there is one instance of the variable per extant thread. ESP-IDF provides three ways to make use of such variables:

- *FreeRTOS Native API*: ESP-IDF FreeRTOS native API.
- *Pthread API*: ESP-IDF's pthread API.
- *C11 Standard*: C11 standard introduces special keyword to declare variables as thread local.

### 4.23.2 FreeRTOS Native API

The ESP-IDF FreeRTOS provides the following API to manage thread local variables:

- *vTaskSetThreadLocalStoragePointer()*
- *pvTaskGetThreadLocalStoragePointer()*
- *vTaskSetThreadLocalStoragePointerAndDelCallback()*

In this case maximum number of variables that can be allocated is limited by `CONFIG_FREERTOS_THREAD_LOCAL_STORAGE_POINTERS` configuration value. Variables are kept in the task control block (TCB) and accessed by their index. Note that index 0 is reserved for ESP-IDF internal uses.

Using that API user can allocate thread local variables of an arbitrary size and assign them to any number of tasks. Different tasks can have different sets of TLS variables.

If size of the variable is more than 4 bytes then user is responsible for allocating/deallocating memory for it. Variable's deallocation is initiated by FreeRTOS when task is deleted, but user must provide function (callback) to do proper cleanup.

### 4.23.3 Pthread API

The ESP-IDF provides the following *pthread API* to manage thread local variables:

- `pthread_key_create()`
- `pthread_key_delete()`
- `pthread_getspecific()`
- `pthread_setspecific()`

This API has all benefits of the one above, but eliminates some its limits. The number of variables is limited only by size of available memory on the heap. Due to the dynamic nature this API introduces additional performance overhead compared to the native one.

### 4.23.4 C11 Standard

The ESP-IDF FreeRTOS supports thread local variables according to C11 standard (ones specified with `__thread` keyword). For details on this GCC feature please see <https://gcc.gnu.org/onlinedocs/gcc-5.5.0/gcc/Thread-Local.html#Thread-Local>. Storage for that kind of variables is allocated on the task's stack. Note that area for all such variables in the program will be allocated on the stack of every task in the system even if that task does not use such variables at all. For example ESP-IDF system tasks (like `ipc`, `timer` tasks etc.) will also have that extra stack space allocated. So this feature should be used with care. There is a tradeoff: C11 thread local variables are quite handy to use in programming and can be accessed using minimal CPU instructions, but this benefit goes with the cost of additional stack usage for all tasks in the system. Due to static nature of variables allocation all tasks in the system have the same sets of C11 thread local variables.

## 4.24 Tools

### 4.24.1 IDF Frontend - `idf.py`

The `idf.py` command-line tool provides a front-end for easily managing your project builds, deployment and debugging, and more. It manages several tools, for example:

- `CMake`, which configures the project to be built.
- `Ninja`, which builds the project.
- `esptool.py`, which flashes the target.

The *Step 5. First Steps on ESP-IDF* contains a brief introduction on how to set up `idf.py` to configure, build, and flash projects.

---

**Important:** `idf.py` should be run in an ESP-IDF project directory, i.e., a directory containing a `CMakeLists.txt` file. Older style projects that contain a `Makefile` will not work with `idf.py`.

---

## Commands

### Start a New Project: `create-project`

```
idf.py create-project <project name>
```

This command creates a new ESP-IDF project. Additionally, the folder where the project will be created in can be specified by the `--path` option.

### Create a New Component: `create-component`

```
idf.py create-component <component name>
```

This command creates a new component, which will have a minimum set of files necessary for building. The `-C` option can be used to specify the directory the component will be created in. For more information about components see the [Component CMakeLists Files](#).

**Select the Target Chip: `set-target`** ESP-IDF supports multiple targets (chips). A full list of supported targets in your version of ESP-IDF can be seen by running `idf.py --list-targets`.

```
idf.py set-target <target>
```

This command sets the current project target.

---

**Important:** `idf.py set-target` will clear the build directory and re-generate the `sdkconfig` file from scratch. The old `sdkconfig` file will be saved as `sdkconfig.old`.

---

**Note:** The behavior of the `idf.py set-target` command is equivalent to:

1. clearing the build directory (`idf.py fullclean`)
  2. removing the `sdkconfig` file (`mv sdkconfig sdkconfig.old`)
  3. configuring the project with the new target (`idf.py -DIDF_TARGET=esp32 reconfigure`)
- 

It is also possible to pass the desired `IDF_TARGET` as an environment variable (e.g., `export IDF_TARGET=esp32s2`) or as a CMake variable (e.g., `-DIDF_TARGET=esp32s2` argument to CMake or `idf.py`). Setting the environment variable is a convenient method if you mostly work with one type of the chip.

To specify the default value of `IDF_TARGET` for a given project, please add the `CONFIG_IDF_TARGET` option to the project's `sdkconfig.defaults` file, e.g., `CONFIG_IDF_TARGET="esp32s2"`. This value of the option will be used if `IDF_TARGET` is not specified by other methods, such as using an environment variable, a CMake variable, or the `idf.py set-target` command.

If the target has not been set by any of these methods, the build system will default to `esp32` target.

### Start the Graphical Configuration Tool: `menuconfig`

```
idf.py menuconfig
```

### Build the Project: `build`

```
idf.py build
```

This command builds the project found in the current directory. This can involve multiple steps:

- Create the build directory if needed. The sub-directory `build` is used to hold build output, although this can be changed with the `-B` option.
- Run [CMake](#) as necessary to configure the project and generate build files for the main build tool.

- Run the main build tool ([Ninja](#) or *GNU Make*). By default, the build tool is automatically detected but it can be explicitly set by passing the `-G` option to `idf.py`.

Building is incremental, so if no source files or configuration has changed since the last build, nothing will be done.

Additionally, the command can be run with `app`, `bootloader` and `partition-table` arguments to build only the app, bootloader or partition table as applicable.

### Remove the Build Output: `clean`

```
idf.py clean
```

This command removes the project build output files from the build directory, and the project will be fully rebuilt on next build. Using this command does not remove the CMake configuration output inside the build folder.

### Delete the Entire Build Contents: `fullclean`

```
idf.py fullclean
```

This command deletes the entire “build” directory contents, which includes all CMake configuration output. The next time the project is built, CMake will configure it from scratch. Note that this option recursively deletes **all** files in the build directory, so use with care. Project configuration is not deleted.

### Flash the Project: `flash`

```
idf.py flash
```

This command automatically builds the project if necessary, and then flash it to the target. You can use `-p` and `-b` options to set serial port name and flasher baud rate, respectively.

---

**Note:** The environment variables `ESPPORT` and `ESPBAUD` can be used to set default values for the `-p` and `-b` options, respectively. Providing these options on the command line overrides the default.

---

Similarly to the `build` command, the command can be run with `app`, `bootloader` and `partition-table` arguments to flash only the app, bootloader or partition table as applicable.

### Hints on How to Resolve Errors

`idf.py` will try to suggest hints on how to resolve errors. It works with a database of hints stored in [tools/idf\\_py\\_actions/hints.yml](#) and the hints will be printed if a match is found for the given error. The `menuconfig`, `gdb` and `opencd` targets are not supported at the moment by automatic hints on resolving errors.

The `--no-hints` argument of `idf.py` can be used to turn the hints off in case they are not desired.

### Important Notes

Multiple `idf.py` commands can be combined into one. For example, `idf.py -p COM4 clean flash monitor` will clean the source tree, then build the project and flash it to the target before running the serial monitor.

The order of multiple `idf.py` commands on the same invocation is not important, as they will automatically be executed in the correct order for everything to take effect (e.g., building before flashing, erasing before flashing).

For commands that are not known to `idf.py`, an attempt to execute them as a build system target will be made.

The command `idf.py` supports [shell autocompletion](#) for bash, zsh and fish shells.

In order to make [shell autocompletion](#) supported, please make sure you have at least Python 3.5 and [click 7.1](#) or newer (*Software*).

To enable autocompletion for `idf.py`, use the `export` command ([Step 4. Set up the environment variables](#)). Autocompletion is initiated by pressing the TAB key. Type `idf.py -` and press the TAB key to autocomplete options.

The autocomplete support for PowerShell is planned in the future.

### Advanced Commands

#### Open the Documentation: `docs`

```
idf.py docs
```

This command opens the documentation for the projects target and ESP-IDF version in the browser.

#### Show Size: `size`

```
idf.py size
```

This command prints app size information including the occupied RAM and flash and section (i.e., `.bss`) sizes.

```
idf.py size
```

Similarly, this command prints the same information for each component used in the project.

```
idf.py size-files
```

This command prints size information per source file in the project.

If you define variable `-DOUTPUT_JSON=1` when running CMake (or `idf.py`), the output will be formatted as JSON not as human readable text. See `idf.py-size` for more information.

#### Reconfigure the Project: `reconfigure`

```
idf.py reconfigure
```

This command forces CMake to be rerun regardless of whether it is necessary. It's unnecessary during normal usage, but can be useful after adding/removing files from the source tree, or when modifying CMake cache variables. For example, `idf.py -DNAME='VALUE' reconfigure` can be used to set variable `NAME` in CMake cache to value `VALUE`.

#### Clean the Python Byte Code: `python-clean`

```
idf.py python-clean
```

This command deletes generated python byte code from the ESP-IDF directory. The byte code may cause issues when switching between ESP-IDF and Python versions. It is advised to run this target after switching versions of Python.

#### Generate a UF2 binary: `uf2`

```
idf.py uf2
```

This command will generate a UF2 (USB Flashing Format) binary `uf2.bin` in the build directory. This file includes all the necessary binaries (bootloader, app, and partition table) for flashing the target.

This UF2 file can be copied to a USB mass storage device exposed by another ESP running the [ESP USB Bridge](#) project. The bridge MCU will use it to flash the target MCU. This is as simple copying (or “drag-and-dropping”) the file to the exposed disk accessed by a file explorer in your machine.

To generate a UF2 binary for the application only (not including the bootloader and partition table), use the `uf2-app` command.

```
idf.py uf2-app
```

## Global Options

To list all available root level options, run `idf.py --help`. To list options that are specific for a subcommand, run `idf.py <command> --help`, e.g., `idf.py monitor --help`. Here is a list of some useful options:

- `-C <dir>` allows overriding the project directory from the default current working directory.
- `-B <dir>` allows overriding the build directory from the default `build` subdirectory of the project directory.
- `--ccache` enables **CCache** when compiling source files if the **CCache** tool is installed. This can dramatically reduce the build time.

---

**Important:** Note that some older versions of **CCache** may exhibit bugs on some platforms, so if files are not rebuilt as expected, try disabling **CCache** and rebuilding the project. To enable **CCache** by default, set the `IDF_CCACHE_ENABLE` environment variable to a non-zero value.

---

- `-v` flag causes both `idf.py` and the build system to produce verbose build output. This can be useful for debugging build problems.
- `--cmake-warn-uninitialized` (or `-w`) causes CMake to print uninitialized variable warnings found in the project directory only. This only controls CMake variable warnings inside CMake itself, not other types of build warnings. This option can also be set permanently by setting the `IDF_CMAKE_WARN_UNINITIALIZED` environment variable to a non-zero value.
- `--no-hints` flag disables hints on resolving errors and disable capturing output.

### 4.24.2 IDF Docker Image

IDF Docker image (`espressif/idf`) is intended for building applications and libraries with specific versions of ESP-IDF, when doing automated builds.

The image contains:

- Common utilities such as `git`, `wget`, `curl`, `zip`.
- Python 3.7 or newer.
- A copy of a specific version of ESP-IDF (see below for information about versions). `IDF_PATH` environment variable is set, and points to ESP-IDF location in the container.
- All the build tools required for the specific version of ESP-IDF: CMake, ninja, cross-compiler toolchains, etc.
- All Python packages required by ESP-IDF are installed in a virtual environment.

The image entrypoint sets up `PATH` environment variable to point to the correct version of tools, and activates the Python virtual environment. As a result, the environment is ready to use the ESP-IDF build system.

The image can also be used as a base for custom images, if additional utilities are required.

## Tags

Multiple tags of this image are maintained:

- `latest`: tracks master branch of ESP-IDF
- `vX.Y`: corresponds to ESP-IDF release `vX.Y`
- `release-vX.Y`: tracks `release/vX.Y` branch of ESP-IDF

---

**Note:** Versions of ESP-IDF released before this feature was introduced do not have corresponding Docker image versions. You can check the up-to-date list of available tags at <https://hub.docker.com/r/espressif/idf/tags>.

---

## Usage

**Setting up Docker** Before using the  `espressif/idf`  Docker image locally, make sure you have Docker installed. Follow the instructions at <https://docs.docker.com/install/>, if it is not installed yet.

If using the image in CI environment, consult the documentation of your CI service on how to specify the image used for the build process.

**Building a project with CMake** In the project directory, run:

```
docker run --rm -v $PWD:/project -w /project espressif/idf idf.py build
```

The above command explained:

- `docker run`: runs a Docker image. It is a shorter form of the command `docker container run`.
- `--rm`: removes the container when the build is finished
- `-v $PWD:/project`: mounts the current directory on the host (`$PWD`) as `/project` directory in the container
- `espressif/idf` : uses Docker image  `espressif/idf`  with tag `latest` (implicitly added by Docker when no tag is specified)
- `idf.py build`: runs this command inside the container

---

**Note:** When the mounted directory, `/project`, contains a git repository owned by a different user (UID) than the one running the Docker container, git commands executed within `/project` might fail, displaying an error message `fatal: detected dubious ownership in repository at '/project'`. To resolve this issue, you can designate the `/project` directory as safe by setting the `IDF_GIT_SAFE_DIR` environment variable during the Docker container startup. For instance, you can achieve this by including `-e IDF_GIT_SAFE_DIR='/project'` as a parameter. Additionally, multiple directories can be specified by using a `:` separator. To entirely disable this git security check, `*` can be used.

---

To build with a specific docker image tag, specify it as  `espressif/idf:TAG` , for example:

```
docker run --rm -v $PWD:/project -w /project espressif/idf:release-v4.4 idf.py ↵  
↵build
```

You can check the up-to-date list of available tags at <https://hub.docker.com/r/espressif/idf/tags>.

**Using the image interactively** It is also possible to do builds interactively, to debug build issues or test the automated build scripts. Start the container with `-i -t` flags:

```
docker run --rm -v $PWD:/project -w /project -it espressif/idf
```

Then inside the container, use `idf.py` as usual:

```
idf.py menuconfig  
idf.py build
```

---

**Note:** Commands which communicate with the development board, such as `idf.py flash` and `idf.py monitor` will not work in the container unless the serial port is passed through into the container. However currently this is not possible with Docker for Windows (<https://github.com/docker/for-win/issues/1018>) and Docker for Mac (<https://github.com/docker/for-mac/issues/900>).

---

## Building custom images

The Dockerfile in ESP-IDF repository provides several build arguments which can be used to customize the Docker image:

- `IDF_CLONE_URL`: URL of the repository to clone ESP-IDF from. Can be set to a custom URL when working with a fork of ESP-IDF. Default is `https://github.com/espressif/esp-idf.git`.
- `IDF_CLONE_BRANCH_OR_TAG`: Name of a git branch or tag use when cloning ESP-IDF. This value is passed to `git clone` command using the `--branch` argument. Default is `master`.
- `IDF_CHECKOUT_REF`: If this argument is set to a non-empty value, `git checkout $IDF_CHECKOUT_REF` command will be performed after cloning. This argument can be set to the SHA of the specific commit to check out, for example if some specific commit on a release branch is desired.
- `IDF_CLONE_SHALLOW`: If this argument is set to a non-empty value, `--depth=1 --shallow-submodules` arguments will be used when performing `git clone`. This significantly reduces the amount of data downloaded and the size of the resulting Docker image. However, if switching to a different branch in such a “shallow” repository is necessary, an additional `git fetch origin <branch>` command must be executed first.
- `IDF_INSTALL_TARGETS`: Comma-separated list of IDF targets to install toolchains for, or `all` to install toolchains for all targets. Selecting specific targets reduces the amount of data downloaded and the size of the resulting Docker image. Default is `all`.

To use these arguments, pass them via the `--build-arg` command line option. For example, the following command will build a Docker image with a shallow clone of ESP-IDF v4.4.1 and tools for ESP32-C3, only:

```
docker build -t idf-custom:v4.4.1-esp32c3 \
  --build-arg IDF_CLONE_BRANCH_OR_TAG=v4.4.1 \
  --build-arg IDF_CLONE_SHALLOW=1 \
  --build-arg IDF_INSTALL_TARGETS=esp32c3 \
  tools/docker
```

### 4.24.3 IDF Windows Installer

#### Command-line parameters

Windows Installer `esp-idf-tools-setup` provides the following command-line parameters:

- `/CONFIG=[PATH]` - Path to `ini` configuration file to override default configuration of the installer. Default: `config.ini`.
- `/GITCLEAN=[yes|no]` - Perform git clean and remove untracked directories in Offline mode installation. Default: `yes`.
- `/GITRECURSIVE=[yes|no]` - Clone recursively all git repository submodules. Default: `yes`
- `/GITREPO=[URL|PATH]` - URL of repository to clone ESP-IDF. Default: <https://github.com/espressif/esp-idf.git>
- `/GITRESET=[yes|no]` - Enable/Disable git reset of repository during installation. Default: `yes`.
- `/HELP` - Display command line options provided by Inno Setup installer.
- `/IDFDIR=[PATH]` - Path to directory where it will be installed. Default: `{userdesktop}\esp-idf`
- `/IDFVERSION=[v4.3|v4.1|master]` - Use specific IDF version. E.g. `v4.1`, `v4.2`, `master`. Default: empty, pick the first version in the list.
- `/IDFVERSIONSURL=[URL]` - Use URL to download list of IDF versions. Default: [https://dl.espressif.com/dl/esp-idf/idf\\_versions.txt](https://dl.espressif.com/dl/esp-idf/idf_versions.txt)
- `/LOG=[PATH]` - Store installation log file in specific directory. Default: empty.
- `/OFFLINE=[yes|no]` - Execute installation of Python packages by PIP in offline mode. The same result can be achieved by setting the environment variable `PIP_NO_INDEX`. Default: `no`.
- `/USEEMBEDDEDPYTHON=[yes|no]` - Use Embedded Python version for the installation. Set to `no` to allow Python selection screen in the installer. Default: `yes`.
- `/PYTHONNOUSERSITE=[yes|no]` - Set `PYTHONNOUSERSITE` variable before launching any Python command to avoid loading Python packages from AppDataRoaming. Default: `yes`.
- `/PYTHONWHEELSURL=[URL]` - Specify URLs to PyPi repositories for resolving binary Python Wheel dependencies. The same result can be achieved by setting the environment variable `PIP_EXTRA_INDEX_URL`. Default: <https://dl.espressif.com/pypi>
- `/SKIPSYSTEMCHECK=[yes|no]` - Skip System Check page. Default: `no`.
- `/VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL` - Perform silent installation.

## Unattended installation

The unattended installation of IDF can be achieved by following command-line parameters:

```
esp-idf-tools-setup-x.x.exe /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL
```

The installer detaches its process from the command-line. Waiting for installation to finish could be achieved by following PowerShell script:

```
esp-idf-tools-setup-x.x.exe /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL
$InstallerProcess = Get-Process esp-idf-tools-setup
Wait-Process -Id $InstallerProcess.id
```

## Custom Python and custom location of Python wheels

The IDF installer is using by default embedded Python with reference to Python Wheel mirror.

Following parameters allows to select custom Python and custom location of Python wheels:

```
esp-idf-tools-setup-x.x.exe /USEEMBEDEDDEDPYTHON=no /PYTHONWHEELSURL=https://pypi.
↳org/simple/
```

### 4.24.4 IDF Component Manager

The IDF Component manager is a tool that downloads dependencies for any ESP-IDF CMake project. The download happens automatically during a run of CMake. It can source components either from [the component registry](#) or from a git repository.

A list of components can be found on <https://components.espressif.com/>

#### Using with a project

Dependencies for each component in the project are defined in a separate manifest file named `idf_component.yml` placed in the root of the component. The manifest file template can be created for a component by running `idf.py create-manifest --component=my_component`. When a new manifest is added to one of the components in the project it's necessary to reconfigure it manually by running `idf.py reconfigure`. Then build will track changes in `idf_component.yml` manifests and automatically triggers CMake when necessary.

There is an example application: `example:build_system/cmake/component_manager` that uses components installed by the component manager.

It's not necessary to have a manifest for components that don't need any managed dependencies.

When CMake configures the project (e.g. `idf.py reconfigure`) component manager does a few things:

- Processes `idf_component.yml` manifests for every component in the project and recursively solves dependencies
- Creates a `dependencies.lock` file in the root of the project with a full list of dependencies
- Downloads all dependencies to the `managed_components` directory

The lock-file `dependencies.lock` and content of `managed_components` directory is not supposed to be modified by a user. When the component manager runs it always make sure they are up to date. If these files were accidentally modified it's possible to re-run the component manager by triggering CMake with `idf.py reconfigure`

## Defining dependencies in the manifest

```
dependencies:
  # Required IDF version
  idf: ">=4.1"
  # Defining a dependency from the registry:
  # https://components.espressif.com/component/example/cmp
  example/cmp: ">=1.0.0"

  # # Other ways to define dependencies
  #
  # # For components maintained by Espressif only name can be used.
  # # Same as `espressif/cmp`
  # component: "~1.0.0"
  #
  # # Or in a longer form with extra parameters
  # component2:
  #   version: ">=2.0.0"
  #
  # # For transient dependencies `public` flag can be set.
  # # `public` flag doesn't affect the `main` component.
  # # All dependencies of `main` are public by default.
  # public: true
  #
  # # For components hosted on non-default registry:
  # service_url: "https://componentregistry.company.com"
  #
  # # For components in git repository:
  # test_component:
  #   path: test_component
  #   git: ssh://git@gitlab.com/user/components.git
  #
  # # For test projects during component development
  # # components can be used from a local directory
  # # with relative or absolute path
  # some_local_component:
  #   path: ../../projects/component
```

## Disabling the Component Manager

The component manager can be explicitly disabled by setting `IDF_COMPONENT_MANAGER` environment variable to 0.

### 4.24.5 IDF Clang Tidy

The IDF Clang Tidy is a tool that uses [clang-tidy](#) to run static analysis on your current app.

**Warning:** This functionality and the toolchain it relies on are still under development. There may be breaking changes before a final release.

**Warning:** This tool does not support RISC-V based chips yet. For now, we don't provide clang based toolchain for RISC-V.

## Prerequisites

If you have never run this tool before, take the following steps to get this tool prepared.

1. Run the export scripts (`export.sh / export.bat / ...`) to set up the environment variables.
2. Run `pip install --upgrade pyclang` to install this plugin. The extra commands would be activated in `idf.py` automatically.
3. Run `idf_tools.py install xtensa-clang` to install the clang-tidy required binaries

---

**Note:** This toolchain is still under development. After the final release, you don't have to install them manually.

---

4. Get file from the [llvm repository](#) and add the folder of this script to the `$PATH`. Or you could pass an optional argument `--run-clang-tidy-py` later when you call `idf.py clang-check`. Please don't forget to make the script executable.

---

**Note:** This file would be bundled in future toolchain releases. This is a temporary workaround.

---

5. Run the export scripts (`export.sh / export.bat / ...`) again to refresh the environment variables.

## Extra Commands

**clang-check** Run `idf.py clang-check` to re-generate the compilation database and run `clang-tidy` under your current project folder. The output would be written to `<project_dir>/warnings.txt`.

Run `idf.py clang-check --help` to see the full documentation.

## clang-html-report

1. Run `pip install codereport` to install the additional dependency.
2. Run `idf.py clang-html-report` to generate an HTML report in folder `<project_dir>/html_report` according to the `warnings.txt`. Please open the `<project_dir>/html_report/index.html` in your browser to check the report.

## Bug Report

This tool is hosted in [espressif/clang-tidy-runner](#). If you faced any bugs or have any feature request, please report them via [github issues](#).

## 4.24.6 Downloadable Tools

ESP-IDF build process relies on a number of tools: cross-compiler toolchains, CMake build system, and others.

Installing the tools using an OS-specific package manager (like `apt`, `yum`, `brew`, etc.) is the preferred method when the required version of the tool is available. This recommendation is reflected in the Getting Started guide. For example, on Linux and macOS it is recommended to install CMake using an OS package manager.

However, some of the tools are IDF-specific and are not available in OS package repositories. Furthermore, different versions of ESP-IDF require different versions of the tools to operate correctly. To solve these two problems, ESP-IDF provides a set of scripts for downloading and installing the correct versions of tools, and exposing them in the environment.

The rest of the document refers to these downloadable tools simply as “tools”. Other kinds of tools used in ESP-IDF are:

- Python scripts bundled with ESP-IDF (such as `idf.py`)
- Python packages installed from PyPI.

The following sections explain the installation method, and provide the list of tools installed on each platform.

---

**Note:** This document is provided for advanced users who need to customize their installation, users who wish to understand the installation process, and ESP-IDF developers.

If you are looking for instructions on how to install the tools, see the [Getting Started Guide](#).

---

### Tools metadata file

The list of tools and tool versions required for each platform is located in [tools/tools.json](#). The schema of this file is defined by [tools/tools\\_schema.json](#).

This file is used by [tools/idf\\_tools.py](#) script when installing the tools or setting up the environment variables.

### Tools installation directory

`IDF_TOOLS_PATH` environment variable specifies the location where the tools are to be downloaded and installed. If not set, `IDF_TOOLS_PATH` defaults to `HOME/.espressif` on Linux and macOS, and `%USER_PROFILE%\espressif` on Windows.

Inside `IDF_TOOLS_PATH`, the scripts performing tools installation create the following directories and files:

- `dist` —where the archives of the tools are downloaded.
- `tools` —where the tools are extracted. The tools are extracted into subdirectories: `tools/TOOL_NAME/VERSION/`. This arrangement allows different versions of tools to be installed side by side.
- `idf-env.json` —user install options (targets, features) are stored in this file. Targets are selected chip targets for which tools are installed and kept up-to-date. Features determine the Python package set which should be installed. These options will be discussed later.
- `python_env` —not tools related; virtual Python environments are installed in the sub-directories. Note that the Python environment directory can be placed elsewhere by setting the `IDF_PYTHON_ENV_PATH` environment variable.
- `espidf.constraints.*.txt` —one constraint file for each ESP-IDF release containing Python package version requirements.

### GitHub Assets Mirror

Most of the tools downloaded by the tools installer are GitHub Release Assets, which are files attached to a software release on GitHub.

If GitHub downloads are inaccessible or slow to access, it's possible to configure a GitHub assets mirror.

To use Espressif's download server, set the environment variable `IDF_GITHUB_ASSETS` to `dl.espressif.com/github_assets`. When the install process is downloading a tool from `github.com`, the URL will be rewritten to use this server instead.

Any mirror server can be used provided the URL matches the `github.com` download URL format: the install process will replace `https://github.com` with `https://{IDF_GITHUB_ASSETS}` for any GitHub asset URL that it downloads.

---

**Note:** The Espressif download server doesn't currently mirror everything from GitHub, it only mirrors files attached as Assets to some releases as well as source archives for some releases.

---

### `idf_tools.py` script

[tools/idf\\_tools.py](#) script bundled with ESP-IDF performs several functions:

- `install`: Download the tool into `${IDF_TOOLS_PATH}/dist` directory, extract it into `${IDF_TOOLS_PATH}/tools/TOOL_NAME/VERSION`. `install` command accepts the list of tools to install, in `TOOL_NAME` or `TOOL_NAME@VERSION` format. If all is given, all the tools (required and optional ones) are installed. If no argument or `required` is given, only the required tools are installed.
- `download`: Similar to `install` but doesn't extract the tools. An optional `--platform` argument may be used to download the tools for the specific platform.
- `export`: Lists the environment variables which need to be set to use the installed tools. For most of the tools, setting `PATH` environment variable is sufficient, but some tools require extra environment variables. The environment variables can be listed in either of `shell` or `key-value` formats, set by `--format` parameter:

– `export` optional parameters:

- \* `--unset` Creates statement that `unset` some global variables, so the environment gets to the state it was before calling `export`. `{sh/fish}`.
- \* `--add_paths_extras` Adds extra ESP-IDF-related paths of `$PATH` to `${IDF_TOOLS_PATH}/esp-idf.json`, which is used to remove global variables when the active ESP-IDF environment is deactivated. Example: While processing `export`.`{sh/fish}` script, new paths are added to global variable `$PATH`. This option is used to save these new paths to the `${IDF_TOOLS_PATH}/esp-idf.json`.

– `shell` produces output suitable for evaluation in the shell. For example,

```
export PATH="/home/user/.espressif/tools/tool/v1.0.0/bin:$PATH"
```

on Linux and macOS, and

```
set "PATH=C:\Users\user\.espressif\tools\v1.0.0\bin;%PATH%"
```

on Windows.

---

**Note:** Exporting environment variables in Powershell format is not supported at the moment. `key-value` format may be used instead.

---

The output of this command may be used to update the environment variables, if the shell supports this. For example:

```
eval $(${IDF_PATH}/tools/idf_tools.py export)
```

– `key-value` produces output in `VARIABLE=VALUE` format, suitable for parsing by other scripts:

```
PATH=/home/user/.espressif/tools/tool/v1.0.0:$PATH
```

Note that the script consuming this output has to perform expansion of `$VAR` or `%VAR%` patterns found in the output.

- `list`: Lists the known versions of the tools, and indicates which ones are installed.
- `check`: For each tool, checks whether the tool is available in the system path and in `IDF_TOOLS_PATH`.
- `install-python-env`: Create a Python virtual environment in the `${IDF_TOOLS_PATH}/python_env` directory (or directly in the directory set by the `IDF_PYTHON_ENV_PATH` environment variable) and install there the required Python packages. An optional `--features` argument allows one to specify a comma-separated list of features to be added or removed. Feature that begins with `-` will be removed and features with `+` or without any sign will be added. Example syntax for removing feature `XY` is `--features=-XY` and for adding `--features=+XY` or `--features=XY`. If both removing and adding options are provided with the same feature, no operation is performed. For each feature a requirements file must exist. For example, feature `XY` is a valid feature if `${IDF_PATH}/tools/requirements/requirements.XY.txt` is an existing file with a list of Python packages to be installed. There is one mandatory `core` feature ensuring core functionality of ESP-IDF (`build`, `flash`, `monitor`, `debug in console`). There can be an arbitrary number of optional features. The selected list of features is stored in `idf-env.json`. The requirement files contain a list of the desired Python packages to be installed and `espidf.constraints.*.txt` downloaded from <https://dl.espressif.com> and stored in `${IDF_TOOLS_PATH}` the package version requirements for a given ESP-IDF version. Although it is not recommended, the download and use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to `no`.

- `check-python-dependencies`: Checks if all required Python packages are installed. Packages from `${IDF_PATH}/tools/requirements/requirements.*.txt` files selected by the feature list of `idf-env.json` are checked with the package versions specified in the `espidf.constraints.*.txt` file. The constraint file is downloaded with `install-python-env` command. The use of constraints files can be disabled similarly to the `install-python-env` command.
- `uninstall`: Print and remove tools, that are currently not used by active ESP-IDF version.
  - `--dry-run` Print installed unused tools.
  - `--remove-archives` Additionally remove all older versions of previously downloaded installation packages.

## Install scripts

Shell-specific user-facing scripts are provided in the root of ESP-IDF repository to facilitate tools installation. These are:

- `install.bat` for Windows Command Prompt
- `install.ps1` for Powershell
- `install.sh` for Bash
- `install.fish` for Fish

Aside from downloading and installing the tools into `IDF_TOOLS_PATH`, these scripts prepare a Python virtual environment, and install the required packages into that environment.

These scripts accept optionally a comma separated list of chip targets and `--enable-*` arguments for enabling features. These arguments are passed to the `idf_tools.py` script which stores them in `idf-env.json`. Therefore, chip targets and features can be enabled incrementally.

Running the scripts without any optional arguments will install tools for all chip targets (by running `idf_tools.py install --targets=all`) and Python packages for core ESP-IDF functionality (by running `idf_tools.py install-python-env --features=core`).

Or for example, `install.sh esp32` will install tools only for ESP32. See the [Getting Started Guide](#) for more examples.

`install.sh --enable-XY` will enable feature XY (by running `idf_tools.py install-python-env --features=core,XY`).

## Export scripts

Since the installed tools are not permanently added into the user or system `PATH` environment variable, an extra step is required to use them in the command line. The following scripts modify the environment variables in the current shell to make the correct versions of the tools available:

- `export.bat` for Windows Command Prompt
- `export.ps1` for Powershell
- `export.sh` for Bash
- `export.fish` for Fish

---

**Note:** To modify the shell environment in Bash, `export.sh` must be “sourced” : `. ./export.sh` (note the leading dot and space).

`export.sh` may be used with shells other than Bash (such as zsh). However in this case the `IDF_PATH` environment variable must be set before running the script. When used in Bash, the script will guess the `IDF_PATH` value from its own location.

---

In addition to calling `idf_tools.py`, these scripts list the directories which have been added to the `PATH`.

## Other installation methods

Depending on the environment, more user-friendly wrappers for `idf_tools.py` are provided:

- [IDF Tools installer for Windows](#) can download and install the tools. Internally the installer uses `idf_tools.py`.
- [Eclipse Plugin](#) includes a menu item to set up the tools. Internally the plugin calls `idf_tools.py`.
- [VSCode Extension](#) for ESP-IDF includes an onboarding flow. This flow helps setting up the tools. Although the extension does not rely on `idf_tools.py`, the same installation method is used.

## Custom installation

Although the methods above are recommended for ESP-IDF users, they are not a must for building ESP-IDF applications. ESP-IDF build system expects that all the necessary tools are installed somewhere, and made available in the `PATH`.

## Uninstall ESP-IDF

Uninstalling ESP-IDF requires removing both the tools and the environment variables that have been configured during the installation.

- Windows users using the [Windows ESP-IDF Tools Installer](#) can simply run the uninstall wizard to remove ESP-IDF.
- To remove an installation performed by running the supported [install scripts](#), simply delete the [tools installation directory](#) including the downloaded and installed tools. Any environment variables set by the [export scripts](#) are not permanent and will not be present after opening a new environment.
- When dealing with a custom installation, in addition to deleting the tools as mentioned above, you may also need to manually revert any changes to environment variables or system paths that were made to accommodate the ESP-IDF tools (e.g., `IDF_PYTHON_ENV_PATH` or `IDF_TOOLS_PATH`). If you manually copied any tools, you would need to track and delete those files manually.
- If you installed any plugins like the [ESP-IDF Eclipse Plugin](#) or [VSCode ESP-IDF Extension](#), you should follow the specific uninstallation instructions described in the documentation of those components.

---

**Note:** Uninstalling the ESP-IDF tools does not remove any project files or your code. Be mindful of what you are deleting to avoid losing any work. If you are unsure about a step, refer back to the installation instructions.

These instructions assume that the tools were installed following the procedures in this provided document. If you've used a custom installation method, you might need to adapt these instructions accordingly.

---

## 4.25 Unit Testing in ESP32-C3

ESP-IDF provides the following methods to test software.

- Target based tests using a central unit test application which runs on the esp32c3. These tests use the [Unity](#) unit test framework. They can be integrated into an ESP-IDF component by placing them in the component's `test` subdirectory. This document mainly introduces this target based tests.
- Linux-host based unit tests in which all the hardware are abstracted via mocks. Linux-host based tests are still under development and only a small fraction of IDF components support them, currently. They are covered here: [Unit Testing on Linux](#).

### 4.25.1 Normal Test Cases

Unit tests are located in the `test` subdirectory of a component. Tests are written in C, and a single C source file can contain multiple test cases. Test files start with the word “test” .

Each test file should include the `unity.h` header and the header for the C module to be tested.

Tests are added in a function in the C file as follows:

```
TEST_CASE("test name", "[module name]")
{
    // Add test here
}
```

- The first argument is a descriptive name for the test.
- The second argument is an identifier in square brackets. Identifiers are used to group related test, or tests with specific properties.

---

**Note:** There is no need to add a main function with `UNITY_BEGIN()` and `UNITY_END()` in each test case. `unity_platform.c` will run `UNITY_BEGIN()` autonomously, and run the test cases, then call `UNITY_END()`.

---

The `test` subdirectory should contain a *component CMakeLists.txt*, since they are themselves components (i.e., a test component). ESP-IDF uses the Unity test framework located in the `unity` component. Thus, each test component should specify the `unity` component as a component requirement using the `REQUIRES` argument. Normally, components *should list their sources manually*; for component tests however, this requirement is relaxed and the use of the `SRC_DIRS` argument in `idf_component_register` is advised.

Overall, the minimal `test` subdirectory `CMakeLists.txt` file should contain the following:

```
idf_component_register(SRC_DIRS "."
                      INCLUDE_DIRS "."
                      REQUIRES unity)
```

See <http://www.throwtheswitch.org/unity> for more information about writing tests in Unity.

### 4.25.2 Multi-device Test Cases

The normal test cases will be executed on one DUT (Device Under Test). However, components that require some form of communication (e.g., GPIO, SPI) require another device to communicate with, thus cannot be tested through normal test cases. Multi-device test cases involve writing multiple test functions, and running them on multiple DUTs.

The following is an example of a multi-device test case:

```
void gpio_master_test()
{
    gpio_config_t slave_config = {
        .pin_bit_mask = 1 << MASTER_GPIO_PIN,
        .mode = GPIO_MODE_INPUT,
    };
    gpio_config(&slave_config);
    unity_wait_for_signal("output high level");
    TEST_ASSERT(gpio_get_level(MASTER_GPIO_PIN) == 1);
}

void gpio_slave_test()
{
    gpio_config_t master_config = {
        .pin_bit_mask = 1 << SLAVE_GPIO_PIN,
        .mode = GPIO_MODE_OUTPUT,
    };
    gpio_config(&master_config);
    gpio_set_level(SLAVE_GPIO_PIN, 1);
    unity_send_signal("output high level");
}

TEST_CASE_MULTIPLE_DEVICES("gpio multiple devices test example", "[driver]", gpio_
↪master_test, gpio_slave_test);
```

The macro `TEST_CASE_MULTIPLE_DEVICES` is used to declare a multi-device test case.

- The first argument is test case name.
- The second argument is test case description.
- From the third argument, up to 5 test functions can be defined, each function will be the entry point of tests running on each DUT.

Running test cases from different DUTs could require synchronizing between DUTs. We provide `unity_wait_for_signal` and `unity_send_signal` to support synchronizing with UART. As the scenario in the above example, the slave should get GPIO level after master set level. DUT UART console will prompt and user interaction is required:

DUT1 (master) console:

```
Waiting for signal: [output high level]!
Please press "Enter" key to once any board send this signal.
```

DUT2 (slave) console:

```
Send signal: [output high level]!
```

Once the signal is sent from DUT2, you need to press “Enter” on DUT1, then DUT1 unblocks from `unity_wait_for_signal` and starts to change GPIO level.

### 4.25.3 Multi-stage Test Cases

The normal test cases are expected to finish without reset (or only need to check if reset happens). Sometimes we expect to run some specific tests after certain kinds of reset. For example, we want to test if the reset reason is correct after a wake up from deep sleep. We need to create a deep-sleep reset first and then check the reset reason. To support this, we can define multi-stage test cases, to group a set of test functions:

```
static void trigger_deepsleep(void)
{
    esp_sleep_enable_timer_wakeup(2000);
    esp_deep_sleep_start();
}

void check_deepsleep_reset_reason()
{
    soc_reset_reason_t reason = esp_rom_get_reset_reason(0);
    TEST_ASSERT(reason == RESET_REASON_CORE_DEEP_SLEEP);
}

TEST_CASE_MULTIPLE_STAGES("reset reason check for deepsleep", "[esp32c3]", trigger_
↪deepsleep, check_deepsleep_reset_reason);
```

Multi-stage test cases present a group of test functions to users. It needs user interactions (select cases and select different stages) to run the case.

### 4.25.4 Tests For Different Targets

Some tests (especially those related to hardware) cannot run on all targets. Below is a guide how to make your unit tests run on only specified targets.

1. Wrap your test code by `!(TEMPORARY_)DISABLED_FOR_TARGETS()` macros and place them either in the original test file, or separate the code into files grouped by functions, but make sure all these files will be processed by the compiler. E.g.:

```
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
TEST_CASE("a test that is not ready for esp32 and esp8266 yet", "[ ]")
{
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
```

Once you need one of the tests to be compiled on a specified target, just modify the targets in the disabled list. It's more encouraged to use some general conception that can be described in `soc_caps.h` to control the disabling of tests. If this is done but some of the tests are not ready yet, use both of them (and remove `!(TEMPORARY_)DISABLED_FOR_TARGETS()` later). E.g.:

```
#if SOC_SDIO_SLAVE_SUPPORTED
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
TEST_CASE("a sdio slave tests that is not ready for esp64 yet", "[sdio_slave]")
{
    //available for esp32 now, and will be available for esp64 in the future
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
#endif //SOC_SDIO_SLAVE_SUPPORTED
```

2. For test code that you are 100% for sure that will not be supported (e.g. no peripheral at all), use `DISABLED_FOR_TARGETS`; for test code that should be disabled temporarily, or due to lack of runners, etc., use `TEMPORARY_DISABLED_FOR_TARGETS`.

Some old ways of disabling unit tests for targets, that have obvious disadvantages, are deprecated:

- DON'T put the test code under `test/target` folder and use `CMakeLists.txt` to choose one of the target folder. This is prevented because test code is more likely to be reused than the implementations. If you put

something into `test/esp32` just to avoid building it on `esp32s2`, it's hard to make the code tidy if you want to enable the test again on `esp32s3`.

- DON'T use `CONFIG_IDF_TARGET_XXX` macros to disable the test items any more. This makes it harder to track disabled tests and enable them again. Also, a black-list style `#if !disabled` is preferred to white-list style `#if CONFIG_IDF_TARGET_XXX`, since you will not silently disable cases when new targets are added in the future. But for test implementations, it's allowed to use `#if CONFIG_IDF_TARGET_XXX` to pick one of the implementation code.
  - Test item: some items that will be performed on some targets, but skipped on other targets. E.g. There are three test items SD 1-bit, SD 4-bit and SDSPI. For ESP32-S2, which doesn't have SD host, among the tests only SDSPI is enabled on ESP32-S2.
  - Test implementation: some code will always happen, but in different ways. E.g. There is no SDIO PKT\_LEN register on ESP8266. If you want to get the length from the slave as a step in the test process, you can have different implementation code protected by `#if CONFIG_IDF_TARGET_XXX` reading in different ways. But please avoid using `#else` macro. When new target is added, the test case will fail at building stage, so that the maintainer will be aware of this, and choose one of the implementations explicitly.

### 4.25.5 Building Unit Test App

Follow the setup instructions in the top-level `esp-idf` README. Make sure that `IDF_PATH` environment variable is set to point to the path of `esp-idf` top-level directory.

Change into `tools/unit-test-app` directory to configure and build it:

- `idf.py menuconfig` - configure unit test app.
- `idf.py -T all build` - build unit test app with tests for each component having tests in the `test` subdirectory.
- `idf.py -T "xxx yyy" build` - build unit test app with tests for some space-separated specific components (For instance: `idf.py -T heap build` - build unit tests only for `heap` component directory).
- `idf.py -T all -E "xxx yyy" build` - build unit test app with all unit tests, except for unit tests of some components (For instance: `idf.py -T all -E "ulp mbedtls" build` - build all unit tests excludes `ulp` and `mbedtls` components).

---

**Note:** Due to inherent limitations of Windows command prompt, following syntax has to be used in order to build `unit-test-app` with multiple components: `idf.py -T xxx -T yyy build` or with escaped quotes: `idf.py -T \"xxx yyy\" build` in PowerShell or `idf.py -T ^\"ssd1306 hts221\" build` in Windows command prompt.

---

When the build finishes, it will print instructions for flashing the chip. You can simply run `idf.py flash` to flash all build output.

You can also run `idf.py -T all flash` or `idf.py -T xxx flash` to build and flash. Everything needed will be rebuilt automatically before flashing.

Use `menuconfig` to set the serial port for flashing. For more information, see <tools/unit-test-app/README.md>.

### 4.25.6 Running Unit Tests

After flashing reset the ESP32-C3 and it will boot the unit test app.

When unit test app is idle, press “Enter” will make it print test menu with all available tests:

```
Here's the test menu, pick your combo:
(1)  "esp_ota_begin() verifies arguments" [ota]
(2)  "esp_ota_get_next_update_partition logic" [ota]
(3)  "Verify bootloader image in flash" [bootloader_support]
(4)  "Verify unit test app image" [bootloader_support]
(5)  "can use new and delete" [cxx]
```

(continues on next page)

(continued from previous page)

```

(6)    "can call virtual functions" [cxx]
(7)    "can use static initializers for non-POD types" [cxx]
(8)    "can use std::vector" [cxx]
(9)    "static initialization guards work as expected" [cxx]
(10)   "global initializers run in the correct order" [cxx]
(11)   "before scheduler has started, static initializers work correctly" [cxx]
(12)   "adc2 work with wifi" [adc]
(13)   "gpio master/slave test example" [ignore][misc][test_env=UT_T2_1][multi_
↪device]
      (1)    "gpio_master_test"
      (2)    "gpio_slave_test"
(14)   "SPI Master clockdiv calculation routines" [spi]
(15)   "SPI Master test" [spi][ignore]
(16)   "SPI Master test, interaction of multiple devs" [spi][ignore]
(17)   "SPI Master no response when switch from host1 (SPI2) to host2 (SPI3)" ↪
↪[spi]
(18)   "SPI Master DMA test, TX and RX in different regions" [spi]
(19)   "SPI Master DMA test: length, start, not aligned" [spi]
(20)   "reset reason check for deepsleep" [esp32c3][test_env=UT_T2_1][multi_stage]
      (1)    "trigger_deepsleep"
      (2)    "check_deepsleep_reset_reason"

```

The normal case will print the case name and description. Master-slave cases will also print the sub-menu (the registered test function names).

Test cases can be run by inputting one of the following:

- Test case name in quotation marks to run a single test case
- Test case index to run a single test case
- Module name in square brackets to run all test cases for a specific module
- An asterisk to run all test cases

[multi\_device] and [multi\_stage] tags tell the test runner whether a test case is a multiple devices or multiple stages of test case. These tags are automatically added by `TEST_CASE_MULTIPLE_STAGES` and `TEST_CASE_MULTIPLE_DEVICES` macros.

After you select a multi-device test case, it will print sub-menu:

```

Running gpio master/slave test example...
gpio master/slave test example
      (1)    "gpio_master_test"
      (2)    "gpio_slave_test"

```

You need to input a number to select the test running on the DUT.

Similar to multi-device test cases, multi-stage test cases will also print sub-menu:

```

Running reset reason check for deepsleep...
reset reason check for deepsleep
      (1)    "trigger_deepsleep"
      (2)    "check_deepsleep_reset_reason"

```

First time you execute this case, input 1 to run first stage (trigger deepsleep). After DUT is rebooted and able to run test cases, select this case again and input 2 to run the second stage. The case only passes if the last stage passes and all previous stages trigger reset.

### 4.25.7 Timing Code with Cache Compensated Timer

Instructions and data stored in external memory (e.g. SPI Flash and SPI RAM) are accessed through the CPU's unified instruction and data cache. When code or data is in cache, access is very fast (i.e., a cache hit).

However, if the instruction or data is not in cache, it needs to be fetched from external memory (i.e., a cache miss). Access to external memory is significantly slower, as the CPU must execute stall cycles whilst waiting for the instruction or data to be retrieved from external memory. This can cause the overall code execution speed to vary depending on the number of cache hits or misses.

Code and data placements can vary between builds, and some arrangements may be more favorable with regards to cache access (i.e., minimizing cache misses). This can technically affect execution speed, however these factors are usually irrelevant as their effect ‘average out’ over the device’s operation.

The effect of the cache on execution speed, however, can be relevant in benchmarking scenarios (especially micro benchmarks). There might be some variability in measured time between runs and between different builds. A technique for eliminating for some of the variability is to place code and data in instruction or data RAM (IRAM/DRAM), respectively. The CPU can access IRAM and DRAM directly, eliminating the cache out of the equation. However, this might not always be viable as the size of IRAM and DRAM is limited.

The cache compensated timer is an alternative to placing the code/data to be benchmarked in IRAM/DRAM. This timer uses the processor’s internal event counters in order to determine the amount of time spent on waiting for code/data in case of a cache miss, then subtract that from the recorded wall time.

```
// Start the timer
ccomp_timer_start();

// Function to time
func_code_to_time();

// Stop the timer, and return the elapsed time in microseconds relative to
// ccomp_timer_start
int64_t t = ccomp_timer_stop();
```

One limitation of the cache compensated timer is that the task that benchmarked functions should be pinned to a core. This is due to each core having its own event counters that are independent of each other. For example, if `ccomp_timer_start` gets called on one core, put to sleep by the scheduler, wakes up, and gets rescheduled on the other core, then the corresponding `ccomp_timer_stop` will be invalid.

## 4.25.8 Mocks

---

**Note:** Currently, mocking is only possible with some selected components when running on the Linux host. In the future, we plan to make essential components in IDF mockable. This will also include mocking when running on the ESP32-C3.

---

One of the biggest problems regarding unit testing of embedded systems are the strong hardware dependencies. Running unit tests directly on the ESP32-C3 can be especially difficult for higher layer components for the following reasons:

- Decreased test reliability due to lower layer components and/or hardware setup.
- Increased difficulty in testing edge cases due to limitations of lower layer components and/or hardware setup
- Increased difficulty in identifying the root cause due to the large number of dependencies influencing the behavior

When testing a particular component, (i.e., the component under test), software mocking allows the dependencies of the component under test to be substituted (i.e., mocked) entirely in software. To allow software mocking, ESP-IDF integrates the **CMock** mocking framework as a component. With the addition of some CMake functions in the ESP-IDF’s build system, it is possible to conveniently mock the entirety (or a part of) an IDF component.

Ideally, all components that the component under test is dependent on should be mocked, thus allowing the test environment complete control over all interactions with the component under test. However, if mocking all dependent components becomes too complex or too tedious (e.g. because you need to mock too many function calls) you have the following options:

- Include more “real” IDF code in the tests. This may work but increases the dependency on the “real” code’s behavior. Furthermore, once a test fails, you may not know if the failure is in your actual code under tests or the “real” IDF code.
- Re-evaluate the design of the code under test and attempt to reduce its dependencies by dividing the code under test into more manageable components. This may seem burdensome but it is common knowledge that unit tests often expose software design weaknesses. Fixing design weaknesses will not only help with unit testing in the short term, but will help future code maintenance as well.

Refer to [cmock/CMock/docs/CMock\\_Summary.md](#) for more details on how CMock works and how to create and use mocks.

## Requirements

The Linux target is the only target where mocking currently works. The following requirements are necessary to generate the mocks:

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the `CMakeLists.txt` of the application’s root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

## Mock a Component

To create a mock version of a component, called a *component mock*, the component needs to be overwritten in a particular way. Overriding a component entails creating a component with the exact same name as the original component, then let the build system discover it later than the original component (see [Multiple components with the same name](#) for more details).

In the component mock, the following parts are specified:

- The headers providing the functions to generate mocks for
- Include paths of the aforementioned headers
- Dependencies of the mock component (this is necessary e.g. if the headers include files from other components)

All these parts have to be specified using the IDF build system function `idf_component_mock`. You can use the IDF build system function `idf_component_get_property` with the tag `COMPONENT_OVERRIDEN_DIR` to access the component directory of the original component and then register the mock component parts using `idf_component_mock`:

```
idf_component_get_property(original_component_dir <original-component-name>_
↳COMPONENT_OVERRIDEN_DIR)
...
idf_component_mock(INCLUDE_DIRS "${original_component_dir}/include"
  REQUIRES freertos
  MOCK_HEADER_FILES ${original_component_dir}/include/header_containing_
↳functions_to_mock.h)
```

The component mock also requires a separate mock directory containing a `mock_config.yaml` file that configures CMock. A simple `mock_config.yaml` could look like this:

```
:cmock:  
  :plugins:  
    - expect  
    - expect_any_args
```

For more details about the CMock configuration yaml file, have a look at [cmock/CMock/docs/CMock\\_Summary.md](#).

Note that the component mock does not have to mock the original component in its entirety. As long as the test project's dependencies and dependencies of other code to the original components are satisfied by the component mock, partial mocking is adequate. In fact, most of the component mocks in IDF in `tools/mocks` are only partially mocking the original component.

Examples of component mocks can be found under [tools/mocks](#) in the IDF directory. General information on how to *override an IDF component* can be found in [Multiple components with the same name](#).

### Adjustments in Unit Test

The unit test needs to inform the cmake build system to mock dependent components (i.e., it needs to override the original component with the mock component). This is done by either placing the component mock into the project's `components` directory or adding the mock component's directory using the following line in the project's root `CMakeLists.txt`:

```
list(APPEND EXTRA_COMPONENT_DIRS "<mock_component_dir>")
```

Both methods will override existing components in ESP-IDF with the component mock. The latter is particularly convenient if you use component mocks that are already supplied by IDF.

Users should refer to the `esp_event` host-based unit test and its [esp\\_event/host\\_test/esp\\_event\\_unit\\_test/CMakeLists.txt](#) as an example of a component mock.

## 4.26 Unit Testing on Linux

---

**Note:** Host testing with IDF is experimental for now. We try our best to keep interfaces stable but can't guarantee it for now. Feedback via [github](#) or the forum on [esp32.com](#) is highly welcome, though and may influence the future design of the host-based tests.

---

This article provides an overview of unit tests with IDF on Linux. For using unit tests on the target, please refer to [target based unit testing](#).

### 4.26.1 Embedded Software Tests

Embedded software tests are challenging due to the following factors:

- Difficulties running tests efficiently.
- Lack of many operating system abstractions when interfacing with hardware, making it difficult to isolate code under test.

To solve these two problems, Linux host-based tests with [CMock](#) are introduced. Linux host-based tests are more efficient than unit tests on the target since they:

- Compile the necessary code only
- Don't need time to upload to a target
- Run much faster on a host-computer, compared to an ESP

Using the [CMock](#) framework also solves the problem of hardware dependencies. Through mocking, hardware details are emulated and specified at run time, but only if necessary.

Of course, using code on the host and using mocks does not fully represent the target device. Thus, two kinds of tests are recommended:

1. Unit tests which test program logic on a Linux machine, isolated through mocks.
2. System/Integration tests which test the interaction of components and the whole system. They run on the target, where irrelevant components and code may as well be emulated via mocks.

This documentation is about the first kind of tests. Refer to *target based unit testing* for more information on target tests (the second kind of tests).

### 4.26.2 IDF Unit Tests on Linux Host

The current focus of the Linux host tests is on creating isolated unit tests of components, while mocking the component's dependencies with CMock.

A complete implementation of IDF to run on Linux does not exist currently.

There are currently two examples for running IDF-built code on Linux host:

- An example [hello-world application](#)
- A [unit test for NVS](#).

Inside the component which should be tested, there is a separate directory `host_test`, besides the “traditional” test directory or the `test_apps` directory. It has one or more subdirectories:

```
- host_test/
    - fixtures/
        contains test fixtures (structs/functions to do test case set-up
        ↪and tear-down) .
        If there are no fixtures, this can be omitted.
    - <test_name>/
        IDF applications which run the tests
    - <test_name2>/
        Further tests are possible.
```

The IDF applications inside `host_test` set the mocking configuration as described in the *IDF unit test documentation*.

The [NVS page unit test](#) provides some illustration of how to control the mocks.

#### Requirements

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the `CMakeLists.txt` of the application's root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

The host tests have been tested on Ubuntu 20.04 with GCC version 9 and 10.

## 4.27 USB Serial/JTAG Controller Console

On chips with an integrated USB Serial/JTAG Controller, it is possible to use the part of this controller that implements a serial port (CDC) to implement the serial console, instead of using UART with an external USB-UART bridge chip. ESP32-C3 contains this controller, providing the following functions:

- Bidirectional serial console, which can be used with *IDF Monitor* or another serial monitor.
- Flashing using `esptool.py` and `idf.py flash`.
- JTAG debugging using e.g. OpenOCD, simultaneous with serial operations.

Note that, in contrast with the USB OTG peripheral in some Espressif chips, the USB Serial/JTAG Controller is a fixed function device, implemented entirely in hardware. This means it cannot be reconfigured to perform any function other than to provide a serial channel and JTAG debugging functionality.

### 4.27.1 Hardware Requirements

Connect ESP32-C3 to the USB port as follows:

GPIO	USB
19	D+ (green)
18	D- (white)
GND	GND (black)
	+5V (red)

Some development boards may offer a USB connector for the USB Serial/JTAG Controller —in that case, no extra connections are required.

### 4.27.2 Software Configuration

USB console feature can be enabled using `CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG` option in `menuconfig` tool (see [CONFIG\\_ESP\\_CONSOLE\\_UART](#)).

Once the option is enabled, build the project as usual.

Alternatively, you can access the output through `usb_serial_jtag` port but make sure the option `CONFIG_ESP_CONSOLE_SECONDARY_USB_SERIAL_JTAG` in choice `ESP_CONSOLE_SECONDARY` is selected.

**Warning:** Besides output, if you also want to input or use REPL with console, please select `CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG`.

### 4.27.3 Uploading the Application

The USB Serial/JTAG Controller is able to put the ESP32-C3 into download mode automatically. Simply flash as usual, but specify the USB Serial/JTAG Controller port on your system: `idf.py flash -p PORT` where `PORT` is the name of the proper port.

### 4.27.4 Limitations

There are several limitations to the USB Serial/JTAG console feature. These may or may not be significant, depending on the type of application being developed, and the development workflow.

1. If the application accidentally reconfigures the USB peripheral pins, or disables the USB Serial/JTAG Controller, the device will disappear from the system. After fixing the issue in the application, you will need to manually put the ESP32-C3 into download mode by pulling low GPIO9 and resetting the chip.

2. If the application enters deep sleep mode, the USB Serial/JTAG device will disappear from the system.
3. For data sent in the direction of ESP32-C3 to PC Terminal (e.g. stdout, logs), the ESP32-C3 first writes to a small internal buffer. If this buffer becomes full (for example, if no PC Terminal is connected), the ESP32-C3 will do a one-time wait of 50ms hoping for the PC Terminal to request the data. This can appear as a very brief ‘pause’ in your application.
4. For data sent in the PC Terminal to ESP32-C3 direction (e.g. console commands), many PC Terminals will wait for the ESP32-C3 to ingest the bytes before allowing you to sending more data. This is in contrast to using a USB-to-Serial (UART) bridge chip, which will always ingest the bytes and send them to a (possibly not listening) ESP32-C3.
5. The USB Serial/JTAG device won’ t work in sleep modes as normal due to the lack of APB clock in sleep modes. This includes deep-sleep, light-sleep (automataic light-sleep as well).
6. The power consumption in sleep modes will be higher if the USB Serial/JTAG device is in use. This is because we want to keep the USB Serial/JTAG device alive during software reset by default. However there is an issue that this might also increase the power consumption in sleep modes. This is because the software keeps a clock source on during the reset to keep the USB Serial/JTAG device alive. As a side-effect, the clock is also kept on during sleep modes. There is one exception: the clock will only be kept on when your USB Serial/JTAG port is really in use (like data transaction), therefore, if your USB Serial/JTAG is connected to power bank or battery, etc., instead of a valid USB host (for example, a PC), the power consumption will not increase.

If you still want to keep low power consumption in sleep modes:

1. If you are not using the USB Serial/JTAG port, you don’ t need to do anything. Software will detect if the USB Serial/JTAG is connected to a valid host before going to sleep, and keep the clocks only when the host is connected. Otherwise the clocks will be turned off as normal.
2. If you are using the USB Serial/JTAG port, please disable the menuconfig option `CONFIG_RTC_CLOCK_BBPLL_POWER_ON_WITH_USB`. The clock will be switched off as normal during software reset and in sleep modes. In these cases, the USB Serial/JTAG device may be unplugged from the host.

## 4.28 Wi-Fi Driver

### 4.28.1 ESP32-C3 Wi-Fi Feature List

The following features are supported:

- 4 virtual Wi-Fi interfaces, which are STA, AP, Sniffer and reserved.
- Station-only mode, AP-only mode, station/AP-coexistence mode
- IEEE 802.11b, IEEE 802.11g, IEEE 802.11n, and APIs to configure the protocol mode
- WPA/WPA2/WPA3/WPA2-Enterprise/WPA3-Enterprise/WAPI/WPS and DPP
- AMSDU, AMPDU, HT40, QoS, and other key features
- Modem-sleep
- The Espressif-specific ESP-NOW protocol and Long Range mode, which supports up to **1 km** of data traffic
- Up to 20 MBit/s TCP throughput and 30 MBit/s UDP throughput over the air
- Sniffer
- Both fast scan and all-channel scan
- Multiple antennas
- Channel state information

### 4.28.2 How To Write a Wi-Fi Application

#### Preparation

Generally, the most effective way to begin your own Wi-Fi application is to select an example which is similar to your own application, and port the useful part into your project. It is not a MUST, but it is strongly recommended that you

take some time to read this article first, especially if you want to program a robust Wi-Fi application.

This article is supplementary to the Wi-Fi APIs/Examples. It describes the principles of using the Wi-Fi APIs, the limitations of the current Wi-Fi API implementation, and the most common pitfalls in using Wi-Fi. This article also reveals some design details of the Wi-Fi driver. We recommend you to select an [example](#) .

### Setting Wi-Fi Compile-time Options

Refer to [Wi-Fi Menuconfig](#).

### Init Wi-Fi

Refer to [ESP32-C3 Wi-Fi station General Scenario](#) and [ESP32-C3 Wi-Fi AP General Scenario](#).

### Start/Connect Wi-Fi

Refer to [ESP32-C3 Wi-Fi station General Scenario](#) and [ESP32-C3 Wi-Fi AP General Scenario](#).

### Event-Handling

Generally, it is easy to write code in “sunny-day” scenarios, such as [WIFI\\_EVENT\\_STA\\_START](#) and [WIFI\\_EVENT\\_STA\\_CONNECTED](#). The hard part is to write routines in “rainy-day” scenarios, such as [WIFI\\_EVENT\\_STA\\_DISCONNECTED](#). Good handling of “rainy-day” scenarios is fundamental to robust Wi-Fi applications. Refer to [ESP32-C3 Wi-Fi Event Description](#), [ESP32-C3 Wi-Fi station General Scenario](#), and [ESP32-C3 Wi-Fi AP General Scenario](#). See also [an overview of event handling in ESP-IDF](#).

### Write Error-Recovery Routines Correctly at All Times

Just like the handling of “rainy-day” scenarios, a good error-recovery routine is also fundamental to robust Wi-Fi applications. Refer to [ESP32-C3 Wi-Fi API Error Code](#).

#### 4.28.3 ESP32-C3 Wi-Fi API Error Code

All of the ESP32-C3 Wi-Fi APIs have well-defined return values, namely, the error code. The error code can be categorized into:

- No errors, e.g., ESP\_OK means that the API returns successfully.
- Recoverable errors, such as ESP\_ERR\_NO\_MEM.
- Non-recoverable, non-critical errors.
- Non-recoverable, critical errors.

Whether the error is critical or not depends on the API and the application scenario, and it is defined by the API user.

**The primary principle to write a robust application with Wi-Fi API is to always check the error code and write the error-handling code.** Generally, the error-handling code can be used:

- For recoverable errors, in which case you can write a recoverable-error code. For example, when [esp\\_wifi\\_start\(\)](#) returns ESP\_ERR\_NO\_MEM, the recoverable-error code `vTaskDelay` can be called in order to get a microseconds’ delay for another try.
- For non-recoverable, yet non-critical errors, in which case printing the error code is a good method for error handling.
- For non-recoverable and also critical errors, in which case “assert” may be a good method for error handling. For example, if [esp\\_wifi\\_set\\_mode\(\)](#) returns ESP\_ERR\_WIFI\_NOT\_INIT, it means that the Wi-Fi driver is not initialized by [esp\\_wifi\\_init\(\)](#) successfully. You can detect this kind of error very quickly in the application development phase.

In `esp_err.h`, `ESP_ERROR_CHECK` checks the return values. It is a rather commonplace error-handling code and can be used as the default error-handling code in the application development phase. However, it is strongly recommended that API users write their own error-handling code.

#### 4.28.4 ESP32-C3 Wi-Fi API Parameter Initialization

When initializing struct parameters for the API, one of two approaches should be followed:

- Explicitly set all fields of the parameter.
- Use `get API` to get current configuration first, then set application specific fields.

Initializing or getting the entire structure is very important, because most of the time the value 0 indicates that the default value is used. More fields may be added to the struct in the future and initializing these to zero ensures the application will still work correctly after ESP-IDF is updated to a new release.

#### 4.28.5 ESP32-C3 Wi-Fi Programming Model

The ESP32-C3 Wi-Fi programming model is depicted as follows:

Fig. 75: Wi-Fi Programming Model

The Wi-Fi driver can be considered a black box that knows nothing about high-layer code, such as the TCP/IP stack, application task, and event task. The application task (code) generally calls *Wi-Fi driver APIs* to initialize Wi-Fi and handles Wi-Fi events when necessary. Wi-Fi driver receives API calls, handles them, and posts events to the application.

Wi-Fi event handling is based on the *esp\_event library*. Events are sent by the Wi-Fi driver to the *default event loop*. Application may handle these events in callbacks registered using `esp_event_handler_register()`. Wi-Fi events are also handled by *esp\_netif component* to provide a set of default behaviors. For example, when Wi-Fi station connects to an AP, `esp_netif` will automatically start the DHCP client by default.

#### 4.28.6 ESP32-C3 Wi-Fi Event Description

##### WIFI\_EVENT\_WIFI\_READY

The Wi-Fi driver will never generate this event, which, as a result, can be ignored by the application event callback. This event may be removed in future releases.

### WIFI\_EVENT\_SCAN\_DONE

The scan-done event is triggered by `esp_wifi_scan_start()` and will arise in the following scenarios:

- The scan is completed, e.g., the target AP is found successfully, or all channels have been scanned.
- The scan is stopped by `esp_wifi_scan_stop()`.
- The `esp_wifi_scan_start()` is called before the scan is completed. A new scan will override the current scan and a scan-done event will be generated.

The scan-done event will not arise in the following scenarios:

- It is a blocked scan.
- The scan is caused by `esp_wifi_connect()`.

Upon receiving this event, the event task does nothing. The application event callback needs to call `esp_wifi_scan_get_ap_num()` and `esp_wifi_scan_get_ap_records()` to fetch the scanned AP list and trigger the Wi-Fi driver to free the internal memory which is allocated during the scan (**do not forget to do this!**). Refer to *ESP32-C3 Wi-Fi Scan* for a more detailed description.

### WIFI\_EVENT\_STA\_START

If `esp_wifi_start()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will initialize the LwIP network interface (netif). Generally, the application event callback needs to call `esp_wifi_connect()` to connect to the configured AP.

### WIFI\_EVENT\_STA\_STOP

If `esp_wifi_stop()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will release the station's IP address, stop the DHCP client, remove TCP/UDP-related connections, and clear the LwIP station netif, etc. The application event callback generally does not need to do anything.

### WIFI\_EVENT\_STA\_CONNECTED

If `esp_wifi_connect()` returns `ESP_OK` and the station successfully connects to the target AP, the connection event will arise. Upon receiving this event, the event task starts the DHCP client and begins the DHCP process of getting the IP address. Then, the Wi-Fi driver is ready for sending and receiving data. This moment is good for beginning the application work, provided that the application does not depend on LwIP, namely the IP address. However, if the application is LwIP-based, then you need to wait until the `got ip` event comes in.

### WIFI\_EVENT\_STA\_DISCONNECTED

This event can be generated in the following scenarios:

- When `esp_wifi_disconnect()` or `esp_wifi_stop()` is called and the station is already connected to the AP.
- When `esp_wifi_connect()` is called, but the Wi-Fi driver fails to set up a connection with the AP due to certain reasons, e.g., the scan fails to find the target AP or the authentication times out. If there are more than one AP with the same SSID, the disconnected event will be raised after the station fails to connect all of the found APs.
- When the Wi-Fi connection is disrupted because of specific reasons, e.g., the station continuously loses N beacons, the AP kicks off the station, or the AP's authentication mode is changed.

Upon receiving this event, the default behaviors of the event task are:

- Shutting down the station's LwIP netif.
- Notifying the LwIP task to clear the UDP/TCP connections which cause the wrong status to all sockets. For socket-based applications, the application callback can choose to close all sockets and re-create them, if necessary, upon receiving this event.

The most common event handle code for this event in application is to call `esp_wifi_connect()` to reconnect the Wi-Fi. However, if the event is raised because `esp_wifi_disconnect()` is called, the application should not call `esp_wifi_connect()` to reconnect. It is the application's responsibility to distinguish whether the event is caused by `esp_wifi_disconnect()` or other reasons. Sometimes a better reconnection strategy is required. Refer to *Wi-Fi Reconnect* and *Scan When Wi-Fi Is Connecting*.

Another thing that deserves attention is that the default behavior of LwIP is to abort all TCP socket connections on receiving the disconnect. In most cases, it is not a problem. However, for some special applications, this may not be what they want. Consider the following scenarios:

- The application creates a TCP connection to maintain the application-level keep-alive data that is sent out every 60 seconds.
- Due to certain reasons, the Wi-Fi connection is cut off, and the `WIFI_EVENT_STA_DISCONNECTED` is raised. According to the current implementation, all TCP connections will be removed and the keep-alive socket will be in a wrong status. However, since the application designer believes that the network layer should **ignore** this error at the Wi-Fi layer, the application does not close the socket.
- Five seconds later, the Wi-Fi connection is restored because `esp_wifi_connect()` is called in the application event callback function. **Moreover, the station connects to the same AP and gets the same IPV4 address as before.**
- Sixty seconds later, when the application sends out data with the keep-alive socket, the socket returns an error and the application closes the socket and re-creates it when necessary.

In above scenarios, ideally, the application sockets and the network layer should not be affected, since the Wi-Fi connection only fails temporarily and recovers very quickly. The application can enable “Keep TCP connections when IP changed” via LwIP menuconfig.

### IP\_EVENT\_STA\_GOT\_IP

This event arises when the DHCP client successfully gets the IPV4 address from the DHCP server, or when the IPV4 address is changed. The event means that everything is ready and the application can begin its tasks (e.g., creating sockets).

The IPV4 may be changed because of the following reasons:

- The DHCP client fails to renew/rebind the IPV4 address, and the station's IPV4 is reset to 0.
- The DHCP client rebinds to a different address.
- The static-configured IPV4 address is changed.

Whether the IPV4 address is changed or not is indicated by the field `ip_change` of `ip_event_got_ip_t`.

The socket is based on the IPV4 address, which means that, if the IPV4 changes, all sockets relating to this IPV4 will become abnormal. Upon receiving this event, the application needs to close all sockets and recreate the application when the IPV4 changes to a valid one.

### IP\_EVENT\_GOT\_IP6

This event arises when the IPV6 SLAAC support auto-configures an address for the ESP32-C3, or when this address changes. The event means that everything is ready and the application can begin its tasks, e.g., creating sockets.

### IP\_EVENT\_STA\_LOST\_IP

This event arises when the IPV4 address becomes invalid.

`IP_EVENT_STA_LOST_IP` does not arise immediately after the Wi-Fi disconnects. Instead, it starts an IPV4 address lost timer. If the IPV4 address is got before ip lost timer expires, `IP_EVENT_STA_LOST_IP` does not happen. Otherwise, the event arises when the IPV4 address lost timer expires.

Generally, the application can ignore this event, because it is just a debug event to inform that the IPV4 address is lost.

### WIFI\_EVENT\_AP\_START

Similar to [WIFI\\_EVENT\\_STA\\_START](#).

### WIFI\_EVENT\_AP\_STOP

Similar to [WIFI\\_EVENT\\_STA\\_STOP](#).

### WIFI\_EVENT\_AP\_STACONNECTED

Every time a station is connected to ESP32-C3 AP, the [WIFI\\_EVENT\\_AP\\_STACONNECTED](#) will arise. Upon receiving this event, the event task will do nothing, and the application callback can also ignore it. However, you may want to do something, for example, to get the info of the connected STA.

### WIFI\_EVENT\_AP\_STADISCONNECTED

This event can happen in the following scenarios:

- The application calls [esp\\_wifi\\_disconnect\(\)](#), or [esp\\_wifi\\_deinit\\_sta\(\)](#), to manually disconnect the station.
- The Wi-Fi driver kicks off the station, e.g., because the AP has not received any packets in the past five minutes. The time can be modified by [esp\\_wifi\\_set\\_inactive\\_time\(\)](#).
- The station kicks off the AP.

When this event happens, the event task will do nothing, but the application event callback needs to do something, e.g., close the socket which is related to this station.

### WIFI\_EVENT\_AP\_PROBEREQRCVD

This event is disabled by default. The application can enable it via API [esp\\_wifi\\_set\\_event\\_mask\(\)](#). When this event is enabled, it will be raised each time the AP receives a probe request.

### WIFI\_EVENT\_STA\_BEACON\_TIMEOUT

If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens, the [WIFI\\_EVENT\\_STA\\_BEACON\\_TIMEOUT](#) will arise. The application can set inactive time via API [esp\\_wifi\\_set\\_inactive\\_time\(\)](#).

### WIFI\_EVENT\_CONNECTIONLESS\_MODULE\_WAKE\_INTERVAL\_START

The [WIFI\\_EVENT\\_CONNECTIONLESS\\_MODULE\\_WAKE\\_INTERVAL\\_START](#) will arise at the start of connectionless module *Interval*. See [connectionless module power save](#).

## 4.28.7 ESP32-C3 Wi-Fi Station General Scenario

Below is a “big scenario” which describes some small scenarios in station mode:

Fig. 76: Sample Wi-Fi Event Scenarios in Station Mode

## 1. Wi-Fi/LwIP Init Phase

- s1.1: The main task calls `esp_netif_init()` to create an LwIP core task and initialize LwIP-related work.
- s1.2: The main task calls `esp_event_loop_create()` to create a system Event task and initialize an application event's callback function. In the scenario above, the application event's callback function does nothing but relaying the event to the application task.
- s1.3: The main task calls `esp_netif_create_default_wifi_ap()` or `esp_netif_create_default_wifi_sta()` to create default network interface instance binding station or AP with TCP/IP stack.
- s1.4: The main task calls `esp_wifi_init()` to create the Wi-Fi driver task and initialize the Wi-Fi driver.
- s1.5: The main task calls OS API to create the application task.

Step 1.1 ~ 1.5 is a recommended sequence that initializes a Wi-Fi/LwIP-based application. However, it is **NOT** a must-follow sequence, which means that you can create the application task in step 1.1 and put all other initializations in the application task. Moreover, you may not want to create the application task in the initialization phase if the application task depends on the sockets. Rather, you can defer the task creation until the IP is obtained.

## 2. Wi-Fi Configuration Phase

Once the Wi-Fi driver is initialized, you can start configuring the Wi-Fi driver. In this scenario, the mode is station, so you may need to call `esp_wifi_set_mode()` (WIFI\_MODE\_STA) to configure the Wi-Fi mode as station. You can call other `esp_wifi_set_xxx` APIs to configure more settings, such as the protocol mode, the country code, and the bandwidth. Refer to [ESP32-C3 Wi-Fi Configuration](#).

Generally, the Wi-Fi driver should be configured before the Wi-Fi connection is set up. But this is **NOT** mandatory, which means that you can configure the Wi-Fi connection anytime, provided that the Wi-Fi driver is initialized successfully. However, if the configuration does not need to change after the Wi-Fi connection is set up, you should configure the Wi-Fi driver at this stage, because the configuration APIs (such as `esp_wifi_set_protocol()`) will cause the Wi-Fi to reconnect, which may not be desirable.

If the Wi-Fi NVS flash is enabled by menuconfig, all Wi-Fi configuration in this phase, or later phases, will be stored into flash. When the board powers on/reboots, you do not need to configure the Wi-Fi driver from scratch. You only need to call `esp_wifi_get_xxx` APIs to fetch the configuration stored in flash previously. You can also configure the Wi-Fi driver if the previous configuration is not what you want.

## 3. Wi-Fi Start Phase

- s3.1: Call `esp_wifi_start()` to start the Wi-Fi driver.
- s3.2: The Wi-Fi driver posts `WIFI_EVENT_STA_START` to the event task; then, the event task will do some common things and will call the application event callback function.
- s3.3: The application event callback function relays the `WIFI_EVENT_STA_START` to the application task. We recommend that you call `esp_wifi_connect()`. However, you can also call `esp_wifi_connect()` in other phrases after the `WIFI_EVENT_STA_START` arises.

## 4. Wi-Fi Connect Phase

- s4.1: Once `esp_wifi_connect()` is called, the Wi-Fi driver will start the internal scan/connection process.
- s4.2: If the internal scan/connection process is successful, the `WIFI_EVENT_STA_CONNECTED` will be generated. In the event task, it starts the DHCP client, which will finally trigger the DHCP process.
- s4.3: In the above-mentioned scenario, the application event callback will relay the event to the application task. Generally, the application needs to do nothing, and you can do whatever you want, e.g., print a log.

In step 4.2, the Wi-Fi connection may fail because, for example, the password is wrong, or the AP is not found. In a case like this, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason for such a failure will be provided. For handling events that disrupt Wi-Fi connection, please refer to phase 6.

## 5. Wi-Fi ‘Got IP’ Phase

- s5.1: Once the DHCP client is initialized in step 4.2, the *got IP* phase will begin.
- s5.2: If the IP address is successfully received from the DHCP server, then *IP\_EVENT\_STA\_GOT\_IP* will arise and the event task will perform common handling.
- s5.3: In the application event callback, *IP\_EVENT\_STA\_GOT\_IP* is relayed to the application task. For LwIP-based applications, this event is very special and means that everything is ready for the application to begin its tasks, e.g., creating the TCP/UDP socket. A very common mistake is to initialize the socket before *IP\_EVENT\_STA\_GOT\_IP* is received. **DO NOT start the socket-related work before the IP is received.**

## 6. Wi-Fi Disconnect Phase

- s6.1: When the Wi-Fi connection is disrupted, e.g., the AP is powered off or the RSSI is poor, *WIFI\_EVENT\_STA\_DISCONNECTED* will arise. This event may also arise in phase 3. Here, the event task will notify the LwIP task to clear/remove all UDP/TCP connections. Then, all application sockets will be in a wrong status. In other words, no socket can work properly when this event happens.
- s6.2: In the scenario described above, the application event callback function relays *WIFI\_EVENT\_STA\_DISCONNECTED* to the application task. The recommended actions are: 1) call *esp\_wifi\_connect()* to reconnect the Wi-Fi, 2) close all sockets, and 3) re-create them if necessary. For details, please refer to *WIFI\_EVENT\_STA\_DISCONNECTED*.

## 7. Wi-Fi IP Change Phase

- s7.1: If the IP address is changed, the *IP\_EVENT\_STA\_GOT\_IP* will arise with “ip\_change” set to true.
- s7.2: **This event is important to the application. When it occurs, the timing is good for closing all created sockets and recreating them.**

## 8. Wi-Fi Deinit Phase

- s8.1: Call *esp\_wifi\_disconnect()* to disconnect the Wi-Fi connectivity.
- s8.2: Call *esp\_wifi\_stop()* to stop the Wi-Fi driver.
- s8.3: Call *esp\_wifi\_deinit()* to unload the Wi-Fi driver.

### 4.28.8 ESP32-C3 Wi-Fi AP General Scenario

Below is a “big scenario” which describes some small scenarios in AP mode:

#### 4.28.9 ESP32-C3 Wi-Fi Scan

Currently, the *esp\_wifi\_scan\_start()* API is supported only in station or station/AP mode.

Fig. 77: Sample Wi-Fi Event Scenarios in AP Mode

## Scan Type

Mode	Description
Active Scan	Scan by sending a probe request. The default scan is an active scan.
Passive Scan	No probe request is sent out. Just switch to the specific channel and wait for a beacon. Application can enable it via the <code>scan_type</code> field of <code>wifi_scan_config_t</code> .
Foreground Scan	This scan is applicable when there is no Wi-Fi connection in station mode. Foreground or background scanning is controlled by the Wi-Fi driver and cannot be configured by the application.
Background Scan	This scan is applicable when there is a Wi-Fi connection in station mode or in station/AP mode. Whether it is a foreground scan or background scan depends on the Wi-Fi driver and cannot be configured by the application.
All-Channel Scan	It scans all of the channels. If the <code>channel</code> field of <code>wifi_scan_config_t</code> is set to 0, it is an all-channel scan.
Specific Channel Scan	It scans specific channels only. If the <code>channel</code> field of <code>wifi_scan_config_t</code> set to 1-14, it is a specific-channel scan.

The scan modes in above table can be combined arbitrarily, so there are in total 8 different scans:

- All-Channel Background Active Scan
- All-Channel Background Passive Scan
- All-Channel Foreground Active Scan
- All-Channel Foreground Passive Scan
- Specific-Channel Background Active Scan
- Specific-Channel Background Passive Scan
- Specific-Channel Foreground Active Scan
- Specific-Channel Foreground Passive Scan

## Scan Configuration

The scan type and other per-scan attributes are configured by `esp_wifi_scan_start()`. The table below provides a detailed description of `wifi_scan_config_t`.

Field	Description
<code>ssid</code>	If the SSID is not NULL, it is only the AP with the same SSID that can be scanned.
<code>bssid</code>	If the BSSID is not NULL, it is only the AP with the same BSSID that can be scanned.
<code>channel</code>	If “channel” is 0, there will be an all-channel scan; otherwise, there will be a specific-channel scan.
<code>show_hidden</code>	If “show_hidden” is 0, the scan ignores the AP with a hidden SSID; otherwise, the scan considers the hidden AP a normal one.
<code>scan_type</code>	If “scan_type” is <code>WIFI_SCAN_TYPE_ACTIVE</code> , the scan is “active” ; otherwise, it is a “passive” one.
<code>scan_time</code>	<p>This field is used to control how long the scan dwells on each channel.</p> <p>For passive scans, <code>scan_time.passive</code> designates the dwell time for each channel.</p> <p>For active scans, dwell times for each channel are listed in the table below. Here, <code>min</code> is short for <code>scan_time.active.min</code> and <code>max</code> is short for <code>scan_time.active.max</code>.</p> <ul style="list-style-type: none"> <li>• <code>min=0, max=0</code>: scan dwells on each channel for 120 ms.</li> <li>• <code>min&gt;0, max=0</code>: scan dwells on each channel for 120 ms.</li> <li>• <code>min=0, max&gt;0</code>: scan dwells on each channel for <code>max</code> ms.</li> <li>• <code>min&gt;0, max&gt;0</code>: the minimum time the scan dwells on each channel is <code>min</code> ms. If no AP is found during this time frame, the scan switches to the next channel. Otherwise, the scan dwells on the channel for <code>max</code> ms.</li> </ul> <p>If you want to improve the performance of the the scan, you can try to modify these two parameters.</p>

There are also some global scan attributes which are configured by API `esp_wifi_set_config()`, refer to

*Station Basic Configuration***Scan All APs on All Channels (Foreground)**

Scenario:

Fig. 78: Foreground Scan of all Wi-Fi Channels

The scenario above describes an all-channel, foreground scan. The foreground scan can only occur in station mode where the station does not connect to any AP. Whether it is a foreground or background scan is totally determined by the Wi-Fi driver, and cannot be configured by the application.

Detailed scenario description:

**Scan Configuration Phase**

- s1.1: Call `esp_wifi_set_country()` to set the country info if the default country info is not what you want. Refer to *Wi-Fi Country Code*.

- s1.2: Call `esp_wifi_scan_start()` to configure the scan. To do so, you can refer to [Scan Configuration](#). Since this is an all-channel scan, just set the SSID/BSSID/channel to 0.

### Wi-Fi Driver's Internal Scan Phase

- s2.1: The Wi-Fi driver switches to channel 1. In this case, the scan type is `WIFI_SCAN_TYPE_ACTIVE`, and a probe request is broadcasted. Otherwise, the Wi-Fi will wait for a beacon from the APs. The Wi-Fi driver will stay in channel 1 for some time. The dwell time is configured in min/max time, with the default value being 120 ms.
- s2.2: The Wi-Fi driver switches to channel 2 and performs the same operation as in step 2.1.
- s2.3: The Wi-Fi driver scans the last channel N, where N is determined by the country code which is configured in step 1.1.

### Scan-Done Event Handling Phase

- s3.1: When all channels are scanned, `WIFI_EVENT_SCAN_DONE` will arise.
- s3.2: The application's event callback function notifies the application task that `WIFI_EVENT_SCAN_DONE` is received. `esp_wifi_scan_get_ap_num()` is called to get the number of APs that have been found in this scan. Then, it allocates enough entries and calls `esp_wifi_scan_get_ap_records()` to get the AP records. Please note that the AP records in the Wi-Fi driver will be freed once `esp_wifi_scan_get_ap_records()` is called. Do not call `esp_wifi_scan_get_ap_records()` twice for a single scan-done event. If `esp_wifi_scan_get_ap_records()` is not called when the scan-done event occurs, the AP records allocated by the Wi-Fi driver will not be freed. So, make sure you call `esp_wifi_scan_get_ap_records()`, yet only once.

### Scan All APs on All Channels (Background)

Scenario:

The scenario above is an all-channel background scan. Compared to [Scan All APs on All Channels \(Foreground\)](#), the difference in the all-channel background scan is that the Wi-Fi driver will scan the back-to-home channel for 30 ms before it switches to the next channel to give the Wi-Fi connection a chance to transmit/receive data.

### Scan for Specific AP on All Channels

Scenario:

This scan is similar to [Scan All APs on All Channels \(Foreground\)](#). The differences are:

- s1.1: In step 1.2, the target AP will be configured to SSID/BSSID.
- s2.1 ~ s2.N: Each time the Wi-Fi driver scans an AP, it will check whether it is a target AP or not. If the scan is `WIFI_FAST_SCAN` scan and the target AP is found, then the scan-done event will arise and scanning will end; otherwise, the scan will continue. Please note that the first scanned channel may not be channel 1, because the Wi-Fi driver optimizes the scanning sequence.

It is a possible situation that there are multiple APs that match the target AP info, e.g., two APs with the SSID of "ap" are scanned. In this case, if the scan is `WIFI_FAST_SCAN`, then only the first scanned "ap" will be found. If the scan is `WIFI_ALL_CHANNEL_SCAN`, both "ap" will be found and the station will connect the "ap" according to the configured strategy. Refer to [Station Basic Configuration](#).

You can scan a specific AP, or all of them, in any given channel. These two scenarios are very similar.

### Scan in Wi-Fi Connect

When `esp_wifi_connect()` is called, the Wi-Fi driver will try to scan the configured AP first. The scan in "Wi-Fi Connect" is the same as [Scan for Specific AP On All Channels](#), except that no scan-done event will be generated

Fig. 79: Background Scan of all Wi-Fi Channels

Fig. 80: Scan of specific Wi-Fi Channels

when the scan is completed. If the target AP is found, the Wi-Fi driver will start the Wi-Fi connection; otherwise, `WIFI_EVENT_STA_DISCONNECTED` will be generated. Refer to [Scan for Specific AP On All Channels](#).

### Scan in Blocked Mode

If the block parameter of `esp_wifi_scan_start()` is true, then the scan is a blocked one, and the application task will be blocked until the scan is done. The blocked scan is similar to an unblocked one, except that no scan-done event will arise when the blocked scan is completed.

### Parallel Scan

Two application tasks may call `esp_wifi_scan_start()` at the same time, or the same application task calls `esp_wifi_scan_start()` before it gets a scan-done event. Both scenarios can happen. **However, the Wi-Fi driver does not support multiple concurrent scans adequately. As a result, concurrent scans should be avoided.** Support for concurrent scan will be enhanced in future releases, as the ESP32-C3's Wi-Fi functionality improves continuously.

### Scan When Wi-Fi Is Connecting

The `esp_wifi_scan_start()` fails immediately if the Wi-Fi is connecting, because the connecting has higher priority than the scan. If scan fails because of connecting, the recommended strategy is to delay for some time and retry scan again. The scan will succeed once the connecting is completed.

However, the retry/delay strategy may not work all the time. Considering the following scenarios:

- The station is connecting a non-existing AP or it connects the existing AP with a wrong password, it always raises the event `WIFI_EVENT_STA_DISCONNECTED`.
- The application calls `esp_wifi_connect()` to reconnect on receiving the disconnect event.
- Another application task, e.g., the console task, calls `esp_wifi_scan_start()` to do scan, the scan always fails immediately because the station keeps connecting.
- When scan fails, the application simply delays for some time and retries the scan.

In the above scenarios, the scan will never succeed because the connecting is in process. So if the application supports similar scenario, it needs to implement a better reconnection strategy. For example:

- The application can choose to define a maximum continuous reconnection counter and stop reconnecting once the counter reaches the maximum.
- The application can choose to reconnect immediately in the first N continuous reconnection, then give a delay sometime and reconnect again.

The application can define its own reconnection strategy to avoid the scan starve to death. Refer to [<Wi-Fi Reconnect>](#).

## 4.28.10 ESP32-C3 Wi-Fi Station Connecting Scenario

This scenario depicts the case if only one target AP is found in the scan phase. For scenarios where more than one AP with the same SSID is found, refer to [ESP32-C3 Wi-Fi Station Connecting When Multiple APs Are Found](#).

Generally, the application can ignore the connecting process. Below is a brief introduction to the process for those who are really interested.

Scenario:

### Scan Phase

- s1.1: The Wi-Fi driver begins scanning in “Wi-Fi Connect” . Refer to [Scan in Wi-Fi Connect](#) for more details.
- s1.2: If the scan fails to find the target AP, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_NO_AP_FOUND`. Refer to [Wi-Fi Reason Code](#).

Fig. 81: Wi-Fi Station Connecting Process

### Auth Phase

- s2.1: The authentication request packet is sent and the auth timer is enabled.
- s2.2: If the authentication response packet is not received before the authentication timer times out, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_AUTH_EXPIRE`. Refer to *Wi-Fi Reason Code*.
- s2.3: The auth-response packet is received and the auth-timer is stopped.
- s2.4: The AP rejects authentication in the response and `WIFI_EVENT_STA_DISCONNECTED` arises, while the reason code is `WIFI_REASON_AUTH_FAIL` or the reasons specified by the AP. Refer to *Wi-Fi Reason Code*.

### Association Phase

- s3.1: The association request is sent and the association timer is enabled.
- s3.2: If the association response is not received before the association timer times out, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_DISASSOC_DUE_TO_INACTIVITY`. Refer to *Wi-Fi Reason Code*.
- s3.3: The association response is received and the association timer is stopped.
- s3.4: The AP rejects the association in the response and `WIFI_EVENT_STA_DISCONNECTED` arises, while the reason code is the one specified in the association response. Refer to *Wi-Fi Reason Code*.

### Four-way Handshake Phase

- s4.1: The handshake timer is enabled, and the 1/4 EAPOL is not received before the handshake timer expires. `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to *Wi-Fi Reason Code*.
- s4.2: The 1/4 EAPOL is received.
- s4.3: The station replies 2/4 EAPOL.
- s4.4: If the 3/4 EAPOL is not received before the handshake timer expires, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to *Wi-Fi Reason Code*.
- s4.5: The 3/4 EAPOL is received.
- s4.6: The station replies 4/4 EAPOL.
- s4.7: The station raises `WIFI_EVENT_STA_CONNECTED`.

### Wi-Fi Reason Code

The table below shows the reason-code defined in ESP32-C3. The first column is the macro name defined in `esp_wifi_types.h`. The common prefix `WIFI_REASON` is removed, which means that `UNSPECIFIED` actually stands for `WIFI_REASON_UNSPECIFIED` and so on. The second column is the value of the reason. The third column is the standard value to which this reason is mapped in section 9.4.1.7 of IEEE 802.11-2020. (For more information, refer to the standard mentioned above.) The last column describes the reason.

Reason code	Value	Mapped To	Description
UNSPECIFIED	1	1	Generally, it means an internal failure, e.g., the memory runs out, the internal TX fails, or the reason is received from the remote side.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Mapped To	Description
AUTH_EXPIRE		2	The previous authentication is no longer valid. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• auth is timed out.</li> <li>• the reason is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>• the AP has not received any packets from the station in the past five minutes.</li> <li>• the AP is stopped by calling <code>esp_wifi_stop()</code>.</li> <li>• the station is de-authed by calling <code>esp_wifi_deauth_sta()</code>.</li> </ul>
AUTH_BEAVE		3	De-authenticated, because the sending station is leaving (or has left). For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• it is received from the AP.</li> </ul>
DIS-AS-SOC_DUE_TO_INACTIVITY	4	4	Disassociated due to inactivity. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• assoc is timed out.</li> <li>• it is received from the AP.</li> </ul>
AS-SOC_TOOMANY	5	5	Disassociated, because the AP is unable to handle all currently associated STAs at the same time. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• it is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>• the stations associated with the AP reach the maximum number that the AP can support.</li> </ul>
CLASS2_FRAME_FROM_NONAUTH_STA			Class-2 frame received from a non-authenticated STA. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• it is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>• the AP receives a packet with data from a non-authenticated station.</li> </ul>
CLASS3_FRAME_FROM_NONASSOC_STA			Class-3 frame received from a non-associated STA. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• it is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>• the AP receives a packet with data from a non-associated station.</li> </ul>
AS-SOC_LEAVE	8	8	Disassociated, because the sending station is leaving (or has left) BSS. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>• it is received from the AP.</li> <li>• the station is disconnected by <code>esp_wifi_disconnect()</code> and other APIs.</li> </ul>

continues on next page

Table 29 – continued from previous page

Reason code	Value	Mapped To	Description
AS-SOC_NOT_AUTHED	9	9	station requesting (re)association is not authenticated by the responding STA. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>the AP receives packets with data from an associated, yet not authenticated, station.</li> </ul>
DIS-AS-SOC_PWRCAP_BAD	10	10	Disassociated, because the information in the Power Capability element is unacceptable. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
DIS-AS-SOC_SUPCHAN_BAD	11	11	Disassociated, because the information in the Supported Channels element is unacceptable. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
IE_INVABID		13	Invalid element, i.e., an element whose content does not meet the specifications of the Standard in frame formats clause. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>the AP parses a wrong WPA or RSN IE.</li> </ul>
MIC_FAILURE		14	Message integrity code (MIC) failure. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
4WAY_HANDSHAKE_TIMEOUT			Four-way handshake times out. For legacy reasons, in ESP this reason code is replaced with WIFI_REASON_HANDSHAKE_TIMEOUT. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>the handshake times out.</li> <li>it is received from the AP.</li> </ul>
GROUP_KEY_UPDATE_TIMEOUT			Group-Key Handshake times out. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
IE_IN_4WAY_DIFFERS	17		The element in the four-way handshake is different from the (Re-)Association Request/Probe and Response/Beacon frame. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> <li>the station finds that the four-way handshake IE differs from the IE in the (Re-)Association Request/Probe and Response/Beacon frame.</li> </ul>
GROUP_CIPHER_INVALID			Invalid group cipher. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>

continues on next page

Table 29 – continued from previous page

Reason code	Value	Mapped To	Description
PAIR-WISE_CIPHER_INVALID	19	19	Invalid pairwise cipher. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
AKMP_INVALID	20	20	Invalid AKMP. For the ESP station, this reason is reported when: - it is received from the AP.
UN-SUPP_RSN_IE_VERSION	21	21	Unsupported RSNE version. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
IN-VALID_RSN_IE_CAP	22	22	Invalid RSNE capabilities. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
802_1X_AUTH_FAILED	23	23	IEEE 802.1X. authentication failed. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul> For the ESP AP, this reason is reported when: <ul style="list-style-type: none"> <li>IEEE 802.1X. authentication fails.</li> </ul>
CI-PHER_SUITE_REJECTED	24	24	Cipher suite rejected due to security policies. For the ESP station, this reason is reported when: <ul style="list-style-type: none"> <li>it is received from the AP.</li> </ul>
TDLS_PEER_UNREACHABLE	25	25	TDLS direct-link teardown due to TDLS peer STA unreachable via the TDLS direct link.
TDLS_UNSPECIFIED	26	26	TDLS direct-link teardown for unspecified reason.
SSP_REQUESTED_DISASSOC	27	27	Disassociated because session terminated by SSP request.
NO_SSP_ROAMING_AGREEMENT	28	28	Disassociated because of lack of SSP roaming agreement.
BAD_CIPHER_OR_AKM	29	29	Requested service rejected because of SSP cipher suite or AKM requirement.
NOT_AUTHORIZED_THIS_LOCATION	30	30	Requested service not authorized in this location.
SERVICE_CHANGE_PRECLUDES_TS	31	31	TS deleted because QoS AP lacks sufficient bandwidth for this QoS STA due to a change in BSS service characteristics or operational mode (e.g., an HT BSS change from 40 MHz channel to 20 MHz channel).
UNSPECIFIED_QOS	32	32	Disassociated for unspecified, QoS-related reason.
NOT_ENOUGH_BANDWIDTH	33	33	Disassociated because QoS AP lacks sufficient bandwidth for this QoS STA.
MISSING_ACKS	34	34	Disassociated because excessive number of frames need to be acknowledged, but are not acknowledged due to AP transmissions and/or poor channel conditions.
EXCEEDED_TXOP	35	35	Disassociated because STA is transmitting outside the limits of its TXOPs.
STA_LEAVING	36	36	Requesting STA is leaving the BSS (or resetting).
END_BA	37	37	Requesting STA is no longer using the stream or session.
UNKNOWN_BA	38	38	Requesting STA received frames using a mechanism for which a setup has not been completed.

continues on next page

Table 29 – continued from previous page

Reason code	Value	Mapped To	Description
TIME-OUT	39	39	Requested from peer STA due to timeout
Reserved	40 ~ 45	40 ~ 45	
PEER_INITIATED	46	46	In a Disassociation frame: Disassociated because authorized access limit reached.
AP_INITIATED	47	47	In a Disassociation frame: Disassociated due to external service requirements.
INVALID_FT_ACTION_FRAME_COUNT	48	48	Invalid FT Action frame count.
INVALID_PMKID	49	49	Invalid pairwise master key identifier (PMKID).
INVALID_MDE	50	50	Invalid MDE.
INVALID_FTE	51	51	Invalid FTE
TRANSMISSION_LINK_ESTABLISHMENT_FAILED	67	67	Transmission link establishment in alternative channel failed.
ALTERNATIVE_CHANNEL_OCCUPIED	68	68	The alternative channel is occupied.
BEACON_TIMEOUT	200	reserved	Espressif-specific Wi-Fi reason code: when the station loses N beacons continuously, it will disrupt the connection and report this reason.
NO_AP_FOUND	201	reserved	Espressif-specific Wi-Fi reason code: when the station fails to scan the target AP, this reason code will be reported.
AUTH_FAIL	202	reserved	Espressif-specific Wi-Fi reason code: the authentication fails, but not because of a timeout.
ASSOC_FAIL	203	reserved	Espressif-specific Wi-Fi reason code: the association fails, but not because of DISASSOC_DUE_TO_INACTIVITY or ASSOC_TOOMANY.
HANDSHAKE_TIMEOUT	204	reserved	Espressif-specific Wi-Fi reason code: the handshake fails for the same reason as that in WIFI_REASON_4WAY_HANDSHAKE_TIMEOUT.
CONNECTION_FAIL	205	reserved	Espressif-specific Wi-Fi reason code: the connection to the AP has failed.

### Wi-Fi Reason code related to wrong password

The table below shows the Wi-Fi reason-code may related to wrong password.

Reason code	Value	Description
4WAY_HANDSHAKE_TIMEOUT	204	Four-way handshake times out. Setting wrong password when STA connecting to an encrypted AP.
NO_AP_FOUND	205	This may related to wrong password in the two scenarios: <ul style="list-style-type: none"> <li>Setting password when STA connecting to an unencrypted AP.</li> <li>Doesn't setting password when STA connecting to an encrypted AP.</li> </ul>
HANDSHAKE_TIMEOUT	204	Four-way handshake fails.

### Wi-Fi Reason code related to low RSSI

The table below shows the Wi-Fi reason-code may related to low RSSI.

Reason code	Value	Description
NO_AP_FOUND	205	The station fails to scan the target AP due to low RSSI
HANDSHAKE_TIMEOUT	204	Four-way handshake fails.

#### 4.28.11 ESP32-C3 Wi-Fi Station Connecting When Multiple APs Are Found

This scenario is similar as *ESP32-C3 Wi-Fi Station Connecting Scenario*. The difference is that the station will not raise the event *WIFI\_EVENT\_STA\_DISCONNECTED* unless it fails to connect all of the found APs.

#### 4.28.12 Wi-Fi Reconnect

The station may disconnect due to many reasons, e.g., the connected AP is restarted. It is the application's responsibility to reconnect. The recommended reconnection strategy is to call *esp\_wifi\_connect()* on receiving event *WIFI\_EVENT\_STA\_DISCONNECTED*.

Sometimes the application needs more complex reconnection strategy:

- If the disconnect event is raised because the *esp\_wifi\_disconnect()* is called, the application may not want to do the reconnection.
- If the *esp\_wifi\_scan\_start()* may be called at anytime, a better reconnection strategy is necessary. Refer to *Scan When Wi-Fi Is Connecting*.

Another thing that need to be considered is that the reconnection may not connect the same AP if there are more than one APs with the same SSID. The reconnection always select current best APs to connect.

#### 4.28.13 Wi-Fi Beacon Timeout

The beacon timeout mechanism is used by ESP32-C3 station to detect whether the AP is alive or not. If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens. The application can set inactive time via API *esp\_wifi\_set\_inactive\_time()*.

After the beacon times out, the station sends 5 probe requests to the AP. If still no probe response or beacon is received from AP, the station disconnects from the AP and raises the event *WIFI\_EVENT\_STA\_DISCONNECTED*.

It should be considered that the timer used for beacon timeout will be reset during the scanning process. It means that the scan process will affect the triggering of the event *WIFI\_EVENT\_STA\_BEACON\_TIMEOUT*.

### 4.28.14 ESP32-C3 Wi-Fi Configuration

All configurations will be stored into flash when the Wi-Fi NVS is enabled; otherwise, refer to [Wi-Fi NVS Flash](#).

#### Wi-Fi Mode

Call `esp_wifi_set_mode()` to set the Wi-Fi mode.

Mode	Description
WIFI_MODE_NULL	NULL mode: in this mode, the internal data struct is not allocated to the station and the AP, while both the station and AP interfaces are not initialized for RX/TX Wi-Fi data. Generally, this mode is used for Sniffer, or when you only want to stop both the station and the AP without calling <code>esp_wifi_deinit()</code> to unload the whole Wi-Fi driver.
WIFI_MODE_STA	Station mode: in this mode, <code>esp_wifi_start()</code> will init the internal station data, while the station's interface is ready for the RX and TX Wi-Fi data. After <code>esp_wifi_connect()</code> , the station will connect to the target AP.
WIFI_MODE_AP	AP mode: in this mode, <code>esp_wifi_start()</code> will init the internal AP data, while the AP's interface is ready for RX/TX Wi-Fi data. Then, the Wi-Fi driver starts broad-casting beacons, and the AP is ready to get connected to other stations.
WIFI_MODE_APSTA	Station/AP coexistence mode: in this mode, <code>esp_wifi_start()</code> will simultaneously init both the station and the AP. This is done in station mode and AP mode. Please note that the channel of the external AP, which the ESP station is connected to, has higher priority over the ESP AP channel.

#### Station Basic Configuration

API `esp_wifi_set_config()` can be used to configure the station. And the configuration will be stored in NVS. The table below describes the fields in detail.

Field	Description
ssid	This is the SSID of the target AP, to which the station wants to connect.
password	Password of the target AP.
scan_method	For WIFI_FAST_SCAN scan, the scan ends when the first matched AP is found. For WIFI_ALL_CHANNEL_SCAN, the scan finds all matched APs on all channels. The default scan is WIFI_FAST_SCAN.
bssid_set	If bssid_set is 0, the station connects to the AP whose SSID is the same as the field “ssid” , while the field “bssid” is ignored. In all other cases, the station connects to the AP whose SSID is the same as the “ssid” field, while its BSSID is the same the “bssid” field .
bssid	This is valid only when bssid_set is 1; see field “bssid_set” .
channel	If the channel is 0, the station scans the channel 1 ~ N to search for the target AP; otherwise, the station starts by scanning the channel whose value is the same as that of the “channel” field, and then scans the channel 1 ~ N but skip the specific channel to find the target AP. For example, if the channel is 3, the scan order will be 3, 1, 2, 4, ... , N. If you do not know which channel the target AP is running on, set it to 0.
sort_method	This field is only for WIFI_ALL_CHANNEL_SCAN. If the sort_method is WIFI_CONNECT_AP_BY_SIGNAL, all matched APs are sorted by signal, and the AP with the best signal will be connected firstly. For example, the station wants to connect an AP whose SSID is “apxx” . If the scan finds two APs whose SSID equals to “apxx” , and the first AP’ s signal is -90 dBm while the second AP’ s signal is -30 dBm, the station connects the second AP firstly, and it would not connect the first one unless it fails to connect the second one. If the sort_method is WIFI_CONNECT_AP_BY_SECURITY, all matched APs are sorted by security. For example, the station wants to connect an AP whose SSID is “apxx” . If the scan finds two APs whose SSID is “apxx” , and the security of the first found AP is open while the second one is WPA2, the station connects to the second AP firstly, and it would not connect the first one unless it fails to connect the second one.
threshold	The threshold is used to filter the found AP. If the RSSI or security mode is less than the configured threshold, the AP will be discarded. If the RSSI is set to 0, it means the default threshold and the default RSSI threshold are -127 dBm. If the authmode threshold is set to 0, it means the default threshold and the default authmode threshold are open.

**Attention:** WEP/WPA security modes are deprecated in IEEE 802.11-2016 specifications and are recommended not to be used. These modes can be rejected using authmode threshold by setting threshold as WPA2 by threshold.authmode as WIFI\_AUTH\_WPA2\_PSK.

### AP Basic Configuration

API `esp_wifi_set_config()` can be used to configure the AP. And the configuration will be stored in NVS. The table below describes the fields in detail.

Field	Description
ssid	SSID of AP; if the ssid[0] is 0xFF and ssid[1] is 0xFF, the AP defaults the SSID to ESP_aabbcc, where “aabbcc” is the last three bytes of the AP MAC.
password	Password of AP; if the auth mode is WIFI_AUTH_OPEN, this field will be ignored.
ssid_len	Length of SSID; if ssid_len is 0, check the SSID until there is a termination character. If ssid_len > 32, change it to 32; otherwise, set the SSID length according to ssid_len.
channel	Channel of AP; if the channel is out of range, the Wi-Fi driver defaults to channel 1. So, please make sure the channel is within the required range. For more details, refer to <a href="#">Wi-Fi Country Code</a> .
authmode	Auth mode of ESP AP; currently, ESP AP does not support AUTH_WEP. If the authmode is an invalid value, AP defaults the value to WIFI_AUTH_OPEN.
ssid_hidden	If ssid_hidden is 1, AP does not broadcast the SSID; otherwise, it does broadcast the SSID.
max_connection	The max number of stations allowed to connect in, the default value is 10. ESP Wi-Fi supports up to 10 (ESP_WIFI_MAX_CONN_NUM) Wi-Fi connections. Please note that ESP AP and ESP-NOW share the same encryption hardware keys, so the max_connection parameter will be affected by the <a href="#">CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM</a> . The total number of encryption hardware keys is 17, if <a href="#">CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM</a> <= 7, the max_connection can be set up to 10, otherwise the max_connection can be set up to (17 - <a href="#">CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM</a> ).
beacon_interval	Beacon interval; the value is 100 ~ 60000 ms, with default value being 100 ms. If the value is out of range, AP defaults it to 100 ms.

### Wi-Fi Protocol Mode

Currently, the ESP-IDF supports the following protocol modes:

Protocol Mode	Description
802.11b	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B)</code> to set the station/AP to 802.11b-only mode.
802.11bg	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B WIFI_PROTOCOL_11G)</code> to set the station/AP to 802.11bg mode.
802.11g	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B WIFI_PROTOCOL_11G)</code> and <code>esp_wifi_config_11b_rate(ifx, true)</code> to set the station/AP to 802.11g mode.
802.11bgn	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B WIFI_PROTOCOL_11G WIFI_PROTOCOL_11N)</code> to set the station/ AP to BGN mode.
802.11gn	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B WIFI_PROTOCOL_11G WIFI_PROTOCOL_11N)</code> and <code>esp_wifi_config_11b_rate(ifx, true)</code> to set the station/AP to 802.11gn mode.
802.11 BGNLR	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B WIFI_PROTOCOL_11G WIFI_PROTOCOL_11N WIFI_PROTOCOL_LR)</code> to set the station/AP to BGN and the LR mode.
802.11 LR	Call <code>esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_LR)</code> to set the station/AP only to the LR mode. <b>This mode is an Espressif-patented mode which can achieve a one-kilometer line of sight range. Please make sure both the station and the AP are connected to an ESP device.</b>

### Long Range (LR)

Long Range (LR) mode is an Espressif-patented Wi-Fi mode which can achieve a one-kilometer line of sight range. Compared to the traditional 802.11b mode, it has better reception sensitivity, stronger anti-interference ability, and longer transmission distance.

**LR Compatibility** Since LR is Espressif-unique Wi-Fi mode, only ESP32-C3 devices can transmit and receive the LR data. In other words, the ESP32-C3 device should NOT transmit the data in LR data rate if the connected device does not support LR. The application can achieve this by configuring suitable Wi-Fi mode. If the negotiated mode supports LR, the ESP32-C3 may transmit data in LR rate. Otherwise, ESP32-C3 will transmit all data in traditional Wi-Fi data rate.

The following table depicts the Wi-Fi mode negotiation:

APSTA	BGN	BG	B	BGNLR	BGLR	BLR	LR
BGN	BGN	BG	B	BGN	BG	B	.
BG	BG	BG	B	BG	BG	B	.
B	B	B	B	B	B	B	.
BGNLR	.	.	.	BGNLR	BGLR	BLR	LR
BGLR	.	.	.	BGLR	BGLR	BLR	LR
BLR	.	.	.	BLR	BLR	BLR	LR
LR	.	.	.	LR	LR	LR	LR

In the above table, the row is the Wi-Fi mode of AP and the column is the Wi-Fi mode of station. The “-” indicates Wi-Fi mode of the AP and station are not compatible.

According to the table, the following conclusions can be drawn:

- For LR-enabled AP of ESP32-C3, it is incompatible with traditional 802.11 mode, because the beacon is sent in LR mode.
- For LR-enabled station of ESP32-C3 whose mode is NOT LR-only mode, it is compatible with traditional 802.11 mode.
- If both station and AP are ESP32-C3 devices and both of them have enabled LR mode, the negotiated mode supports LR.

If the negotiated Wi-Fi mode supports both traditional 802.11 mode and LR mode, it is the Wi-Fi driver’s responsibility to automatically select the best data rate in different Wi-Fi modes and the application can ignore it.

**LR Impacts to Traditional Wi-Fi Device** The data transmission in LR rate has no impacts on the traditional Wi-Fi device because:

- The CCA and backoff process in LR mode are consistent with 802.11 specification.
- The traditional Wi-Fi device can detect the LR signal via CCA and do backoff.

In other words, the transmission impact in LR mode is similar to that in 802.11b mode.

**LR Transmission Distance** The reception sensitivity gain of LR is about 4 dB larger than that of the traditional 802.11b mode. Theoretically, the transmission distance is about 2 to 2.5 times the distance of 11B.

**LR Throughput** The LR rate has very limited throughput, because the raw PHY data rate LR is 1/2 Mbps and 1/4 Mbps.

**When to Use LR** The general conditions for using LR are:

- Both the AP and station are Espressif devices.
- Long distance Wi-Fi connection and data transmission is required.
- Data throughput requirements are very small, such as remote device control.

### Wi-Fi Country Code

Call `esp_wifi_set_country()` to set the country info. The table below describes the fields in detail. Please consult local 2.4 GHz RF operating regulations before configuring these fields.

Field	Description
cc[3]	Country code string. This attribute identifies the country or noncountry entity in which the station/AP is operating. If it is a country, the first two octets of this string is the two-character country info as described in the document ISO/IEC3166-1. The third octet is one of the following: <ul style="list-style-type: none"> <li>• an ASCII space character, which means the regulations under which the station/AP is operating encompass all environments for the current frequency band in the country.</li> <li>• an ASCII 'O' character, which means the regulations under which the station/AP is operating are for an outdoor environment only.</li> <li>• an ASCII 'I' character, which means the regulations under which the station/AP is operating are for an indoor environment only.</li> <li>• an ASCII 'X' character, which means the station/AP is operating under a non-country entity. The first two octets of the noncountry entity is two ASCII 'XX' characters.</li> <li>• the binary representation of the Operating Class table number currently in use. Refer to Annex E of IEEE Std 802.11-2020.</li> </ul>
schan	Start channel. It is the minimum channel number of the regulations under which the station/AP can operate.
nchan	Total number of channels as per the regulations. For example, if the schan=1, nchan=13, then the station/AP can send data from channel 1 to 13.
policy	Country policy. This field controls which country info will be used if the configured country info is in conflict with the connected AP's. For more details on related policies, see the following section.

The default country info is:

```
wifi_country_t config = {
    .cc = "01",
    .schan = 1,
    .nchan = 11,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

If the Wi-Fi Mode is station/AP coexist mode, they share the same configured country info. Sometimes, the country info of AP, to which the station is connected, is different from the country info of configured. For example, the configured station has country info:

```
wifi_country_t config = {
    .cc = "JP",
    .schan = 1,
    .nchan = 14,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

but the connected AP has country info:

```
wifi_country_t config = {
    .cc = "CN",
    .schan = 1,
    .nchan = 13,
};
```

then country info of connected AP' s is used.

The following table depicts which country info is used in different Wi-Fi modes and different country policies, and it also describes the impact on active scan.

Wi-Fi Mode	Policy	Description
Station	WIFI_COUNTRY_POLICY_AUTO	If the connected AP has country IE in its beacon, the country info equals to the country info in beacon. Otherwise, use the default country info. For scan: Use active scan from 1 to 11 and use passive scan from 12 to 14. Always keep in mind that if an AP with hidden SSID and station is set to a passive scan channel, the passive scan will not find it. In other words, if the application hopes to find the AP with hidden SSID in every channel, the policy of country info should be configured to WIFI_COUNTRY_POLICY_MANUAL.
Station	WIFI_COUNTRY_POLICY_MANUAL	Always use the configured country info. For scan: Use active scan from schan to schan+nchan-1.
AP	WIFI_COUNTRY_POLICY_AUTO	Always use the configured country info.
AP	WIFI_COUNTRY_POLICY_MANUAL	Always use the configured country info.
Station/AP-coexistence	WIFI_COUNTRY_POLICY_AUTO	Same as station mode with policy WIFI_COUNTRY_POLICY_AUTO. AP: If the station does not connect to any external AP, the AP uses the configured country info. If the station connects to an external AP, the AP has the same country info as the station.
Station/AP-coexistence	WIFI_COUNTRY_POLICY_MANUAL	Same as station mode with policy WIFI_COUNTRY_POLICY_MANUAL. AP: Same as AP mode with policy WIFI_COUNTRY_POLICY_MANUAL.

**Home Channel** In AP mode, the home channel is defined as the AP channel. In station mode, home channel is defined as the channel of AP which the station is connected to. In station/AP-coexistence mode, the home channel of AP and station must be the same, and if they are different, the station' s home channel is always in priority. For example, assume that the AP is on channel 6, and the station connects to an AP whose channel is 9. Since the station' s home channel has higher priority, the AP needs to switch its channel from 6 to 9 to make sure that it has the same home channel as the station. While switching channel, the ESP32-C3 in AP mode will notify the connected stations about the channel migration using a Channel Switch Announcement (CSA). Station that supports channel switching will transit without disconnecting and reconnecting to the AP.

### Wi-Fi Vendor IE Configuration

By default, all Wi-Fi management frames are processed by the Wi-Fi driver, and the application can ignore them. However, some applications may have to handle the beacon, probe request, probe response, and other management frames. For example, if you insert some vendor-specific IE into the management frames, it is only the management frames which contain this vendor-specific IE that will be processed. In ESP32-C3,

`esp_wifi_set_vendor_ie()` and `esp_wifi_set_vendor_ie_cb()` are responsible for this kind of tasks.

#### 4.28.15 Wi-Fi Easy Connect™ (DPP)

Wi-Fi Easy Connect™ (or Device Provisioning Protocol) is a secure and standardized provisioning protocol for configuring Wi-Fi devices. More information can be found in [esp\\_dpp](#).

#### WPA2-Enterprise

WPA2-Enterprise is the secure authentication mechanism for enterprise wireless networks. It uses RADIUS server for authentication of network users before connecting to the Access Point. The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, and PEAP. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both. When ESP32-C3 in station mode tries to connect an AP in enterprise mode, it sends authentication request to AP which is sent to RADIUS server by AP for authenticating the station. Based on different EAP methods, the parameters can be set in configuration which can be opened using `idf.py menuconfig`. WPA2\_Enterprise is supported by ESP32-C3 only in station mode.

For establishing a secure connection, AP and station negotiate and agree on the best possible cipher suite to be used. ESP32-C3 supports 802.1X/EAP (WPA) method of AKM and Advanced encryption standard with Counter Mode Cipher Block Chaining Message Authentication protocol (AES-CCM) cipher suite. It also supports the cipher suites supported by mbedtls if `USE_MBEDTLS_CRYPT` flag is set.

#### ESP32-C3 currently supports the following EAP methods:

- EAP-TLS: This is a certificate-based method and only requires SSID and EAP-IDF.
- PEAP: This is a Protected EAP method. Username and Password are mandatory.
- **EAP-TTLS: This is a credential-based method. Only server authentication is mandatory while user authentication is optional.**
  - PAP: Password Authentication Protocol.
  - CHAP: Challenge Handshake Authentication Protocol.
  - MSCHAP and MSCHAP-V2.
- EAP-FAST: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, `USE_MBEDTLS_CRYPT` flag should be disabled to use this feature.

Detailed information on creating certificates and how to run `wpa2_enterprise` example on ESP32-C3 can be found in [wifi/wifi\\_enterprise](#).

#### 4.28.16 Wireless Network Management

Wireless Network Management allows client devices to exchange information about the network topology, including information related to RF environment. This makes each client network-aware, facilitating overall improvement in the performance of the wireless network. It is part of 802.11v specification. It also enables the client to support Network assisted Roaming. - Network assisted Roaming: Enables WLAN to send messages to associated clients, resulting clients to associate with APs with better link metrics. This is useful for both load balancing and in directing poorly connected clients.

Current implementation of 802.11v includes support for BSS transition management frames.

#### 4.28.17 Radio Resource Measurement

Radio Resource Measurement (802.11k) is intended to improve the way traffic is distributed within a network. In a WLAN, each device normally connects to the access point (AP) that provides the strongest signal. Depending on the number and geographic locations of the subscribers, this arrangement can sometimes lead to excessive demand on one AP and underutilization of others, resulting in degradation of overall network performance. In a network

conforming to 802.11k, if the AP having the strongest signal is loaded to its full capacity, a wireless device can be moved to one of the underutilized APs. Even though the signal may be weaker, the overall throughput is greater because more efficient use is made of the network resources.

Current implementation of 802.11k includes support for beacon measurement report, link measurement report, and neighbor request.

Refer ESP-IDF example [examples/wifi/roaming/README.md](#) to set up and use these APIs. Example code only demonstrates how these APIs can be used, and the application should define its own algorithm and cases as required.

### 4.28.18 Fast BSS Transition

Fast BSS transition (802.11R FT), is a standard to permit continuous connectivity aboard wireless devices in motion, with fast and secure client transitions from one Basic Service Set (abbreviated BSS, and also known as a base station or more colloquially, an access point) to another performed in a nearly seamless manner **avoiding 802.11 4 way handshake**. 802.11R specifies transitions between access points by redefining the security key negotiation protocol, allowing both the negotiation and requests for wireless resources to occur in parallel. The key derived from the server to be cached in the wireless network, so that a reasonable number of future connections can be based on the cached key, avoiding the 802.1X process

ESP32-C3 station supports FT for WPA2-PSK networks. Do note that ESP32-C3 station only support FT over the air protocol only.

A config option `CONFIG_WPA_11R_SUPPORT` and configuration parameter `ft_enabled` in `wifi_sta_config_t` is provided to enable 802.11R support for station. Refer ESP-IDF example [examples/wifi/roaming/README.md](#) for further details.

### 4.28.19 Wi-Fi Location

Wi-Fi Location will improve the accuracy of a device's location data beyond the Access Point, which will enable creation of new and feature-rich applications and services such as geo-fencing, network management, and navigation. One of the protocols used to determine the device location with respect to the Access Point is Fine Timing Measurement which calculates Time-of-Flight of a Wi-Fi frame.

#### Fine Timing Measurement (FTM)

FTM is used to measure Wi-Fi Round Trip Time (Wi-Fi RTT) which is the time a Wi-Fi signal takes to travel from a device to another device and back again. Using Wi-Fi RTT, the distance between the devices can be calculated with a simple formula of  $RTT * c / 2$ , where  $c$  is the speed of light.

FTM uses timestamps given by Wi-Fi interface hardware at the time of arrival or departure of frames exchanged between a pair of devices. One entity called FTM Initiator (mostly a station device) discovers the FTM Responder (can be a station or an Access Point) and negotiates to start an FTM procedure. The procedure uses multiple Action frames sent in bursts and its ACK's to gather the timestamps data. FTM Initiator gathers the data in the end to calculate an average Round-Trip-Time.

ESP32-C3 supports FTM in below configuration:

- ESP32-C3 as FTM Initiator in station mode.
- ESP32-C3 as FTM Responder in AP mode.

Distance measurement using RTT is not accurate, and factors such as RF interference, multi-path travel, antenna orientation, and lack of calibration increase these inaccuracies. For better results, it is suggested to perform FTM between two ESP32-C3 devices as station and AP.

Refer to ESP-IDF example [examples/wifi/ftm/README.md](#) for steps on how to set up and perform FTM.

### 4.28.20 ESP32-C3 Wi-Fi Power-saving Mode

This subsection will briefly introduce the concepts and usage related to Wi-Fi Power Saving Mode, for a more detailed introduction please refer to the [Low Power Mode User Guide](#)

#### Station Sleep

Currently, ESP32-C3 Wi-Fi supports the Modem-sleep mode which refers to the legacy power-saving mode in the IEEE 802.11 protocol. Modem-sleep mode works in station-only mode and the station must connect to the AP first. If the Modem-sleep mode is enabled, station will switch between active and sleep state periodically. In sleep state, RF, PHY and BB are turned off in order to reduce power consumption. Station can keep connection with AP in modem-sleep mode.

Modem-sleep mode includes minimum and maximum power-saving modes. In minimum power-saving mode, station wakes up every DTIM to receive beacon. Broadcast data will not be lost because it is transmitted after DTIM. However, it cannot save much more power if DTIM is short for DTIM is determined by AP.

In maximum power-saving mode, station wakes up in every listen interval to receive beacon. This listen interval can be set to be longer than the AP DTIM period. Broadcast data may be lost because station may be in sleep state at DTIM time. If listen interval is longer, more power is saved, but broadcast data is more easy to lose. Listen interval can be configured by calling API `esp_wifi_set_config()` before connecting to AP.

Call `esp_wifi_set_ps(WIFI_PS_MIN_MODEM)` to enable Modem-sleep minimum power-saving mode or `esp_wifi_set_ps(WIFI_PS_MAX_MODEM)` to enable Modem-sleep maximum power-saving mode after calling `esp_wifi_init()`. When station connects to AP, Modem-sleep will start. When station disconnects from AP, Modem-sleep will stop.

Call `esp_wifi_set_ps(WIFI_PS_NONE)` to disable Modem-sleep entirely. This has much higher power consumption, but provides minimum latency for receiving Wi-Fi data in real time. When Modem-sleep is enabled, received Wi-Fi data can be delayed for as long as the DTIM period (minimum power-saving mode) or the listen interval (maximum power-saving mode).

Notice that at coexist mode, Wi-Fi would still keep active state in Wi-Fi time slice and only keep sleep state in non Wi-Fi time slice even when calling “`esp_wifi_set_ps(WIFI_PS_NONE)`”. Please refer to [coexist policy](#).

The default Modem-sleep mode is `WIFI_PS_MIN_MODEM`.

#### AP Sleep

Currently, ESP32-C3 AP does not support all of the power-saving feature defined in Wi-Fi specification. To be specific, the AP only caches unicast data for the stations connect to this AP, but does not cache the multicast data for the stations. If stations connected to the ESP32-C3 AP are power-saving enabled, they may experience multicast packet loss.

In the future, all power-saving features will be supported on ESP32-C3 AP.

#### Disconnected State Sleep

Disconnected state is the duration without Wi-Fi connection between `esp_wifi_start()` to `esp_wifi_stop()`.

Currently, ESP32-C3 Wi-Fi supports sleep mode in disconnected state if running at station mode. This feature could be configured by Menuconfig choice [CONFIG\\_ESP\\_WIFI\\_STA\\_DISCONNECTED\\_PM\\_ENABLE](#).

If [CONFIG\\_ESP\\_WIFI\\_STA\\_DISCONNECTED\\_PM\\_ENABLE](#) is enabled, RF, PHY and BB would be turned off in disconnected state when IDLE. The current would be same with current at modem-sleep.

The choice [CONFIG\\_ESP\\_WIFI\\_STA\\_DISCONNECTED\\_PM\\_ENABLE](#) would be selected by default, while it would be selected forcefully in Menuconfig at coexistence mode.

### Connectionless Modules Power-saving

Connectionless modules are those Wi-Fi modules not relying on Wi-Fi connection, e.g ESP-NOW, DPP, FTM. These modules start from `esp_wifi_start()`, working until `esp_wifi_stop()`.

Currently, if ESP-NOW works at station mode, its supported to sleep at both connected state and disconnected state.

**Connectionless Modules TX** For each connectionless module, its supported to TX at any sleeping time without any extra configuration.

Meanwhile, `esp_wifi_80211_tx()` is supported at sleep as well.

**Connectionless Modules RX** For each connectionless module, two parameters shall be configured to RX at sleep, which are *Window* and *Interval*.

At the start of *Interval* time, RF, PHY, BB would be turned on and kept for *Window* time. Connectionless Module could RX in the duration.

#### Interval

- There is only one *Interval*. Its configured by `esp_wifi_set_connectionless_interval()`. The unit is milliseconds.
- The default value of *Interval* is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE`.
- Event `WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START` would be posted at the start of *Interval*. Since *Window* also starts at that moment, its recommended to TX in that event.
- At connected state, the start of *Interval* would be aligned with TBTT.

#### Window

- Each connectionless module has its own *Window* after start. Connectionless Modules Power-saving would work with the max one among them.
- *Window* is configured by `module_name_set_wake_window()`. The unit is milliseconds.
- The default value of *Window* is the maximum.

Table 30: RF, PHY and BB usage under different circumstances

		Interval	
		ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE	
Win- dow	0	not used	
	1 - max- imum	default mode	used periodically (Window < Interval) / used all time (Window ≥ Interval)

**Default mode** If *Interval* is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE` with non-zero *Window*, Connectionless Modules Power-saving would work in default mode.

In default mode, RF, PHY, BB would be kept on if no coexistence with non-Wi-Fi protocol.

With coexistence, RF, PHY, BB resources are allocated by coexistence module to Wi-Fi connectionless module and non-Wi-Fi module, using time-division method. In default mode, Wi-Fi connectionless module is allowed to use RF, BB, PHY periodically under a stable performance.

Its recommended to configure Connectionless Modules Power-saving to default mode if there is Wi-Fi connectionless module coexists with non-Wi-Fi module.

### 4.28.21 ESP32-C3 Wi-Fi Throughput

The table below shows the best throughput results gained in Espressif's lab and in a shielded box.

Type/Throughput	Test In Lab	Shield-box	Test Tool	IDF Version (commit ID)
Raw 802.11 Packet RX	N/A	<b>130 MBit/s</b>	Internal tool	NA
Raw 802.11 Packet TX	N/A	<b>130 MBit/s</b>	Internal tool	NA
UDP RX	30 MBit/s	50 MBit/s	iperf example	15575346
UDP TX	30 MBit/s	40 MBit/s	iperf example	15575346
TCP RX	20 MBit/s	35 MBit/s	iperf example	15575346
TCP TX	20 MBit/s	37 MBit/s	iperf example	15575346

When the throughput is tested by iperf example, the sdkconfig is [examples/wifi/iperf/sdkconfig.defaults.esp32c3](#).

## 4.28.22 Wi-Fi 80211 Packet Send

The `esp_wifi_80211_tx()` API can be used to:

- Send the beacon, probe request, probe response, and action frame.
- Send the non-QoS data frame.

It cannot be used for sending encrypted or QoS frames.

### Preconditions of Using `esp_wifi_80211_tx()`

- The Wi-Fi mode is station, or AP, or station/AP.
- Either `esp_wifi_set_promiscuous(true)`, or `esp_wifi_start()`, or both of these APIs return ESP\_OK. This is because Wi-Fi hardware must be initialized before `esp_wifi_80211_tx()` is called. In ESP32-C3, both `esp_wifi_set_promiscuous(true)` and `esp_wifi_start()` can trigger the initialization of Wi-Fi hardware.
- The parameters of `esp_wifi_80211_tx()` are hereby correctly provided.

### Data Rate

- The default data rate is 1 Mbps.
- Can set any rate through `esp_wifi_config_80211_tx_rate()` API.
- Can set any bandwidth through `esp_wifi_set_bandwidth()` API.

### Side-Effects to Avoid in Different Scenarios

Theoretically, if the side-effects the API imposes on the Wi-Fi driver or other stations/APs are not considered, a raw 802.11 packet can be sent over the air with any destination MAC, any source MAC, any BSSID, or any other types of packet. However, robust or useful applications should avoid such side-effects. The table below provides some tips and recommendations on how to avoid the side-effects of `esp_wifi_80211_tx()` in different scenarios.

Scenario	Description
No Wi-Fi connection	<p>In this scenario, no Wi-Fi connection is set up, so there are no side-effects on the Wi-Fi driver. If <code>en_sys_seq==true</code>, the Wi-Fi driver is responsible for the sequence control. If <code>en_sys_seq==false</code>, the application needs to ensure that the buffer has the correct sequence. Theoretically, the MAC address can be any address. However, this may impact other stations/APs with the same MAC/BSSID.</p> <p>Side-effect example#1 The application calls <code>esp_wifi_80211_tx()</code> to send a beacon with <code>BSSID == mac_x</code> in AP mode, but the <code>mac_x</code> is not the MAC of the AP interface. Moreover, there is another AP, e.g., “other-AP”, whose BSSID is <code>mac_x</code>. If this happens, an “unexpected behavior” may occur, because the stations which connect to the “other-AP” cannot figure out whether the beacon is from the “other-AP” or the <code>esp_wifi_80211_tx()</code>. To avoid the above-mentioned side-effects, it is recommended that:</p> <ul style="list-style-type: none"> <li>• If <code>esp_wifi_80211_tx</code> is called in station mode, the first MAC should be a multicast MAC or the exact target-device’s MAC, while the second MAC should be that of the station interface.</li> <li>• If <code>esp_wifi_80211_tx</code> is called in AP mode, the first MAC should be a multicast MAC or the exact target-device’s MAC, while the second MAC should be that of the AP interface.</li> </ul> <p>The recommendations above are only for avoiding side-effects and can be ignored when there are good reasons.</p>
Have Wi-Fi connection	<p>When the Wi-Fi connection is already set up, and the sequence is controlled by the application, the latter may impact the sequence control of the Wi-Fi connection as a whole. So, the <code>en_sys_seq</code> need to be true, otherwise <code>ESP_ERR_INVALID_ARG</code> is returned. The MAC-address recommendations in the “No Wi-Fi connection” scenario also apply to this scenario.</p> <p>If the Wi-Fi mode is station mode, the MAC address1 is the MAC of AP to which the station is connected, and the MAC address2 is the MAC of station interface, it is said that the packet is sent from the station to AP. Otherwise, if the Wi-Fi is in AP mode, the MAC address1 is the MAC of the station that connects to this AP, and the MAC address2 is the MAC of AP interface, it is said that the packet is sent from the AP to station. To avoid conflicting with Wi-Fi connections, the following checks are applied:</p> <ul style="list-style-type: none"> <li>• If the packet type is data and is sent from the station to AP, the ToDS bit in IEEE 80211 frame control should be 1 and the FromDS bit should be 0. Otherwise, the packet will be discarded by Wi-Fi driver.</li> <li>• If the packet type is data and is sent from the AP to station, the ToDS bit in IEEE 80211 frame control should be 0 and the FromDS bit should be 1. Otherwise, the packet will be discarded by Wi-Fi driver.</li> <li>• If the packet is sent from station to AP or from AP to station, the Power Management, More Data, and Re-Transmission bits should be 0. Otherwise, the packet will be discarded by Wi-Fi driver.</li> </ul> <p><code>ESP_ERR_INVALID_ARG</code> is returned if any check fails.</p>

### 4.28.23 Wi-Fi Sniffer Mode

The Wi-Fi sniffer mode can be enabled by `esp_wifi_set_promiscuous()`. If the sniffer mode is enabled, the following packets **can** be dumped to the application:

- 802.11 Management frame.
- 802.11 Data frame, including MPDU, AMPDU, and AMSDU.
- 802.11 MIMO frame, for MIMO frame, the sniffer only dumps the length of the frame.
- 802.11 Control frame.
- 802.11 CRC error frame.

The following packets will **NOT** be dumped to the application:

- Other 802.11 error frames.

For frames that the sniffer **can** dump, the application can additionally decide which specific type of

packets can be filtered to the application by using `esp_wifi_set_promiscuous_filter()` and `esp_wifi_set_promiscuous_ctrl_filter()`. By default, it will filter all 802.11 data and management frames to the application. If you want to filter the 802.11 control frames, the filter parameter in `esp_wifi_set_promiscuous_filter()` should include `WIFI_PROMIS_FILTER_MASK_CTRL` type, and if you want to differentiate control frames further, then call `esp_wifi_set_promiscuous_ctrl_filter()`.

The Wi-Fi sniffer mode can be enabled in the Wi-Fi mode of `WIFI_MODE_NULL`, `WIFI_MODE_STA`, `WIFI_MODE_AP`, or `WIFI_MODE_APSTA`. In other words, the sniffer mode is active when the station is connected to the AP, or when the AP has a Wi-Fi connection. Please note that the sniffer has a **great impact** on the throughput of the station or AP Wi-Fi connection. Generally, the sniffer should be enabled **only if** the station/AP Wi-Fi connection does not experience heavy traffic.

Another noteworthy issue about the sniffer is the callback `wifi_promiscuous_cb_t`. The callback will be called directly in the Wi-Fi driver task, so if the application has a lot of work to do for each filtered packet, the recommendation is to post an event to the application task in the callback and defer the real work to the application task.

## 4.28.24 Wi-Fi Multiple Antennas

The Wi-Fi multiple antennas selecting can be depicted as following picture:

ESP32-C3 supports up to sixteen antennas through external antenna switch. The antenna switch can be controlled by up to four address pins - `antenna_select[0:3]`. Different input value of `antenna_select[0:3]` means selecting different antenna. For example, the value '0b1011' means the antenna 11 is selected. The default value of `antenna_select[3:0]` is '0b0000', which means the antenna 0 is selected by default.

Up to four GPIOs are connected to the four active high antenna\_select pins. ESP32-C3 can select the antenna by control the GPIO[0:3]. The API `esp_wifi_set_ant_gpio()` is used to configure which GPIOs are connected to antenna\_selects. If GPIO[x] is connected to antenna\_select[x], then `gpio_config->gpio_cfg[x].gpio_select` should be set to 1 and `gpio_config->gpio_cfg[x].gpio_num` should be provided.

For the specific implementation of the antenna switch, there may be illegal values in `antenna_select[0:3]`. It means that ESP32-C3 may support less than sixteen antennas through the switch. For example, ESP32-WROOM-DA which uses RTC6603SP as the antenna switch, supports two antennas. Two GPIOs are connected to two active high antenna selection inputs. The value '0b01' means the antenna 0 is selected, the value '0b10' means the antenna 1 is selected. Values '0b00' and '0b11' are illegal.

Although up to sixteen antennas are supported, only one or two antennas can be simultaneously enabled for RX/TX. The API `esp_wifi_set_ant()` is used to configure which antennas are enabled.

The enabled antennas selecting algorithm is also configured by `esp_wifi_set_ant()`. The RX/TX antenna mode can be `WIFI_ANT_MODE_ANT0`, `WIFI_ANT_MODE_ANT1`, or `WIFI_ANT_MODE_AUTO`. If the antenna mode is `WIFI_ANT_MODE_ANT0`, the enabled antenna 0 is selected for RX/TX data. If the antenna mode is `WIFI_ANT_MODE_ANT1`, the enabled antenna 1 is selected for RX/TX data. Otherwise, Wi-Fi automatically selects the enabled antenna that has better signal.

If the RX antenna mode is `WIFI_ANT_MODE_AUTO`, the default antenna mode also needs to be set, because the RX antenna switching only happens when some conditions are met. For example, the RX antenna starts to switch if the RSSI is lower than -65 dBm or another antenna has better signal. RX uses the default antenna if the conditions are not met. If the default antenna mode is `WIFI_ANT_MODE_ANT1`, the enabled antenna 1 is used as the default RX antenna, otherwise the enabled antenna 0 is used.

Some limitations need to be considered:

- The TX antenna can be set to `WIFI_ANT_MODE_AUTO` only if the RX antenna mode is `WIFI_ANT_MODE_AUTO`, because TX antenna selecting algorithm is based on RX antenna in `WIFI_ANT_MODE_AUTO` type.
- When the TX antenna mode or RX antenna mode is configured to `WIFI_ANT_MODE_AUTO` the switching mode will easily trigger the switching phase, as long as there is deterioration of the RF signal. So in situations where the RF signal is not stable, the antenna switching will occur frequently, resulting in an RF performance that may not meet expectations.
- Currently, Bluetooth® does not support the multiple antennas feature, so please do not use multiple antennas related APIs.

Following is the recommended scenarios to use the multiple antennas:

- The applications can always choose to select a specified antenna or implement their own antenna selecting algorithm, e.g., selecting the antenna mode based on the information collected by the application. Refer to ESP-IDF example <examples/wifi/antenna/README.md> for the antenna selecting algorithm design.
- Both RX/TX antenna modes are configured to `WIFI_ANT_MODE_ANT0` or `WIFI_ANT_MODE_ANT1`.

## Wi-Fi Multiple Antennas Configuration

Generally, following steps can be taken to configure the multiple antennas:

- Configure which GPIOs are connected to the antenna\_selects. For example, if four antennas are supported and GPIO20/GPIO21 are connected to antenna\_select[0]/antenna\_select[1], the configurations look like:

```
wifi_ant_gpio_config_t ant_gpio_config = {
    .gpio_cfg[0] = { .gpio_select = 1, .gpio_num = 20 },
    .gpio_cfg[1] = { .gpio_select = 1, .gpio_num = 21 }
};
```

- Configure which antennas are enabled and how RX/TX use the enabled antennas. For example, if antenna1 and antenna3 are enabled, the RX needs to select the better antenna automatically and uses antenna1 as its default antenna, the TX always selects the antenna3. The configuration looks like:

```
wifi_ant_config_t config = {
    .rx_ant_mode = WIFI_ANT_MODE_AUTO,
    .rx_ant_default = WIFI_ANT_ANT0,
    .tx_ant_mode = WIFI_ANT_MODE_ANT1,
    .enabled_ant0 = 1,
    .enabled_ant1 = 3
};
```

### 4.28.25 Wi-Fi Channel State Information

Channel state information (CSI) refers to the channel information of a Wi-Fi connection. In ESP32-C3, this information consists of channel frequency responses of sub-carriers and is estimated when packets are received from the transmitter. Each channel frequency response of sub-carrier is recorded by two bytes of signed characters. The first one is imaginary part and the second one is real part. There are up to three fields of channel frequency responses according to the type of received packet. They are legacy long training field (LLTF), high throughput LTF (HT-LTF), and space time block code HT-LTF (STBC-HT-LTF). For different types of packets which are received on channels with different state, the sub-carrier index and total bytes of signed characters of CSI are shown in the following table.

chan- nel	sec- ondary chan- nel	none			below					above				
		sig- nal mode	non HT	HT		non HT	HT		40 MHz		non HT	HT		
packet in- for- ma- tion	chan- nel band- width	20 MHz	20 MHz		20 MHz	20 MHz		40 MHz		20 MHz	20 MHz		40 MHz	
		STBC	non STBC	non STBC	STBC	non STBC	non STBC	STBC	non STBC	STBC	non STBC	non STBC	STBC	non STBC
sub- carrier in- dex	LLTF	0~31, - 32~ 1	0~31, - 32~ 1	0~31, - 32~ 1	0~63	0~63	0~63	0~63	0~63	- 64~ 1	- 64~ 1	- 64~ 1	- 64~ 1	- 64~ 1
	HT- LTF	•	0~31, - 32~ 1	0~31, - 32~ 1	•	0~63	0~62	0~63, - 64~ 1	0~60, - 60~ 1	•	- 64~ 1	- 62~ 1	0~63, - 64~ 1	0~60, - 60~ 1
	STBC- HT- LTF	•	•	0~31, - 32~ 1	•	•	0~62	•	0~60, - 60~ 1	•	•	- 62~ 1	•	0~60, - 60~ 1
total bytes		128	256	384	128	256	380	384	612	128	256	376	384	612

All of the information in the table can be found in the structure `wifi_csi_info_t`.

- Secondary channel refers to `secondary_channel` field of `rx_ctrl` field.
- Signal mode of packet refers to `sig_mode` field of `rx_ctrl` field.
- Channel bandwidth refers to `cwb` field of `rx_ctrl` field.
- STBC refers to `stbc` field of `rx_ctrl` field.
- Total bytes refers to `len` field.
- The CSI data corresponding to each Long Training Field (LTF) type is stored in a buffer starting from the `buf` field. Each item is stored as two bytes: imaginary part followed by real part. The order of each item is the same as the sub-carrier in the table. The order of LTF is: LLTF, HT-LTF, STBC-HT-LTF. However, all 3 LTFs may not be present, depending on the channel and packet information (see above).
- If `first_word_invalid` field of `wifi_csi_info_t` is true, it means that the first four bytes of CSI data is invalid due to a hardware limitation in ESP32-C3.
- More information like RSSI, noise floor of RF, receiving time and antenna is in the `rx_ctrl` field.

When imaginary part and real part data of sub-carrier are used, please refer to the table below.

PHY standard	Sub-carrier range	Pilot sub-carrier	Sub-carrier(total/data)
802.11a/g	-26 to +26	-21, -7, +7, +21	52 total, 48 usable
802.11n, 20MHz	-28 to +28	-21, -7, +7, +21	56 total, 52 usable
802.11n, 40MHz	-57 to +57	-53, -25, -11, +11, +25, +53	114 total, 108 usable

#### Note:

- For STBC packet, CSI is provided for every space-time stream without CSD (cyclic shift delay). As each cyclic shift on the additional chains shall be -200 ns, only the CSD angle of first space-time stream is recorded in sub-carrier 0 of HT-LTF and STBC-HT-LTF for there is no channel frequency response in sub-carrier 0. CSD[10:0] is 11 bits, ranging from -pi to pi.
- If LLTF, HT-LTF, or STBC-HT-LTF is not enabled by calling API `esp_wifi_set_csi_config()`, the total bytes of CSI data will be fewer than that in the table. For example, if LLTF and HT-LTF is not enabled

and STBC-HT-LTF is enabled, when a packet is received with the condition above/HT/40MHz/STBC, the total bytes of CSI data is 244  $((61 + 60) * 2 + 2 = 244$ . The result is aligned to four bytes, and the last two bytes are invalid).

---

#### 4.28.26 Wi-Fi Channel State Information Configure

To use Wi-Fi CSI, the following steps need to be done.

- Select Wi-Fi CSI in menuconfig. Go to `Menuconfig > Components config > Wi-Fi > Wi-Fi CSI (Channel State Information)`.
- Set CSI receiving callback function by calling API `esp_wifi_set_csi_rx_cb()`.
- Configure CSI by calling API `esp_wifi_set_csi_config()`.
- Enable CSI by calling API `esp_wifi_set_csi()`.

The CSI receiving callback function runs from Wi-Fi task. So, do not do lengthy operations in the callback function. Instead, post necessary data to a queue and handle it from a lower priority task. Because station does not receive any packet when it is disconnected and only receives packets from AP when it is connected, it is suggested to enable sniffer mode to receive more CSI data by calling `esp_wifi_set_promiscuous()`.

#### 4.28.27 Wi-Fi HT20/40

ESP32-C3 supports Wi-Fi bandwidth HT20 or HT40 and does not support HT20/40 coexist. `esp_wifi_set_bandwidth()` can be used to change the default bandwidth of station or AP. The default bandwidth for ESP32-C3 station and AP is HT40.

In station mode, the actual bandwidth is firstly negotiated during the Wi-Fi connection. It is HT40 only if both the station and the connected AP support HT40, otherwise it is HT20. If the bandwidth of connected AP is changes, the actual bandwidth is negotiated again without Wi-Fi disconnecting.

Similarly, in AP mode, the actual bandwidth is negotiated between AP and the stations that connect to the AP. It is HT40 if the AP and one of the stations support HT40, otherwise it is HT20.

In station/AP coexist mode, the station/AP can configure HT20/40 separately. If both station and AP are negotiated to HT40, the HT40 channel should be the channel of station because the station always has higher priority than AP in ESP32-C3. For example, the configured bandwidth of AP is HT40, the configured primary channel is 6, and the configured secondary channel is 10. The station is connected to a router whose primary channel is 6 and secondary channel is 2, then the actual channel of AP is changed to primary 6 and secondary 2 automatically.

Theoretically, the HT40 can gain better throughput because the maximum raw physical (PHY) data rate for HT40 is 150 Mbps while it is 72 Mbps for HT20. However, if the device is used in some special environment, e.g., there are too many other Wi-Fi devices around the ESP32-C3 device, the performance of HT40 may be degraded. So if the applications need to support same or similar scenarios, it is recommended that the bandwidth is always configured to HT20.

#### 4.28.28 Wi-Fi QoS

ESP32-C3 supports all the mandatory features required in WFA Wi-Fi QoS Certification.

Four ACs (Access Category) are defined in Wi-Fi specification, and each AC has its own priority to access the Wi-Fi channel. Moreover, a map rule is defined to map the QoS priority of other protocol, e.g., 802.11D or TCP/IP precedence is mapped to Wi-Fi AC.

The table below describes how the IP Precedences are mapped to Wi-Fi ACs in ESP32-C3. It also indicates whether the AMPDU is supported for this AC. The table is sorted from high to low priority. That is to say, the AC\_VO has the highest priority.

IP Precedence	Wi-Fi AC	Support AMPDU?
6, 7	AC_VO (Voice)	No
4, 5	AC_VI (Video)	Yes
3, 0	AC_BE (Best Effort)	Yes
1, 2	AC_BK (Background)	Yes

The application can make use of the QoS feature by configuring the IP precedence via socket option IP\_TOS. Here is an example to make the socket to use VI queue:

```
const int ip_precedence_vi = 4;
const int ip_precedence_offset = 5;
int priority = (ip_precedence_vi << ip_precedence_offset);
setsockopt(socket_id, IPPROTO_IP, IP_TOS, &priority, sizeof(priority));
```

Theoretically, the higher priority AC has better performance than the lower priority AC. However, it is not always true. Here are some suggestions about how to use the Wi-Fi QoS:

- Some really important application traffic can be put into the AC\_VO queue. But avoid using the AC\_VO queue for heavy traffic, as it may impact the management frames which also use this queue. Eventually, it is worth noting that the AC\_VO queue does not support AMPDU, and its performance with heavy traffic is no better than other queues.
- Avoid using more than two precedences supported by different AMPDUs, e.g., when socket A uses precedence 0, socket B uses precedence 1, and socket C uses precedence 2. This can be a bad design because it may need much more memory. To be specific, the Wi-Fi driver may generate a Block Ack session for each precedence and it needs more memory if the Block Ack session is set up.

#### 4.28.29 Wi-Fi AMSDU

ESP32-C3 supports receiving AMSDU.

#### 4.28.30 Wi-Fi Fragment

ESP32-C3 supports Wi-Fi receiving and transmitting fragment.

#### 4.28.31 WPS Enrollee

ESP32-C3 supports WPS enrollee feature in Wi-Fi mode *WIFI\_MODE\_STA* or *WIFI\_MODE\_APSTA*. Currently, ESP32-C3 supports WPS enrollee type PBC and PIN.

#### 4.28.32 Wi-Fi Buffer Usage

This section is only about the dynamic buffer configuration.

##### Why Buffer Configuration Is Important

In order to get a high-performance system, consider the memory usage/configuration carefully for the following reasons:

- the available memory in ESP32-C3 is limited.
- currently, the default type of buffer in LwIP and Wi-Fi drivers is “dynamic” , **which means that both the LwIP and Wi-Fi share memory with the application**. Programmers should always keep this in mind; otherwise, they will face a memory issue, such as “running out of heap memory” .
- it is very dangerous to run out of heap memory, as this will cause ESP32-C3 an “undefined behavior” . Thus, enough heap memory should be reserved for the application, so that it never runs out of it.

- the Wi-Fi throughput heavily depends on memory-related configurations, such as the TCP window size and Wi-Fi RX/TX dynamic buffer number.
- the peak heap memory that the ESP32-C3 LwIP/Wi-Fi may consume depends on a number of factors, such as the maximum TCP/UDP connections that the application may have.
- the total memory that the application requires is also an important factor when considering memory configuration.

Due to these reasons, there is not a good-for-all application configuration. Rather, it is recommended to consider memory configurations separately for every different application.

### Dynamic vs. Static Buffer

The default type of buffer in Wi-Fi drivers is “dynamic”. Most of the time the dynamic buffer can significantly save memory. However, it makes the application programming a little more difficult, because in this case the application needs to consider memory usage in Wi-Fi.

lwIP also allocates buffers at the TCP/IP layer, and this buffer allocation is also dynamic. See [lwIP documentation section about memory use and performance](#).

### Peak Wi-Fi Dynamic Buffer

The Wi-Fi driver supports several types of buffer (refer to [Wi-Fi Buffer Configure](#)). However, this section is about the usage of the dynamic Wi-Fi buffer only. The peak heap memory that Wi-Fi consumes is the **theoretically-maximum memory** that the Wi-Fi driver consumes. Generally, the peak memory depends on:

- the number of dynamic RX buffers that are configured: `wifi_rx_dynamic_buf_num`
- the number of dynamic TX buffers that are configured: `wifi_tx_dynamic_buf_num`
- the maximum packet size that the Wi-Fi driver can receive: `wifi_rx_pkt_size_max`
- the maximum packet size that the Wi-Fi driver can send: `wifi_tx_pkt_size_max`

So, the peak memory that the Wi-Fi driver consumes can be calculated with the following formula:

$$\text{wifi\_dynamic\_peek\_memory} = (\text{wifi\_rx\_dynamic\_buf\_num} * \text{wifi\_rx\_pkt\_size\_max}) + (\text{wifi\_tx\_dynamic\_buf\_num} * \text{wifi\_tx\_pkt\_size\_max})$$

Generally, the dynamic TX long buffers and dynamic TX long long buffers can be ignored, because they are management frames which only have a small impact on the system.

## 4.28.33 How to Improve Wi-Fi Performance

The performance of ESP32-C3 Wi-Fi is affected by many parameters, and there are mutual constraints between each parameter. A proper configuration cannot only improve performance, but also increase available memory for applications and improve stability.

This section briefly explains the operating mode of the Wi-Fi/LwIP protocol stack and the role of each parameter. It also gives several recommended configuration ranks to help choose the appropriate rank according to the usage scenario.

### Protocol Stack Operation Mode

The ESP32-C3 protocol stack is divided into four layers: Application, LwIP, Wi-Fi, and Hardware.

- During receiving, hardware puts the received packet into DMA buffer, and then transfers it into the RX buffer of Wi-Fi and LwIP in turn for related protocol processing, and finally to the application layer. The Wi-Fi RX buffer and the LwIP RX buffer shares the same buffer by default. In other words, the Wi-Fi forwards the packet to LwIP by reference by default.
- During sending, the application copies the messages to be sent into the TX buffer of the LwIP layer for TCP/IP encapsulation. The messages will then be passed to the TX buffer of the Wi-Fi layer for MAC encapsulation and wait to be sent.

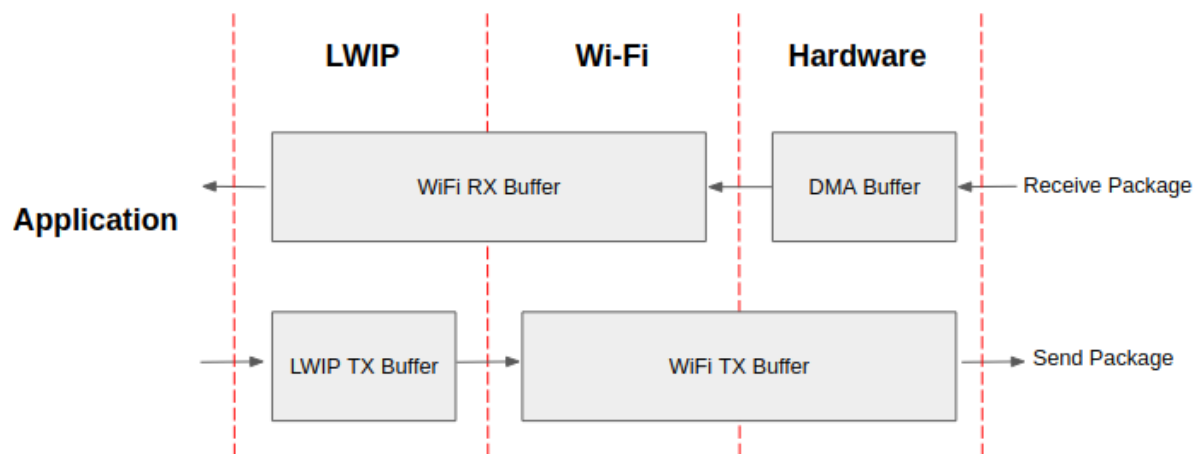

Fig. 82: ESP32-C3 datapath

### Parameters

Increasing the size or number of the buffers mentioned above properly can improve Wi-Fi performance. Meanwhile, it will reduce available memory to the application. The following is an introduction to the parameters that users need to configure:

#### RX direction:

- ***CONFIG\_ESP32\_WIFI\_STATIC\_RX\_BUFFER\_NUM*** This parameter indicates the number of DMA buffer at the hardware layer. Increasing this parameter will increase the sender's one-time receiving throughput, thereby improving the Wi-Fi protocol stack ability to handle burst traffic.
- ***CONFIG\_ESP32\_WIFI\_DYNAMIC\_RX\_BUFFER\_NUM*** This parameter indicates the number of RX buffer in the Wi-Fi layer. Increasing this parameter will improve the performance of packet reception. This parameter needs to match the RX buffer size of the LwIP layer.
- ***CONFIG\_ESP32\_WIFI\_RX\_BA\_WIN*** This parameter indicates the size of the AMPDU BA Window at the receiving end. This parameter should be configured to the smaller value between twice of ***CONFIG\_ESP32\_WIFI\_STATIC\_RX\_BUFFER\_NUM*** and ***CONFIG\_ESP32\_WIFI\_DYNAMIC\_RX\_BUFFER\_NUM***.
- ***CONFIG\_LWIP\_TCP\_WND\_DEFAULT*** This parameter represents the RX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of ***WIFI\_DYNAMIC\_RX\_BUFFER\_NUM*** (KB) to reach a high and stable performance. Meanwhile, in case of multiple streams, this value needs to be reduced proportionally.

#### TX direction:

- ***CONFIG\_ESP32\_WIFI\_TX\_BUFFER*** This parameter indicates the type of TX buffer, it is recommended to configure it as a dynamic buffer, which can make full use of memory.
- ***CONFIG\_ESP32\_WIFI\_DYNAMIC\_TX\_BUFFER\_NUM*** This parameter indicates the number of TX buffer on the Wi-Fi layer. Increasing this parameter will improve the performance of packet sending. The parameter value needs to match the TX buffer size of the LwIP layer.
- ***CONFIG\_LWIP\_TCP\_SND\_BUF\_DEFAULT*** This parameter represents the TX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of ***WIFI\_DYNAMIC\_TX\_BUFFER\_NUM*** (KB) to reach a high and stable performance. In case of multiple streams, this value needs to be reduced proportionally.

#### Throughput optimization by placing code in IRAM:

**Note:** The buffer size mentioned above is fixed as 1.6 KB.

## How to Configure Parameters

The memory of ESP32-C3 is shared by protocol stack and applications.

Here, several configuration ranks are given. In most cases, the user should select a suitable rank for parameter configuration according to the size of the memory occupied by the application.

The parameters not mentioned in the following table should be set to the default.

Rank	Iperf	Default	Minimum
Available memory (KB)	59	160	180
WIFI_STATIC_RX_BUFFER_NUM	8	8	3
WIFI_DYNAMIC_RX_BUFFER_NUM	16	16	6
WIFI_DYNAMIC_TX_BUFFER_NUM	16	16	6
WIFI_RX_BA_WIN	32	16	6
TCP_SND_BUF_DEFAULT (KB)	40	16	6
TCP_WND_DEFAULT (KB)	40	16	6
LWIP_IRAM_OPTIMIZATION	DISABLE	ENABLE	DISABLE
TCP TX throughput (Mbit/s)	38.1	27.2	20.4
TCP RX throughput (Mbit/s)	35.3	24.2	17.4
UDP TX throughput (Mbit/s)	40.6	38.9	34.1
UDP RX throughput (Mbit/s)	52.4	44.5	44.2

**Note:** The test was performed with a single stream in a shielded box using an ASUS RT-N66U router. ESP32-C3's CPU is single core with 160 MHz. ESP32-C3's flash is in QIO mode with 80 MHz.

### Ranks:

- **Iperf rank** ESP32-C3 extreme performance rank used to test extreme performance.
- **Default rank** ESP32-C3's default configuration rank, the available memory, and performance are in balance.
- **Minimum rank** This is the minimum configuration rank of ESP32-C3. The protocol stack only uses the necessary memory for running. It is suitable for scenarios where there is no requirement for performance and the application requires lots of space.

## 4.28.34 Wi-Fi Menuconfig

### Wi-Fi Buffer Configure

If you are going to modify the default number or type of buffer, it would be helpful to also have an overview of how the buffer is allocated/freed in the data path. The following diagram shows this process in the TX direction:

Description:

- The application allocates the data which needs to be sent out.
- The application calls TCP/IP-/Socket-related APIs to send the user data. These APIs will allocate a PBUF used in LwIP, and make a copy of the user data.
- When LwIP calls a Wi-Fi API to send the PBUF, the Wi-Fi API will allocate a "Dynamic Tx Buffer" or "Static Tx Buffer", make a copy of the LwIP PBUF, and finally send the data.

The following diagram shows how buffer is allocated/freed in the RX direction:

Fig. 83: TX Buffer Allocation

Fig. 84: RX Buffer Allocation

## Description:

- The Wi-Fi hardware receives a packet over the air and puts the packet content to the “Static Rx Buffer” , which is also called “RX DMA Buffer” .
- The Wi-Fi driver allocates a “Dynamic Rx Buffer” , makes a copy of the “Static Rx Buffer” , and returns the “Static Rx Buffer” to hardware.
- The Wi-Fi driver delivers the packet to the upper-layer (LwIP), and allocates a PBUF for holding the “Dynamic Rx Buffer” .
- The application receives data from LwIP.

The diagram shows the configuration of the Wi-Fi internal buffer.

Buffer Type	Alloc Type	Default	Configurable	Description
Static RX Buffer (Hardware RX Buffer)	Static	10 * 1600 Bytes	Yes	<p>This is a kind of DMA memory. It is initialized in <code>esp_wifi_init()</code> and freed in <code>esp_wifi_deinit()</code>. The ‘Static Rx Buffer’ forms the hardware receiving list. Upon receiving a frame over the air, hardware writes the frame into the buffer and raises an interrupt to the CPU. Then, the Wi-Fi driver reads the content from the buffer and returns the buffer back to the list.</p> <p>If needs be, the application can reduce the memory statically allocated by Wi-Fi. It can reduce this value from 10 to 6 to save 6400 Bytes of memory. It is not recommended to reduce the configuration to a value less than 6 unless the AMPDU feature is disabled.</p>
Dynamic RX Buffer	Dynamic	32	Yes	<p>The buffer length is variable and it depends on the received frames’ length. When the Wi-Fi driver receives a frame from the ‘Hardware Rx Buffer’, the ‘Dynamic Rx Buffer’ needs to be allocated from the heap. The number of the Dynamic Rx Buffer, configured in the menuconfig, is used to limit the total un-freed Dynamic Rx Buffer number.</p>
Dynamic TX Buffer	Dynamic	32	Yes	<p>This is a kind of DMA memory. It is allocated to the heap. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a ‘Dynamic TX Buffer’ and makes a copy of the upper-layer buffer.</p> <p>The Dynamic and Static TX Buffers are mutually exclusive.</p>
Static TX Buffer	Static	16 * 1600Bytes	Yes	<p>This is a kind of DMA memory. It is initialized in <code>esp_wifi_init()</code> and freed in <code>esp_wifi_deinit()</code>. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a ‘Static TX Buffer’ and makes a copy of the upper-layer buffer.</p> <p>The Dynamic and Static TX Buffer are mutually exclusive.</p> <p>The TX buffer must be a DMA buffer. For this reason, if PSRAM is enabled, the TX buffer must be static.</p>
Management Short Buffer	Dynamic	8	NO	Wi-Fi driver’ s internal buffer.
Management Long Buffer	Dynamic	32	NO	Wi-Fi driver’ s internal buffer.
Management Long Long Buffer	Dynamic	32	NO	Wi-Fi driver’ s internal buffer.

## Wi-Fi NVS Flash

If the Wi-Fi NVS flash is enabled, all Wi-Fi configurations set via the Wi-Fi APIs will be stored into flash, and the Wi-Fi driver will start up with these configurations the next time it powers on/reboots. However, the application can choose to disable the Wi-Fi NVS flash if it does not need to store the configurations into persistent memory, or has its own persistent storage, or simply due to debugging reasons, etc.

## Wi-Fi Aggregate MAC Protocol Data Unit (AMPDU)

ESP32-C3 supports both receiving and transmitting AMPDU, and the AMPDU can greatly improve the Wi-Fi throughput.

Generally, the AMPDU should be enabled. Disabling AMPDU is usually for debugging purposes.

### 4.28.35 Troubleshooting

Please refer to a separate document with *Espressif Wireshark User Guide*.

## Espressif Wireshark User Guide

### 1. Overview

**1.1 What is Wireshark?** *Wireshark* (originally named “Ethereal” ) is a network packet analyzer that captures network packets and displays the packet data as detailed as possible. It uses WinPcap as its interface to directly capture network traffic going through a network interface controller (NIC).

You could think of a network packet analyzer as a measuring device used to examine what is going on inside a network cable, just like a voltmeter is used by an electrician to examine what is going on inside an electric cable.

In the past, such tools were either very expensive, proprietary, or both. However, with the advent of Wireshark, all that has changed.

Wireshark is released under the terms of the GNU General Public License, which means you can use the software and the source code free of charge. It also allows you to modify and customize the source code.

Wireshark is, perhaps, one of the best open source packet analyzers available today.

**1.2 Some Intended Purposes** Here are some examples of how Wireshark is typically used:

- Network administrators use it to troubleshoot network problems.
- Network security engineers use it to examine security problems.
- Developers use it to debug protocol implementations.
- People use it to learn more about network protocol internals.

Beside these examples, Wireshark can be used for many other purposes.

**1.3 Features** The main features of Wireshark are as follows:

- Available for UNIX and Windows
- Captures live packet data from a network interface
- Displays packets along with detailed protocol information
- Opens/saves the captured packet data
- Imports/exports packets into a number of file formats, supported by other capture programs
- Advanced packet filtering
- Searches for packets based on multiple criteria

- Colorizes packets according to display filters
- Calculates statistics
- ...and a lot more!

### 1.4 Wireshark Can or Can't Do

- **Live capture from different network media.**  
Wireshark can capture traffic from different network media, including wireless LAN.
- **Import files from many other capture programs.**  
Wireshark can import data from a large number of file formats, supported by other capture programs.
- **Export files for many other capture programs.**  
Wireshark can export data into a large number of file formats, supported by other capture programs.
- **Numerous protocol dissectors.**  
Wireshark can dissect, or decode, a large number of protocols.
- **Wireshark is not an intrusion detection system.**  
It will not warn you if there are any suspicious activities on your network. However, if strange things happen, Wireshark might help you figure out what is really going on.
- **Wireshark does not manipulate processes on the network, it can only perform “measurements” within it.**  
Wireshark does not send packets on the network or influence it in any other way, except for resolving names (converting numerical address values into a human readable format), but even that can be disabled.

**2. Where to Get Wireshark** You can get Wireshark from the official website: <https://www.wireshark.org/download.html>

Wireshark can run on various operating systems. Please download the correct version according to the operating system you are using.

### 3. Step-by-step Guide This demonstration uses Wireshark 2.2.6 on Linux.

#### a) Start Wireshark

On Linux, you can run the shell script provided below. It starts Wireshark, then configures NIC and the channel for packet capture.

```
ifconfig $1 down
iwconfig $1 mode monitor
iwconfig $1 channel $2
ifconfig $1 up
Wireshark&
```

In the above script, the parameter \$1 represents NIC and \$2 represents channel. For example, `wlan0` in `./xxx.sh wlan0 6`, specifies the NIC for packet capture, and `6` identifies the channel of an AP or Soft-AP.

#### b) Run the Shell Script to Open Wireshark and Display Capture Interface

#### c) Select the Interface to Start Packet Capture

As the red markup shows in the picture above, many interfaces are available. The first one is a local NIC and the second one is a wireless NIC.

Please select the NIC according to your requirements. This document will use the wireless NIC to demonstrate packet capture.

Double click `wlan0` to start packet capture.

#### d) Set up Filters

Since all packets in the channel will be captured, and many of them are not needed, you have to set up filters to get the packets that you need.

Please find the picture below with the red markup, indicating where the filters should be set up.

Fig. 85: Wireshark Capture Interface

Fig. 86: Setting up Filters in Wireshark

Click *Filter*, the top left blue button in the picture below. The *display filter* dialogue box will appear.

Fig. 87: *Display Filter* Dialogue Box

Click the *Expression* button to bring up the *Filter Expression* dialogue box and set the filter according to your requirements.

**The quickest way:** enter the filters directly in the toolbar.

Click on this area to enter or modify the filters. If you enter a wrong or unfinished filter, the built-in syntax check turns the background red. As soon as the correct expression is entered, the background becomes green.

The previously entered filters are automatically saved. You can access them anytime by opening the drop down list.

For example, as shown in the picture below, enter two MAC addresses as the filters and click *Apply* (the blue arrow). In this case, only the packet data transmitted between these two MAC addresses will be captured.

#### e) Packet List

You can click any packet in the packet list and check the detailed information about it in the box below the list. For example, if you click the first packet, its details will appear in that box.

#### f) Stop/Start Packet Capture

As shown in the picture below, click the red button to stop capturing the current packet.

Click the top left blue button to start or resume packet capture.

#### g) Save the Current Packet

On Linux, go to *File* -> *Export Packet Dissections* -> *As Plain Text File* to save the packet.

Please note that *All packets*, *Displayed* and *All expanded* must be selected.

By default, Wireshark saves the captured packet in a libpcap file. You can also save the file in other formats, e.g. txt, to analyze it in other tools.

## 4.29 Wi-Fi Security

### 4.29.1 ESP32-C3 Wi-Fi Security Features

- Support for Protected Management Frames (PMF)
- Support for WPA3-Personal
- Support for Opportunistic Wireless Encryption

Fig. 88: Filter Expression Dialogue Box

Fig. 89: Filter Toolbar

Fig. 90: Example of MAC Addresses applied in the Filter Toolbar

Fig. 91: Example of Packet List Details

Fig. 92: Stopping Packet Capture

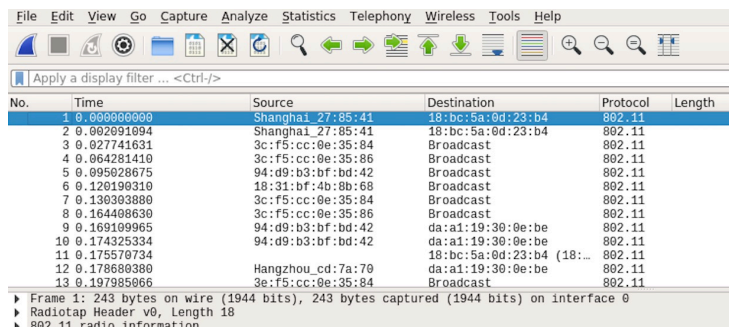

Fig. 93: Starting or Resuming the Packets Capture

Fig. 94: Saving Captured Packets

In addition to traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), ESP32-C3 Wi-Fi supports state-of-the-art security protocols, namely Protected Management, Wi-Fi Protected Access 3 and Enhanced Open based on Opportunistic Wireless Encryption. WPA3 provides better privacy and robustness against known attacks on traditional modes. Enhanced Open enhances security and privacy of users connecting to open (public) Wireless Network without authentication.

## 4.29.2 Protected Management Frames (PMF)

### Introduction

In Wi-Fi, management frames such as beacons, probes, (de)authentication, (dis)association are used by non-AP stations to scan and connect to an AP. Unlike data frames, these frames are sent unencrypted. An attacker can use eavesdropping and packet injection to send spoofed (de)authentication/(dis)association frames at the right time, leading to attacks such as Denial-of-Service (DOS) and man-in-the-middle

PMF provides protection against these attacks by encrypting unicast management frames and providing integrity checks for broadcast management frames. These include deauthentication, disassociation and robust management frames. It also provides Secure Association (SA) teardown mechanism to prevent spoofed association/authentication frames from disconnecting already connected clients.

**There are 3 types of PMF configuration modes on both station and AP side -**

- PMF Optional
- PMF Required
- PMF Disabled

### API & Usage

ESP32-C3 supports PMF in both Station and SoftAP mode. For both, the default mode is PMF Optional and disabling PMF is not possible. For even higher security, PMF required mode can be enabled by setting the `required` flag in `pmf_cfg` while using the `esp_wifi_set_config()` API. This will result in the device only connecting to a PMF enabled device and rejecting others.

**Attention:** `capable` flag in `pmf_cfg` is deprecated and set to true internally. This is to take the additional security benefit of PMF whenever possible.

### 4.29.3 WiFi Enterprise

#### Introduction

Enterprise security is the secure authentication mechanism for enterprise wireless networks. It uses RADIUS server for authentication of network users before connecting to the Access Point. The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, PEAP and EAP-FAST. RADIUS server authenticates the users based on their credentials (username and password), digital certificates or both.

#### ESP32-C3 supports WiFi Enterprise only in station mode.

ESP32-C3 Supports **WPA2-Enterprise** and **WPA3-Enterprise**. WPA3-Enterprise builds upon the foundation of WPA2-Enterprise with the additional requirement of using Protected Management Frames (PMF) and server certificate validation on all WPA3 connections. **WPA3-Enterprise also offers an addition secure mode using 192-bit minimum-strength security protocols and cryptographic tools to better protect sensitive data.** The 192-bit security mode offered by WPA3-Enterprise ensures the right combination of cryptographic tools are used and sets a consistent baseline of security within a WPA3 network. WPA3-Enterprise 192-bit mode is only supported by modules having `SOC_WIFI_GCMP_SUPPORT` support. Enable `CONFIG_WPA_SUITE_B_192` flag to support WPA3-Enterprise with 192-bit mode.

#### ESP32-C3 supports the following EAP methods:

- EAP-TLS: This is a certificate-based method and only requires SSID and EAP-IDF.
- PEAP: This is a Protected EAP method. Username and password are mandatory.
- **EAP-TTLS: This is a credential-based method. Only server authentication is mandatory while user authentication is optional.**
  - PAP: Password Authentication Protocol.
  - CHAP: Challenge Handshake Authentication Protocol.
  - MSCHAP and MSCHAP-V2.
- EAP-FAST: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, `CONFIG_WPA_MBEDTLS_TLS_CLIENT` flag should be disabled to use this feature.

Example [wifi/wifi\\_enterprise](#) demonstrates all the supported WiFi Enterprise methods except EAP-FAST. Please refer [wifi/wifi\\_eap\\_fast](#) for EAP-FAST example. EAP method can be selected from the Example Configuration menu in `idf.py menuconfig`. Refer to [examples/wifi/wifi\\_enterprise/README.md](#) for information on how to generate certificates and run the example.

### 4.29.4 WPA3-Personal

#### Introduction

Wi-Fi Protected Access-3 (WPA3) is a set of enhancements to Wi-Fi access security intended to replace the current WPA2 standard. It includes new features and capabilities that offer significantly better protection against different types of attacks. It improves upon WPA2-Personal in following ways:

- WPA3 uses Simultaneous Authentication of Equals (SAE), which is password-authenticated key agreement method based on Diffie-Hellman key exchange. Unlike WPA2, the technology is resistant to offline-dictionary attack, where the attacker attempts to determine shared password based on captured 4-way handshake without any further network interaction.
- Disallows outdated protocols such as TKIP, which is susceptible to simple attacks like MIC key recovery attack.
- Mandates Protected Management Frames (PMF), which provides protection for unicast and multicast robust management frames which include Disassoc and Deauth frames. This means that the attacker cannot disrupt an established WPA3 session by sending forged Assoc frames to the AP or Deauth/Disassoc frames to the Station.
- Provides forward secrecy, which means the captured data cannot be decrypted even if password is compromised after data transmission.

**ESP32-C3 station also supports following additional Wi-Fi CERTIFIED WPA3™ features.**

- **Transition Disable** : WPA3 defines transition modes for client devices so that they can connect to a network even when some of the APs in that network do not support the strongest security mode. Client device implementations typically configure network profiles in a transition mode by default. However, such a client device could be subject to an active downgrade attack in which the attacker causes the client device to use a lower security mode in order to exploit a vulnerability with that mode. WPA3 has introduced the Transition Disable feature to mitigate such attacks, by enabling client devices to change from a transition mode to an “only” mode when connecting to a network, once that network indicates it fully supports the higher security mode. Enable `transition_disable` in `wifi_sta_config_t` to enable this feature for ESP32-C3 station.
- **SAE PWE Methods**: ESP32-C3 station supports SAE Password Element derivation method *Hunt And Peck* and *Hash to Element (H2E)*. H2E is computationally efficient as it uses less iterations than Hunt and Peck, also it mitigates side channel attacks. These can be configured using parameter `sae_pwe_h2e` from `wifi_sta_config_t` for station. Hunt and peck, H2E both can be enabled by using `WPA3_SAE_PWE_BOTH` configuration.

Please refer to [Security](#) section of Wi-Fi Alliance’s official website for further details.

### Setting up WPA3 Personal with ESP32-C3

A config option `CONFIG_ESP32_WIFI_ENABLE_WPA3_SAE` is provided to Enable/Disable WPA3 for station. By default it is kept enabled, if disabled ESP32-C3 will not be able to establish a WPA3 connection. Additionally, since PMF is mandated by WPA3 protocol, PMF Mode Optional is set by default for station. PMF Required can be configured using WiFi config.

Refer to [Protected Management Frames \(PMF\)](#) on how to set this mode.

After configuring all required settings for WPA3-Personal station, application developers need not worry about the underlying security mode of the AP. WPA3-Personal is now the highest supported protocol in terms of security, so it will be automatically selected for the connection whenever available. For example, if an AP is configured to be in WPA3 Transition Mode, where it will advertise as both WPA2 and WPA3 capable, Station will choose WPA3 for the connection with above settings. Note that Wi-Fi stack size requirement will increase 3kB when “Enable WPA3-Personal” is used.

## 4.29.5 Wi-Fi Enhanced Open™

### Introduction

Enhanced open is used for providing security and privacy to users connecting to open (public) wireless networks, particularly in scenarios where user authentication is not desired or distribution of credentials impractical. Each user is provided with unique individual encryption keys that protect data exchange between a user device and the Wi-Fi network. Protected Management Frames further protects management traffic between the access point and user device. Enhanced Open is based on Opportunistic Wireless Encryption (OWE) standard. OWE Transition Mode enables a seamless transition from Open unencrypted WLANs to OWE WLANs without adversely impacting the end user experience.

**ESP32-C3 supports Wi-Fi Enhanced Open™ only in station mode.**

### Setting up OWE with ESP32-C3

A config option `CONFIG_ESP32_WIFI_ENABLE_WPA3_OWE_STA` and configuration parameter `owe_enabled` in `wifi_sta_config_t` is provided to enable OWE support for station. To use OWE transition mode, along with the config provided above, `authmode` from `wifi_scan_threshold_t` should be set to `WIFI_AUTH_OPEN`.

## 4.30 RF Coexistence

### 4.30.1 Overview

ESP32-C3 has only one 2.4 GHz ISM band RF module, which is shared by Bluetooth (BT & BLE) and Wi-Fi, so Bluetooth can't receive or transmit data while Wi-Fi is receiving or transmitting data and vice versa. Under such circumstances, ESP32-C3 uses the time-division multiplexing method to receive and transmit packets.

### 4.30.2 Supported Coexistence Scenario for ESP32-C3

Table 31: Supported Features of Wi-Fi and BLE Coexistence

			BLE		
			Scan	Advertising	Connected
Wi-Fi	STA	Scan	Y	Y	Y
		Connecting	Y	Y	Y
		Connected	Y	Y	Y
	SOFTAP	TX Beacon	Y	Y	Y
		Connecting	C1	C1	C1
		Connected	C1	C1	C1
	Sniffer	RX	C1	C1	C1
	ESP-NOW	RX	S	S	S
		TX	Y	Y	Y

#### Note:

- Y: supported and the performance is stable
- C1: supported but the performance is unstable
- X: not supported
- S: supported and the performance is stable in STA mode, otherwise not supported

### 4.30.3 Coexistence Mechanism and Policy

#### Coexistence Mechanism

The RF resource allocation mechanism is based on priority. As shown below, both Bluetooth module and Wi-Fi module request RF resources from the coexistence module, and the coexistence module decides who will use the RF resource based on their priority.

Fig. 95: Coexistence Mechanism

## Coexistence Policy

**Coexistence Period and Time Slice** Wi-Fi and BLE have their fixed time slice to use the RF. In the Wi-Fi time slice, Wi-Fi will send a higher priority request to the coexistence arbitration module. Similarly, BLE can enjoy higher priority at their own time slice. The duration of the coexistence period and the proportion of each time slice are divided into four categories according to the Wi-Fi status:

- 1) IDLE status: RF module is controlled by Bluetooth module.
- 2) CONNECTED status: the coexistence period starts at the Target Beacon Transmission Time (TBTT) and is more than 100 ms.
- 3) SCAN status: Wi-Fi slice and coexistence period are longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.
- 4) CONNECTING status: Wi-Fi slice is longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.

According to the coexistence logic, different coexistence periods and time slice strategies will be selected based on the Wi-Fi and Bluetooth usage scenarios. A Coexistence policy corresponding to a certain usage scenarios is called a “coexistence scheme”. For example, the scenario of Wi-Fi CONNECTED and BLE CONNECTED has a corresponding coexistence scheme. In this scheme, the time slices of Wi-Fi and BLE in a coexistence period each account for 50%. The time allocation is shown in the following figure:

Fig. 96: Time Slice Under the Status of Wi-Fi CONNECTED and BLE CONNECTED

**Dynamic Priority** The coexistence module assigns varying priorities to different statuses of each module, and these priorities are dynamic. For example, in every N BLE Advertising events, there is always one event with high priority. If a high-priority BLE Advertising event occurs within the Wi-Fi time slice, the right to use the RF may be preempted by BLE.

**Wi-Fi Connectionless Modules Coexistence** To some extent, some combinations of connectionless power-saving parameters *Window* and *Interval* would lead to extra Wi-Fi priority request out of Wi-Fi time slice. It's for obtaining RF resources at coexistence for customized parameters, while leading to impact on Bluetooth performance.

If connectionless power-saving parameters are configured with default values, the coexistence module would perform in stable mode and the behaviour above would not happen. So please configure Wi-Fi connectionless power-saving parameters to default values unless you have plenty of coexistence performance tests for customized parameters.

Please refer to [connectionless module power save](#) to get more detail.

### 4.30.4 How to Use the Coexistence Feature

#### Coexistence API

For most coexistence cases, ESP32-C3 will switch the coexistence status automatically without calling API. However, ESP32-C3 provides two APIs for the coexistence of BLE MESH and Wi-Fi. When the status of BLE MESH changes, call `esp_coex_status_bit_clear` to clear the previous status first and then call `esp_coex_status_bit_set` to set the current status.

**BLE MESH Coexistence Status** As the firmware of Wi-Fi and Bluetooth are not aware of the current scenario of the upper layer application, some coexistence schemes require application code to call the coexistence API to take effect. The application layer needs to pass the working status of BLE MESH to the coexistence module for selecting the coexistence scheme.

- `ESP_COEX_BLE_ST_MESH_CONFIG`: network is provisioning
- `ESP_COEX_BLE_ST_MESH_TRAFFIC`: data is transmitting
- `ESP_COEX_BLE_ST_MESH_STANDBY`: in idle status with no significant data interaction

### Coexistence API Error Codes

All coexistence APIs have custom return values, i.e. error codes. These error codes can be categorized as:

- No error. For example, the return value `ESP_OK` signifies the API returned successfully.
- Recoverable errors. For example, the return value `ESP_ERR_INVALID_ARG` signifies API parameter errors.

### Setting Coexistence Compile-time Options

- After writing the coexistence program, you must check `CONFIG_ESP32_WIFI_SW_COEXIST_ENABLE` option through menuconfig to open coexistence configuration on software, otherwise the coexistence function mentioned above cannot be used.
- When using LE Coded PHY during a BLE connection, to avoid affecting Wi-Fi performance due to the long duration of Bluetooth packets, you can select `BT_CTRL_COEX_PHY_CODED_TX_RX_TLIM_EN` in the sub-options of `CONFIG_BT_CTRL_COEX_PHY_CODED_TX_RX_TLIM` to limit the maximum time of TX/RX.
- You can reduce the memory consumption by configuring the following options on menuconfig.
  - `CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY`: enable the configuration of dynamic memory for Bluetooth protocol stack.
  - `CONFIG_ESP32_WIFI_STATIC_RX_BUFFER_NUM`: reduce the number of Wi-Fi static RX buffers.
  - `CONFIG_ESP32_WIFI_DYNAMIC_RX_BUFFER_NUM`: reduce the number of Wi-Fi dynamic RX buffers.
  - `CONFIG_ESP32_WIFI_TX_BUFFER`: enable the configuration of dynamic allocation TX buffers.
  - `CONFIG_ESP32_WIFI_DYNAMIC_TX_BUFFER_NUM`: reduce the number of Wi-Fi dynamic TX buffers.
  - `CONFIG_ESP32_WIFI_TX_BA_WIN`: reduce the number of Wi-Fi Block Ack TX windows.
  - `CONFIG_ESP32_WIFI_RX_BA_WIN`: reduce the number of Wi-Fi Block Ack RX windows.
  - `CONFIG_ESP32_WIFI_MGMT_SBUF_NUM`: reduce the number of Wi-Fi Management Short Buffer.
  - `CONFIG_ESP32_WIFI_RX_IRAM_OPT`: turning off this configuration option will reduce the IRAM memory by approximately 17 KB.
  - `CONFIG_LWIP_TCP_SND_BUF_DEFAULT`: reduce the default TX buffer size for TCP sockets.
  - `CONFIG_LWIP_TCP_WND_DEFAULT`: reduce the default size of the RX window for TCP sockets.
  - `CONFIG_LWIP_TCP_RECVMBOX_SIZE`: reduce the size of the TCP receive mailbox. Receive mailbox buffers data within active connections and handles data flow during connections.
  - `CONFIG_LWIP_UDP_RECVMBOX_SIZE`: reduce the size of the UDP receive mailbox.
  - `CONFIG_LWIP_TCPIP_RECVMBOX_SIZE`: reduce the size of TCPIP task receive mailbox.

---

**Note:** Since the coexistence configuration option depends on the Bluetooth configuration option, please turn on the Bluetooth configuration option first before configuring the coexistence feature in the Wi-Fi configuration option.

---

## 4.31 Reproducible Builds

### 4.31.1 Introduction

ESP-IDF build system has support for [reproducible builds](#).

When reproducible builds are enabled, the application built with ESP-IDF doesn't depend on the build environment. Both the .elf file and .bin files of the application remains exactly the same, even if the following variables change:

- Directory where the project is located
- Directory where ESP-IDF is located (`IDF_PATH`)
- Build time

### 4.31.2 Reasons for non-reproducible builds

There are several reasons why an application may depend on the build environment, even when the same source code and tools versions are used.

- In C code, `__FILE__` preprocessor macro is expanded to the full path of the source file.
- `__DATE__` and `__TIME__` preprocessor macros are expanded to compilation date and time.
- When the compiler generates object files, it adds sections with debug information. These sections help debuggers, like GDB, to locate the source code which corresponds to a particular location in the machine code. These sections typically contain paths of relevant source files. These paths may be absolute, and will include the path to ESP-IDF or to the project.

There are also other possible reasons, such as unstable order of inputs and non-determinism in the build system.

### 4.31.3 Enabling reproducible builds in ESP-IDF

Reproducible builds can be enabled in ESP-IDF using `CONFIG_APP_REPRODUCIBLE_BUILD` option.

This option is disabled by default. It can be enabled in `menuconfig`.

The option may also be added into `sdkconfig.defaults`. If adding the option into `sdkconfig.defaults`, delete the `sdkconfig` file and run the build again. See [Custom sdkconfig defaults](#) for more information.

### 4.31.4 How reproducible builds are achieved

ESP-IDF achieves reproducible builds using the following measures:

- In ESP-IDF source code, `__DATE__` and `__TIME__` macros are not used when reproducible builds are enabled. Note, if the application source code uses these macros, the build will not be reproducible.
- ESP-IDF build system passes a set of `-fmacro-prefix-map` and `-fdebug-prefix-map` flags to replace base paths with placeholders:
  - Path to ESP-IDF is replaced with `/IDF`
  - Path to the project is replaced with `/IDF_PROJECT`
  - Path to the build directory is replaced with `/IDF_BUILD`
  - Paths to components are replaced with `/COMPONENT_NAME_DIR` (where `NAME` is the name of the component)
- Build date and time are not included into the *application metadata structure* if `CONFIG_APP_REPRODUCIBLE_BUILD` is enabled.
- ESP-IDF build system ensures that source file lists, component lists and other sequences are sorted before passing them to CMake. Various other parts of the build system, such as the linker script generator also perform sorting to ensure that same output is produced regardless of the environment.

### 4.31.5 Reproducible builds and debugging

When reproducible builds are enabled, file names included in debug information sections are altered as shown in the previous section. Due to this fact, the debugger (GDB) is not able to locate the source files for the given code location.

This issue can be solved using GDB `set substitute-path` command. For example, by adding the following command to GDB init script, the altered paths can be reverted to the original ones:

```
set substitute-path /COMPONENT_FREERTOS_DIR /home/user/esp/esp-idf/components/  
↪freertos
```

ESP-IDF build system generates a file with the list of such `set substitute-path` commands automatically during the build process. The file is called `prefix_map_gdbinit` and is located in the project `build` directory.

When `idf.py gdb` is used to start debugging, this additional `gdbinit` file is automatically passed to GDB. When launching GDB manually or from an IDE, please pass this additional `gdbinit` script to GDB using `-x build/prefix_map_gdbinit` argument.

### 4.31.6 Factors which still affect reproducible builds

Note that the built application still depends on:

- ESP-IDF version
- Versions of the build tools (CMake, Ninja) and the cross-compiler

*IDF Docker Image* can be used to ensure that these factors do not affect the build.

## 4.32 Low Power Mode User Guide

The document has not been translated into English yet. In the meantime, please refer to the Chinese version.

# Chapter 5

## Migration Guides

### 5.1 ESP-IDF 5.x Migration Guide

#### 5.1.1 Migration from 4.4 to 5.0

##### Bluetooth Low Energy

##### Bluedroid

The following Bluedroid macros, types, and functions have been renamed:

- [bt/host/bluedroid/api/include/api/esp\\_gap\\_ble\\_api.h](#)
  - In *esp\_gap\_ble\_cb\_event\_t*
    - \* `ESP_GAP_BLE_SET_PREFERED_DEFAULT_PHY_COMPLETE_EVT` renamed to `ESP_GAP_BLE_SET_PREFERRED_DEFAULT_PHY_COMPLETE_EVT`
    - \* `ESP_GAP_BLE_SET_PREFERED_PHY_COMPLETE_EVT` renamed to `ESP_GAP_BLE_SET_PREFERRED_PHY_COMPLETE_EVT`
    - \* `ESP_GAP_BLE_CHANNEL_SELETE_ALGORITHM_EVT` renamed to `ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT`
  - `esp_ble_wl_opration_t` renamed to *esp\_ble\_wl\_operation\_t*
  - `esp_ble_gap_cb_param_t.pkt_data_lenth_cmpl` renamed to `pkt_data_length_cmpl`
  - `esp_ble_gap_cb_param_t.update_whitelist_cmpl.wl_opration` renamed to `wl_operation`
  - `esp_ble_gap_set_prefered_default_phy` renamed to *esp\_ble\_gap\_set\_preferred\_default\_phy()*
  - `esp_ble_gap_set_prefered_phy` renamed to *esp\_ble\_gap\_set\_preferred\_phy()*
- [bt/host/bluedroid/api/include/api/esp\\_gatt\\_defs.h](#)
  - In *esp\_gatt\_status\_t*
    - \* `ESP_GATT_ENCRYPED_MITM` renamed to `ESP_GATT_ENCRYPTED_MITM`
    - \* `ESP_GATT_ENCRYPED_NO_MITM` renamed to `ESP_GATT_ENCRYPTED_NO_MITM`

##### Nimble

The following Nimble APIs have been removed:

- [bt/host/nimble/esp-hci/include/esp\\_nimble\\_hci.h](#)

- Remove : `esp_err_t esp_nimble_hci_and_controller_init(void);`
  - \* Controller initialization, enable and HCI initialization calls have been moved to `nimble_port_init`. This function can be deleted directly.
- Remove : `esp_err_t esp_nimble_hci_and_controller_deinit(void);`
  - \* Controller deinitialization, disable and HCI deinitialization calls have been moved to `nimble_port_deinit`. This function can be deleted directly.

## ESP-BLE-MESH

The following ESP-BLE-MESH macro has been renamed:

- `bt/esp_ble_mesh/api/esp_ble_mesh_defs.h`
  - In `esp_ble_mesh_prov_cb_event_t`:
    - \* `ESP_BLE_MESH_PROVISIONER_DRIECT_ERASE_SETTINGS_COMP_EVT` renamed to `ESP_BLE_MESH_PROVISIONER_DIRECT_ERASE_SETTINGS_COMP_EVT`

## Build System

**Migrating from GNU Make Build System** ESP-IDF v5.0 no longer supports GNU make-based projects. Please follow the [build system](#) guide for migration.

**Update Fragment File Grammar** Please follow the [migrate linker script fragment files grammar](#) chapter for migrating v3.x grammar to the new one.

**Specify Component Requirements Explicitly** In previous versions of ESP-IDF, some components were always added as public requirements (dependencies) to every component in the build, in addition to the [common component requirements](#):

- `driver`
- `efuse`
- `esp_timer`
- `lwip`
- `vfs`
- `esp_wifi`
- `esp_event`
- `esp_netif`
- `esp_eth`
- `esp_phy`

This means that it was possible to include header files of those components without specifying them as requirements in `idf_component_register`. This behavior was caused by transitive dependencies of various common components.

In ESP-IDF v5.0, this behavior is fixed and these components are no longer added as public requirements by default.

Every component depending on one of the components which isn't part of common requirements has to declare this dependency explicitly. This can be done by adding `REQUIRES <component_name>` or `PRIV_REQUIRES <component_name>` in `idf_component_register` call inside component's `CMakeLists.txt`. See [Component Requirements](#) for more information on specifying requirements.

**Setting `COMPONENT_DIRS` and `EXTRA_COMPONENT_DIRS` Variables** ESP-IDF v5.0 includes a number of improvements to support building projects with space characters in their paths. To make that possible, there are some changes related to setting `COMPONENT_DIRS` and `EXTRA_COMPONENT_DIRS` variables in project `CMakeLists.txt` files.

Adding non-existent directories to `COMPONENT_DIRS` or `EXTRA_COMPONENT_DIRS` is no longer supported and will result in an error.

Using string concatenation to define `COMPONENT_DIRS` or `EXTRA_COMPONENT_DIRS` variables is now deprecated. These variables should be defined as CMake lists, instead. For example, use:

```
set(EXTRA_COMPONENT_DIRS path1 path2)
list(APPEND EXTRA_COMPONENT_DIRS path3)
```

instead of:

```
set(EXTRA_COMPONENT_DIRS "path1 path2")
set(EXTRA_COMPONENT_DIRS "${EXTRA_COMPONENT_DIRS} path3")
```

Defining these variables as CMake lists is compatible with previous ESP-IDF versions.

**Update Usage of target\_link\_libraries with project\_elf** ESP-IDF v5.0 fixes CMake variable propagation issues for components. This issue caused compiler flags and definitions that were supposed to apply to one component to be applied to every component in the project.

As a side effect of this, user projects from ESP-IDF v5.0 onwards must use `target_link_libraries` with `project_elf` explicitly and custom CMake projects must specify `PRIVATE`, `PUBLIC`, or `INTERFACE` arguments. This is a breaking change and is not backward compatible with previous ESP-IDF versions.

For example:

```
target_link_libraries(${project_elf} PRIVATE "-Wl,--wrap=esp_panic_handler")
```

instead of:

```
target_link_libraries(${project_elf} "-Wl,--wrap=esp_panic_handler")
```

**Update CMake Version** In ESP-IDF v5.0 minimal CMake version was increased to 3.16 and versions lower than 3.16 are not supported anymore. Run `tools/idf_tools.py install cmake` to install a suitable version if your OS version doesn't have one.

This affects ESP-IDF users who use system-provided CMake and custom CMake.

**Reorder the Applying of the Target-Specific Config Files** ESP-IDF v5.0 reorders the applying order of target-specific config files and other files listed in `SDKCONFIG_DEFAULTS`. Now, target-specific files will be applied right after the file brings it in, before all latter files in `SDKCONFIG_DEFAULTS`.

For example:

```
If ``SDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig_devkit1"`` , and there is a
↪file ``sdkconfig.defaults.esp32`` in the same folder, then the files will be
↪applied in the following order: (1) sdkconfig.defaults (2) sdkconfig.defaults.
↪esp32 (3) sdkconfig_devkit1.
```

If you have a key with different values in the target-specific files of the former item (e.g., `sdkconfig.defaults.esp32` above) and the latter item (e.g., `sdkconfig_devkit1` above), please note the latter will override the target-specific file of the former.

If you do want to have some target-specific config values, please put it into the target-specific file of the latter item (e.g., `sdkconfig_devkit1.esp32`).

## GCC

**GCC Version** The previous GCC version was GCC 8.4.0. This has now been upgraded to GCC 11.2.0 on all targets. Users that need to port their code from GCC 8.4.0 to 11.2.0 should refer to the series of official GCC porting guides listed below:

- [Porting to GCC 9](#)
- [Porting to GCC 10](#)
- [Porting to GCC 11](#)

**Warnings** The upgrade to GCC 11.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in [GCC Warning Options](#). Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user's code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter, and ways to suppress them.

**Warning:** Users are advised to check that a warning is indeed a false positive before attempting to suppress them it.

**-Wstringop-overflow, -Wstringop-overread, -Wstringop-truncation, and -Warray-bounds** Users that use memory/string copy/compare functions will run into one of the `-Wstringop` warnings if the compiler cannot properly determine the size of the memory/string. The examples below demonstrate code that triggers these warnings and how to suppress them.

```
#pragma GCC diagnostic push
#pragma GCC diagnostic ignored "-Wstringop-overflow"
#pragma GCC diagnostic ignored "-Warray-bounds"
    memset(RTC_SLOW_MEM, 0, CONFIG_ULP_COPROC_RESERVE_MEM); // <<-- This line
↳leads to warnings
#pragma GCC diagnostic pop
```

```
#pragma GCC diagnostic push
#if __GNUC__ >= 11
#pragma GCC diagnostic ignored "-Wstringop-overread" // <<-- This key had been
↳introduced since GCC 11
#endif
#pragma GCC diagnostic ignored "-Warray-bounds"
    memcpy(backup_write_data, (void *)EFUSE_PGM_DATA0_REG, sizeof(backup_
↳write_data)); // <<-- This line leads to warnings
#pragma GCC diagnostic pop
```

**-Waddress-of-packed-member** GCC will issue this warning when accessing an unaligned member of a packed struct due to the incurred penalty of unaligned memory access. However, all ESP chips (on both Xtensa and RISC-V architectures) allow for unaligned memory access and incur no extra penalty. Thus, this warning can be ignored in most cases.

```
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c: In function
↳'btc_to_bta_gatt_id':
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c:105:21: warning:
↳taking address of packed member of 'struct <anonymous>' may result in an
↳unaligned pointer value [-Waddress-of-packed-member]
    105 |     btc_to_bta_uuid(&p_dest->uuid, &p_src->uuid);
        |                   ^~~~~~
```

If the warning occurs in multiple places across multiple source files, users can suppress the warning at the CMake level as demonstrated below.

```

set_source_files_properties (
    "host/bluedroid/bta/gatt/bta_gattc_act.c"
    "host/bluedroid/bta/gatt/bta_gattc_cache.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatts.c"
    PROPERTIES COMPILE_FLAGS -Wno-address-of-packed-member)

```

However, if there are only one or two instances, users can suppress the warning directly in the source code itself as demonstrated below.

```

#pragma GCC diagnostic push
#if __GNUC__ >= 9
#pragma GCC diagnostic ignored "-Waddress-of-packed-member" <<-- This key had been
↳introduced since GCC 9
#endif
    uint32_t* reg_ptr = (uint32_t*)src;
#pragma GCC diagnostic pop

```

**labs () for 64-bit Integers** The function `abs ()` from `stdlib.h` takes `int` argument. Please use `labs ()` for types that are intended to be 64-bit. It is particularly important for `time_t`.

### Espressif Toolchain Changes

**int32\_t and uint32\_t for Xtensa Compiler** The types `int32_t` and `uint32_t` have been changed from the previous `int` and `unsigned int` to `long` and `unsigned long` respectively for the Xtensa compiler. This change now matches upstream GCC which `long` integers for `int32_t` and `uint32_t` on Xtensa, RISC-V, and other architectures.

	2021r2 and older, GCC 8	2022r1, GCC 11
Xtensa	(unsigned) int	(unsigned) long
riscv32	(unsigned) long	(unsigned) long

The change mostly affects code that formats strings using types provided by `<inttypes.h>`. Users will need to replace placeholders such as `%i` and `%x` with `PRId32` and `PRIdxx` respectively.

In other cases, it should be noted that enums have the `int` type.

In common, `int32_t` and `int`, as well as `uint32_t` and `unsigned int`, are different types.

**Removing CONFIG\_COMPILER\_DISABLE\_GCC8\_WARNINGS Build Option** `CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` option was introduced to allow building of legacy code dating from the rigid GCC 5 toolchain. However, enough time has passed to allow for the warnings to be fixed, thus this option has been removed.

For now in GCC 11, users are advised to review their code and fix the compiler warnings where possible.

### Networking

#### Wi-Fi

**Callback function type `esp_now_recv_cb_t`** Previously, the first parameter of `esp_now_recv_cb_t` was of type `const uint8_t *mac_addr`, which only included the address of ESP-NOW peer device.

This now changes. The first parameter is of type `esp_now_recv_info_t`, which has members `src_addr`, `des_addr` and `rx_ctrl`. Therefore, the following updates are required:

- Redefine ESP-NOW receive callback function.
- `src_addr` can be used to replace original `mac_addr`.
- `des_addr` is the destination MAC address of ESP-NOW packet, which can be unicast or broadcast address. With `des_addr`, the user can distinguish unicast and broadcast ESP-NOW packets where broadcast ESP-NOW packets can be non-encrypted even when encryption policy is configured for the ESP-NOW.
- `rx_ctrl` is Rx control info of the ESP-NOW packet, which provides more information about the packet.

Please refer to the ESP-NOW example: [wifi/espnow/main/espnow\\_example\\_main.c](#)

## Ethernet

**`esp_eth_ioctl()` API** Previously, the `esp_eth_ioctl()` API had the following issues:

- The third parameter (which is of type `void *`) would accept an `int/bool` type arguments (i.e., not pointers) as input in some cases. However, these cases were not documented properly.
- To pass `int/bool` type argument as the third parameter, the argument had to be “unnaturally” casted to a `void *` type, to prevent a compiler warning as demonstrated in the code snippet below. This casting could lead to misuse of the `esp_eth_ioctl()` function.

```
esp_eth_ioctl(eth_handle, ETH_CMD_S_FLOW_CTRL, (void *)true);
```

Therefore, the usage of `esp_eth_ioctl()` is now unified. Arguments to the third parameter must be passed as pointers to a specific data type to/from where data will be stored/read by `esp_eth_ioctl()`. The code snippets below demonstrate the usage of `esp_eth_ioctl()`.

Usage example to set Ethernet configuration:

```
eth_duplex_t new_duplex_mode = ETH_DUPLEX_HALF;
esp_eth_ioctl(eth_handle, ETH_CMD_S_DUPLEX_MODE, &new_duplex_mode);
```

Usage example to get Ethernet configuration:

```
eth_duplex_t duplex_mode;
esp_eth_ioctl(eth_handle, ETH_CMD_G_DUPLEX_MODE, &duplex_mode);
```

**KSZ8041/81 and LAN8720 Driver Update** The KSZ8041/81 and LAN8720 drivers are updated to support more devices (i.e., generations) from their associated product families. The drivers can recognize particular chip numbers and their potential support by the driver.

As a result, the specific “chip number” functions calls are replaced by generic ones as follows:

- Removed `esp_eth_phy_new_ksz8041()` and `esp_eth_phy_new_ksz8081()`, and use `esp_eth_phy_new_ksz80xx()` instead
- Removed `esp_eth_phy_new_lan8720()`, and use `esp_eth_phy_new_lan87xx()` instead

**ESP NETIF Glue Event Handlers** `esp_eth_set_default_handlers()` and `esp_eth_clear_default_handlers()` functions are removed. Registration of the default IP layer handlers for Ethernet is now handled automatically. If you have already followed the suggestion to fully initialize the Ethernet driver and network interface before registering their Ethernet/IP event handlers, then no action is required (except for deleting the affected functions). Otherwise, you may start the Ethernet driver right after they register the user event handler.

**PHY Address Auto-detect** The Ethernet PHY address auto-detect function `esp_eth_detect_phy_addr()` is renamed to `esp_eth_phy_802_3_detect_phy_addr()` and its header declaration is moved to `esp_eth/include/esp_eth_phy_802_3.h`.

**SPI-Ethernet Module Initialization** The SPI-Ethernet Module initialization is now simplified. Previously, you had to manually allocate an SPI device using `spi_bus_add_device()` before instantiating the SPI-Ethernet MAC.

Now, you no longer need to call `spi_bus_add_device()` as SPI devices are allocated internally. As a result, the `eth_dm9051_config_t`, `eth_w5500_config_t`, and `eth_ksz8851snl_config_t` configuration structures are updated to include members for SPI device configuration (e.g., to allow fine tuning of SPI timing which may be dependent on PCB design). Likewise, the `ETH_DM9051_DEFAULT_CONFIG`, `ETH_W5500_DEFAULT_CONFIG`, and `ETH_KSZ8851SNL_DEFAULT_CONFIG` configuration initialization macros are updated to accept new input parameters. Refer to *Ethernet API Reference Guide* for an example of SPI-Ethernet Module initialization.

**SPI-Ethernet Modules Initialization** The SPI-Ethernet Module's initialization has been simplified. The previous initialization process required you to manually allocate an SPI device using `spi_bus_add_device()` before instantiating the SPI-Ethernet MAC.

Now, you no longer need to call `spi_bus_add_device()` as the allocation of the SPI device is done internally. As a result, the `eth_dm9051_config_t`, `eth_w5500_config_t`, and `eth_ksz8851snl_config_t` configuration structures were updated to include members for SPI device configuration (e.g., to allow fine tuning of SPI timing which may be dependent on PCB design). Likewise, the `ETH_DM9051_DEFAULT_CONFIG`, `ETH_W5500_DEFAULT_CONFIG`, and `ETH_KSZ8851SNL_DEFAULT_CONFIG` configuration initialization macros have been updated to accept new input parameters. Refer to the *Ethernet API-Reference Guide* for an example of SPI-Ethernet Module initialization

**Ethernet Driver** APIs for creating MAC instances (`esp_eth_mac_new_*`) have been reworked to accept two parameters, instead of one common configuration. Now, the configuration includes

- Vendor specific MAC configuration
- Ethernet driver MAC configuration

This is applicable to internal Ethernet MAC `esp_eth_mac_new_esp32()` as well as to external MAC devices, such as `esp_eth_mac_new_ksz8851snl()`, `esp_eth_mac_new_dm9051()`, and `esp_eth_mac_new_w5500()`

**TCP/IP Adapter** The TCP/IP Adapter was a network interface abstraction component used in ESP-IDF prior to v4.1. This section outlines migration from `tcpip_adapter` API to its successor *ESP-NETIF*.

## Updating Network Connection Code

### Network Stack Initialization

- You may simply replace `tcpip_adapter_init()` with `esp_netif_init()`. However, please should note that the `esp_netif_init()` function now returns standard error codes. See *ESP-NETIF* for more details.
- The `esp_netif_deinit()` function is provided to de-initialize the network stack.
- You should also replace `#include "tcpip_adapter.h"` with `#include "esp_netif.h"`.

**Network Interface Creation** Previously, the TCP/IP Adapter defined the following network interfaces statically:

- WiFi Station
- WiFi Access Point
- Ethernet

This now changes. Network interface instance should be explicitly constructed, so that the *ESP-NETIF* can connect to the TCP/IP stack. For example, after the TCP/IP stack and the event loop are initialized, the initialization code for WiFi must explicitly call `esp_netif_create_default_wifi_sta();` or `esp_netif_create_default_wifi_ap();`.

Please refer to the example initialization code for these three interfaces:

- WiFi Station: [wifi/getting\\_started/station/main/station\\_example\\_main.c](#)
- WiFi Access Point: [wifi/getting\\_started/softAP/main/softap\\_example\\_main.c](#)
- Ethernet: [ethernet/basic/main/ethernet\\_example\\_main.c](#)

**Other tcpip\_adapter API Replacement** All the `tcpip_adapter` functions have their `esp-netif` counter-part. Please refer to the `esp_netif.h` grouped into these sections:

- [Setters/Getters](#)
- [DHCP](#)
- [DNS](#)
- [IP address](#)

The TCP/IP Adapter API `tcpip_adapter_get_sta_list()` that was used to acquire a list of associated Wi-Fi stations to the Software Access Point (softAP) has been moved to the Wi-Fi component and renamed to `esp_wifi_ap_get_sta_list_with_ip()`, which is a special case of the ESP-NETIF API [`esp\_netif\_dhcps\_get\_clients\_by\_mac\(\)`](#) that could be used more generally to provide a list of clients connected to a DHCP server no matter which network interface the server is running on.

**Default Event Handlers** Event handlers are moved from `tcpip_adapter` to appropriate driver code. There is no change from application code perspective, as all events should be handled in the same way. Please note that for IP-related event handlers, application code usually receives IP addresses in the form of an `esp-netif` specific struct instead of the LwIP structs. However, both structs are binary compatible.

This is the preferred way to print the address:

```
ESP_LOGI(TAG, "got ip:" IPSTR "\n", IP2STR(&event->ip_info.ip));
```

Instead of

```
ESP_LOGI(TAG, "got ip:%s\n", ip4addr_ntoa(&event->ip_info.ip));
```

Since `ip4addr_ntoa()` is a LwIP API, the `esp-netif` provides `esp_ip4addr_ntoa()` as a replacement. However, the above method using `IP2STR()` is generally preferred.

**IP Addresses** You are advised to use `esp-netif` defined IP structures. Please note that with default compatibility enabled, the LwIP structs will still work.

- [esp-netif IP address definitions](#)

**Next Steps** To port an application which may fully benefit from the *ESP-NETIF*, you also need to disable the `tcpip_adapter` compatibility layer in the component configuration option. Please go to `ESP_NETIF Adapter > Enable backward compatible tcpip_adapter interface`. After that, check if your project compiles.

The TCP/IP adapter includes many dependencies. Thus, disabling its compatibility might help separate the application from using specific TCP/IP stack API directly.

## Peripherals

**Peripheral Clock Gating** As usual, peripheral clock gating is still handled by driver itself, users don't need to take care of the peripheral module clock gating.

However, for advanced users who implement their own drivers based on `hal` and `soc` components, the previous clock gating include path has been changed from `driver/periph_ctrl.h` to `esp_private/periph_ctrl.h`.

**RTC Subsystem Control** RTC control APIs have been moved from `driver/rtc_ctrl.h` to `esp_private/rtc_ctrl.h`.

## ADC

**ADC Oneshot & Continuous Mode drivers** The ADC oneshot mode driver has been redesigned.

- The new driver is in `esp_adc` component and the include path is `esp_adc/adc_oneshot.h`.
- The legacy driver is still available in the previous include path `driver/adc.h`.

The ADC continuous mode driver has been moved from `driver` component to `esp_adc` component.

- The include path has been changed from `driver/adc.h` to `esp_adc/adc_continuous.h`.

Attempting to use the legacy include path `driver/adc.h` of either driver will trigger the build warning below by default. However, the warning can be suppressed by enabling the `CONFIG_ADC_SUPPRESS_DEPRECATED_WARN` Kconfig option.

```
legacy adc driver is deprecated, please migrate to use esp_adc/adc_oneshot.h and
↳esp_adc/adc_continuous.h for oneshot mode and continuous mode drivers↳
↳respectively
```

**ADC Calibration Driver** The ADC calibration driver has been redesigned.

- The new driver is in `esp_adc` component and the include path is `esp_adc/adc_cali.h` and `esp_adc/adc_cali_scheme.h`.

Legacy driver is still available by including `esp_adc_cal.h`. However, if users still would like to use the include path of the legacy driver, users should add `esp_adc` component to the list of component requirements in `CMakeLists.txt`.

Attempting to use the legacy include path `esp_adc_cal.h` will trigger the build warning below by default. However, the warning can be suppressed by enabling the `CONFIG_ADC_CALI_SUPPRESS_DEPRECATED_WARN` Kconfig option.

```
legacy adc calibration driver is deprecated, please migrate to use esp_adc/adc_
↳cali.h and esp_adc/adc_cali_scheme.h
```

## API Changes

- The ADC power management APIs `adc_power_acquire` and `adc_power_release` have made private and moved to `esp_private/adc_share_hw_ctrl.h`.
  - The two APIs were previously made public due to a HW errata workaround.
  - Now, ADC power management is completely handled internally by drivers.
  - Users who still require this API can include `esp_private/adc_share_hw_ctrl.h` to continue using these functions.
- `driver/adc2_wifi_private.h` has been moved to `esp_private/adc_share_hw_ctrl.h`.
- Enums `ADC_UNIT_BOTH`, `ADC_UNIT_ALTER`, and `ADC_UNIT_MAX` in `adc_unit_t` have been removed.
- The following enumerations have been removed as some of their enumeration values are not supported on all chips. This would lead to the driver triggering a runtime error if an unsupported value is used.
  - Enum `ADC_CHANNEL_MAX`
  - Enum `ADC_ATTEN_MAX`

- Enum `ADC_CONV_UNIT_MAX`
- API `hall_sensor_read` on ESP32 has been removed. Hall sensor is no longer supported on ESP32.
- API `adc_set_i2s_data_source` and `adc_i2s_mode_init` have been deprecated. Related enum `adc_i2s_source_t` has been deprecated. Please migrate to use `esp_adc/adc_continuous.h`.
- API `adc_digi_filter_reset`, `adc_digi_filter_set_config`, `adc_digi_filter_get_config` and `adc_digi_filter_enable` have been removed. These APIs behaviours are not guaranteed. Enum `adc_digi_filter_idx_t`, `adc_digi_filter_mode_t` and structure `adc_digi_iir_filter_t` have been removed as well.
- API `esp_adc_cal_characterize` has been deprecated, please migrate to `adc_cali_create_scheme_curve_fitting` or `adc_cali_create_scheme_line_fitting` instead.
- API `esp_adc_cal_raw_to_voltage` has been deprecated, please migrate to `adc_cali_raw_to_voltage` instead.
- API `esp_adc_cal_get_voltage` has been deprecated, please migrate to `adc_one_shot_get_calibrated_result` instead.

## GPIO

- The previous Kconfig option `RTCIO_SUPPORT_RTC_GPIO_DESC` has been removed, thus the `rtc_gpio_desc` array is unavailable. Please use `rtc_io_desc` array instead.
- The user callback of a GPIO interrupt should no longer read the GPIO interrupt status register to get the GPIO's pin number of triggering the interrupt. You should use the callback argument to determine the GPIO's pin number instead.
  - Previously, when a GPIO interrupt occurs, the GPIO's interrupt status register is cleared after calling the user callbacks. Thus, it was possible for users to read the GPIO's interrupt status register inside the callback to determine which GPIO was used to trigger the interrupt.
  - However, clearing the interrupt status register after calling the user callbacks can potentially cause edge-triggered interrupts to be lost. For example, if an edge-triggered interrupt (re)is triggered while the user callbacks are being called, that interrupt will be cleared without its registered user callback being handled.
  - Now, the GPIO's interrupt status register is cleared **before** invoking the user callbacks. Thus, users can no longer read the GPIO interrupt status register to determine which pin has triggered the interrupt. Instead, users should use the callback argument to pass the pin number.

**Sigma-Delta Modulator** The Sigma-Delta Modulator driver has been redesigned into *SDM*.

- The new driver implements a factory pattern, where the SDM channels are managed in a pool internally, thus users don't have to fix a SDM channel to a GPIO manually.
- All SDM channels can be allocated dynamically.

Although it's recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/sigmadelat.h`. However, by default, including `driver/sigmadelat.h` will trigger the build warning below. The warning can be suppressed by Kconfig option `CONFIG_SDM_SUPPRESS_DEPRECATED_WARN`.

The legacy sigma-delta driver is deprecated, please use `driver/sdm.h`

The major breaking changes in concept and usage are listed as follows:

### Breaking Changes in Concepts

- SDM channel representation has changed from `sigmadelta_channel_t` to `sdm_channel_handle_t`, which is an opaque pointer.
- SDM channel configurations are stored in `sdm_config_t` now, instead the previous `sigmadelta_config_t`.
- In the legacy driver, users don't have to set the clock source for SDM channel. But in the new driver, users need to set a proper one in the `sdm_config_t::clk_src`. The available clock sources are listed in the `soc_periph_sdm_clk_src_t`.

- In the legacy driver, users need to set a `prescale` for the channel, which reflects the frequency in which the modulator outputs a pulse. In the new driver, users should use `sdm_config_t::sample_rate_hz`.

### Breaking Changes in Usage

- Channel configuration was done by channel allocation, in `sdm_new_channel()`. In the new driver, only the duty can be changed at runtime, by `sdm_channel_set_duty()`. Other parameters like `gpio` number and `prescale` are only allowed to set during channel allocation.
- Before further channel operations, users should **enable** the channel in advance, by calling `sdm_channel_enable()`. This function will help to manage some system level services, like **Power Management**.

**Timer Group Driver** Timer Group driver has been redesigned into *GPTimer*, which aims to unify and simplify the usage of general purpose timer.

Although it's recommended to use the the new driver APIs, the legacy driver is still available in the previous include path `driver/timer.h`. However, by default, including `driver/timer.h` will trigger the build warning below. The warning can be suppressed by the Kconfig option `CONFIG_GPTIMER_SUPPRESS_DEPRECATED_WARN`.

```
legacy timer group driver is deprecated, please migrate to driver/gptimer.h
```

The major breaking changes in concept and usage are listed as follows:

### Breaking Changes in Concepts

- `timer_group_t` and `timer_idx_t` which used to identify the hardware timer are removed from user's code. In the new driver, a timer is represented by `gptimer_handle_t`.
- Definition of timer clock source is moved to `gptimer_clock_source_t`, the previous `timer_src_clk_t` is not used.
- Definition of timer count direction is moved to `gptimer_count_direction_t`, the previous `timer_count_dir_t` is not used.
- Only level interrupt is supported, `timer_intr_t` and `timer_intr_mode_t` are not used.
- Auto-reload is enabled by set the `gptimer_alarm_config_t::auto_reload_on_alarm` flag. `timer_autoreload_t` is not used.

### Breaking Changes in Usage

- Timer initialization is done by creating a timer instance from `gptimer_new_timer()`. Basic configurations like clock source, resolution and direction should be set in `gptimer_config_t`. Note that, specific configurations of alarm events are not needed during the installation stage of the driver.
- Alarm event is configured by `gptimer_set_alarm_action()`, with parameters set in the `gptimer_alarm_config_t`.
- Setting and getting count value are done by `gptimer_get_raw_count()` and `gptimer_set_raw_count()`. The driver doesn't help convert the raw value into UTC time-stamp. Instead, the conversion should be done from user's side as the timer resolution is also known to the user.
- The driver will install the interrupt service as well if `gptimer_event_callbacks_t::on_alarm` is set to a valid callback function. In the callback, users do not have to deal with the low level registers (like "clear interrupt status", "re-enable alarm event" and so on). So functions like `timer_group_get_intr_status_in_isr` and `timer_group_get_auto_reload_in_isr` are not used anymore.
- To update the alarm configurations when alarm event happens, one can call `gptimer_set_alarm_action()` in the interrupt callback, then the alarm will be re-enabled again.
- Alarm will always be re-enabled by the driver if `gptimer_alarm_config_t::auto_reload_on_alarm` is set to true.

## UART

Removed/Deprecated items	Replacement	Remarks
<code>uart_isr_register()</code>	None	UART interrupt handling is implemented by driver itself.
<code>uart_isr_free()</code>	None	UART interrupt handling is implemented by driver itself.
<code>use_ref_tick</code> in <code>uart_config_t</code>	<code>uart_config_t::source_clk</code>	Select the clock source.
<code>uart_enable_pattern_detection()</code>	<code>uart_enable_pattern_det_ba</code>	Enable pattern detection interrupt.

## I2C

Removed/Deprecated items	Replacement	Remarks
<code>i2c_isr_register()</code>	None	I2C interrupt handling is implemented by driver itself.
<code>i2c_isr_register()</code>	None	I2C interrupt handling is implemented by driver itself.
<code>i2c_opmode_t</code>	None	It' s not used anywhere in esp-idf.

## SPI

Removed/Deprecated items	Replacement	Remarks
<code>spi_cal_clock()</code>	<code>spi_get_actual_clock()</code>	Get SPI real working frequency.

- The internal header file `spi_common_internal.h` has been moved to `esp_private/spi_common_internal.h`.

## LEDC

Removed/Deprecated items	Replacement	Remarks
<code>bit_num</code> in <code>ledc_timer_config_t</code>	<code>ledc_timer_config_t::duty_resolution</code>	Set resolution of the duty cycle.

**Temperature Sensor Driver** The temperature sensor driver has been redesigned and it is recommended to use the new driver. However, the old driver is still available but cannot be used with the new driver simultaneously.

The new driver can be included via `driver/temperature_sensor.h`. The old driver is still available in the previous include path `driver/temp_sensor.h`. However, including `driver/temp_sensor.h` will trigger the build warning below by default. The warning can be suppressed by enabling the menuconfig option `CONFIG_TEMP_SENSOR_SUPPRESS_DEPRECATED_WARN`.

```
legacy temperature sensor driver is deprecated, please migrate to driver/
↳temperature_sensor.h
```

Configuration contents has been changed. In the old version, users need to configure `clk_div` and `dac_offset`. While in the new version, users only need to choose `tsens_range`.

The process of using temperature sensor has been changed. In the old version, users can use `config->start->read_celsius` to get value. In the new version, users should install the temperature sensor driver firstly, by `temperature_sensor_install` and `uninstall` it when finished. For more information, please refer to [Temperature Sensor](#).

**RMT Driver** RMT driver has been redesigned (see [RMT transceiver](#)), which aims to unify and extend the usage of RMT peripheral.

Although it' s recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/rmt.h`. However, including `driver/rmt.h` will trigger the build warning below by default. The warning can be suppressed by the Kconfig option `CONFIG_RMT_SUPPRESS_DEPRECATED_WARN`.

The legacy RMT driver is deprecated, please use `driver/rmt_tx.h` and/or `driver/rmt_↪rx.h`

The major breaking changes in concept and usage are listed as follows:

### Breaking Changes in Concepts

- `rmt_channel_t` which used to identify the hardware channel are removed from user space. In the new driver, RMT channel is represented by `rmt_channel_handle_t`. The channel is dynamically allocated by the driver, instead of designated by user.
- `rmt_item32_t` is replaced by `rmt_symbol_word_t`, which avoids a nested union inside a struct.
- `rmt_mem_t` is removed, as we don't allow users to access RMT memory block (a.k.a. an RMTMEM) directly. Direct access to RMTMEM doesn't make sense but make mistakes, especially when the RMT channel also connected with a DMA channel.
- `rmt_mem_owner_t` is removed, as the ownership is controlled by driver, not by user anymore.
- `rmt_source_clk_t` is replaced by `rmt_clock_source_t`, and note they're not binary compatible.
- `rmt_data_mode_t` is removed, the RMT memory access mode is configured to always use Non-FIFO and DMA mode.
- `rmt_mode_t` is removed, as the driver has stand alone install functions for TX and RX channels.
- `rmt_idle_level_t` is removed, setting IDLE level for TX channel is available in `rmt_transmit_config_t::eot_level`.
- `rmt_carrier_level_t` is removed, setting carrier polarity is available in `rmt_carrier_config_t::polarity_active_low`.
- `rmt_channel_status_t` and `rmt_channel_status_result_t` are removed, they're not used anywhere.
- Transmitting by RMT channel doesn't expect user to prepare the RMT symbols, instead, user needs to provide an RMT Encoder to tell the driver how to convert user data into RMT symbols.

### Breaking Changes in Usage

- Channel installation has been separated for TX and RX channels into `rmt_new_tx_channel()` and `rmt_new_rx_channel()`.
- `rmt_set_clk_div` and `rmt_get_clk_div` are removed. Channel clock configuration can only be done during channel installation.
- `rmt_set_rx_idle_thresh` and `rmt_get_rx_idle_thresh` are removed. In the new driver, the RX channel IDLE threshold is redesigned into a new concept `rmt_receive_config_t::signal_range_max_ns`.
- `rmt_set_mem_block_num` and `rmt_get_mem_block_num` are removed. In the new driver, the memory block number is determined by `rmt_tx_channel_config_t::mem_block_symbols` and `rmt_rx_channel_config_t::mem_block_symbols`.
- `rmt_set_tx_carrier` is removed, the new driver uses `rmt_apply_carrier()` to set carrier behavior.
- `rmt_set_mem_pd` and `rmt_get_mem_pd` are removed. The memory power is managed by the driver automatically.
- `rmt_memory_rw_rst`, `rmt_tx_memory_reset` and `rmt_rx_memory_reset` are removed. Memory reset is managed by the driver automatically.
- `rmt_tx_start` and `rmt_rx_start` are merged into a single function `rmt_enable()`, for both TX and RX channels.
- `rmt_tx_stop` and `rmt_rx_stop` are merged into a single function `rmt_disable()`, for both TX and RX channels.
- `rmt_set_memory_owner` and `rmt_get_memory_owner` are removed. RMT memory owner guard is added automatically by the driver.
- `rmt_set_tx_loop_mode` and `rmt_get_tx_loop_mode` are removed. In the new driver, the loop mode is configured in `rmt_transmit_config_t::loop_count`.
- `rmt_set_source_clk` and `rmt_get_source_clk` are removed. Configuring clock source is only possible during channel installation by `rmt_tx_channel_config_t::clk_src` and `rmt_rx_channel_config_t::clk_src`.

- `rmt_set_rx_filter` is removed. In the new driver, the filter threshold is redesigned into a new concept `rmt_receive_config_t::signal_range_min_ns`.
- `rmt_set_idle_level` and `rmt_get_idle_level` are removed. Setting IDLE level for TX channel is available in `rmt_transmit_config_t::eot_level`.
- `rmt_set_rx_intr_en`, `rmt_set_err_intr_en`, `rmt_set_tx_intr_en`, `rmt_set_tx_thr_intr_en` and `rmt_set_rx_thr_intr_en` are removed. The new driver doesn't allow user to turn on/off interrupt from user space. Instead, it provides callback functions.
- `rmt_set_gpio` and `rmt_set_pin` are removed. The new driver doesn't support to switch GPIO dynamically at runtime.
- `rmt_config` is removed. In the new driver, basic configuration is done during the channel installation stage.
- `rmt_isr_register` and `rmt_isr_deregister` are removed, the interrupt is allocated by the driver itself.
- `rmt_driver_install` is replaced by `rmt_new_tx_channel()` and `rmt_new_rx_channel()`.
- `rmt_driver_uninstall` is replaced by `rmt_del_channel()`.
- `rmt_fill_tx_items`, `rmt_write_items` and `rmt_write_sample` are removed. In the new driver, user needs to provide an encoder to "translate" the user data into RMT symbols.
- `rmt_get_counter_clock` is removed, as the channel clock resolution is configured by user from `rmt_tx_channel_config_t::resolution_hz`.
- `rmt_wait_tx_done` is replaced by `rmt_tx_wait_all_done()`.
- `rmt_translator_init`, `rmt_translator_set_context` and `rmt_translator_get_context` are removed. In the new driver, the translator has been replaced by the RMT encoder.
- `rmt_get_ringbuf_handle` is removed. The new driver doesn't use Ringbuffer to save RMT symbols. Instead, the incoming data are saved to the user provided buffer directly. The user buffer can even be mounted to DMA link internally.
- `rmt_register_tx_end_callback` is replaced by `rmt_tx_register_event_callbacks()`, where user can register `rmt_tx_event_callbacks_t::on_trans_done` event callback.
- `rmt_set_intr_enable_mask` and `rmt_clr_intr_enable_mask` are removed, as the interrupt is handled by the driver, user doesn't need to take care of it.
- `rmt_add_channel_to_group` and `rmt_remove_channel_from_group` are replaced by RMT sync manager. Please refer to `rmt_new_sync_manager()`.
- `rmt_set_tx_loop_count` is removed. The loop count in the new driver is configured in `rmt_transmit_config_t::loop_count`.
- `rmt_enable_tx_loop_autostop` is removed. In the new driver, TX loop auto stop is always enabled if available, it's not configurable anymore.

## LCD

- The LCD panel initialization flow is slightly changed. Now the `esp_lcd_panel_init()` won't turn on the display automatically. User needs to call `esp_lcd_panel_disp_on_off()` to manually turn on the display. Note, this is different from turning on backlight. With this breaking change, user can flash a predefined pattern to the screen before turning on the screen. This can help avoid random noise on the screen after a power on reset.
- `esp_lcd_panel_disp_off()` is deprecated, please use `esp_lcd_panel_disp_on_off()` instead.
- `dc_as_cmd_phase` is removed. The SPI LCD driver currently doesn't support a 9-bit SPI LCD. Please always use a dedicated GPIO to control the LCD D/C line.
- The way to register RGB panel event callbacks has been moved from the `esp_lcd_rgb_panel_config_t` into a separate API `esp_lcd_rgb_panel_register_event_callbacks()`. However, the event callback signature is not changed.
- Previous `relax_on_idle` flag in `esp_lcd_rgb_panel_config_t` has been renamed into `esp_lcd_rgb_panel_config_t::refresh_on_demand`, which expresses the same meaning but with a clear name.
- If the RGB LCD is created with the `refresh_on_demand` flag enabled, the driver will not start a refresh in the `esp_lcd_panel_draw_bitmap()`. Now users have to call `esp_lcd_rgb_panel_refresh()` to refresh the screen by themselves.
- `esp_lcd_color_space_t` is deprecated, please use `lcd_color_space_t` to describe the color

space, and use `lcd_rgb_element_order_t` to describe the data order of RGB color.

### Dedicated GPIO Driver

- All of the dedicated GPIO related Low Level (LL) functions in `cpu_ll.h` have been moved to `dedic_gpio_cpu_ll.h` and renamed.

**I2S driver** The I2S driver has been redesigned (see [I2S Driver](#)), which aims to rectify the shortcomings of the driver that were exposed when supporting all the new features of ESP32-C3 & ESP32-S3. The new driver's APIs are available by including corresponding I2S mode's header files `driver/include/driver/i2s_std.h`, `driver/include/driver/i2s_pdm.h`, or `driver/include/driver/i2s_tdm.h`.

Meanwhile, the old driver's APIs in `driver/deprecated/driver/i2s.h` are still supported for backward compatibility. But there will be warnings if users keep using the old APIs in their projects, these warnings can be suppressed by the Kconfig option `CONFIG_I2S_SUPPRESS_DEPRECATED_WARN`.

Here is the general overview of the current I2S files:

### Breaking changes in Concepts

**Independent TX/RX channels** The minimum control unit in new I2S driver are now individual TX/RX channels instead of an entire I2S controller (that consists of multiple channels).

- The TX and RX channels of the same I2S controller can be controlled separately, meaning that they are configured such that they can be started or stopped separately.
- The `c:type:i2s_chan_handle_t` handle type is used to uniquely identify I2S channels. All the APIs will require the channel handle and users need to maintain the channel handles by themselves.
- On the ESP32-C3 and ESP32-S3, TX and RX channels in the same controller can be configured to different clocks or modes.
- However, on the ESP32 and ESP32-S2, the TX and RX channels of the same controller still share some hardware resources. Thus, configurations may cause one channel to affect another channel in the same controller.
- The channels can be registered to an available I2S controller automatically by setting `i2s_port_t::I2S_NUM_AUTO` as I2S port ID which will cause the driver to search for the available TX/RX channels. However, the driver also supports registering channels to a specific port.
- In order to distinguish between TX/RX channels and sound channels, the term 'channel' in the context of the I2S driver will only refer to TX/RX channels. Meanwhile, sound channels will be referred to as "slots".

**I2S Mode Categorization** I2S communication modes are categorized into the following three modes. Note that:

- **Standard mode:** Standard mode always has two slots, it can support Philips, MSB, and PCM (short frame sync) formats. Please refer to [driver/include/driver/i2s\\_std.h](#) for more details.
- **PDM mode:** PDM mode only supports two slots with 16-bit data width, but the configurations of PDM TX and PDM RX are slightly different. For PDM TX, the sample rate can be set by `i2s_pdm_tx_clk_config_t::sample_rate`, and its clock frequency depends on the up-sampling configuration. For PDM RX, the sample rate can be set by `i2s_pdm_rx_clk_config_t::sample_rate`, and its clock frequency depends on the down-sampling configuration. Please refer to [driver/include/driver/i2s\\_pdm.h](#) for details.
- **TDM mode:** TDM mode can support up to 16 slots. It can work in Philips, MSB, PCM (short frame sync), and PCM (long frame sync) formats. Please refer to [driver/include/driver/i2s\\_tdm.h](#) for details.

When allocating a new channel in a specific mode, users should initialize that channel by its corresponding function. It is strongly recommended to use the helper macros to generate the default configurations in case the default values are changed in the future.

**Independent Slot and Clock Configuration** The slot configurations and clock configurations can be configured separately.

- Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()`, or `i2s_channel_init_tdm_mode()` to initialize the slot/clock/gpio\_pin configurations.
- Calling `i2s_channel_reconfig_std_slot()`, `i2s_channel_reconfig_pdm_rx_slot()`, `i2s_channel_reconfig_pdm_tx_slot()`, or `i2s_channel_reconfig_tdm_slot()` can change the slot configurations after initialization.
- Calling `i2s_channel_reconfig_std_clock()`, `i2s_channel_reconfig_pdm_rx_clock()`, `i2s_channel_reconfig_pdm_tx_clock()`, or `i2s_channel_reconfig_tdm_clock()` can change the clock configurations after initialization.
- Calling `i2s_channel_reconfig_std_gpio()`, `i2s_channel_reconfig_pdm_rx_gpio()`, `i2s_channel_reconfig_pdm_tx_gpio()`, or `i2s_channel_reconfig_tdm_gpio()` can change the GPIO configurations after initialization.

### Misc

- States and state-machine are adopted in the new I2S driver to avoid APIs called in wrong state.
- ADC and DAC modes are removed. They will only be supported in their own drivers and the legacy I2S driver.

**Breaking Changes in Usage** To use the new I2S driver, please follow these steps:

1. Call `i2s_new_channel()` to acquire channel handles. We should specify the work role and I2S port in this step. Besides, the TX or RX channel handle will be generated by the driver. Inputting both two TX and RX channel handles is not necessary but at least one handle is needed. In the case of inputting both two handles, the driver will work at the duplex mode. Both TX and RX channels will be available on a same port, and they will share the MCLK, BCLK and WS signal. But if only one of the TX or RX channel handle is inputted, this channel will only work in the simplex mode.
2. Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()` or `i2s_channel_init_tdm_mode()` to initialize the channel to the specified mode. Corresponding slot, clock and GPIO configurations are needed in this step.
3. (Optional) Call `i2s_channel_register_event_callback()` to register the ISR event callback functions. I2S events now can be received by the callback function synchronously, instead of from the event queue asynchronously.
4. Call `i2s_channel_enable()` to start the hardware of I2S channel. In the new driver, I2S won't start automatically after installed, and users are supposed to know clearly whether the channel has started or not.
5. Read or write data by `i2s_channel_read()` or `i2s_channel_write()`. Certainly, only the RX channel handle is supposed to be inputted in `i2s_channel_read()` and the TX channel handle in `i2s_channel_write()`.
6. (Optional) The slot, clock and GPIO configurations can be changed by corresponding 'reconfig' functions, but `i2s_channel_disable()` must be called before updating the configurations.

7. Call `i2s_channel_disable()` to stop the hardware of I2S channel.
8. Call `i2s_del_channel()` to delete and release the resources of the channel if it is not needed any more, but the channel must be disabled before deleting it.

**TWAI Driver** The deprecated CAN peripheral driver is removed. Please use TWAI driver instead (i.e. include `driver/twai.h` in your application).

**Register Access Macros** Previously, all register access macros could be used as expressions, so the following was allowed:

```
uint32_t val = REG_SET_BITS(reg, mask);
```

In ESP-IDF v5.0, register access macros which write or read-modify-write the register can no longer be used as expressions, and can only be used as statements. This applies to the following macros: `REG_WRITE`, `REG_SET_BIT`, `REG_CLR_BIT`, `REG_SET_BITS`, `REG_SET_FIELD`, `WRITE_PERI_REG`, `CLEAR_PERI_REG_MASK`, `SET_PERI_REG_MASK`, `SET_PERI_REG_BITS`.

To store the value which would have been written into the register, split the operation as follows:

```
uint32_t new_val = REG_READ(reg) | mask;
REG_WRITE(reg, new_val);
```

To get the value of the register after modification (which may be different from the value written), add an explicit read:

```
REG_SET_BITS(reg, mask);
uint32_t new_val = REG_READ(reg);
```

## Protocols

**Mbed TLS** For ESP-IDF v5.0, [Mbed TLS](#) has been updated from v2.x to v3.1.0.

For more details about Mbed TLS' s migration from version 2.x to version 3.0 or greater, please refer to the [official guide](#).

## Breaking Changes (Summary)

### Most structure fields are now private

- Direct access to fields of structures (`struct` types) declared in public headers is no longer supported.
- Appropriate accessor functions (getter/setter) must be used for the same. A temporary workaround would be to use `MBEDTLS_PRIVATE` macro (**not recommended**).
- For more details, refer to the [official guide](#).

## SSL

- Removed support for TLS 1.0, 1.1, and DTLS 1.0
- Removed support for SSL 3.0

## Deprecated Functions Were Removed from Cryptography Modules

- The functions `mbedtls*_ret()` (related to MD, SHA, RIPEMD, RNG, HMAC modules) was renamed to replace the corresponding functions without `_ret` appended and updated return value.
- For more details, refer to the [official guide](#).

**Deprecated Config Options** Following are some of the important config options deprecated by this update. The configs related to and/or dependent on these have also been deprecated.

- `MBEDTLS_SSL_PROTO_SSL3` : Support for SSL 3.0
- `MBEDTLS_SSL_PROTO_TLS1` : Support for TLS 1.0
- `MBEDTLS_SSL_PROTO_TLS1_1` : Support for TLS 1.1
- `MBEDTLS_SSL_PROTO_DTLS` : Support for DTLS 1.1 (Only DTLS 1.2 is supported now)
- `MBEDTLS_DES_C` : Support for 3DES ciphersuites
- `MBEDTLS_RC4_MODE` : Support for RC4-based ciphersuites

---

**Note:** This list includes only major options configurable through `idf.py menuconfig`. For more details on deprecated options, refer to the [official guide](#).

---

## Miscellaneous

**Disabled Diffie-Hellman Key Exchange Modes** The Diffie-Hellman Key Exchange modes have now been disabled by default due to security risks (see warning text [here](#)). Related configs are given below:

- `MBEDTLS_DHM_C` : Support for the Diffie-Hellman-Merkle module
- `MBEDTLS_KEY_EXCHANGE_DHE_PSK` : Support for Diffie-Hellman PSK (pre-shared-key) TLS authentication modes
- `MBEDTLS_KEY_EXCHANGE_DHE_RSA` : Support for cipher suites with the prefix `TLS-DHE-RSA-WITH-`

---

**Note:** During the initial step of the handshake (i.e. `client_hello`), the server selects a cipher from the list that the client publishes. As the `DHE_PSK/DHE_RSA` ciphers have now been disabled by the above change, the server would fall back to an alternative cipher; if in a rare case, it does not support any other cipher, the handshake would fail. To retrieve the list of ciphers supported by the server, one must attempt to connect with the server with a specific cipher from the client-side. Few utilities can help do this, e.g. `sslsan`.

---

## Remove `certs` Module from X509 Library

- The `mbdtdls/certs.h` header is no longer available in `mbdtdls 3.1`. Most applications can safely remove it from the list of includes.

## Breaking Change for `esp_crt_bundle_set` API

- The `esp_crt_bundle_set()` API now requires one additional argument named `bundle_size`. The return type of the API has also been changed to `esp_err_t` from `void`.

## Breaking Change for `esp_ds_rsa_sign` API

- The `esp_ds_rsa_sign()` API now requires one less argument. The argument `mode` is no longer required.

## HTTPS Server

**Breaking Changes (Summary)** Names of variables holding different certs in `httpd_ssl_config_t` structure have been updated.

- `httpd_ssl_config::servercert` variable inherits role of `cacert_pem` variable.
- `httpd_ssl_config::servercert_len` variable inherits role of `cacert_len` variable
- `httpd_ssl_config::cacert_pem` variable inherits role of `client_verify_cert_pem` variable

- `httpd_ssl_config::cacert_len` variable inherits role of `client_verify_cert_len` variable

The return type of the `httpd_ssl_stop()` API has been changed to `esp_err_t` from `void`.

## ESP HTTPS OTA

### Breaking Changes (Summary)

- The function `esp_https_ota()` now requires pointer to `esp_https_ota_config_t` as argument instead of pointer to `esp_http_client_config_t`.

## ESP-TLS

### Breaking Changes (Summary)

**esp\_tls\_t Structure is Now Private** The `esp_tls_t` has now been made completely private. You cannot access its internal structures directly. Any necessary data that needs to be obtained from the ESP-TLS handle can be done through respective getter/setter functions. If there is a requirement of a specific getter/setter function, please raise an [issue](#) on ESP-IDF.

The list of newly added getter/setter function is as follows:

- `esp_tls_get_ssl_context()` - Obtain the ssl context of the underlying ssl stack from the ESP-TLS handle.

**Function Deprecations And Recommended Alternatives** Following table summarizes the deprecated functions removed and their alternatives to be used from ESP-IDF v5.0 onwards.

Deprecated Function	Alternative
<code>esp_tls_conn_new()</code>	<code>esp_tls_conn_new_sync()</code>
<code>esp_tls_conn_delete()</code>	<code>esp_tls_conn_destroy()</code>

- The function `esp_tls_conn_http_new()` has now been termed as deprecated. Please use the alternative function `esp_tls_conn_http_new_sync()` (or its asynchronous `esp_tls_conn_http_new_async()`). Note that the alternatives need an additional parameter `esp_tls_t`, which has to be initialized using the `esp_tls_init()` function.

## HTTP Server

### Breaking Changes (Summary)

- `http_server.h` header is no longer available in `esp_http_server`. Please use `esp_http_server.h` instead.

## ESP HTTP Client

### Breaking Changes (Summary)

- The functions `esp_http_client_read()` and `esp_http_client_fetch_headers()` now return an additional return value `-ESP_ERR_HTTP_EAGAIN` for timeout errors - call timed-out before any data was ready.

## TCP Transport

### Breaking Changes (Summary)

- The function `esp_transport_read()` now returns 0 for a connection timeout and < 0 for other errors. Please refer `esp_tcp_transport_err_t` for all possible return values.

## MQTT Client

### Breaking Changes (Summary)

- `esp_mqtt_client_config_t` have all fields grouped in sub structs.

Most common configurations are listed below:

- Broker address now is set in `esp_mqtt_client_config_t::broker::address::uri`
- Security related to broker verification in `esp_mqtt_client_config_t::broker::verification`
- Client username is set in `esp_mqtt_client_config_t::credentials::username`
- `esp_mqtt_client_config_t` no longer supports the `user_context` field. Please use `esp_mqtt_client_register_event()` instead for registering an event handler; the last argument `event_handler_arg` can be used to pass user context to the handler.

## ESP-Modbus

**Breaking Changes (Summary)** The ESP-IDF component `freemodbus` has been removed from ESP-IDF and is supported as a separate component. Additional information for the ESP-Modbus component can be found in the separate repository:

- [ESP-Modbus component on GitHub](#)

The main component folder of the new application shall include the component manager manifest file `idf_component.yml` as in the example below:

```
dependencies:
  espressif/esp-modbus:
    version: "^1.0"
```

The `esp-modbus` component can be found in [component manager registry](#). Refer to [component manager documentation](#) for more information on how to set up the component manager.

For applications targeting v4.x releases of ESP-IDF that need to use new `esp-modbus` component, adding the component manager manifest file `idf_component.yml` will be sufficient to pull in the new component. However, users should also exclude the legacy `freemodbus` component from the build. This can be achieved using the statement below in the project's `CMakeLists.txt`:

```
set(EXCLUDE_COMPONENTS freemodbus)
```

## Provisioning

**Protocomm** The `pop` field in the `protocomm_set_security()` API is now deprecated. Please use the `sec_params` field instead of `pop`. This parameter should contain the structure (including the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` parameter should contain the pointer to the structure of type `protocomm_security2_params_t`.

### Wi-Fi Provisioning

- The `pop` field in the `wifi_prov_mgr_start_provisioning()` API is now deprecated. For backward compatibility, `pop` can be still passed as a string for security1. However for Security2 the `wifi_prov_sec_params` argument needs to be passed instead of `pop`. This parameter should contain the structure (containing the security parameters) as required by the protocol version used. For example, when using security version 2, the `wifi_prov_sec_params` parameter should contain the pointer to the structure of type `wifi_prov_security2_params_t`. For security 1 the behaviour and the usage of the API remains same.
- The API `wifi_prov_mgr_is_provisioned()` does not return `ESP_ERR_INVALID_STATE` error any more. This API now works without any dependency on provisioning manager initialization state.

**ESP Local Control** The `pop` field in the `esp_local_ctrl_proto_sec_cfg_t` API is now deprecated. Please use the `sec_params` field instead of `pop`. This field should contain the structure (containing the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` field should contain pointer to the structure of type `esp_local_ctrl_security2_params_t`.

### Removed or Deprecated Components

**Components Moved to IDF Component Registry** Following components are removed from ESP-IDF and moved to IDF Component Registry:

- `libsodium`
- `cbor`
- `jsmn`
- `esp_modem`
- `nghttp`
- `mdns`
- `esp_websocket_client`
- `asio`
- `freemodbus`
- `sh2lib`
- `expat`
- `coap`
- `esp-cryptoauthlib`
- `qrcode`
- `tjpgd`
- `esp_serial_slave_link`
- `tinycbor`

---

**Note:** Please note that http parser functionality which was previously part of `nghttp` component is now part of `http_parser` component.

---

These components can be installed using `idf.py add-dependency` command.

For example, to install `libsodium` component with the exact version X.Y, run `idf.py add-dependency libsodium==X.Y`.

To install `libsodium` component with the latest version compatible to X.Y according to [semver](#) rules, run `idf.py add-dependency libsodium~X.Y`.

To find out which versions of each component are available, open <https://components.espressif.com>, search for the component by its name and check the versions listed on the component page.

**Deprecated Components** The following components are removed since they were deprecated in IDF v4.x:

- `tcpip_adapter`. Please use the *ESP-NETIF* component instead; you can follow the *TCP/IP Adapter*.

---

**Note:** OpenSSL-API component is no longer supported. It is not available in the IDF Component Registry, either. Please use *ESP-TLS* or *MBEDTLS* API directly.

---

The targets components are no longer necessary after refactoring and have been removed:

- `esp32`
- `esp32s2`
- `esp32s3`
- `esp32c2`
- `esp32c3`
- `esp32h2`

## Storage

**New Component for the Partition APIs** Breaking change: all the Partition API code has been moved to a new component `esp_partition`. For the complete list of affected functions and data-types, see header file `esp_partition.h`.

These API functions and data-types were previously a part of the `spi_flash` component, and thus possible dependencies on the `spi_flash` in existing applications may cause the build failure, in case of direct `esp_partition_*` APIs/data-types use (for instance, fatal error: `esp_partition.h: No such file or directory` at lines with `#include "esp_partition.h"`). If you encounter such an issue, please update your project's `CMakeLists.txt` file as follows:

Original dependency setup:

```
idf_component_register(...
                        REQUIRES spi_flash)
```

Updated dependency setup:

```
idf_component_register(...
                        REQUIRES spi_flash esp_partition)
```

---

**Note:** Please update relevant `REQUIRES` or `PRIV_REQUIRES` section according to your project. The above-presented code snippet is just an example.

---

If the issue persists, please let us know and we will assist you with your code migration.

**SDMMC/SDSPI** SD card frequency on SDMMC/SDSPI interface can be now configured through `sdmmc_host_t.max_freq_khz` to a specific value, not only `SDMMC_FREQ_PROBING` (400 kHz), `SDMMC_FREQ_DEFAULT` (20 MHz), or `SDMMC_FREQ_HIGHSPEED` (40 MHz). Previously, in case you have specified a custom frequency other than any of the above-mentioned values, the closest lower-or-equal one was selected anyway.

Now, the underlying drivers calculate the nearest fitting value, given by available frequency dividers instead of an enumeration item selection. This could cause troubles in communication with your SD card without a change of the existing application code. If you encounter such an issue, please, keep trying different frequencies around your desired value unless you find the one working well. To check the frequency value calculated and actually applied, use `void sdmmc_card_print_info(FILE* stream, const sdmmc_card_t* card)` function.

**FatFs** FatFs is now updated to v0.14. As a result, the function signature of `f_mkfs()` has changed. The new signature is `FRESULT f_mkfs(const TCHAR* path, const MKFS_PARM* opt, void* work, UINT len);` which uses `MKFS_PARM` struct as a second argument.

**Partition Table** The partition table generator no longer supports misaligned partitions. When generating a partition table, ESP-IDF only accepts partitions with offsets that align to 4 KB. This change only affects generating new partition tables. Reading and writing to already existing partitions remains unchanged.

**VFS** The `esp_vfs_semihost_register()` function signature is changed as follows:

- The new signature is `esp_err_t esp_vfs_semihost_register(const char* base_path);`
- The `host_path` parameter of the old signature no longer exists. Instead, the OpenOCD command `ESP_SEMIHOST_BASEDIR` should be used to set the full path on the host.

**Function Signature Changes** The following functions now return `esp_err_t` instead of `void` or `nvs_iterator_t`. Previously, when parameters were invalid or when something goes wrong internally, these functions would `assert()` or return a `nullptr`. With an `esp_err_t` returned, you can get better error reporting.

- `nvs_entry_find()`
- `nvs_entry_next()`
- `nvs_entry_info()`

Because the `esp_err_t` return type changes, the usage patterns of `nvs_entry_find()` and `nvs_entry_next()` become different. Both functions now modify iterators via parameters instead of returning an iterator.

The old programming pattern to iterate over an NVS partition was as follows:

```
nvs_iterator_t it = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_
↳ANY);
while (it != NULL) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info);
    it = nvs_entry_next(it);
    printf("key '%s', type '%d'", info.key, info.type);
};
```

The new programming pattern to iterate over an NVS partition is now:

```
nvs_iterator_t it = nullptr;
esp_err_t res = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY, &
↳it);
while(res == ESP_OK) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info); // Can omit error check if parameters are_
↳guaranteed to be non-NULL
    printf("key '%s', type '%d'", info.key, info.type);
    res = nvs_entry_next(&it);
}
nvs_release_iterator(it);
```

**Iterator Validity** Note that because the function signature changes, if there is a parameter error, you may get an invalid iterator from `nvs_entry_find()`. Hence, it is important to initialize the iterator to `NULL` before using `nvs_entry_find()`, so that you can avoid complex error checking before calling `nvs_release_iterator()`. A good example is the programming pattern above.

**Removed SDSPI Deprecated API Structure** `sdspi_slot_config_t` and function `sdspi_host_init_slot()` are removed, and replaced by structure `sdspi_device_config_t` and function `sdspi_host_init_device()` respectively.

**ROM SPI Flash** In versions before v5.0, ROM SPI flash functions were included via `esp32**/rom/spi_flash.h`. Thus, code written to support different ESP chips might be filled with ROM headers of different targets. Furthermore, not all of the APIs could be used on all ESP chips.

Now, the common APIs are extracted to `esp_rom_spiflash.h`. Although it is not a breaking change, you are strongly recommended to only use the functions from this header (i.e., prefixed with `esp_rom_spiflash` and included by `esp_rom_spiflash.h`) for better cross-compatibility between ESP chips.

To make ROM SPI flash APIs clearer, the following functions are also renamed:

- `esp_rom_spiflash_lock()` to `esp_rom_spiflash_set_bp()`
- `esp_rom_spiflash_unlock()` to `esp_rom_spiflash_clear_bp()`

**SPI Flash Driver** The `esp_flash_speed_t` enum type is now deprecated. Instead, you may now directly pass the real clock frequency value to the flash configuration structure. The following example demonstrates how to configure a flash frequency of 80MHz:

```
esp_flash_spi_device_config_t dev_cfg = {
    // Other members
    .freq_mhz = 80,
    // Other members
};
```

**Legacy SPI Flash Driver** To make SPI flash drivers more stable, the legacy SPI flash driver is removed from v5.0. The legacy SPI flash driver refers to default `spi_flash` driver since v3.0, and the SPI flash driver with configuration option `CONFIG_SPI_FLASH_USE_LEGACY_IMPL` enabled since v4.0. The major breaking change here is that the legacy `spi_flash` driver is no longer supported from v5.0. Therefore, the legacy driver APIs and the `CONFIG_SPI_FLASH_USE_LEGACY_IMPL` configuration option are both removed. Please use the new `spi_flash` driver's APIs instead.

Removed items	Replacement
<code>spi_flash_erase_sector()</code>	<code>esp_flash_erase_region()</code>
<code>spi_flash_erase_range()</code>	<code>esp_flash_erase_region()</code>
<code>spi_flash_write()</code>	<code>esp_flash_write()</code>
<code>spi_flash_read()</code>	<code>esp_flash_read()</code>
<code>spi_flash_write_encrypted()</code>	<code>esp_flash_write_encrypted()</code>
<code>spi_flash_read_encrypted()</code>	<code>esp_flash_read_encrypted()</code>

**Note:** New functions with prefix `esp_flash` accept an additional `esp_flash_t*` parameter. You can simply set it to `NULL`. This will make the function to run the main flash (`esp_flash_default_chip`).

The `esp_spi_flash.h` header is deprecated as system functions are no longer public. To use flash memory mapping APIs, you may include `spi_flash_mmap.h` instead.

## System

**Inter-Processor Call** IPC (Inter-Processor Call) feature is no longer a stand-alone component and has been integrated into the `esp_system` component.

Thus, any project presenting a `CMakeLists.txt` file with the parameters `PRIV_REQUIRES esp_ipc` or `REQUIRES esp_ipc` should be modified to simply remove these options as the `esp_system` component is included by default.

**ESP Clock** The ESP Clock API (functions/types/macros prefixed with `esp_clk`) has been made into a private API. Thus, the previous include paths `#include "ESP32-C3/clk.h"` and `#include "esp_clk.h"` have been removed. If users still require usage of the ESP Clock API (though this is not recommended), it can be included via `#include "esp_private/esp_clk.h"`.

---

**Note:** Private APIs are not stable and no are longer subject to the ESP-IDF versioning scheme's breaking change rules. Thus, it is not recommended for users to continue calling private APIs in their applications.

---

**Cache Error Interrupt** The Cache Error Interrupt API (functions/types/macros prefixed with `esp_cache_err`) has been made into a private API. Thus, the previous include path `#include "ESP32-C3/cache_err_int.h"` has been removed. If users still require usage of the Cache Error Interrupt API (though this is not recommended), it can be included via `#include "esp_private/cache_err_int.h"`.

### bootloader\_support

- The function `bootloader_common_get_reset_reason()` has been removed. Please use the function `esp_rom_get_reset_reason()` in the ROM component.
- The functions `esp_secure_boot_verify_sbv2_signature_block()` and `esp_secure_boot_verify_rsa_signature_block()` have been removed without replacement. We do not expect users to use these directly. If they are indeed still necessary, please open a feature request on [GitHub](#) explaining why these functions are necessary to you.

**Brownout** The Brownout API (functions/types/macros prefixed with `esp_brownout`) has been made into a private API. Thus, the previous include path `#include "brownout.h"` has been removed. If users still require usage of the Brownout API (though this is not recommended), it can be included via `#include "esp_private/brownout.h"`.

**Trax** The Trax API (functions/types/macros prefixed with `trax_`) has been made into a private API. Thus, the previous include path `#include "trax.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/trax.h"`.

**ROM** The previously deprecated ROM-related header files located in `components/esp32/rom/` (old include path: `rom/*.h`) have been moved. Please use the new target-specific path from `components/esp_rom/include/ESP32-C3/` (new include path: `ESP32-C3/rom/*.h`).

### esp\_hw\_support

- The header files `soc/cpu.h` have been deleted and deprecated CPU util functions have been removed. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header files `hal/cpu_ll.h`, `hal/cpu_hal.h`, `hal/soc_ll.h`, `hal/soc_hal.h` and `interrupt_controller_hal.h` CPU API functions have been deprecated. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header file `compare_set.h` have been deleted. ESP-IDF developers should use `esp_cpu_compare_and_set()` function provided in `esp_cpu.h` instead.
- `esp_cpu_get_ccount()`, `esp_cpu_set_ccount()` and `esp_cpu_in_ocr_debug_mode()` were removed from `esp_cpu.h`. ESP-IDF developers should use respectively `esp_cpu_get_cycle_count()`, `esp_cpu_set_cycle_count()` and `esp_cpu_dbggr_is_attached()` instead.
- The header file `esp_intr.h` has been deleted. Please include `esp_intr_alloc.h` to allocate and manipulate interrupts.
- The Panic API (functions/types/macros prefixed with `esp_panic`) has been made into a private API. Thus, the previous include path `#include "esp_panic.h"` has been removed. If users still require usage

of the Trax API (though this is not recommended), it can be included via `#include "esp_private/panic_reason.h"`. Besides, developers should include `esp_debug_helpers.h` instead to use any debug-related helper functions, e.g., `print_backtrace`.

- The header file `soc_log.h` is now renamed to `esp_hw_log.h` and has been made private. Users are encouraged to use logging APIs provided under `esp_log.h` instead.
- The header files `spinlock.h`, `clk_ctrl_os.h`, and `rtc_wdt.h` must now be included without the `soc` prefix. For example, `#include "spinlock.h"`.
- `esp_chip_info()` returns the chip version in the format `= 100 * major eFuse version + minor eFuse version`. Thus, the revision in the `esp_chip_info_t` structure is expanded to `uint16_t` to fit the new format.

## PSRAM

- The target-specific header file `spiram.h` and the header file `esp_spiram.h` have been removed. A new component `esp_psram` is created instead. For PSRAM/SPIRAM-related functions, users now include `esp_psram.h` and set the `esp_psram` component as a component requirement in their `CMakeLists.txt` project files.
- `esp_spiram_get_chip_size` and `esp_spiram_get_size` have been deleted. You should use `esp_psram_get_size` instead.

## eFuse

- The parameter type of function `esp_secure_boot_read_key_digests()` changed from `ets_secure_boot_key_digests_t*` to `esp_secure_boot_key_digests_t*`. The new type is the same as the old one, except that the `allow_key_revoke` flag has been removed. The latter was always set to `true` in current code, not providing additional information.
- Added eFuse wafer revisions: `major` and `minor`. The `esp_efuse_get_chip_ver()` API is not compatible with these changes, so it was removed. Instead, please use the following APIs: `efuse_hal_get_major_chip_version()`, `efuse_hal_get_minor_chip_version()` or `efuse_hal_chip_revision()`.

**esp\_common** `EXT_RAM_ATTR` is deprecated. Use the new macro `EXT_RAM_BSS_ATTR` to put `.bss` on PSRAM.

## esp\_system

- The header files `esp_random.h`, `esp_mac.h`, and `esp_chip_info.h`, which were all previously indirectly included via the header file `esp_system.h`, must now be included directly. These indirect inclusions from `esp_system.h` have been removed.
- The Backtrace Parser API (functions/types/macros prefixed with `esp_ah_frame_`) has been made into a private API. Thus, the previous include path `#include "eh_frame_parser.h"` has been removed. If users still require usage of the Backtrace Parser API (though this is not recommended), it can be included via `#include "esp_private/eh_frame_parser.h"`.
- The Interrupt Watchdog API (functions/types/macros prefixed with `esp_int_wdt_`) has been made into a private API. Thus, the previous include path `#include "esp_int_wdt.h"` has been removed. If users still require usage of the Interrupt Watchdog API (though this is not recommended), it can be included via `#include "esp_private/esp_int_wdt.h"`.

## SOC Dependency

- Public API headers listed in the Doxyfiles will not expose unstable and unnecessary soc header files, such as `soc/soc.h` and `soc/rtc.h`. That means the user has to explicitly include them in their code if these “missing” header files are still wanted.
- Kconfig option `LEGACY_INCLUDE_COMMON_HEADERS` is also removed.
- The header file `soc/soc_memory_types.h` has been deprecated. Users should use the `esp_memory_utils.h` instead. Including `soc/soc_memory_types.h` will bring a build warning like `soc_memory_types.h is deprecated, please migrate to esp_memory_utils.h`

**APP Trace** One of the timestamp sources has changed from the legacy timer group driver to the new *GPTimer*. Kconfig choices like `APPTRACE_SV_TS_SOURCE_TIMER00` has been changed to `APPTRACE_SV_TS_SOURCE_GPTIMER`. User no longer need to choose the group and timer ID.

**esp\_timer** The FRC2-based legacy implementation of `esp_timer` available on ESP32 has been removed. The simpler and more efficient implementation based on the LAC timer is now the only option.

**ESP Image** The image SPI speed enum definitions have been renamed.

- Enum `ESP_IMAGE_SPI_SPEED_80M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_1`.
- Enum `ESP_IMAGE_SPI_SPEED_40M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_2`.
- Enum `ESP_IMAGE_SPI_SPEED_26M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_3`.
- Enum `ESP_IMAGE_SPI_SPEED_20M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_4`.

### Task Watchdog Timers

- The API for `esp_task_wdt_init()` has changed as follows:
  - Configuration is now passed as a configuration structure.
  - The function will now handle subscribing of the idle tasks if configured to do so.
- The former `CONFIG_ESP_TASK_WDT` configuration option has been renamed to `CONFIG_ESP_TASK_WDT_INIT` and a new `CONFIG_ESP_TASK_WDT_EN` option has been introduced.

### FreeRTOS

**Legacy API and Data Types** Previously, the `configENABLE_BACKWARD_COMPATIBILITY` option was set by default, thus allowing pre FreeRTOS v8.0.0 function names and data types to be used. The `configENABLE_BACKWARD_COMPATIBILITY` is now disabled by default, thus legacy FreeRTOS names/types are no longer supported by default. Users should do one of the followings:

- Update their code to remove usage of legacy FreeRTOS names/types.
- Enable the `CONFIG_FREERTOS_ENABLE_BACKWARD_COMPATIBILITY` to explicitly allow the usage of legacy names/types.

**Tasks Snapshot** The header `task_snapshot.h` has been removed from `freertos/task.h`. ESP-IDF developers should include `freertos/task_snapshot.h` if they need tasks snapshot API.

The function `vTaskGetSnapshot()` now returns  `BaseType_t` . Return value shall be `pdTRUE` on success and `pdFALSE` otherwise.

**FreeRTOS Asserts** Previously, FreeRTOS asserts were configured separately from the rest of the system using the `FREERTOS_ASSERT` kconfig option. This option has now been removed and the configuration is now done through `COMPILER_OPTIMIZATION_ASSERTION_LEVEL`.

**Port Macro API** The file `portmacro_deprecated.h` which was added to maintain backward compatibility for deprecated APIs is removed. Users are advised to use the alternate functions for the deprecated APIs as listed below:

- `portENTER_CRITICAL_NESTED()` is removed. Users should use the `portSET_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `portEXIT_CRITICAL_NESTED()` is removed. Users should use the `portCLEAR_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `vPortCPUInitializeMutex()` is removed. Users should use the `spinlock_initialize()` function instead.
- `vPortCPUAcquireMutex()` is removed. Users should use the `spinlock_acquire()` function instead.

- `vPortCPUAcquireMutexTimeout()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUReleaseMutex()` is removed. Users should use the `spinlock_release()` function instead.

### App Update

- The functions `esp_ota_get_app_description()` and `esp_ota_get_app_elf_sha256()` have been termed as deprecated. Please use the alternative functions `esp_app_get_description()` and `esp_app_get_elf_sha256()` respectively. These functions have now been moved to a new component `esp_app_format`. (Refer header file `esp_app_desc.h`)

### Bootloader Support

- The `esp_app_desc_t` structure, which used to be declared in `esp_app_format.h`, is now declared in `esp_app_desc.h`.
- The function `bootloader_common_get_partition_description()` has now been made private. Please use the alternative function `esp_ota_get_partition_description()`. Note that this function takes `esp_partition_t` as its first argument instead of `esp_partition_pos_t`.

**Chip Revision** The bootloader checks the chip revision at the beginning of the application loading. The application can only be loaded if the version is  $\geq$  `CONFIG_ESP32C3_REV_MIN` and  $<$  `CONFIG_ESP32C3_REV_MAX_FULL`.

During the OTA upgrade, the version requirements and chip revision in the application header are checked for compatibility. The application can only be updated if the version is  $\geq$  `CONFIG_ESP32C3_REV_MIN` and  $<$  `CONFIG_ESP32C3_REV_MAX_FULL`.

### Tools

**IDF Monitor** IDF Monitor makes the following changes regarding baud-rate:

- IDF monitor now uses the custom console baud-rate (`CONFIG_ESP_CONSOLE_UART_BAUDRATE`) by default instead of 115200.
- Setting a custom baud from menuconfig is no longer supported.
- A custom baud-rate can be specified from command line with the `idf.py monitor -b <baud>` command or through setting environment variables.
- Please note that the baud-rate argument has been renamed from `-B` to `-b` in order to be consistent with the global baud-rate `idf.py -b <baud>`. Run `idf.py monitor --help` for more information.

**Deprecated Commands** `idf.py` sub-commands and `cmake` target names have been unified to use hyphens (-) instead of underscores (\_). Using a deprecated sub-command or target name will produce a warning. Users are advised to migrate to using the new sub-commands and target names. The following changes have been made:

Table 1: Deprecated Sub-command and Target Names

Old Name	New Name
efuse_common_table	efuse-common-table
efuse_custom_table	efuse-custom-table
erase_flash	erase-flash
partition_table	partition-table
partition_table-flash	partition-table-flash
post_debug	post-debug
show_efuse_table	show-efuse-table
erase_otadata	erase-otadata
read_otadata	read-otadata

**Esptool** The `CONFIG_ESPTOOLPY_FLASHSIZE_DETECT` option has been renamed to `CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE` and has been disabled by default. New and existing projects migrated to ESP-IDF v5.0 will have to set `CONFIG_ESPTOOLPY_FLASHSIZE`. If this is not possible due to an unknown flash size at build time, then `CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE` can be enabled. However, once enabled, to keep the digest valid, a SHA256 digest will no longer be appended to the image when updating the binary header with the flash size during flashing.

**Windows Environment** The Msys/Mingw-based Windows environment support got deprecated in ESP-IDF v4.0 and was entirely removed in v5.0. Please use *ESP-IDF Tools Installer* to set up a compatible environment. The options include Windows Command Line, Power Shell and the graphical user interface based on Eclipse IDE. In addition, a VS Code-based environment can be set up with the supported plugin: <https://github.com/espressif/vscode-esp-idf-extension>.

## WiFi

**WiFi Enterprise security** APIs defined in `esp_wpa2.h` have been deprecated. Please use newer APIs from `esp_eap_client.h`.

## Chapter 6

# Libraries and Frameworks

### 6.1 Cloud Frameworks

ESP32-C3 supports multiple cloud frameworks using agents built on top of ESP-IDF. Here are the pointers to various supported cloud frameworks' agents and examples:

#### 6.1.1 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. [ESP RainMaker on GitHub](#).

#### 6.1.2 AWS IoT

<https://github.com/espressif/esp-aws-iot> is an open source repository for ESP32-C3 based on Amazon Web Services' `aws-iot-device-sdk-embedded-C`.

#### 6.1.3 Azure IoT

<https://github.com/espressif/esp-azure> is an open source repository for ESP32-C3 based on Microsoft Azure' s `azure-iot-sdk-c` SDK.

#### 6.1.4 Google IoT Core

<https://github.com/espressif/esp-google-iot> is an open source repository for ESP32-C3 based on Google' s `iot-device-sdk-embedded-c` SDK.

#### 6.1.5 Aliyun IoT

<https://github.com/espressif/esp-aliyun> is an open source repository for ESP32-C3 based on Aliyun' s `iotkit-embedded` SDK.

#### 6.1.6 Joylink IoT

<https://github.com/espressif/esp-joylink> is an open source repository for ESP32-C3 based on Joylink' s `joylink_dev_sdk` SDK.

### 6.1.7 Tencent IoT

<https://github.com/espressif/esp-welink> is an open source repository for ESP32-C3 based on Tencent's [welink SDK](#).

### 6.1.8 Tencentyun IoT

<https://github.com/espressif/esp-qcloud> is an open source repository for ESP32-C3 based on Tencentyun's [qcloud-iot-sdk-embedded-c SDK](#).

### 6.1.9 Baidu IoT

<https://github.com/espressif/esp-baidu-iot> is an open source repository for ESP32-C3 based on Baidu's [iot-sdk-c SDK](#).

## 6.2 Espressif's Frameworks

Here you will find a collection of the official Espressif libraries and frameworks.

### 6.2.1 Espressif Audio Development Framework

The ESP-ADF is a comprehensive framework for audio applications including:

- CODEC's HAL
- Music Players and Recorders
- Audio Processing
- Bluetooth Speakers
- Internet Radios
- Hands-free devices
- Speech Recognition

This framework is available at GitHub: [ESP-ADF](#).

### 6.2.2 ESP-CSI

ESP-CSI is an experimental implementation that uses the Wi-Fi Channel State Information to detect the presence of a human body.

See [ESP-CSI](#) project for more information about it.

### 6.2.3 Espressif DSP Library

The library provides algorithms optimized specifically for digital signal processing applications. This library supports:

- Matrix multiplication
- Dot product
- FFT (Fast Fourier Transform)
- IIR (Infinite Impulse Response)
- FIR (Finite Impulse Response)
- Vector math operations

This library is available here: [ESP-DSP library](#).

## 6.2.4 ESP-WIFI-MESH Development Framework

This framework is based on the ESP-WIFI-MESH protocol with the following features:

- Fast network configuration
- Stable upgrade
- Efficient debugging
- LAN control
- Various application demos

[ESP-MDF](#).

## 6.2.5 ESP-WHO

The ESP-WHO is a face detection and recognition framework using the ESP32 and camera. To know more about the project, see [ESP-WHO](#) on GitHub.

## 6.2.6 ESP RainMaker

[ESP RainMaker](#) is a complete solution for accelerated AIoT development. Using ESP RainMaker, you can create AIoT devices from the firmware to the integration with voice-assistant, phone apps and cloud backend.

[ESP RainMaker on GitHub](#).

## 6.2.7 ESP-IoT-Solution

[ESP-IoT-Solution](#) contains commonly used device drivers and code frameworks when developing IoT systems. The device drivers and code frameworks within the ESP-IoT-Solution are organized as separate components, allowing them to be easily integrated into an ESP-IDF project.

ESP-IoT-Solution includes:

- Device drivers for sensors, display, audio, GUI, input, actuators, etc.
- Framework and documentation for low power, security, storage, etc.
- Guide for Espressif open source solutions from practical application point.

[ESP-IoT-Solution on GitHub](#).

## 6.2.8 ESP-Protocols

[ESP-Protocols](#) repository contains collection of protocol components for ESP-IDF. The code within the ESP-Protocols is organized into separate components, allowing them to be easily integrated into an ESP-IDF project. In addition to that, each component is available in [IDF Component Registry](#).

ESP-Protocols components:

- [esp\\_modem](#) enables connectivity with GSM/LTE modems using AT commands or PPP protocol, see the [esp\\_modem documentation](#).
- [mdns](#) (mDNS) is a multicast UDP service that is used to provide local network service and host discovery, see the [mdns documentation](#).
- [esp\\_websocket\\_client](#) is a managed component for *esp-idf* that contains implementation of [WebSocket protocol client](<https://datatracker.ietf.org/doc/html/rfc6455>) for ESP32, see the [esp\\_websocket\\_client documentation](#).
- [asio](#) is a cross-platform C++ library, see <https://think-async.com/Asio/>. It provides a consistent asynchronous model using a modern C++ approach. , see the [asio documentation](#).

## 6.2.9 ESP-BSP

[ESP-BSP](#) repository contains Board Support Packages (BSPs) for various Espressif's and 3rd party development boards. BSPs are useful for quick start on a supported board. Usually they contain pinout definition and helper functions, that will initialize peripherals for the specific board. Additionally, the BSP would contain drivers for external chips populated on the development board, such as sensors, displays, audio codecs etc.

# Chapter 7

## Contributions Guide

We welcome contributions to the esp-idf project!

### 7.1 How to Contribute

Contributions to esp-idf - fixing bugs, adding features, adding documentation - are welcome. We accept contributions via [Github Pull Requests](#).

### 7.2 Before Contributing

Before sending us a Pull Request, please consider this list of points:

- Is the contribution entirely your own work, or already licensed under an Apache License 2.0 compatible Open Source License? If not then we unfortunately cannot accept it. Please check the [Copyright Header Guide](#) for additional information.
- Does any new code conform to the esp-idf [Style Guide](#)?
- Have you installed the [pre-commit hook](#) for esp-idf project?
- Does the code documentation follow requirements in [Documenting Code](#)?
- Is the code adequately commented for people to understand how it is structured?
- Is there documentation or examples that go with code contributions? There are additional suggestions for writing good examples in [examples](#) readme.
- Are comments and documentation written in clear English, with no spelling or grammar errors?
- Example contributions are also welcome. Please check the [Creating Examples](#) guide for these.
- If the contribution contains multiple commits, are they grouped together into logical changes (one major change per pull request)? Are any commits with names like “fixed typo” [squashed into previous commits](#)?
- If you’re unsure about any of these points, please open the Pull Request anyhow and then ask us for feedback.

### 7.3 Pull Request Process

After you open the Pull Request, there will probably be some discussion in the comments field of the request itself.

Once the Pull Request is ready to merge, it will first be merged into our internal git system for in-house automated testing.

If this process passes, it will be merged into the public GitHub repository.

## 7.4 Legal Part

Before a contribution can be accepted, you will need to sign our *Contributor Agreement*. You will be prompted for this automatically as part of the Pull Request process.

## 7.5 Related Documents

### 7.5.1 Espressif IoT Development Framework Style Guide

#### About This Guide

Purpose of this style guide is to encourage use of common coding practices within the ESP-IDF.

Style guide is a set of rules which are aimed to help create readable, maintainable, and robust code. By writing code which looks the same way across the code base we help others read and comprehend the code. By using same conventions for spaces and newlines we reduce chances that future changes will produce huge unreadable diffs. By following common patterns for module structure and by using language features consistently we help others understand code behavior.

We try to keep rules simple enough, which means that they can not cover all potential cases. In some cases one has to bend these simple rules to achieve readability, maintainability, or robustness.

When doing modifications to third-party code used in ESP-IDF, follow the way that particular project is written. That will help propose useful changes for merging into upstream project.

#### C Code Formatting

##### Naming

- Any variable or function which is only used in a single source file should be declared `static`.
- Public names (non-static variables and functions) should be namespaced with a per-component or per-unit prefix, to avoid naming collisions. ie `esp_vfs_register()` or `esp_console_run()`. Starting the prefix with `esp_` for Espressif-specific names is optional, but should be consistent with any other names in the same component.
- Static variables should be prefixed with `s_` for easy identification. For example, `static bool s_invert`.
- Avoid unnecessary abbreviations (ie shortening `data` to `dat`), unless the resulting name would otherwise be very long.

**Indentation** Use 4 spaces for each indentation level. Don't use tabs for indentation. Configure the editor to emit 4 spaces each time you press tab key.

**Vertical Space** Place one empty line between functions. Don't begin or end a function with an empty line.

```
void function1()
{
    do_one_thing();
    do_another_thing();
}
// INCORRECT, don't place empty line here
// place empty line here
void function2()
{
    // INCORRECT, don't use an empty line here
    int var = 0;
    while (var < SOME_CONSTANT) {
        do_stuff(&var);
    }
}
```

(continues on next page)

(continued from previous page)

```

}
}

```

The maximum line length is 120 characters as long as it doesn't seriously affect the readability.

**Horizontal Space** Always add single space after conditional and loop keywords:

```

if (condition) {      // correct
    // ...
}

switch (n) {          // correct
    case 0:
        // ...
}

for(int i = 0; i < CONST; ++i) {    // INCORRECT
    // ...
}

```

Add single space around binary operators. No space is necessary for unary operators. It is okay to drop space around multiply and divide operators:

```

const int y = y0 + (x - x0) * (y1 - y0) / (x1 - x0);    // correct

const int y = y0 + (x - x0)*(y1 - y0)/(x1 - x0);        // also okay

int y_cur = -y;                                         // correct
++y_cur;

const int y = y0+(x-x0)*(y1-y0)/(x1-x0);                // INCORRECT

```

No space is necessary around `.` and `->` operators.

Sometimes adding horizontal space within a line can help make code more readable. For example, you can add space to align function arguments:

```

esp_rom_gpio_connect_in_signal(PIN_CAM_D6,    I2S0I_DATA_IN14_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_D7,    I2S0I_DATA_IN15_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_HREF,  I2S0I_H_ENABLE_IDX,  false);
esp_rom_gpio_connect_in_signal(PIN_CAM_PCLK,  I2S0I_DATA_IN15_IDX, false);

```

Note however that if someone goes to add new line with a longer identifier as first argument (e.g. `PIN_CAM_VSYNC`), it will not fit. So other lines would have to be realigned, adding meaningless changes to the commit.

Therefore, use horizontal alignment sparingly, especially if you expect new lines to be added to the list later.

Never use TAB characters for horizontal alignment.

Never add trailing whitespace at the end of the line.

## Braces

- Function definition should have a brace on a separate line:

```

// This is correct:
void function(int arg)
{
}

```

(continues on next page)

(continued from previous page)

```
// NOT like this:
void function(int arg) {
}
```

- Within a function, place opening brace on the same line with conditional and loop statements:

```
if (condition) {
    do_one();
} else if (other_condition) {
    do_two();
}
```

**Comments** Use `//` for single line comments. For multi-line comments it is okay to use either `//` on each line or a `/* */` block.

Although not directly related to formatting, here are a few notes about using comments effectively.

- Don't use single comments to disable some functionality:

```
void init_something()
{
    setup_dma();
    // load_resources();           // WHY is this thing commented, asks_
    ↪the reader?
    start_timer();
}
```

- If some code is no longer required, remove it completely. If you need it you can always look it up in git history of this file. If you disable some call because of temporary reasons, with an intention to restore it in the future, add explanation on the adjacent line:

```
void init_something()
{
    setup_dma();
    // TODO: we should load resources here, but loader is not fully integrated_
    ↪yet.
    // load_resources();
    start_timer();
}
```

- Same goes for `#if 0 ... #endif` blocks. Remove code block completely if it is not used. Otherwise, add comment explaining why the block is disabled. Don't use `#if 0 ... #endif` or comments to store code snippets which you may need in the future.
- Don't add trivial comments about authorship and change date. You can always look up who modified any given line using git. E.g. this comment adds clutter to the code without adding any useful information:

```
void init_something()
{
    setup_dma();
    // XXX add 2016-09-01
    init_dma_list();
    fill_dma_item(0);
    // end XXX add
    start_timer();
}
```

**Line Endings** Commits should only contain files with LF (Unix style) endings.

Windows users can configure git to check out CRLF (Windows style) endings locally and commit LF endings by setting the `core.autocrlf` setting. *Github has a document about setting this option* <[github-line-endings](#)>.

If you accidentally have some commits in your branch that add LF endings, you can convert them to Unix by running this command in an MSYS2 or Unix terminal (change directory to the IDF working directory and check the correct branch is currently checked out, beforehand):

```
git rebase --exec 'git diff-tree --no-commit-id --name-only -r HEAD | xargs_
↳dos2unix && git commit -a --amend --no-edit --allow-empty' master
```

(Note that this line rebases on master, change the branch name at the end to rebase on another branch.)

For updating a single commit, it's possible to run `dos2unix FILENAME` and then run `git commit --amend`

**Formatting Your Code** You can use `astyle` program to format your code according to the above recommendations.

If you are writing a file from scratch, or doing a complete rewrite, feel free to re-format the entire file. If you are changing a small portion of file, don't re-format the code you didn't change. This will help others when they review your changes.

To re-format a file, run:

```
tools/format.sh components/my_component/file.c
```

**Type Definitions** Should be snake\_case, ending with `_t` suffix:

```
typedef int signed_32_bit_t;
```

**Enum** Enums should be defined through the `typedef` and be namespaced:

```
typedef enum
{
    MODULE_FOO_ONE,
    MODULE_FOO_TWO,
    MODULE_FOO_THREE
} module_foo_t;
```

**Assertions** The standard C `assert()` function, defined in `assert.h` should be used to check conditions that should be true in source code. In the default configuration, an assert condition that returns `false` or `0` will call `abort()` and trigger a *Fatal Error*.

`assert()` should only be used to detect unrecoverable errors due to a serious internal logic bug or corruption, where it's not possible for the program to continue. For recoverable errors, including errors that are possible due to invalid external input, an *error value should be returned*.

---

**Note:** When asserting a value of type `esp_err_t` is equal to `ESP_OK`, use the [ESP\\_ERROR\\_CHECK macro](#) instead of an `assert()`.

---

It's possible to configure ESP-IDF projects with assertions disabled (see [CONFIG\\_COMPILER\\_OPTIMIZATION\\_ASSERTION\\_LEVEL](#)). Therefore, functions called in an `assert()` statement should not have side-effects.

It's also necessary to use particular techniques to avoid “variable set but not used” warnings when assertions are disabled, due to code patterns such as:

```
int res = do_something();
assert(res == 0);
```

Once the `assert` is optimized out, the `res` value is unused and the compiler will warn about this. However the function `do_something()` must still be called, even if assertions are disabled.

When the variable is declared and initialized in a single statement, a good strategy is to cast it to `void` on a new line. The compiler will not produce a warning, and the variable can still be optimized out of the final binary:

```
int res = do_something();
assert(res == 0);
(void)res;
```

If the variable is declared separately, for example if it is used for multiple assertions, then it can be declared with the GCC attribute `__attribute__((unused))`. The compiler will not produce any unused variable warnings, but the variable can still be optimized out:

```
int res __attribute__((unused));

res = do_something();
assert(res == 0);

res = do_something_else();
assert(res != 0);
```

## Header file guards

All public facing header files should have preprocessor guards. A pragma is preferred:

```
#pragma once
```

over the following pattern:

```
#ifndef FILE_NAME_H
#define FILE_NAME_H
...
#endif // FILE_NAME_H
```

In addition to guard macros, all C header files should have `extern "C"` guards to allow the header to be used from C++ code. Note that the following order should be used: `pragma once`, then any `#include` statements, then `extern "C"` guards:

```
#pragma once

#include <stdint.h>

#ifdef __cplusplus
extern "C" {
#endif

/* declarations go here */

#ifdef __cplusplus
}
#endif
```

## Include statements

When writing `#include` statements, try to maintain the following order:

- C standard library headers.
- Other POSIX standard headers and common extensions to them (such as `sys/queue.h`.)
- Common IDF headers (`esp_log.h`, `esp_system.h`, `esp_timer.h`, `esp_sleep.h`, etc.)

- Headers of other components, such as FreeRTOS.
- Public headers of the current component.
- Private headers.

Use angle brackets for C standard library headers and other POSIX headers (`#include <stdio.h>`).

Use double quotes for all other headers (`#include "esp_log.h"`).

## C++ Code Formatting

The same rules as for C apply. Where they are not enough, apply the following rules.

**File Naming** C++ Header files have the extension `.hpp`. C++ source files have the extension `.cpp`. The latter is important for the compiler to distinguish them from normal C source files.

## Naming

- **Class and struct** names shall be written in CamelCase with a capital letter as beginning. Member variables and methods shall be in snake\_case.
- **Namespaces** shall be in lower snake\_case.
- **Templates** are specified in the line above the function declaration.
- Interfaces in terms of Object-Oriented Programming shall be named without the suffix `...Interface`. Later, this makes it easier to extract interfaces from normal classes and vice versa without making a breaking change.

**Member Order in Classes** In order of precedence:

- First put the public members, then the protected, then private ones. Omit public, protected or private sections without any members.
- First put constructors/destructors, then member functions, then member variables.

For example:

```
class ForExample {
public:
    // first constructors, then default constructor, then destructor
    ForExample(double example_factor_arg);
    ForExample();
    ~ForExample();

    // then remaining public methods
    set_example_factor(double example_factor_arg);

    // then public member variables
    uint32_t public_data_member;

private:
    // first private methods
    void internal_method();

    // then private member variables
    double example_factor;
};
```

## Spacing

- Don't indent inside namespaces.
- Put public, protected and private labels at the same indentation level as the corresponding class label.

## Simple Example

```

// file spaceship.h
#ifndef SPACESHIP_H_
#define SPACESHIP_H_
#include <cstdlib>

namespace spaceships {

class SpaceShip {
public:
    SpaceShip(size_t crew);
    size_t get_crew_size() const;

private:
    const size_t crew;
};

class SpaceShuttle : public SpaceShip {
public:
    SpaceShuttle();
};

class Sojuz : public SpaceShip {
public:
    Sojuz();
};

template <typename T>
class CargoShip {
public:
    CargoShip(const T &cargo);

private:
    T cargo;
};

} // namespace spaceships

#endif // SPACESHIP_H_

// file spaceship.cpp
#include "spaceship.h"

namespace spaceships {

// Putting the curly braces in the same line for constructors is OK if it only
↳initializes
// values in the initializer list
SpaceShip::SpaceShip(size_t crew) : crew(crew) { }

size_t SpaceShip::get_crew_size() const
{
    return crew;
}

SpaceShuttle::SpaceShuttle() : SpaceShip(7)
{
    // doing further initialization
}

Sojuz::Sojuz() : SpaceShip(3)
{

```

(continues on next page)

(continued from previous page)

```
    // doing further initialization
}

template <typename T>
CargoShip<T>::CargoShip(const T &cargo) : cargo(cargo) { }

} // namespace spaceships
```

## CMake Code Style

- Indent with four spaces.
- Maximum line length 120 characters. When splitting lines, try to focus on readability where possible (for example, by pairing up keyword/argument pairs on individual lines).
- Don't put anything in the optional parentheses after `endforeach()`, `endif()`, etc.
- Use lowercase (`with_underscores`) for command, function, and macro names.
- For locally scoped variables, use lowercase (`with_underscores`).
- For globally scoped variables, use uppercase (`WITH_UNDERSCORES`).
- Otherwise follow the defaults of the [cmake-lint](#) project.

## Configuring the Code Style for a Project Using EditorConfig

EditorConfig helps developers define and maintain consistent coding styles between different editors and IDEs. The EditorConfig project consists of a file format for defining coding styles and a collection of text editor plugins that enable editors to read the file format and adhere to defined styles. EditorConfig files are easily readable and they work nicely with version control systems.

For more information, see [EditorConfig Website](#).

## Documenting Code

Please see the guide here: [Documenting Code](#).

## Structure

To be written.

## Language Features

To be written.

## 7.5.2 Install pre-commit Hook for ESP-IDF Project

### Required Dependency

Python 3.7.\* or above. This is our recommended python version for IDF developers.

If you still have python versions not compatible, update your python versions before installing the pre-commit hook.

### Install pre-commit

```
Run pip install pre-commit
```

### Install pre-commit hook

1. Go to the IDF Project Directory
2. Run `pre-commit install --allow-missing-config`. Install hook by this approach will let you commit successfully even in branches without the `.pre-commit-config.yaml`
3. pre-commit hook will run automatically when you're running `git commit` command

### Uninstall pre-commit

Run `pre-commit uninstall`

### What's More?

For detailed usage, please refer to the documentation of [pre-commit](#).

### Common Problems For Windows Users

`/usr/bin/env: python: Permission denied.`

If you're in Git Bash, please check the python executable location by run `which python`.

If the executable is under `~/AppData/Local/Microsoft/WindowsApps/`, then it's a link to Windows AppStore, not a real one.

Please install python manually and update this in your PATH environment variable.

Your `%USERPROFILE%` contains non-ASCII characters

`pre-commit` may fail when initializing an environment for a particular hook when the path of `pre-commit`'s cache contains non-ASCII characters. The solution is to set `PRE_COMMIT_HOME` to a path containing only standard characters before running `pre-commit`.

- CMD: `set PRE_COMMIT_HOME=C:\somepath\pre-commit`
- PowerShell: `$Env:PRE_COMMIT_HOME = "C:\somepath\pre-commit"`
- git bash: `export PRE_COMMIT_HOME="/c/somepath/pre-commit"`

## 7.5.3 Documenting Code

The purpose of this description is to provide quick summary on documentation style used in [espressif/esp-idf](#) repository and how to add new documentation.

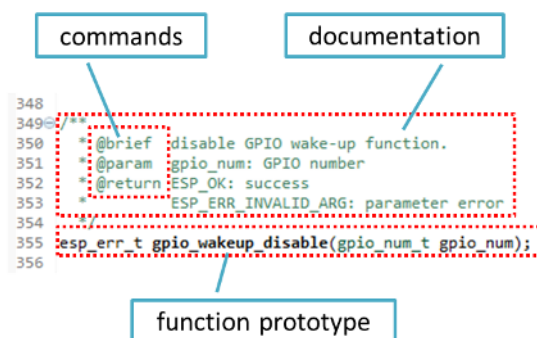

### Introduction

When documenting code for this repository, please follow [Doxygen style](#). You are doing it by inserting special commands, for instance `@param`, into standard comments blocks, for example:

```
/**
 * @param ratio this is oxygen to air ratio
 */
```

Doxygen is phrasing the code, extracting the commands together with subsequent text, and building documentation out of it.

Typical comment block, that contains documentation of a function, looks like below.

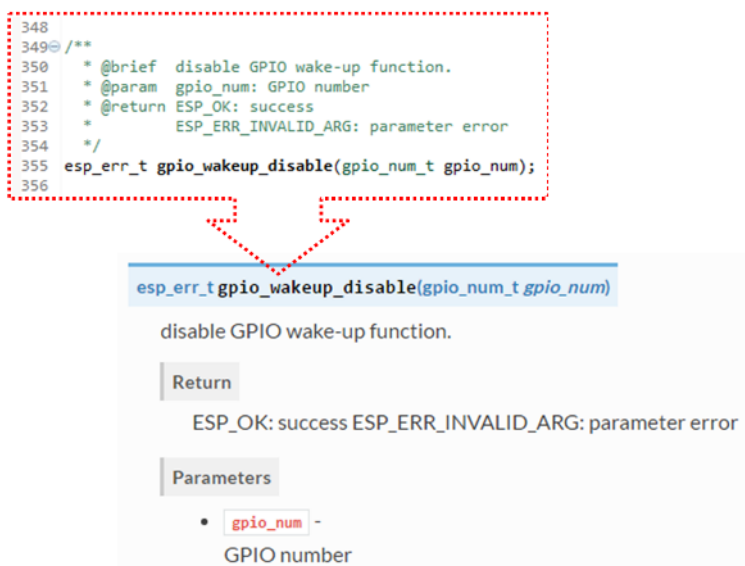

Doxygen supports couple of formatting styles. It also gives you great flexibility on level of details to include in documentation. To get familiar with available features, please check data rich and very well organized [Doxygen Manual](#).

### Why we need it?

The ultimate goal is to ensure that all the code is consistently documented, so we can use tools like [Sphinx](#) and [Breathe](#) to aid preparation and automatic updates of API documentation when the code changes.

With these tools the above piece of code renders like below:

### Go for it!

When writing code for this repository, please follow guidelines below.

1. Document all building blocks of code: functions, structs, typedefs, enums, macros, etc. Provide enough information about purpose, functionality and limitations of documented items, as you would like to see them documented when reading the code by others.
2. Documentation of function should describe what this function does. If it accepts input parameters and returns some value, all of them should be explained.
3. Do not add a data type before parameter or any other characters besides spaces. All spaces and line breaks are compressed into a single space. If you like to break a line, then break it twice.

```

41 @/**
42  * @brief Set log level for given tag
43  *
44  * If logging for given component has already been enabled, changes previous setting.
45  *
46  * @param tag Tag of the log entries to enable. Must be a non-NULL zero terminated string.
47  *           Value "" resets log level for all tags to the given value.
48  *
49  * @param level Selects log level to enable.
50  *             Only logs at this and lower levels will be shown.
51  */
52 void esp_log_level_set(const char* tag, esp_log_level_t level);

```

do not add data type

white spaces are compressed

a line break that will render

this line break will not render

```
void esp_log_level_set(const char* tag, esp_log_level_t level)
```

Set log level for given tag.

If logging for given component has already been enabled, changes previous setting.

**Parameters**

- tag** - Tag of the log entries to enable. Must be a non-NULL zero terminated string. Value "" resets log level for all tags to the given value.
- level** - Selects log level to enable. Only logs at this and lower levels will be shown.

4. If function has void input or does not return any value, then skip @param or @return

```

26 @/**
27  * @brief Initialize BT controller
28  *
29  * This function should be called only once,
30  * before any other BT functions are called.
31  */
32 void bt_controller_init(void);

```

```
void bt_controller_init(void)
```

Initialize BT controller.

This function should be called only once, before any other BT functions are called.

5. When documenting a define as well as members of a struct or enum, place specific comment like below after each member.

```

45 @/**
46  * Mode of opening the non-volatile storage
47  *
48  */
49 @typedef enum {
50     NVS_READONLY, /*!< Read only */
51     NVS_READWRITE /*!< Read and write */
52 } nvs_open_mode;

```

**enum nvs\_open\_mode**

Mode of opening the non-volatile storage.

**Values:**

- NVS\_READONLY**  
Read only
- NVS\_READWRITE**  
Read and write

/\*!< how to documented members \*/

6. To provide well formatted lists, break the line after command (like @return in example below).

```

*
* @return
*   - ESP_OK if erase operation was successful

```

(continues on next page)

(continued from previous page)

```
* - ESP_ERR_NVS_INVALID_HANDLE if handle has been closed or is NULL
* - ESP_ERR_NVS_READ_ONLY if handle was opened as read only
* - ESP_ERR_NVS_NOT_FOUND if the requested key doesn't exist
* - other error codes from the underlying storage driver
*
```

7. Overview of functionality of documented header file, or group of files that make a library, should be placed in a separate README.rst file of the same directory. If this directory contains header files for different APIs, then the file name should be apiname-readme.rst.

### Go one extra mile

Here are a couple of tips on how you can make your documentation even better and more useful to the reader and writer.

When writing codes, please follow the guidelines below:

1. Add code snippets to illustrate implementation. To do so, enclose snippet using `@code{c}` and `@endcode` commands.

```
*
* @code{c}
* // Example of using nvs_get_i32:
* int32_t max_buffer_size = 4096; // default value
* esp_err_t err = nvs_get_i32(my_handle, "max_buffer_size", &max_buffer_size);
* assert(err == ESP_OK || err == ESP_ERR_NVS_NOT_FOUND);
* // if ESP_ERR_NVS_NOT_FOUND was returned, max_buffer_size will still
* // have its default value.
* @endcode
*
```

The code snippet should be enclosed in a comment block of the function that it illustrates.

2. To highlight some important information use command `@attention` or `@note`.

```
*
* @attention
* 1. This API only impact WIFI_MODE_STA or WIFI_MODE_APSTA mode
* 2. If the ESP32 is connected to an AP, call esp_wifi_disconnect to
* ↪disconnect.
*
```

Above example also shows how to use a numbered list.

3. To provide common description to a group of similar functions, enclose them using `/**@{*/` and `/**@}*/` markup commands:

```
/**@{*/
/**
* @brief common description of similar functions
*
*/
void first_similar_function (void);
void second_similar_function (void);
/**@}*/
```

For practical example see [nvs\\_flash/include/nvs.h](#).

4. You may want to go even further and skip some code like repetitive defines or enumerations. In such case, enclose the code within `/** @cond */` and `/** @endcond */` commands. Example of such implementation is provided in [driver/include/driver/gpio.h](#).
5. Use markdown to make your documentation even more readable. You will add headers, links, tables and more.

```
*
* [ESP32-C3 Technical Reference Manual] (https://www.espressif.com/sites/
* →default/files/documentation/esp32-c3_technical_reference_manual_en.pdf)
*
```

**Note:** Code snippets, notes, links, etc. will not make it to the documentation, if not enclosed in a comment block associated with one of documented objects.

6. Prepare one or more complete code examples together with description. Place description to a separate file README.md in specific folder of `examples` directory.

### Standardize Document Format

When it comes to text, please follow guidelines below to provide well formatted Markdown (.md) or reST (.rst) documents.

1. Please ensure that one paragraph is written in one line. Don't break lines like below. Breaking lines to enhance readability is only suitable for writing codes. To make the text easier to read, it is recommended to place an empty line to separate the paragraph.

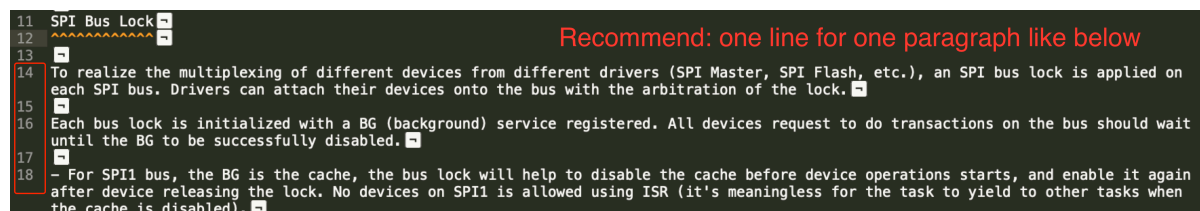

Fig. 1: One line for one paragraph (click to enlarge)

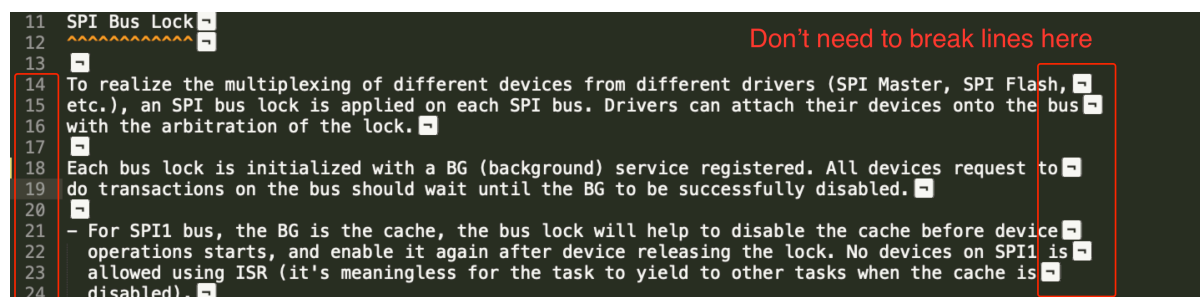

Fig. 2: No line breaks within the same paragraph (click to enlarge)

2. Please make the line number of CN and EN documents consistent like below. The benefit of this approach is that it can save time for both writers and translators. When non-bilingual writers need to update text, they only need to update the same line in the corresponding CN or EN document. For translators, if documents are updated in English, then translators can quickly locate where to update in the corresponding CN document later. Besides, by comparing the total number of lines in EN and CN documents, you can quickly find out whether the CN version lags behind the EN version.

### Building Documentation

The documentation is built with the `esp-docs` Python package, which is a wrapper around [Sphinx](#)

To install it simply do:

Fig. 3: Keep the line number for EN and CN documents consistent (click to enlarge)

```
pip install esp-docs
```

After a successful install then the documentation can be built from the docs folder with:

```
build-docs build
```

or for specific target and language with:

```
build-docs -t esp32 -l en build
```

For more in-depth documentation about *esp-docs* features please see the documentation in the [esp-docs repository](#).

## Wrap up

We love good code that is doing cool things. We love it even better, if it is well documented, so we can quickly make it run and also do the cool things.

Go ahead, contribute your code and documentation!

## 7.5.4 Creating Examples

Each ESP-IDF example is a complete project that someone else can copy and adapt the code to solve their own problem. Examples should demonstrate ESP-IDF functionality, while keeping this purpose in mind.

### Structure

- The main directory should contain a source file named `(something)_example_main.c` with the main functionality.
- If the example has additional functionality, split it logically into separate C or C++ source files under main and place a corresponding header file in the same directory.

- If the example has a lot of additional functionality, consider adding a `components` directory to the example project and make some example-specific components with library functionality. Only do this if the components are specific to the example, if they're generic or common functionality then they should be added to ESP-IDF itself.
- The example should have a `README.md` file. Use the [template example README](#) and adapt it for your particular example.
- Examples should have a `pytest_<example name>.py` file for running an automated example test. If submitting a GitHub Pull Request which includes an example, it's OK not to include this file initially. The details can be discussed as part of the [Pull Request](#). Please refer to [IDF Tests with Pytest Guide](#) for details.

## General Guidelines

Example code should follow the [Espressif IoT Development Framework Style Guide](#).

## Checklist

Checklist before submitting a new example:

- Example project name (in `README.md`) uses the word “example”. Use “example” instead of “demo”, “test” or similar words.
- Example does one distinct thing. If the example does more than one thing at a time, split it into two or more examples.
- Example has a `README.md` file which is similar to the [template example README](#).
- Functions and variables in the example are named according to [naming section of the style guide](#). (For non-static names which are only specific to the example's source files, you can use `example` or something similar as a prefix.)
- All code in the example is well structured and commented.
- Any unnecessary code (old debugging logs, commented-out code, etc.) is removed from the example.
- Options in the example (like network names, addresses, etc) are not hard-coded. Use configuration items if possible, or otherwise declare macros or constants)
- Configuration items are provided in a `KConfig.projbuild` file with a menu named “Example Configuration”. See existing example projects to see how this is done.
- All original example code has a license header saying it is “in the public domain / CC0”, and a warranty disclaimer clause. Alternatively, the example is licensed under Apache License 2.0. See existing examples for headers to adapt from.
- Any adapted or third party example code has the original license header on it. This code must be licensed compatible with Apache License 2.0.

## 7.5.5 API Documentation Template

---

**Note:** *INSTRUCTIONS*

1. Use this file ([docs/en/api-reference/template.rst](#)) as a template to document API.
  2. Change the file name to the name of the header file that represents documented API.
  3. Include respective files with descriptions from the API folder using `..include::`
    - `README.rst`
    - `example.rst`
    - ...
  4. Optionally provide description right in this file.
  5. Once done, remove all instructions like this one and any superfluous headers.
-

## Overview

---

**Note:** *INSTRUCTIONS*

1. Provide overview where and how this API may be used.
  2. Where applicable include code snippets to illustrate functionality of particular functions.
  3. To distinguish between sections, use the following [heading levels](#):
    - # with overline, for parts
    - \* with overline, for chapters
    - =, for sections
    - -, for subsections
    - ^, for subsubsections
    - ", for paragraphs
- 

## Application Example

---

**Note:** *INSTRUCTIONS*

1. Prepare one or more practical examples to demonstrate functionality of this API.
  2. Each example should follow pattern of projects located in `esp-idf/examples/` folder.
  3. Place example in this folder complete with `README.md` file.
  4. Provide overview of demonstrated functionality in `README.md`.
  5. With good overview reader should be able to understand what example does without opening the source code.
  6. Depending on complexity of example, break down description of code into parts and provide overview of functionality of each part.
  7. Include flow diagram and screenshots of application output if applicable.
  8. Finally add in this section synopsis of each example together with link to respective folder in `esp-idf/examples/`.
- 

## API Reference

---

**Note:** *INSTRUCTIONS*

1. This repository provides for automatic update of API reference documentation using *code markup retrieved by Doxygen from header files*.
1. Update is done on each documentation build by invoking Sphinx extension `:esp_extensions/run_doxygen.py` for all header files listed in the `INPUT` statement of `docs/doxygen/Doxyfile`.
1. Each line of the `INPUT` statement (other than a comment that begins with `##`) contains a path to header file `*.h` that will be used to generate corresponding `*.inc` files:

```
##
## Wi-Fi - API Reference
##
../components/esp32/include/esp_wifi.h \
../components/esp32/include/esp_smartconfig.h \
```

1. When the headers are expanded, any macros defined by default in `sdkconfig.h` as well as any macros defined in SOC-specific `include/soc/*_caps.h` headers will be expanded. This allows the headers to include/exclude material based on the `IDF_TARGET` value.
1. The `*.inc` files contain formatted reference of API members generated automatically on each documentation build. All `*.inc` files are placed in `Sphinx_build` directory. To see directives generated for e.g. `esp_wifi.h`, run `python gen-dxd.py esp32/include/esp_wifi.h`.

1. To show contents of \*.inc file in documentation, include it as follows:

```
.. include-build-file:: inc/esp_wifi.inc
```

For example see [docs/en/api-reference/network/esp\\_wifi.rst](#)

1. Optionally, rather than using \*.inc files, you may want to describe API in your own way. See [docs/en/api-reference/storage/fatfs.rst](#) for example.

Below is the list of common .. doxygen...:: directives:

- Functions - .. doxygenfunction:: name\_of\_function
- Unions - .. doxygenunion:: name\_of\_union
- Structures - .. doxygenstruct:: name\_of\_structure together with :members:
- Macros - .. doxygendefine:: name\_of\_define
- Type Definitions - .. doxygentypedef:: name\_of\_type
- Enumerations - .. doxygenenum:: name\_of\_enumeration

See [Breathe documentation](#) for additional information.

To provide a link to header file, use the *link custom role* directive as follows:

```
* :component_file:`path_to/header_file.h`
```

1. In any case, to generate API reference, the file [docs/doxygen/Doxyfile](#) should be updated with paths to \*.h headers that are being documented.
  1. When changes are committed and documentation is built, check how this section has been rendered. *Correct annotations* in respective header files, if required.
- 

## 7.5.6 Contributor Agreement

### Individual Contributor Non-Exclusive License Agreement including the Traditional Patent License OPTION

Thank you for your interest in contributing to this Espressif project hosted on GitHub ( “We” or “Us” ).

The purpose of this contributor agreement ( “Agreement” ) is to clarify and document the rights granted by contributors to Us. To make this document effective, please follow the instructions in the [Contributions Guide](#).

**1. DEFINITIONS** “You” means the Individual Copyright owner who submits a Contribution to Us. If You are an employee and submit the Contribution as part of your employment, You have had Your employer approve this Agreement or sign the Entity version of this document.

“**Contribution**” means any original work of authorship (software and/or documentation) including any modifications or additions to an existing work, Submitted by You to Us, in which You own the Copyright. If You do not own the Copyright in the entire work of authorship, please contact Us by submitting a comment on GitHub.

“**Copyright**” means all rights protecting works of authorship owned or controlled by You, including copyright, moral and neighboring rights, as appropriate, for the full term of their existence including any extensions by You.

“**Material**” means the software or documentation made available by Us to third parties. When this Agreement covers more than one software project, the Material means the software or documentation to which the Contribution was Submitted. After You Submit the Contribution, it may be included in the Material.

“**Submit**” means any form of physical, electronic, or written communication sent to Us, including but not limited to electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, Us, but excluding communication that is conspicuously marked or otherwise designated in writing by You as “Not a Contribution.”

“**Submission Date**” means the date You Submit a Contribution to Us.

“**Documentation**” means any non-software portion of a Contribution.

## 2. LICENSE GRANT 2.1 Copyright License to Us

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, NON-exclusive, perpetual and irrevocable license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, under the Copyright covering the Contribution to use the Contribution by all means, including, but not limited to:

- to publish the Contribution,
- to modify the Contribution, to prepare derivative works based upon or containing the Contribution and to combine the Contribution with other software code,
- to reproduce the Contribution in original or modified form,
- to distribute, to make the Contribution available to the public, display and publicly perform the Contribution in original or modified form.

2.2 Moral Rights remain unaffected to the extent they are recognized and not waivable by applicable law. Notwithstanding, You may add your name in the header of the source code files of Your Contribution and We will respect this attribution when using Your Contribution.

## 3. PATENTS 3.1 Patent License

Subject to the terms and conditions of this Agreement You hereby grant to us a worldwide, royalty-free, non-exclusive, perpetual and irrevocable (except as stated in Section 3.2) patent license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, to make, have made, use, sell, offer for sale, import and otherwise transfer the Contribution and the Contribution in combination with the Material (and portions of such combination). This license applies to all patents owned or controlled by You, whether already acquired or hereafter acquired, that would be infringed by making, having made, using, selling, offering for sale, importing or otherwise transferring of Your Contribution(s) alone or by combination of Your Contribution(s) with the Material.

### 3.2 Revocation of Patent License

You reserve the right to revoke the patent license stated in section 3.1 if we make any infringement claim that is targeted at your Contribution and not asserted for a Defensive Purpose. An assertion of claims of the Patents shall be considered for a “Defensive Purpose” if the claims are asserted against an entity that has filed, maintained, threatened, or voluntarily participated in a patent infringement lawsuit against Us or any of Our licensees.

**4. DISCLAIMER** THE CONTRIBUTION IS PROVIDED “AS IS” . MORE PARTICULARLY, ALL EXPRESS OR IMPLIED WARRANTIES INCLUDING, WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT ARE EXPRESSLY DISCLAIMED BY YOU TO US AND BY US TO YOU. TO THE EXTENT THAT ANY SUCH WARRANTIES CANNOT BE DISCLAIMED, SUCH WARRANTY IS LIMITED IN DURATION TO THE MINIMUM PERIOD PERMITTED BY LAW.

**5. Consequential Damage Waiver** TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT WILL YOU OR US BE LIABLE FOR ANY LOSS OF PROFITS, LOSS OF ANTICIPATED SAVINGS, LOSS OF DATA, INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL AND EXEMPLARY DAMAGES ARISING OUT OF THIS AGREEMENT REGARDLESS OF THE LEGAL OR EQUITABLE THEORY (CONTRACT, TORT OR OTHERWISE) UPON WHICH THE CLAIM IS BASED.

**6. Approximation of Disclaimer and Damage Waiver** IF THE DISCLAIMER AND DAMAGE WAIVER MENTIONED IN SECTION 4 AND SECTION 5 CANNOT BE GIVEN LEGAL EFFECT UNDER APPLICABLE LOCAL LAW, REVIEWING COURTS SHALL APPLY LOCAL LAW THAT MOST CLOSELY APPROXIMATES AN ABSOLUTE WAIVER OF ALL CIVIL LIABILITY IN CONNECTION WITH THE CONTRIBUTION.

**7. Term** 7.1 This Agreement shall come into effect upon Your acceptance of the terms and conditions.

7.2 In the event of a termination of this Agreement Sections 4, 5, 6, 7 and 8 shall survive such termination and shall remain in full force thereafter. For the avoidance of doubt, Contributions that are already licensed under a free and open source license at the date of the termination shall remain in full force after the termination of this Agreement.

**8. Miscellaneous** 8.1 This Agreement and all disputes, claims, actions, suits or other proceedings arising out of this agreement or relating in any way to it shall be governed by the laws of People’s Republic of China excluding its private international law provisions.

8.2 This Agreement sets out the entire agreement between You and Us for Your Contributions to Us and overrides all other agreements or understandings.

8.3 If any provision of this Agreement is found void and unenforceable, such provision will be replaced to the extent possible with a provision that comes closest to the meaning of the original provision and that is enforceable. The terms and conditions set forth in this Agreement shall apply notwithstanding any failure of essential purpose of this Agreement or any limited remedy to the maximum extent possible under law.

8.4 You agree to notify Us of any facts or circumstances of which you become aware that would make this Agreement inaccurate in any respect.

**7.5.7 Copyright Header Guide**

ESP-IDF is released under [the Apache License 2.0](#) with some additional third-party copyrighted code released under various licenses. For further information please refer to [the list of copyrights and licenses](#).

This page explains how the source code should be properly marked with a copyright header. ESP-IDF uses [The Software Package Data Exchange \(SPDX\)](#) format which is short and can be easily read by humans or processed by automated tools for copyright checks.

**How to Check the Copyright Headers**

Please make sure you have installed [the pre-commit hooks](#) which contain a copyright header checker as well. The checker can suggest a header if it is not able to detect a properly formatted SPDX header.

**What if the Checker’s Suggestion is Incorrect?**

No automated checker (no matter how good is) can replace humans. So the developer’s responsibility is to modify the offered header to be in line with the law and the license restrictions of the original code on which the work is based on. Certain licenses are not compatible between each other. Such corner cases will be covered by the following examples.

The checker can be configured with the `tools/ci/check_copyright_config.yaml` configuration file. Please check the options it offers and consider updating it in order to match the headers correctly.

### Common Examples of Copyright Headers

The simplest case is when the code is not based on any licensed previous work, e.g. it was written completely from scratch. Such code can be decorated with the following copyright header and put under the license of ESP-IDF:

```
/*
 * SPDX-FileCopyrightText: 2015-2022 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Apache-2.0
 */
```

**Less restrictive parts of ESP-IDF** Some parts of ESP-IDF are deliberately under less restrictive licenses in order to ease their re-use in commercial closed source projects. This is the case for [ESP-IDF examples](#) which are in Public domain or under the Creative Commons Zero Universal (CC0) license. The following header can be used in such source files:

```
/*
 * SPDX-FileCopyrightText: 2015-2022 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Unlicense OR CC0-1.0
 */
```

The option allowing multiple licenses joined with the OR keyword from the above example can be achieved with the definition of multiple allowed licenses in the `tools/ci/check_copyright_config.yaml` configuration file. Please use this option with care and only selectively for a limited part of ESP-IDF.

**Third party licenses** Code licensed under different licenses, modified by Espressif Systems and included in ESP-IDF cannot be licensed under Apache License 2.0 not even if the checker suggests it. It is advised to keep the original copyright header and add an SPDX before it.

The following example is a suitable header for a code licensed under the “GNU General Public License v2.0 or later” held by John Doe with some additional modifications done by Espressif Systems:

```
/*
 * SPDX-FileCopyrightText: 1991 John Doe
 *
 * SPDX-License-Identifier: GPL-2.0-or-later
 *
 * SPDX-FileContributor: 2019-2022 Espressif Systems (Shanghai) CO LTD
 */
```

The licenses can be identified and the short SPDX identifiers can be found in the official [SPDX license list](#). Other very common licenses are the GPL-2.0-only, the BSD-3-Clause, and the BSD-2-Clause.

The configuration stored in `tools/ci/check_copyright_config.yaml` offers features useful for third party licenses:

- A different license can be defined for the files part of a third party library.
- The check for a selected set of files can be permanently disabled. Please use this option with care and only in cases when none of the other options are suitable.

## 7.5.8 ESP-IDF Tests with Pytest Guide

This documentation is a guide that introduces the following aspects:

1. The basic idea of different test types in ESP-IDF

2. How to apply the pytest framework to the test python scripts to make sure the apps are working as expected.
3. ESP-IDF CI target test process
4. Run ESP-IDF tests with pytest locally
5. Tips and tricks on pytest

### Disclaimer

In ESP-IDF, we use the following plugins by default:

- [pytest-embedded](#) with default services `esp`, `idf`
- [pytest-rerunfailures](#)

All the introduced concepts and usages are based on the default behavior in ESP-IDF. Not all of them are available in vanilla pytest.

### Installation

All dependencies could be installed by running the install script with the `--enable-pytest` argument, e.g. `$ install.sh --enable-pytest`.

### Common Issues During Installation

**No Package 'dbus-1' found** If you're facing an error message like:

```
configure: error: Package requirements (dbus-1 >= 1.8) were not met:
No package 'dbus-1' found
Consider adjusting the PKG_CONFIG_PATH environment variable if you
installed software in a non-standard prefix.
```

If you're running a ubuntu system, you may need to run:

```
sudo apt-get install libdbus-glib-1-dev
```

or

```
sudo apt-get install libdbus-1-dev
```

For other linux distros, you may Google the error message and find the solution. This issue could be solved by installing the related header files.

**Invalid command 'bdist\_wheel'** If you're facing an error message like:

```
error: invalid command 'bdist_wheel'
```

You may need to run:

```
python -m pip install -U pip
```

Or

```
python -m pip install wheel
```

Before running the pip commands, please make sure you're using the IDF python virtual environment.

## Basic Concepts

**Component-based Unit Tests** Component-based unit tests are our recommended way to test your component. All the test apps should be located under `${IDF_PATH}/components/<COMPONENT_NAME>/test_apps`.

For example:

```

components/
├── my_component/
│   ├── include/
│   │   └── ...
│   ├── test_apps/
│   │   ├── test_app_1
│   │   │   ├── main/
│   │   │   │   └── ...
│   │   │   ├── CMakeLists.txt
│   │   │   └── pytest_my_component_app_1.py
│   │   ├── test_app_2
│   │   │   ├── ...
│   │   │   └── pytest_my_component_app_2.py
│   │   └── parent_folder
│   │       ├── test_app_3
│   │       │   ├── ...
│   │       │   └── pytest_my_component_app_3.py
│   │       └── ...
│   ├── my_component.c
│   └── CMakeLists.txt

```

**Example Tests** Example Tests are tests for examples that are intended to demonstrate parts of the ESP-IDF functionality to our customers.

All the test apps should be located under `${IDF_PATH}/examples`. For more information please refer to the [Examples Readme](#).

For example:

```

examples/
├── parent_folder/
│   └── example_1/
│       ├── main/
│       │   └── ...
│       ├── CMakeLists.txt
│       └── pytest_example_1.py

```

**Custom Tests** Custom Tests are tests that aim to run some arbitrary test internally. They are not intended to demonstrate the ESP-IDF functionality to our customers in any way.

All the test apps should be located under `${IDF_PATH}/tools/test_apps`. For more information please refer to the [Custom Test Readme](#).

## Pytest in ESP-IDF

### Pytest Execution Process

1. Bootstrapping Phase
  - Create session-scoped caches:
    - port-target cache
    - port-app cache
2. Collection Phase
  1. Get all the python files with the prefix `pytest_`

2. Get all the test functions with the prefix `test_`
  3. Apply the [params](#), and duplicate the test functions.
  4. Filter the test cases with CLI options. Introduced detailed usages [here](#)
3. Test Running Phase
    1. Construct the [fixtures](#). In ESP-IDF, the common fixtures are initialized in this order:
      1. `pexpect_proc`: [pexpect](#) instance
      2. `app`: [IdfApp](#) instance  
The information of the app, like `sdkconfig`, `flash_files`, `partition_table`, etc., would be parsed at this phase.
      3. `serial`: [IdfSerial](#) instance  
The port of the host which connected to the target type parsed from the app would be auto-detected.  
The flash files would be auto flashed.
      4. `dut`: [IdfDut](#) instance
    2. Run the real test function
    3. Deconstruct the fixtures in this order:
      1. `dut`
        1. close the `serial` port
        2. (Only for apps with [unity test framework](#)) generate junit report of the unity test cases
      2. `serial`
      3. `app`
      4. `pexpect_proc`: Close the file descriptor
    4. (Only for apps with [unity test framework](#))  
Raise `AssertionError` when detected unity test failed if you call `dut.expect_from_unity_output()` in the test function.
  4. Reporting Phase
    1. Generate junit report of the test functions
    2. Modify the junit report test case name into ESP-IDF test case ID format: `<target>.<config>.<test function name>`
  5. Finalizing Phase (Only for apps with [unity test framework](#))  
Combine the junit reports if the junit reports of the unity test cases are generated.

**Example Code** This code example is taken from `pytest_console_basic.py`.

```
@pytest.mark.esp32
@pytest.mark.esp32c3
@pytest.mark.generic
@pytest.mark.parametrize('config', [
    'history',
    'nohistory',
], indirect=True)
def test_console_advanced(config: str, dut: Dut) -> None:
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```

**Note:** Using `expect_exact` is better here. For further reading about the different types of `expect` functions, please refer to the [pytest-embedded Expecting documentation](#).

**Use Markers to Specify the Supported Targets** You can use markers to specify the supported targets and the test env in CI. You can run `pytest --markers` to get more details about different markers.

```
@pytest.mark.esp32      # <-- support esp32
@pytest.mark.esp32c3    # <-- support esp32c3
@pytest.mark.generic     # <-- test env `generic, would assign to runner with tag_
↳ `generic`
```

Besides, if the test case supports all officially ESP-IDF-supported targets, like esp32, esp32s2, esp32s3, esp32c3 for now (2022.2), you can use a special marker `supported_targets` to apply them all in one line.

This code example is taken from `pytest_gptimer_example.py`.

```
@pytest.mark.supported_targets
@pytest.mark.generic
def test_gptimer_example(dut: Dut) -> None:
    ...
```

**Use Params to Specify the sdkconfig Files** You can use `pytest.mark.parametrize` with “config” to apply the same test to different apps with different sdkconfig files. For more information about `sdkconfig.ci.xxx` files, please refer to the Configuration Files section under [this readme](#).

```
@pytest.mark.parametrize('config', [
    'history',      # <-- run with app built by sdkconfig.ci.history
    'nohistory',   # <-- run with app built by sdkconfig.ci.nohistory
], indirect=True) # <-- `indirect=True` is required
```

Overall, this test function would be replicated to 4 test cases:

- esp32.history.test\_console\_advanced
- esp32.nohistory.test\_console\_advanced
- esp32c3.history.test\_console\_advanced
- esp32c3.nohistory.test\_console\_advanced

## Advanced Examples

### Multi Dut Tests with the Same App

```
@pytest.mark.esp32s2
@pytest.mark.esp32s3
@pytest.mark.usb_host
@pytest.mark.parametrize('count', [
    2,
], indirect=True)
def test_usb_host(dut: Tuple[IdfDut, IdfDut]) -> None:
    device = dut[0] # <-- assume the first dut is the device
    host = dut[1]  # <-- and the second dut is the host
    ...
```

After setting the param `count` to 2, all these fixtures are changed into tuples.

**Multi Dut Tests with Different Apps** This code example is taken from `pytest_wifi_getting_started.py`.

```
@pytest.mark.esp32
@pytest.mark.multi_dut_generic
@pytest.mark.parametrize(
    'count, app_path', [
        (2,
         f'{os.path.join(os.path.dirname(__file__), "softAP")}'|f'{os.path.join(os.
↳path.dirname(__file__), "station")}')],
    ], indirect=True
)
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]
    ...
```

Here the first dut was flashed with the app [softap](#) , and the second dut was flashed with the app [station](#) .

**Note:** Here the `app_path` should be set with absolute path. the `__file__` macro in python would return the absolute path of the test script itself.

**Multi Dut Tests with Different Apps, and Targets** This code example is taken from [pytest\\_wifi\\_getting\\_started.py](#) . As the comment says, for now it' s not running in the ESP-IDF CI.

```
@pytest.mark.parametrize(
    'count, app_path, target', [
        (2,
         f'{os.path.join(os.path.dirname(__file__), "softAP")}|{os.path.join(os.
↳path.dirname(__file__), "station")}|',
         'esp32|esp32s2'),
        (2,
         f'{os.path.join(os.path.dirname(__file__), "softAP")}|{os.path.join(os.
↳path.dirname(__file__), "station")}|',
         'esp32s2|esp32'),
    ],
    indirect=True,
)
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]
    ...
```

Overall, this test function would be replicated to 2 test cases:

- softap with esp32 target, and station with esp32s2 target
- softap with esp32s2 target, and station with esp32 target

**Support different targets with different sdkconfig files** This code example is taken from [pytest\\_panic.py](#) as an advanced example.

```
CONFIGS = [
    pytest.param('coredump_flash_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
↳esp32s2]),
    pytest.param('coredump_flash_elf_sha', marks=[pytest.mark.esp32]), # sha256_
↳only supported on esp32
    pytest.param('coredump_uart_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
↳esp32s2]),
    pytest.param('coredump_uart_elf_crc', marks=[pytest.mark.esp32, pytest.mark.
↳esp32s2]),
    pytest.param('gdbstub', marks=[pytest.mark.esp32, pytest.mark.esp32s2]),
    pytest.param('panic', marks=[pytest.mark.esp32, pytest.mark.esp32s2]),
]

@pytest.mark.parametrize('config', CONFIGS, indirect=True)
...

```

**Use Custom Class** Usually, you can write a custom class in these conditions:

1. Add more reusable functions for a certain number of DUTs
2. Add custom setup and teardown functions in different phases described [here](#)

This code example is taken from [panic/conftest.py](#)

```

class PanicTestDut (IdfDut) :
    ...

@pytest.fixture(scope='module')
def monkeypatch_module(request: FixtureRequest) -> MonkeyPatch:
    mp = MonkeyPatch()
    request.addfinalizer(mp.undo)
    return mp

@pytest.fixture(scope='module', autouse=True)
def replace_dut_class(monkeypatch_module: MonkeyPatch) -> None:
    monkeypatch_module setattr('pytest_embedded_idf.dut.IdfDut', PanicTestDut)

```

monkeypatch\_module provide a [module-scoped monkeypatch](#) fixture.

replace\_dut\_class is a [module-scoped autouse](#) fixture. This function replaces the IdfDut class with your custom class.

**Mark Flaky Tests** Sometimes, our test is based on ethernet or wifi. The network may cause the test flaky. We could mark the single test case within the code repo.

This code example is taken from [pytest\\_esp\\_eth.py](#)

```

@pytest.mark.flaky(reruns=3, reruns_delay=5)
def test_esp_eth_ip101(dut: Dut) -> None:
    ...

```

This flaky marker means that if the test function failed, the test case would rerun for a maximum of 3 times with 5 seconds delay.

**Mark Known Failure Cases** Sometimes a test couldn't pass for the following reasons:

- Has a bug
- The success ratio is too low because of environment issue, such as network issue. Retry couldn't help

Now you may mark this test case with marker [xfail](#) with a user-friendly readable reason.

This code example is taken from [pytest\\_panic.py](#)

```

@pytest.mark.xfail('config.getvalue("target") == "esp32s2"', reason='raised_
↳IllegalInstruction instead')
def test_cache_error(dut: PanicTestDut, config: str, test_func_name: str) -> None:

```

This marker means that if the test would be a known failure one on esp32s2.

**Mark Nightly Run Test Cases** Some tests cases are only triggered in nightly run pipelines due to a lack of runners.

```

@pytest.mark.nightly_run

```

This marker means that the test case would only be run with env var NIGHTLY\_RUN or INCLUDE\_NIGHTLY\_RUN.

## Run the Tests in CI

The workflow in CI is simple, build jobs -> target test jobs.

## Build Jobs

## Build Job Names

- Component-based Unit Tests: `build_pytest_components_<target>`
- Example Tests: `build_pytest_examples_<target>`
- Custom Tests: `build_pytest_test_apps_<target>`

**Build Job Command** The command used by CI to build all the relevant tests is: `python $IDF_PATH/tools/ci/ci_build_apps.py <parent_dir> --target <target> -vv --pytest-apps`

All apps which supported the specified target would be built with all supported sdkconfig files under `build_<target>_<config>`.

For example, If you run `python $IDF_PATH/tools/ci/ci_build_apps.py $IDF_PATH/examples/system/console/basic --target esp32 --pytest-apps`, the folder structure would be like this:

```
basic
├── build_esp32_history/
│   └── ...
├── build_esp32_nohistory/
│   └── ...
├── main/
├── CMakeLists.txt
├── pytest_console_basic.py
└── ...
```

All the binaries folders would be uploaded as artifacts under the same directories.

## Target Test Jobs

### Target Test Job Names

- Component-based Unit Tests: `component_ut_pytest_<target>_<test_env>`
- Example Tests: `example_test_pytest_<target>_<test_env>`
- Custom Tests: `test_app_test_pytest_<target>_<test_env>`

**Target Test Job Command** The command used by CI to run all the relevant tests is: `pytest <parent_dir> --target <target> -m <test_env_marker>`

All test cases with the specified target marker and the test env marker under the parent folder would be executed.

The binaries in the target test jobs are downloaded from build jobs, the artifacts would be placed under the same directories.

## Run the Tests Locally

The local executing process is the same as the CI process.

For example, if you want to run all the esp32 tests under the `$IDF_PATH/examples/system/console/basic` folder, you may:

```
$ pip install pytest-embedded-serial-esp pytest-embedded-idf
$ cd $IDF_PATH
$ ./export.sh
$ cd examples/system/console/basic
$ python $IDF_PATH/tools/ci/ci_build_apps.py . --target esp32 -vv --pytest-apps
$ pytest --target esp32
```

## Tips and Tricks

### Filter the Test Cases

- filter by target with `pytest --target <target>`  
pytest would run all the test cases that support specified target.
- filter by sdkconfig file with `pytest --sdkconfig <sdkconfig>`  
if `<sdkconfig>` is default, pytest would run all the test cases with the sdkconfig file `sdkconfig.defaults`.  
In other cases, pytest would run all the test cases with sdkconfig file `sdkconfig.ci.<sdkconfig>`.

**Add New Markers** We're using two types of custom markers, target markers which indicate that the test cases should support this target, and env markers which indicate that the test case should be assigned to runners with these tags in CI.

You can add new markers by adding one line under the `#{IDF_PATH}/pytest.ini` `markers =` section. The grammar should be: `<marker_name>: <marker_description>`

**Generate JUnit Report** You can call pytest with `--junitxml <filepath>` to generate the JUnit report. In ESP-IDF, the test case name would be unified as “`<target>.<config>.<function_name>`”.

**Skip Auto Flash Binary** Skipping auto-flash binary every time would be useful when you're debugging your test script.

You can call pytest with `--skip-autoflash y` to achieve it.

**Record Statistics** Sometimes you may need to record some statistics while running the tests, like the performance test statistics.

You can use `record_xml_attribute` fixture in your test script, and the statistics would be recorded as attributes in the JUnit report.

**Logging System** Sometimes you may need to add some extra logging lines while running the test cases.

You can use `python logging module` to achieve this.

### Known Limitations and Workarounds

**Avoid Using Thread for Performance Test** `pytest-embedded` is using some threads internally to help gather all stdout to the pexpect process. Due to the limitation of `Global Interpreter Lock`, if you're using threads to do performance tests, these threads would block each other and there would be great performance loss.

#### workaround

Use `Process` instead, the APIs should be almost the same as `Thread`.

- pytest documentation: <https://docs.pytest.org/en/latest/contents.html>
- pytest-embedded documentation: <https://docs.espressif.com/projects/pytest-embedded/en/latest/>

# Chapter 8

## ESP-IDF Versions

The ESP-IDF GitHub repository is updated regularly, especially the master branch where new development takes place.

For production use, there are also stable releases available.

### 8.1 Releases

The documentation for the current stable release version can always be found at this URL:

<https://docs.espressif.com/projects/esp-idf/en/stable/>

Documentation for the latest version (master branch) can always be found at this URL:

<https://docs.espressif.com/projects/esp-idf/en/latest/>

The full history of releases can be found on the GitHub repository [Releases page](#). There you can find release notes, links to each version of the documentation, and instructions for obtaining each version.

### 8.2 Which Version Should I Start With?

- For production purposes, use the [current stable version](#). Stable versions have been manually tested, and are updated with “bugfix releases” which fix bugs without changing other functionality (see [Versioning Scheme](#) for more details). Every stable release version can be found on the [Releases page](#).
- For prototyping, experimentation or for developing new ESP-IDF features, use the [latest version \(master branch in Git\)](#). The latest version in the master branch has all the latest features and has passed automated testing, but has not been completely manually tested ( “bleeding edge” ).
- If a required feature is not yet available in a stable release, but you do not want to use the master branch, it is possible to check out a pre-release version or a release branch. It is recommended to start from a stable version and then follow the instructions for [Updating to a Pre-Release Version](#) or [Updating to a Release Branch](#).
- If you plan to use another project which is based on ESP-IDF, please check the documentation of that project to determine the version(s) of ESP-IDF it is compatible with.

See [Updating ESP-IDF](#) if you already have a local copy of ESP-IDF and wish to update it.

### 8.3 Versioning Scheme

ESP-IDF uses [Semantic Versioning](#). This means that:

- Major Releases, like v3.0, add new functionality and may change functionality. This includes removing deprecated functionality.  
If updating to a new major release (for example, from v2.1 to v3.0), some of your project's code may need updating and functionality may need to be re-tested. The release notes on the [Releases page](#) include lists of Breaking Changes to refer to.
- Minor Releases like v3.1 add new functionality and fix bugs but will not change or remove documented functionality, or make incompatible changes to public APIs.  
If updating to a new minor release (for example, from v3.0 to v3.1), your project's code does not require updating, but you should re-test your project. Pay particular attention to the items mentioned in the release notes on the [Releases page](#).
- Bugfix Releases like v3.0.1 only fix bugs and do not add new functionality.  
If updating to a new bugfix release (for example, from v3.0 to v3.0.1), you do not need to change any code in your project, and you only need to re-test the functionality directly related to bugs listed in the release notes on the [Releases page](#).

## 8.4 Support Periods

Each ESP-IDF major and minor release version has an associated support period. After this period, the release is End of Life and no longer supported.

The [ESP-IDF Support Period Policy](#) explains this in detail, and describes how the support periods for each release are determined.

Each release on the [Releases page](#) includes information about the support period for that particular release.

As a general guideline:

- If starting a new project, use the latest stable release.
- If you have a GitHub account, click the “Watch” button in the top-right of the [Releases page](#) and choose “Releases only”. GitHub will notify you whenever a new release is available. Whenever a bug fix release is available for the version you are using, plan to update to it.
- If possible, periodically update the project to a new major or minor ESP-IDF version (for example, once a year.) The update process should be straightforward for Minor updates, but may require some planning and checking of the release notes for Major updates.
- Always plan to update to a newer release before the release you are using becomes End of Life.

Each ESP-IDF major and minor release (V4.1, V4.2, etc) is supported for 30 months after the initial stable release date.

Supported means that the ESP-IDF team will continue to apply bug fixes, security fixes, etc to the release branch on GitHub, and periodically make new bugfix releases as needed.

Support period is divided into “Service” and “Maintenance” period:

Period	Duration	Recommended for new projects?
Service	12 months	Yes
Maintenance	18 months	No

During the Service period, bugfixes releases are more frequent. In some cases, support for new features may be added during the Service period (this is reserved for features which are needed to meet particular regulatory requirements or standards for new products, and which carry a very low risk of introducing regressions.)

During the Maintenance period, the version is still supported but only bugfixes for high severity issues or security issues will be applied.

Using an “In Service” version is recommended when starting a new project.

Users are encouraged to upgrade all projects to a newer ESP-IDF release before the support period finishes and the release becomes End of Life (EOL). It is our policy to not continue fixing bugs in End of Life releases.

Pre-release versions (betas, previews, *-rc* and *-dev* versions, etc) are not covered by any support period. Sometimes a particular feature is marked as “Preview” in a release, which means it is also not covered by the support period.

The ESP-IDF Programming Guide has information about the [different versions of ESP-IDF](#) (major, minor, bugfix, etc).

## 8.5 Checking the Current Version

The local ESP-IDF version can be checked by using `idf.py`:

```
idf.py --version
```

The ESP-IDF version is also compiled into the firmware and can be accessed (as a string) via the macro `IDF_VER`. The default ESP-IDF bootloader will print the version on boot (the version information is not always updated if the code in the GitHub repo is updated, it only changes if there is a clean build or if that particular source file is recompiled).

If writing code that needs to support multiple ESP-IDF versions, the version can be checked at compile time using [compile-time macros](#).

Examples of ESP-IDF versions:

Version String	Meaning
v3.2-dev-306-gbeb3611ca	<p>Master branch pre-release.</p> <ul style="list-style-type: none"> <li>- v3.2-dev - in development for version 3.2.</li> <li>- 306 - number of commits after v3.2 development started.</li> <li>- beb3611ca - commit identifier.</li> </ul>
v3.0.2	<p>Stable release, tagged v3.0.2.</p>
v3.1-beta1-75-g346d6b0ea	<p>Beta version in development (on a <i>release branch</i>).</p> <ul style="list-style-type: none"> <li>- v3.1-beta1 - pre-release tag.</li> <li>- 75 - number of commits after the pre-release beta tag was assigned.</li> <li>- 346d6b0ea - commit identifier.</li> </ul>
v3.0.1-dirty	<p>Stable release, tagged v3.0.1.</p> <ul style="list-style-type: none"> <li>- dirty means that there are modifications in the local ESP-IDF directory.</li> </ul>

## 8.6 Git Workflow

The development (Git) workflow of the Espressif ESP-IDF team is as follows:

- New work is always added on the master branch (latest version) first. The ESP-IDF version on `master` is always tagged with `-dev` (for “in development”), for example `v3.1-dev`.
- Changes are first added to an internal Git repository for code review and testing but are pushed to GitHub after automated testing passes.
- When a new version (developed on `master`) becomes feature complete and “beta” quality, a new branch is made for the release, for example `release/v3.1`. A pre-release tag is also created, for example `v3.1-beta1`. You can see a full [list of branches](#) and a [list of tags](#) on GitHub. Beta pre-releases have release notes which may include a significant number of Known Issues.
- As testing of the beta version progresses, bug fixes will be added to both the `master` branch and the release branch. New features for the next release may start being added to `master` at the same time.
- Once testing is nearly complete a new release candidate is tagged on the release branch, for example `v3.1-rc1`. This is still a pre-release version.
- If no more significant bugs are found or reported, then the final Major or Minor Version is tagged, for example `v3.1`. This version appears on the [Releases page](#).
- As bugs are reported in released versions, the fixes will continue to be committed to the same release branch.
- Regular bugfix releases are made from the same release branch. After manual testing is complete, a bugfix release is tagged (i.e. `v3.1.1`) and appears on the [Releases page](#).

## 8.7 Updating ESP-IDF

Updating ESP-IDF depends on which version(s) you wish to follow:

- [Updating to Stable Release](#) is recommended for production use.

- [Updating to Master Branch](#) is recommended for the latest features, development use, and testing.
- [Updating to a Release Branch](#) is a compromise between the first two.

---

**Note:** These guides assume that you already have a local copy of ESP-IDF cloned. To get one, check Step 2 in the [Getting Started](#) guide for any ESP-IDF version.

---

### 8.7.1 Updating to Stable Release

To update to a new ESP-IDF release (recommended for production use), this is the process to follow:

- Check the [Releases page](#) regularly for new releases.
- When a bugfix release for the version you are using is released (for example, if using v3.0.1 and v3.0.2 is released), check out the new bugfix version into the existing ESP-IDF directory:

```
cd $IDF_PATH
git fetch
git checkout vX.Y.Z
git submodule update --init --recursive
```

- When major or minor updates are released, check the Release Notes on the releases page and decide if you want to update or to stay with your current release. Updating is via the same Git commands shown above.

---

**Note:** If you installed the stable release via zip file instead of using git, it might not be possible to update versions using the commands. In this case, update by downloading a new zip file and replacing the entire `IDF_PATH` directory with its contents.

---

### 8.7.2 Updating to a Pre-Release Version

It is also possible to `git checkout` a tag corresponding to a pre-release version or release candidate, the process is the same as [Updating to Stable Release](#).

Pre-release tags are not always found on the [Releases page](#). Consult the [list of tags](#) on GitHub for a full list. Caveats for using a pre-release are similar to [Updating to a Release Branch](#).

### 8.7.3 Updating to Master Branch

---

**Note:** Using Master branch means living “on the bleeding edge” with the latest ESP-IDF code.

---

To use the latest version on the ESP-IDF master branch, this is the process to follow:

- Check out the master branch locally:

```
cd $IDF_PATH
git checkout master
git pull
git submodule update --init --recursive
```

- Periodically, re-run `git pull` to pull the latest version of master. Note that you may need to change your project or report bugs after updating your master branch.
- To switch from master to a release branch or stable version, run `git checkout` as shown in the other sections.

**Important:** It is strongly recommended to regularly run `git pull` and then `git submodule update --init --recursive` so a local copy of master does not get too old. Arbitrary old master branch revisions are effectively unsupported “snapshots” that may have undocumented bugs. For a semi-stable version, try [Updating to a Release Branch](#) instead.

---

## 8.7.4 Updating to a Release Branch

In terms of stability, using a release branch is part-way between using the master branch and only using stable releases. A release branch is always beta quality or better, and receives bug fixes before they appear in each stable release.

You can find a [list of branches](#) on GitHub.

For example, to follow the branch for ESP-IDF v3.1, including any bugfixes for future releases like v3.1.1, etc:

```
cd $IDF_PATH
git fetch
git checkout release/v3.1
git pull
git submodule update --init --recursive
```

Each time you `git pull` this branch, ESP-IDF will be updated with fixes for this release.

---

**Note:** There is no dedicated documentation for release branches. It is recommended to use the documentation for the closest version to the branch which is currently checked out.

---

## Chapter 9

# Resources

### 9.1 PlatformIO

- [What is PlatformIO?](#)
- [Installation](#)
- [Configuration](#)
- [Tutorials](#)
- [Project Examples](#)
- [Next Steps](#)

#### 9.1.1 What is PlatformIO?

PlatformIO is a cross-platform embedded development environment with out-of-the-box support for ESP-IDF.

Since ESP-IDF support within PlatformIO is not maintained by the Espressif team, please report any issues with PlatformIO directly to its developers in [the official PlatformIO repositories](#).

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in [the official PlatformIO documentation](#).

#### 9.1.2 Installation

- [PlatformIO IDE](#) is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms
- [PlatformIO Core \(CLI\)](#) is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services

### 9.1.3 Configuration

Please go through [the official PlatformIO configuration guide](#) for ESP-IDF.

### 9.1.4 Tutorials

- [ESP-IDF and ESP32-DevKitC: debugging, unit testing, project analysis](#)

### 9.1.5 Project Examples

Please check ESP-IDF page in [the official PlatformIO documentation](#)

### 9.1.6 Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Learn more about [integrations with other IDEs/Text Editors](#)
- Get help from [PlatformIO community](#)

## 9.2 Useful Links

- The [esp32.com forum](#) is a place to ask questions and find community resources.
- Check the [Issues](#) section on GitHub if you find a bug or have a feature request. Please check existing [Issues](#) before opening a new one.
- A comprehensive collection of [solutions](#), [practical applications](#), [components and drivers](#) based on ESP-IDF is available in [ESP IoT Solution](#) repository. In most of cases descriptions are provided both in English and in 中文.
- To develop applications using Arduino platform, refer to [Arduino core for the ESP32, ESP32-S2 and ESP32-C3](#).
- Several [books](#) have been written about ESP32 and they are listed on [Espressif](#) web site.
- If you're interested in contributing to ESP-IDF, please check the [Contributions Guide](#).
- For additional ESP32-C3 product related information, please refer to [documentation](#) section of [Espressif](#) site.
- [Download](#) latest and previous versions of this documentation in PDF and HTML format.

# Chapter 10

## Copyrights and Licenses

### 10.1 Software Copyrights

All original source code in this repository is Copyright (C) 2015-2022 Espressif Systems. This source code is licensed under the Apache License 2.0 as described in the file LICENSE.

Additional third party copyrighted code is included under the following licenses.

Where source code headers specify Copyright & License information, this information takes precedence over the summaries made here.

Some examples use external components which are not Apache licensed, please check the copyright description in each example source code.

#### 10.1.1 Firmware Components

These third party libraries can be included into the application (firmware) produced by ESP-IDF.

- [Newlib](#) is licensed under the BSD License and is Copyright of various parties, as described in [COPYING.NEWLIB](#).
- [Xtensa header files](#) are Copyright (C) 2013 Tensilica Inc and are licensed under the MIT License as reproduced in the individual header files.
- Original parts of [FreeRTOS](#) (components/freertos) are Copyright (C) 2017 Amazon.com, Inc. or its affiliates are licensed under the MIT License, as described in [license.txt](#).
- Original parts of [LWIP](#) (components/lwip) are Copyright (C) 2001, 2002 Swedish Institute of Computer Science and are licensed under the BSD License as described in [COPYING file](#).
- [wpa\\_supplicant](#) Copyright (c) 2003-2005 Jouni Malinen and licensed under the BSD license.
- [Fast PBKDF2](#) Copyright (c) 2015 Joseph Birr-Pixton and licensed under CC0 Public Domain Dedication license.
- [FreeBSD net80211](#) Copyright (c) 2004-2008 Sam Leffler, Errno Consulting and licensed under the BSD license.
- [argtable3](#) argument parsing library Copyright (C) 1998-2001,2003-2011,2013 Stewart Heitmann and licensed under 3-clause BSD license. [argtable3](#) also includes the following software components. For details, please see [argtable3 LICENSE file](#).
  - C Hash Table library, Copyright (c) 2002, Christopher Clark and licensed under 3-clause BSD license.
  - The Better String library, Copyright (c) 2014, Paul Hsieh and licensed under 3-clause BSD license.
  - TCL library, Copyright the Regents of the University of California, Sun Microsystems, Inc., Scriptics Corporation, ActiveState Corporation and other parties, and licensed under TCL/TK License.
- [linenoise](#) line editing library Copyright (c) 2010-2014 Salvatore Sanfilippo, Copyright (c) 2010-2013 Pieter Noordhuis, licensed under 2-clause BSD license.
- [FatFS](#) library, Copyright (C) 2017 ChaN, is licensed under [a BSD-style license](#) .
- [cJSON](#) library, Copyright (c) 2009-2017 Dave Gamble and cJSON contributors, is licensed under MIT license as described in [LICENSE file](#) .

- [micro-ecc](#) library, Copyright (c) 2014 Kenneth MacKay, is licensed under 2-clause BSD license.
- [Mbed TLS](#) library, Copyright (C) 2006-2018 ARM Limited, is licensed under Apache License 2.0 as described in [LICENSE file](#) .
- [SPIFFS](#) library, Copyright (c) 2013-2017 Peter Andersson, is licensed under MIT license as described in [LICENSE file](#) .
- [SD/MMC driver](#) is derived from [OpenBSD SD/MMC driver](#), Copyright (c) 2006 Uwe Stuehler, and is licensed under BSD license.
- [ESP-MQTT](#) MQTT Package (contiki-mqtt) - Copyright (c) 2014, Stephen Robinson, MQTT-ESP - Tuan PM <tuanpm at live dot com> is licensed under Apache License 2.0 as described in [LICENSE file](#) .
- [BLE Mesh](#) is adapted from Zephyr Project, Copyright (c) 2017-2018 Intel Corporation and licensed under Apache License 2.0.
- [mynewt-nimble](#) Apache Mynewt NimBLE, Copyright 2015-2018, The Apache Software Foundation, is licensed under Apache License 2.0 as described in [LICENSE file](#).
- [TLSF allocator](#) Two Level Segregated Fit memory allocator, Copyright (c) 2006-2016, Matthew Conte, and licensed under the BSD 3-clause license.
- [openthread](#), Copyright (c) The OpenThread Authors, is licensed under BSD License as described in [LICENSE file](#).
- [UBSAN runtime](#) —Copyright (c) 2016, Linaro Limited and Jiří Závěručky, licensed under the BSD 2-clause license.
- [HTTP Parser](#) Based on src/http/nginx\_http\_parse.c from NGINX copyright Igor Sysoev. Additional changes are licensed under the same terms as NGINX and Joyent, Inc. and other Node contributors. For details please check [LICENSE file](#).
- [SEGGER SystemView](#) target-side library, Copyright (c) 2015-2017 SEGGER Microcontroller GmbH & Co. KG, is licensed under BSD 3-clause license.

### 10.1.2 Documentation

- HTML version of the [ESP-IDF Programming Guide](#) uses the Sphinx theme [sphinx\\_idf\\_theme](#), which is Copyright (c) 2013-2020 Dave Snider, Read the Docs, Inc. & contributors, and Espressif Systems (Shanghai) CO., LTD. It is based on [sphinx\\_rtd\\_theme](#). Both are licensed under MIT license.

## 10.2 ROM Source Code Copyrights

ESP32, ESP32-S and ESP32-C Series SoCs mask ROM hardware includes binaries compiled from portions of the following third party software:

- [Newlib](#) , licensed under the BSD License and is Copyright of various parties, as described in [COPYING.NEWLIB](#).
- Xtensa libhal, Copyright (c) Tensilica Inc and licensed under the MIT license (see below).
- [TinyBasic](#) Plus, Copyright Mike Field & Scott Lawrence and licensed under the MIT license (see below).
- [miniz](#), by Rich Geldreich - placed into the public domain.
- [wpa\\_supplicant](#) Copyright (c) 2003-2005 Jouni Malinen and licensed under the BSD license.
- [TJpgDec](#) Copyright (C) 2011, ChaN, all right reserved. See below for license.
- **Parts of Zephyr RTOS USB stack:**
  - [DesignWare USB device driver](#) Copyright (c) 2016 Intel Corporation and licensed under Apache 2.0 license.
  - [Generic USB device driver](#) Copyright (c) 2006 Bertrik Sikken ([bertrik@sikken.nl](mailto:bertrik@sikken.nl)), 2016 Intel Corporation and licensed under BSD 3-clause license.
  - [USB descriptors functionality](#) Copyright (c) 2017 PHYTEC Messtechnik GmbH, 2017-2018 Intel Corporation and licensed under Apache 2.0 license.
  - [USB DFU class driver](#) Copyright(c) 2015-2016 Intel Corporation, 2017 PHYTEC Messtechnik GmbH and licensed under BSD 3-clause license.
  - [USB CDC ACM class driver](#) Copyright(c) 2015-2016 Intel Corporation and licensed under Apache 2.0 license

### 10.3 Xtensa libhal MIT License

Copyright (c) 2003, 2006, 2010 Tensilica Inc.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the “Software” ), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED “AS IS”, WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

### 10.4 TinyBasic Plus MIT License

Copyright (c) 2012-2013

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the “Software” ), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED “AS IS”, WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. ### 10.5 TJpgDec License

TJpgDec - Tiny JPEG Decompressor R0.01 (C)ChaN, 2011 The TJpgDec is a generic JPEG decompressor module for tiny embedded systems. This is a free software that opened for education, research and commercial developments under license policy of following terms.

Copyright (C) 2011, ChaN, all right reserved.

- The TJpgDec module is a free software and there is NO WARRANTY.
- No restriction on use. You can use, modify and redistribute it for personal, non-profit or commercial products UNDER YOUR RESPONSIBILITY.
- Redistributions of source code must retain the above copyright notice.

# Chapter 11

## About

This is documentation of [ESP-IDF](#), the framework to develop applications for ESP32-C3.

The ESP32-C3 is a 2.4 GHz Wi-Fi Bluetooth Low Energy combo SoC, which integrates a 32-bit RISC-V RV32IMC single-core processor.

Fig. 1: Espressif IoT Integrated Development Framework

The ESP-IDF, Espressif IoT Development Framework, provides toolchain, API, components and workflows to develop applications for ESP32-C3 using Windows, Linux and macOS operating systems.

## Chapter 12

# Switch Between Languages

The ESP-IDF Programming Guide is now available in two languages. Please refer to the English version if there is any discrepancy.

- English
- Chinese

You can easily change from one language to another by clicking the language link you can find at the top of every document that has a translation.

The screenshot shows a breadcrumb trail: [Home](#) » [API Guides](#) » [Fatal Errors](#). On the right, there is a link [Edit on GitHub](#). Below the breadcrumb, the title **Fatal Errors** is displayed. A link [\[中文\]](#) is circled in red, indicating the Chinese language option. Below the title, the section **Overview** is shown, followed by the text: "In certain situations, execution of the program can not be continued in a well defined way. In ESP-IDF, these situations include:"
