- ESP_ERR_NO_MEM if no memory to register new heap.
- ESP_ERR_INVALID_SIZE if the memory region is too small to fit a heap
- ESP_FAIL if region overlaps the start and/or end of an existing region
API Reference - Multi Heap API

(Note: The multi heap API is used internally by the heap capabilities allocator. Most IDF programs will never need to call this API directly.)

Header File

- components/heap/include/multi_heap.h

Functions

void *multi_heap_aligned_alloc (multi_heap_handle_t heap, size_t size, size_t alignment)
allocate a chunk of memory with specific alignment

Parameters
- heap - Handle to a registered heap.
- size - size in bytes of memory chunk
- alignment - how the memory must be aligned

Returns pointer to the memory allocated, NULL on failure

void *multi_heap_malloc (multi_heap_handle_t heap, size_t size)
malloc() a buffer in a given heap

Semantics are the same as standard malloc(), only the returned buffer will be allocated in the specified heap.

Parameters
- heap - Handle to a registered heap.
- size - Size of desired buffer.

Returns Pointer to new memory, or NULL if allocation fails.

void multi_heap_aligned_free (multi_heap_handle_t heap, void *p)
free() a buffer aligned in a given heap.

Note: This function is deprecated, consider using multi_heap_free() instead

Parameters
- heap - Handle to a registered heap.
- p - NULL, or a pointer previously returned from multi_heap_aligned_alloc() for the same heap.

void multi_heap_free (multi_heap_handle_t heap, void *p)
free() a buffer in a given heap.

Semantics are the same as standard free(), only the argument ‘p’ must be NULL or have been allocated in the specified heap.

Parameters
- heap - Handle to a registered heap.
- p - NULL, or a pointer previously returned from multi_heap_malloc() or multi_heap_realloc() for the same heap.

void *multi_heap_realloc (multi_heap_handle_t heap, void *p, size_t size)
realloc() a buffer in a given heap.

Semantics are the same as standard realloc(), only the argument ‘p’ must be NULL or have been allocated in the specified heap.

Parameters
- heap - Handle to a registered heap.
- p - NULL, or a pointer previously returned from multi_heap_malloc() or multi_heap_realloc() for the same heap.
Chapter 2. API Reference

- **size** - Desired new size for buffer.

  Returns New buffer of ‘size’ containing contents of ‘p’, or NULL if reallocation failed.

`size_t multi_heap_get_allocated_size(multi_heap_handle_t heap, void *p)`

Return the size that a particular pointer was allocated with.

**Parameters**
- `heap` - Handle to a registered heap.
- `p` - Pointer, must have been previously returned from multi_heap_malloc() or multi_heap_realloc() for the same heap.

**Returns** Size of the memory allocated at this block. May be more than the original size argument, due to padding and minimum block sizes.

`multi_heap_handle_t multi_heap_register(void *start, size_t size)`

Register a new heap for use.

This function initialises a heap at the specified address, and returns a handle for future heap operations.

There is no equivalent function for deregistering a heap - if all blocks in the heap are free, you can immediately start using the memory for other purposes.

**Parameters**
- `start` - Start address of the memory to use for a new heap.
- `size` - Size (in bytes) of the new heap.

**Returns** Handle of a new heap ready for use, or NULL if the heap region was too small to be initialised.

`void multi_heap_set_lock(multi_heap_handle_t heap, void *lock)`

Associate a private lock pointer with a heap.

The lock argument is supplied to the MULTI_HEAP_LOCK() and MULTI_HEAP_UNLOCK() macros, defined in multi_heap_platform.h.

The lock in question must be recursive.

When the heap is first registered, the associated lock is NULL.

**Parameters**
- `heap` - Handle to a registered heap.
- `lock` - Optional pointer to a locking structure to associate with this heap.

`void multi_heap_dump(multi_heap_handle_t heap)`

Dump heap information to stdout.

For debugging purposes, this function dumps information about every block in the heap to stdout.

**Parameters**
- `heap` - Handle to a registered heap.

`bool multi_heap_check(multi_heap_handle_t heap, bool print_errors)`

Check heap integrity.

Walks the heap and checks all heap data structures are valid. If any errors are detected, an error-specific message can be optionally printed to stderr. Print behaviour can be overridden at compile time by defining MULTI_CHECK_FAILPRINTF in multi_heap_platform.h.

**Note:** This function is not thread-safe as it sets a global variable with the value of print_errors.
size_t multi_heap_free_size(multi_heap_handle_t heap)
    Return free heap size.
    Returns the number of bytes available in the heap.
    Equivalent to the total_free_bytes member returned by multi_heap_get_heap_info().
    Note that the heap may be fragmented, so the actual maximum size for a single malloc() may be lower. To
    know this size, see the largest_free_block member returned by multi_heap_get_heap_info().

    Parameters heap – Handle to a registered heap.
    Returns Number of free bytes.

size_t multi_heap_minimum_free_size(multi_heap_handle_t heap)
    Return the lifetime minimum free heap size.
    Equivalent to the minimum_free_bytes member returned by multi_heap_get_info().
    Returns the lifetime “low watermark” of possible values returned from multi_free_heap_size(), for the specified
    heap.

    Parameters heap – Handle to a registered heap.
    Returns Number of free bytes.

void multi_heap_get_info(multi_heap_handle_t heap, multi_heap_info_t *info)
    Return metadata about a given heap.
    Fills a multi_heap_info_t structure with information about the specified heap.

    Parameters
    • heap – Handle to a registered heap.
    • info – Pointer to a structure to fill with heap metadata.

Structures

struct multi_heap_info_t
    Structure to access heap metadata via multi_heap_get_info.

    Public Members

size_t total_free_bytes
    Total free bytes in the heap. Equivalent to multi_free_heap_size().

size_t total_allocated_bytes
    Total bytes allocated to data in the heap.

size_t largest_free_block
    Size of the largest free block in the heap. This is the largest malloc-able size.

size_t minimum_free_bytes
    Lifetime minimum free heap size. Equivalent to multi_minimum_free_heap_size().

size_t allocated_blocks
    Number of (variable size) blocks allocated in the heap.

size_t free_blocks
    Number of (variable size) free blocks in the heap.
size_t total_blocks
Total number of (variable size) blocks in the heap.

Type Definitions
typedef struct multi_heap_info *multi_heap_handle_t
Opaque handle to a registered heap.

2.10.14 Memory Management for MMU Supported Memory

Introduction
ESP32 Memory Management Unit (MMU) is relatively simple. It can do memory address translation between physical memory addresses and virtual memory addresses. So CPU can access physical memories via virtual addresses. There are multiple types of virtual memory addresses, which have different capabilities.

ESP-IDF provides a memory mapping driver that manages the relation between these physical memory addresses and virtual memory addresses, so as to achieve some features such as reading from SPI Flash via a pointer.

Memory mapping driver is actually a capabilities-based virtual memory address allocator that allows apps to make virtual memory address allocations for different purposes. In the following chapters, we call this driver esp_mmap driver.

ESP-IDF also provides a memory synchronisation driver which can be used for potential memory desynchronisation scenarios.

Physical Memory Types
Memory mapping driver currently supports mapping to following physical memory types:

• SPI Flash

Virtual Memory Capabilities

• MMU_MEM_CAP_EXEC. This capability indicates that the virtual memory address has the execute permission. Note this permission scope is within the MMU hardware.
• MMU_MEM_CAP_READ. This capability indicates that the virtual memory address has the read permission. Note this permission scope is within the MMU hardware.
• MMU_MEM_CAP_WRITE. This capability indicates that the virtual memory address has the write permission. Note this permission scope is within the MMU hardware.
• MMU_MEM_CAP_32BIT. This capability indicates that the virtual memory address allows for 32 bits or multiples of 32 bits access.
• MMU_MEM_CAP_8BIT. This capability indicates that the virtual memory address allows for 8 bits or multiples of 8 bits access.

8 MB external memory addresses (from 0x40400000 to 0x40C00000) which have the MMU_MEM_CAP_EXEC and MMU_MEM_CAP_READ capabilities are not available for users to allocate, due to hardware limitations.

You can call esp_mmu_map_get_max_consecutive_free_block_size() to know the largest consecutive mappable block size with certain capabilities.
Memory Management Drivers

Driver Concept

Terminology  The virtual memory pool is made up with one or multiple virtual memory regions, see below figure:

- A virtual memory pool stands for the whole virtual address range that can be mapped to physical memory
- A virtual memory region is a range of virtual address with same attributes
- A virtual memory block is a piece of virtual address range that is dynamically mapped.
- A slot is the virtual address range between two virtual memory blocks.
- A physical memory block is a piece of physical address range that is to-be-mapped or already mapped to a virtual memory block.
- Dynamical mapping is done by calling esp_mmap driver API esp_mmu_map(), this API will map the given physical memory block to a virtual memory block which is allocated by the esp_mmap driver.

Relation between Memory Blocks  When mapping a physical memory block A, block A can have one of the following relations with another previously mapped physical memory block B:

- Enclosed: block A is completely enclosed within block B, see figure below:

- Identical: block A is completely the same as block B, see figure below:

Note esp_mmap driver will consider the identical scenario the same as the enclosed scenario.

- Overlapped: block A is overlapped with block B, see figure below:
There is a special condition, when block A entirely encloses block B, see figure below:

- **esp_mmap** driver will consider this scenario **the same as the overlapped scenario**.

**Driver Behaviour**

**Memory Map** You can call **esp_mmu_map()** to do a dynamical mapping. This API will allocate a certain size of virtual memory block according to the virtual memory capabilities you selected, then map this virtual memory block to the physical memory block as you requested. The **esp_mmap** driver supports mapping to one or more types of physical memory, so you should specify the physical memory target when mapping.

By default, physical memory blocks and virtual memory blocks are one-to-one mapped. This means, when calling **esp_mmu_map()**:

- If it’s the enclosed scenario, this API will return an **ESP_ERR_INVALID_STATE**. The **out_ptr** will be assigned to the start virtual memory address of the previously mapped one which encloses the to-be-mapped one.
- If it’s the identical scenario, this API will behaves exactly the same as the enclosed scenario.
- If it’s the overlapped scenario, this API will by default return an **ESP_ERR_INVALID_ARG**. This means, **esp_mmap** driver by default doesn’t allow mapping a physical memory address to multiple virtual memory addresses.

Specially, you can use **ESP_MMU_MMAP_FLAG_PADDR_SHARED**. This flags stands for one-to-multiple mapping between a physical address and multiple virtual addresses:

- If it’s the overlapped scenario, this API will allocate a new virtual memory block as requested, then map to the given physical memory block.

**Memory Unmap** You can call **esp_mmu_unmap()** to unmap a previously mapped memory block. This API will return an **ESP_ERR_NOT_FOUND** if you are trying to unmap a virtual memory block that isn’t mapped to any physical memory block yet.

**Memory Address Conversion** The **esp_mmap** driver provides two helper APIs to do the conversion between virtual memory address and physical memory address.

- **esp_mmu_vaddr_to_paddr()**, convert virtual address to physical address.
- **esp_mmu_paddr_to_vaddr()**, convert physical address to virtual address.
Memory Synchronisation  MMU supported physical memories can be accessed by one or multiple methods. SPI Flash can be accessed by SPI1 (ESP-IDF esp_flash driver APIs), or by pointers. ESP-IDF esp_flash driver APIs have already considered the memory synchronisation, so users don’t need to worry about this. PSRAM can be accessed by pointers, hardware guarantees the data consistency when PSRAM is only accessed via pointers.

Thread Safety

APIs in esp_mmu_map.h are not guaranteed to be thread-safe.

APIs in esp_cache.h are guaranteed to be thread-safe.

API Reference

API Reference - ESP MMAP Driver

Header File

• components/esp_mmu/include/esp_mmu_map.h

Functions

esp_err_t esp_mmu_map (esp_paddr_t paddr_start, size_t size, mmu_target_t target, mmu_mem_caps_t caps, int flags, void **out_ptr)

Map a physical memory block to external virtual address block, with given capabilities.

Note: This API does not guarantee thread safety

Parameters

• paddr_start – [in] Start address of the physical memory block
• size – [in] Size to be mapped. Size will be rounded up to the nearest multiple of MMU page size
• target – [in] Physical memory target you’re going to map to, see mmu_target_t
• caps – [in] Memory capabilities, see mmu_mem_caps_t
• flags – [in] Mmap flags
• out_ptr – [out] Start address of the mapped virtual memory

Returns

• ESP_OK
• ESP_ERR_INVALID_ARG: Invalid argument, see printed logs
• ESP_ERR_NOT_SUPPORTED: Only on ESP32, PSRAM is not a supported physical memory target
• ESP_ERR_NOT_FOUND: No enough size free block to use
• ESP_ERR_NO_MEM: Out of memory, this API will allocate some heap memory for internal usage
• ESP_ERR_INVALID_STATE: Paddr is mapped already, this API will return corresponding vaddr_start of the previously mapped block. Only to-be-mapped paddr block is totally enclosed by a previously mapped block will lead to this error. (Identical scenario will behave similarly) new_block_start new_block_end —— &8212; New Block —— &8212;&1 —— &8212; Block ——— &8212; block_start block_end

esp_err_t esp_mmu_unmap (void *ptr)

Unmap a previously mapped virtual memory block.
Chapter 2. API Reference

**Note:** This API does not guarantee thread safety

### Parameters
- **ptr** - [in] Start address of the virtual memory

### Returns
- ESP_OK
- ESP_ERR_INVALID_ARG: Null pointer
- ESP_ERR_NOT_FOUND: Vaddr is not in external memory, or it’s not mapped yet

```c
esp_err_t esp_mmu_map_get_max_consecutive_free_block_size(mmu_mem_caps_t caps,
                                                        mmu_target_t target, size_t *
                                                        out_len)
```

Get largest consecutive free external virtual memory block size, with given capabilities and given physical target.

#### Parameters
- **caps** - [in] Bitwise OR of MMU_MEM_CAP_* flags indicating the memory block
- **target** - [in] Physical memory target you’re going to map to, see mmu_target_t.
- **out_len** - [out] Largest free block length, in bytes.

#### Returns
- ESP_OK
- ESP_ERR_INVALID_ARG: Invalid arguments, could be null pointer

```c
esp_err_t esp_mmu_map_dump_mapped_blocks(FILE *stream)
```

Dump all the previously mapped blocks

#### Note: This API shall not be called from an ISR.

#### Note: This API does not guarantee thread safety

### Parameters
- **stream** - stream to print information to; use stdout or stderr to print to the console; use fnmemopen/open_memstream to print to a string buffer.

### Returns
- ESP_OK

```c
esp_err_t esp_mmu_vaddr_to_paddr(void *vaddr, esp_paddr_t *out_paddr, mmu_target_t *out_target)
```

Convert virtual address to physical address.

#### Parameters
- **vaddr** - [in] Virtual address
- **out_paddr** - [out] Physical address
- **out_target** - [out] Physical memory target, see mmu_target_t

#### Returns
- ESP_OK
- ESP_ERR_INVALID_ARG: Null pointer, or vaddr is not within external memory
- ESP_ERR_NOT_FOUND: Vaddr is not mapped yet

```c
esp_err_t esp_mmu_paddr_to_vaddr(esp_paddr_t paddr, mmu_target_t target, mmu_vaddr_t type, void **out_vaddr)
```

Convert physical address to virtual address.

#### Parameters
- **paddr** - [in] Physical address
- **target** - [in] Physical memory target, see mmu_target_t
- **type** - [in] Virtual address type, could be either instruction or data
### Return value
- ESP_OK: Physical address successfully mapped.
- ESP_ERR_INVALID_ARG: Null pointer
- ESP_ERR_NOT_FOUND: Physical address is not mapped successfully.

## Macros

**ESP_MMU_MMAP_FLAG_PADDR_SHARED**
- Share this mapping.

**MMU Memory Mapping Driver APIs for MMUs supported memory**

### Driver Backgrounds:

### Type Definitions

```c
typedef uint32_t esp_paddr_t
```
- Physical memory type.

### API Reference - ESP MSYNC Driver

### Header File
- components/esp_mm/include/esp_cache.h

### Functions

**esp_err_t esp_cache_msync**(void *addr, size_t size, int flags)
- Memory sync between Cache and external memory.

- For cache writeback supported chips (you can refer to SOC_CACHE_WRITEBACK_SUPPORTED in soc_caps.h)
  - this API will do a writeback to synchronise between cache and the PSRAM
– with ESP_CACHE_MSYNC_FLAG_INVALIDATE, this API will also invalidate the values that just written
– note: although ESP32 is with PSRAM, but cache writeback isn’t supported, so this API will do nothing on ESP32
• For other chips, this API will do nothing. The out-of-sync should be already dealt by the SDK
This API is cache-safe and thread-safe

Note: You should not call this during any Flash operations (e.g. esp_flash APIs, nvs and some other APIs that are based on esp_flash APIs)

Note: If XIP_From_PSRAM is enabled (by enabling both CONFIG_SPIRAM_FETCH_INSTRUCTIONS and CONFIG_SPIRAM_RODATA), you can call this API during Flash operations

Parameters
• \texttt{addr} – [in] Starting address to do the msync
• \texttt{size} – [in] Size to do the msync
• \texttt{flags} – [in] Flags, see \texttt{ESP_CACHE_MSYNC_FLAG\_x}

Returns
• ESP_OK:
  – Successful msync
  – If this chip doesn’t support cache writeback, if the input addr is a cache supported one, this API will return ESP_OK
• ESP\_ERR\_INVALID\_ARG: Invalid argument, not cache supported addr, see printed logs

Macros

\texttt{ESP\_CACHE\_MSYNC\_FLAG\_INVALIDATE}

Do an invalidation with the values that just written.
Cache msync flags

\texttt{ESP\_CACHE\_MSYNC\_FLAG\_UNALIGNED}

Allow writeback a block that are not aligned to the data cache line size.

2.10.15 Heap Memory Debugging

Overview

ESP-IDF integrates tools for requesting heap information, detecting heap corruption, and tracing memory leaks. These can help track down memory-related bugs.

For general information about the heap memory allocator, see the \textit{Heap Memory Allocation} page.

Heap Information

To obtain information about the state of the heap:

• \texttt{xPortGetFreeHeapSize()} is a FreeRTOS function which returns the number of free bytes in the (data memory) heap. This is equivalent to calling \texttt{heap\_caps\_get\_free\_size(MALLOC\_CAP\_S8BIT)}.
• \texttt{heap\_caps\_get\_free\_size()} can also be used to return the current free memory for different memory capabilities.
• \texttt{heap\_caps\_get\_largest\_free\_block()} can be used to return the largest free block in the heap. This is the largest single allocation which is currently possible. Tracking this value and comparing to total free heap allows you to detect heap fragmentation.
• xPortGetMinimumEverFreeHeapSize() and the related heap_caps_get_minimum_free_size() can be used to track the heap “low watermark” since boot.
• heap_caps_get_info() returns a multi_heap_info_t structure which contains the information from the above functions, plus some additional heap-specific data (number of allocations, etc.).
• heap_caps_print_heap_info() prints a summary to stdout of the information returned by heap_caps_get_info().
• heap_caps_dump() and heap_caps_dump_all() will output detailed information about the structure of each block in the heap. Note that this can be large amount of output.

Heap allocation and free function hooks

Heap allocation and free detection hooks allows you to be notified of every successful allocation and free operations:
- Providing a definition of esp_heap_trace_alloc_hook() will allow you to be notified of every successful memory allocation operations
- Providing a definition of esp_heap_trace_free_hook() will allow you to be notified of every memory free operations

To activate the feature, navigate to Component config -> Heap Memory Debugging in the configuration menu and select Use allocation and free hooks option (see CONFIG_HEAP_USE_HOOKS). esp_heap_trace_alloc_hook() and esp_heap_trace_free_hook() have weak declarations, it is not necessary to provide a declarations for both hooks. Since allocating and freeing memory is allowed even though strongly recommended against, esp_heap_trace_alloc_hook() and esp_heap_trace_free_hook() can potentially be called from ISR.

Heap Corruption Detection

Heap corruption detection allows you to detect various types of heap memory errors:
- Out of bounds writes & buffer overflow.
- Writes to freed memory.
- Reads from freed or uninitialized memory.

Assertions  The heap implementation (multi_heap.c, etc.) includes a lot of assertions which will fail if the heap memory is corrupted. To detect heap corruption most effectively, ensure that assertions are enabled in the project configuration menu under Compiler options -> CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL.

If a heap integrity assertion fails, a line will be printed like CORRUPT HEAP: multi_heap.c:225 detected at 0x3ffbb71c. The memory address which is printed is the address of the heap structure which has corrupt content.

It’s also possible to manually check heap integrity by calling heap_caps_check_integrity_all() or related functions. This function checks all of requested heap memory for integrity, and can be used even if assertions are disabled. If the integrity check prints an error, it will also contain the address(es) of corrupt heap structures.

Memory Allocation Failed Hook  Users can use heap_caps_register_failed_alloc_callback() to register a callback that will be invoked every time an allocation operation fails.

Additionally, users can enable the generation of a system abort if an allocation operation fails by following the steps below: - In the project configuration menu, navigate to Component config -> Heap Memory Debugging and select Abort if memory allocation fails option (see CONFIG_HEAP_ABORT_WHEN_ALLOCATION_FAILURES).

The example below shows how to register an allocation failure callback:

```c
#include "esp_heap_caps.h"

void heap_caps_alloc_failed_hook(size_t requested_size, uint32_t caps, const char *function_name)
{

(continues on next page)
Finding Heap Corruption  Memory corruption can be one of the hardest classes of bugs to find and fix, as one area of memory can be corrupted from a totally different place. Some tips:

- A crash with a CORRUPT HEAP: message will usually include a stack trace, but this stack trace is rarely useful. The crash is the symptom of memory corruption when the system realises the heap is corrupt, but usually the corruption happened elsewhere and earlier in time.
- Increasing the Heap memory debugging Configuration level to “Light impact” or “Comprehensive” can give you a more accurate message with the first corrupt memory address.
- Adding regular calls to heap_caps_check_integrity_all() or heap_caps_check_integrity_addr() in your code will help you pin down the exact time that the corruption happened. You can move these checks around to “close in on” the section of code that corrupted the heap.
- Based on the memory address which is being corrupted, you can use JTAG debugging to set a watchpoint on this address and have the CPU halt when it is written to.
- If you don’t have JTAG, but you do know roughly when the corruption happens, then you can set a watchpoint in software just beforehand via esp_cpu_set_watchpoint(). A fatal exception will occur when the watchpoint triggers. The following is an example of how to use the function - esp_cpu_set_watchpoint(0, (void *)addr, 4, ESP_WATCHPOINT_STORE). Note that watchpoints are per-CPU and are set on the current running CPU only, so if you don’t know which CPU is corrupting memory then you will need to call this function on both CPUs.
- For buffer overflows, heap tracing in HEAP_TRACE_ALL mode lets you see which callers are allocating which addresses from the heap. See Heap Tracing To Find Heap Corruption for more details. If you can find the function which allocates memory with an address immediately before the address which is corrupted, this will probably be the function which overflows the buffer.
- Calling heap_caps_dump() or heap_caps_dump_all() can give an indication of what heap blocks are surrounding the corrupted region and may have overflowed/underflowed/etc.

Configuration  Temporarily increasing the heap corruption detection level can give more detailed information about heap corruption errors.

In the project configuration menu, under Component config there is a menu Heap memory debugging. The setting CONFIG_HEAP_CORRUPTION_DETECTION can be set to one of three levels:

Basic (no poisoning)  This is the default level. No special heap corruption features are enabled, but provided assertions are enabled (the default configuration) then a heap corruption error will be printed if any of the heap’s internal data structures appear overwritten or corrupted. This usually indicates a buffer overrun or out of bounds write.

If assertions are enabled, an assertion will also trigger if a double-free occurs (the same memory is freed twice). Calling heap_caps_check_integrity() in Basic mode will check the integrity of all heap structures, and print errors if any appear to be corrupted.
Light Impact  At this level, heap memory is additionally “poisoned” with head and tail “canary bytes” before and after each block which is allocated. If an application writes outside the bounds of allocated buffers, the canary bytes will be corrupted and the integrity check will fail.

The head canary word is 0xABBA1234 (3412BAAB in byte order), and the tail canary word is 0xBAAD5678 (7856ADBA in byte order).

“Basic” heap corruption checks can also detect most out of bounds writes, but this setting is more precise as even a single byte overrun can be detected. With Basic heap checks, the number of overrun bytes before a failure is detected will depend on the properties of the heap.

Enabling “Light Impact” checking increases memory usage, each individual allocation will use 9 to 12 additional bytes of memory (depending on alignment).

Each time `free()` is called in Light Impact mode, the head and tail canary bytes of the buffer being freed are checked against the expected values.

When `heap_caps_check_integrity()` is called, all allocated blocks of heap memory have their canary bytes checked against the expected values.

In both cases, the check is that the first 4 bytes of an allocated block (before the buffer returned to the user) should be the word 0xABBA1234. Then the last 4 bytes of the allocated block (after the buffer returned to the user) should be the word 0xBAAD5678.

Different values usually indicate buffer underrun or overrun, respectively.

Comprehensive  This level incorporates the “light impact” detection features plus additional checks for uninitialised-access and use-after-free bugs. In this mode, all freshly allocated memory is filled with the pattern 0xCE, and all freed memory is filled with the pattern 0xFE.

Enabling “Comprehensive” detection has a substantial runtime performance impact (as all memory needs to be set to the allocation patterns each time a malloc/free completes, and the memory also needs to be checked each time.) However, it allows easier detection of memory corruption bugs which are much more subtle to find otherwise. It is recommended to only enable this mode when debugging, not in production.

Crashes in Comprehensive Mode  If an application crashes reading/writing an address related to 0xCECECECE in Comprehensive mode, this indicates it has read uninitialized memory. The application should be changed to either use `calloc()` (which zeroes memory), or initialize the memory before using it. The value 0xCECECECE may also be seen in stack-allocated automatic variables, because in IDF most task stacks are originally allocated from the heap and in C stack memory is uninitialized by default.

If an application crashes and the exception register dump indicates that some addresses or values were 0xFEFEFEFE, this indicates it is reading heap memory after it has been freed (a “use after free bug”.) The application should be changed to not access heap memory after it has been freed.

If a call to `malloc()` or `realloc()` causes a crash because it expected to find the pattern 0xFEFEFEFE in free memory and a different pattern was found, then this indicates the app has a use-after-free bug where it is writing to memory which has already been freed.

Manual Heap Checks in Comprehensive Mode  Calls to `heap_caps_check_integrity()` may print errors relating to 0xFEFEFEFE, 0xABBA1234 or 0xBAAD5678. In each case the checker is expecting to find a given pattern, and will error out if this is not found:

• For free heap blocks, the checker expects to find all bytes set to 0xFE. Any other values indicate a use-after-free bug where free memory has been incorrectly overwritten.
• For allocated heap blocks, the behaviour is the same as for Light Impact mode. The canary bytes 0xABBA1234 and 0xBAAD5678 are checked at the head and tail of each allocated buffer, and any variation indicates a buffer overrun/underun.
Heap Task Tracking

Heap Task Tracking can be used to get per task info for heap memory allocation. Application has to specify the heap capabilities for which the heap allocation is to be tracked.

Example code is provided in `system/heap_task_tracking`

Heap Tracing

Heap Tracing allows tracing of code which allocates/frees memory. Two tracing modes are supported:

- **Standalone.** In this mode trace data are kept on-board, so the size of gathered information is limited by the buffer assigned for that purposes. Analysis is done by the on-board code. There are a couple of APIs available for accessing and dumping collected info.
- **Host-based.** This mode does not have the limitation of the standalone mode, because trace data are sent to the host over JTAG connection using app_trace library. Later on they can be analysed using special tools.

Heap tracing can perform two functions:

- Leak checking: find memory which is allocated and never freed.
- Heap use analysis: show all functions that are allocating/freeing memory while the trace is running.

**How To Diagnose Memory Leaks** If you suspect a memory leak, the first step is to figure out which part of the program is leaking memory. Use the `xPortGetFreeHeapSize()`, `heap_caps_get_free_size()`, or related functions to track memory use over the life of the application. Try to narrow the leak down to a single function or sequence of functions where free memory always decreases and never recovers.

**Standalone Mode** Once you’ve identified the code which you think is leaking:

- In the project configuration menu, navigate to Component settings -> Heap Memory Debugging -> Heap tracing and select Standalone option (see `CONFIG_HEAP_TRACING_DEST`).
- Call the function `heap_trace_init_standalone()` early in the program, to register a buffer which can be used to record the memory trace.
- Call the function `heap_trace_start()` to begin recording all mallocs/frees in the system. Call this immediately before the piece of code which you suspect is leaking memory.
- Call the function `heap_trace_stop()` to stop the trace once the suspect piece of code has finished executing.
- Call the function `heap_trace_dump()` to dump the results of the heap trace.

An example:

```c
#include "esp_heap_trace.h"

#define NUM_RECORDS 100
static heap_trace_record_t trace_record[NUM_RECORDS]; // This buffer must be in internal RAM

void app_main()
{
    ...
    ESP_ERROR_CHECK( heap_trace_init_standalone(trace_record, NUM_RECORDS) );
    ...
}

void some_function()
{
    ESP_ERROR_CHECK( heap_trace_start(HEAP_TRACELeaks) );
}
```

(continues on next page)
do_something_you_suspect_is_leaking();
ESP_ERROR_CHECK( heap_trace_stop() );
heap_trace_dump();
...

The output from the heap trace will look something like this:

```
2 allocations trace (100 entry buffer)
32 bytes (@ 0x3ffaf214) allocated CPU 0 ccount 0x2e9b7384 caller_
   →0x400d276d: leak_some_memory at /path/to/idf/examples/get-started/blink/main/./
   →  blink.c:27
0x400d27c1: blink_task at /path/to/idf/examples/get-started/blink/main/./blink.c:52
8 bytes (@ 0x3ffaf804) allocated CPU 0 ccount 0x2e9b79c0 caller_
   →0x400d2776: leak_some_memory at /path/to/idf/examples/get-started/blink/main/./
   →  blink.c:29
0x400d27c1: blink_task at /path/to/idf/examples/get-started/blink/main/./blink.c:52
40 bytes 'leaked' in trace (2 allocations)
total allocations 2 total frees 0
```

(Above example output is using IDF Monitor to automatically decode PC addresses to their source files & line number.)

The first line indicates how many allocation entries are in the buffer, compared to its total size.

In HEAP_TRACE_LEAKS mode, for each traced memory allocation which has not already been freed a line is printed with:

- XX bytes is the number of bytes allocated
- @ 0x... is the heap address returned from malloc/calloc.
- Internal or PSRAM is the general location of the allocated memory.
- CPU x is the CPU (0 or 1) running when the allocation was made.
- ccount 0x... is the CCOUNT (CPU cycle count) register value when the allocation was made. Is different for CPU 0 vs CPU 1.
- caller 0x... gives the call stack of the call to malloc()/free(), as a list of PC addresses. These can be decoded to source files and line numbers, as shown above.

The depth of the call stack recorded for each trace entry can be configured in the project configuration menu, under Heap Memory Debugging -> Enable heap tracing -> Heap tracing stack depth. Up to 10 stack frames can be recorded for each allocation (the default is 2). Each additional stack frame increases the memory usage of each heap_trace_record_t record by eight bytes.

Finally, the total number of ‘leaked’ bytes (bytes allocated but not freed while trace was running) is printed, and the total number of allocations this represents.

A warning will be printed if the trace buffer was not large enough to hold all the allocations which happened. If you see this warning, consider either shortening the tracing period or increasing the number of records in the trace buffer.

**Host-Based Mode** Once you’ve identified the code which you think is leaking:

- In the project configuration menu, navigate to Component settings -> Heap Memory Debugging -> CONFIG_HEAP_TRACING_DEST and select Host-Based.
- In the project configuration menu, navigate to Component settings -> Application Level Tracing -> CONFIG_APPTRACE_DESTINATION1 and select Trace memory.
• In the project configuration menu, navigate to Component settings -> Application Level Tracing -> FreeRTOS SystemView Tracing and enable `CONFIG_APPTRACE_SV_ENABLE`.
• Call the function `heap_trace_init_tohost()` early in the program, to initialize JTAG heap tracing module.
• Call the function `heap_trace_start()` to begin recording all mallocs/frees in the system. Call this immediately before the piece of code which you suspect is leaking memory. In host-based mode, the argument to this function is ignored, and the heap tracing module behaves like `HEAP_TRACE_ALL` was passed: all allocations and deallocations are sent to the host.
• Call the function `heap_trace_stop()` to stop the trace once the suspect piece of code has finished executing.

An example:

```c
#include "esp_heap_trace.h"
...
void app_main()
{
    ...
    ESP_ERROR_CHECK( heap_trace_init_tohost() );
    ...
}
void some_function()
{
    ESP_ERROR_CHECK( heap_trace_start(HEAP_TRACE_LEAKS) );
    do_something_you_suspect_is_leaking();
    ESP_ERROR_CHECK( heap_trace_stop() );
    ...
}
```

To gather and analyse heap trace do the following on the host:

1. Build the program and download it to the target as described in *Getting Started Guide*.
2. Run OpenOCD (see *JTAG Debugging*).

**Note:** In order to use this feature you need OpenOCD version `v0.10.0-esp32-20181105` or later.

3. You can use GDB to start and/or stop tracing automatically. To do this you need to prepare special gdbinit file:

```bash
target remote :3333
mon reset halt
flushregs
tb heap_trace_start
commands
mon esp sysview start file:///tmp/heap.svdat
end
tb heap_trace_stop
commands
mon esp sysview stop
end
c
```
Chapter 2. API Reference

Using this file GDB will connect to the target, reset it, and start tracing when program hits breakpoint at `heap_trace_start()`. Trace data will be saved to `/tmp/heap_log.svdat`. Tracing will be stopped when program hits breakpoint at `heap_trace_stop()`.

4. Run GDB using the following command:
   `xtensa-esp32-elf-gdb -x gdbinit </path/to/program/elf>

5. Quit GDB when program stops at `heap_trace_stop()`.

6. Run processing script:
   `$IDF_PATH/tools/esp_app_trace/sysviewtrace_proc.py -p -b
   </path/to/program/elf> /tmp/heap_log.svdat`

The output from the heap trace will look something like this:

```
Parse trace from '/tmp/heap.svdat'
Stop parsing trace. (Timeout 0.000000 sec while reading 1 bytes!)
Process events from ['/tmp/heap.svdat']...

```
Heap Tracing To Find Heap Corruption

Heap tracing can also be used to help track down heap corruption. When a region in heap is corrupted, it may be from some other part of the program which allocated memory at a nearby address.

If you have some idea at what time the corruption occurred, enabling heap tracing in `HEAP_TRACE_ALL` mode allows you to record all the functions which allocated memory, and the addresses of the allocations.

Using heap tracing in this way is very similar to memory leak detection as described above. For memory which is allocated and not freed, the output is the same. However, records will also be shown for memory which has been freed.

Performance Impact

Enabling heap tracing in menuconfig increases the code size of your program, and has a very small negative impact on performance of heap allocation/free operations even when heap tracing is not running.
When heap tracing is running, heap allocation/free operations are substantially slower than when heap tracing is stopped. Increasing the depth of stack frames recorded for each allocation (see above) will also increase this performance impact.

False-Positive MemoryLeaks Not everything printed by `heap_trace_dump()` is necessarily a memory leak. Among things which may show up here, but are not memory leaks:

- Any memory which is allocated after `heap_trace_start()` but then freed after `heap_trace_stop()` will appear in the leak dump.
- Allocations may be made by other tasks in the system. Depending on the timing of these tasks, it’s quite possible this memory is freed after `heap_trace_stop()` is called.
- The first time a task uses `stdio` — for example, when it calls `printf()` — a lock (RTOS mutex semaphore) is allocated by the libc. This allocation lasts until the task is deleted.
- Certain uses of `printf()`, such as printing floating point numbers, will allocate some memory from the heap on demand. These allocations last until the task is deleted.
- The Bluetooth, Wi-Fi, and TCP/IP libraries will allocate heap memory buffers to handle incoming or outgoing data. These memory buffers are usually short-lived, but some may be shown in the heap leak trace if the data was received/transmitted by the lower levels of the network while the leak trace was running.
- TCP connections will continue to use some memory after they are closed, because of the `TIME_WAIT` state. After the `TIME_WAIT` period has completed, this memory will be freed.

One way to differentiate between "real" and "false positive" memory leaks is to call the suspect code multiple times while tracing is running, and look for patterns (multiple matching allocations) in the heap trace output.

API Reference - Heap Tracing

Header File

- `components/heap/include/esp_heap_trace.h`

Functions

`esp_err_t heap_trace_init_standalone(heap_trace_record_t *record_buffer, size_t num_records)`

Initialise heap tracing in standalone mode.

This function must be called before any other heap tracing functions.

To disable heap tracing and allow the buffer to be freed, stop tracing and then call `heap_trace_init_standalone(NULL, 0);`

**Parameters**

- `record_buffer` — Provide a buffer to use for heap trace data. Note: External RAM is allowed, but it prevents recording allocations made from ISR’s.
- `num_records` — Size of the heap trace buffer, as number of record structures.

**Returns**

- ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
- ESP_ERR_INVALID_STATE Heap tracing is currently in progress.
- ESP_OK Heap tracing initialised successfully.

`esp_err_t heap_trace_init_tohost(void)`

Initialise heap tracing in host-based mode.

This function must be called before any other heap tracing functions.

**Returns**

- ESP_ERR_INVALID_STATE Heap tracing is currently in progress.
- ESP_OK Heap tracing initialised successfully.
**esp_err_t heap_trace_start (heap_trace_mode_t mode)**

Start heap tracing. All heap allocations & frees will be traced, until heap_trace_stop() is called.

**Note:** heap_trace_init_standalone() must be called to provide a valid buffer, before this function is called.

**Note:** Calling this function while heap tracing is running will reset the heap trace state and continue tracing.

**Parameters**
- **mode** – Mode for tracing.
  - HEAP_TRACE_ALL means all heap allocations and frees are traced.
  - HEAP_TRACE_LEAKS means only suspected memory leaks are traced. (When memory is freed, the record is removed from the trace buffer.)

**Returns**
- ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
- ESP_ERR_INVALID_STATE A non-zero-length buffer has not been set via heap_trace_init_standalone().
- ESP_OK Tracing is started.

**esp_err_t heap_trace_stop (void)**

Stop heap tracing.

**Returns**
- ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
- ESP_ERR_INVALID_STATE Heap tracing was not in progress.
- ESP_OK Heap tracing stopped.

**esp_err_t heap_trace_resume (void)**

Resume heap tracing which was previously stopped.

Unlike heap_trace_start(), this function does not clear the buffer of any pre-existing trace records.

The heap trace mode is the same as when heap_trace_start() was last called (or HEAP_TRACE_ALL if heap_trace_start() was never called).

**Returns**
- ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
- ESP_ERR_INVALID_STATE Heap tracing was already started.
- ESP_OK Heap tracing resumed.

**size_t heap_trace_get_count (void)**

Return number of records in the heap trace buffer.

It is safe to call this function while heap tracing is running.

**esp_err_t heap_trace_get (size_t index, heap_trace_record_t *record)**

Return a raw record from the heap trace buffer.

**Note:** It is safe to call this function while heap tracing is running, however in HEAP_TRACE_LEAK mode record indexing may skip entries unless heap tracing is stopped first.

**Parameters**
- **index** – Index (zero-based) of the record to return.
- **record** – [out] Record where the heap trace record will be copied.

**Returns**
• ESP_ERR_NOT_SUPPORTED Project was compiled without heap tracing enabled in menuconfig.
• ESP_ERR_INVALID_STATE Heap tracing was not initialised.
• ESP_ERR_INVALID_ARG Index is out of bounds for current heap trace record count.
• ESP_OK Record returned successfully.

void heap_trace_dump (void)
    Dump heap trace record data to stdout.

Note: It is safe to call this function while heap tracing is running, however in HEAP_TRACE_LEAK mode the dump may skip entries unless heap tracing is stopped first.

void heap_trace_dump_caps (const uint32_t caps)
    Dump heap trace from the memory of the capabilities passed as parameter.

Parameters caps – Capability(ies) of the memory from which to dump the trace. Set MAL-LOC_CAP_INTERNAL to dump heap trace data from internal memory. Set MAL-LOC_CAP_SPIRAM to dump heap trace data from PSRAM. Set both to dump both heap trace data.

esp_err_t heap_trace_summary (heap_trace_summary_t *summary)
    Get summary information about the result of a heap trace.

Note: It is safe to call this function while heap tracing is running.

Structures

struct heap_trace_record_t
    Trace record data type. Stores information about an allocated region of memory.

Public Members

uint32_t ccount
    CCOUNT of the CPU when the allocation was made. LSB (bit value 1) is the CPU number (0 or 1).

void *address
    Address which was allocated. If NULL, then this record is empty.

size_t size
    Size of the allocation.

void *allocated_by[CONFIG_HEAP_TRACING_STACK_DEPTH]
    Call stack of the caller which allocated the memory.

void *freed_by[CONFIG_HEAP_TRACING_STACK_DEPTH]
    Call stack of the caller which freed the memory (all zero if not freed.)

struct heap_trace_summary_t
    Stores information about the result of a heap trace.
Chapter 2. API Reference

Public Members

heap_trace_mode_t mode
The heap trace mode we just completed / are running.

size_t total_allocations
The total number of allocations made during tracing.

size_t total_frees
The total number of frees made during tracing.

size_t count
The number of records in the internal buffer.

size_t capacity
The capacity of the internal buffer.

size_t high_water_mark
The maximum value that `count` got to.

size_t has_overflowed
True if the internal buffer overflowed at some point.

Macros

CONFIG_HEAP_TRACING_STACK_DEPTH

Type Definitions

typedef struct heap_trace_record_t heap_trace_record_t
Trace record data type. Stores information about an allocated region of memory.

Enumerations

definition heap_trace_mode_t
Values:

enumerator HEAP_TRACE_ALL

enumerator HEAP_TRACE_LEAKS

2.10.16 High Resolution Timer (ESP Timer)
Overview

Although FreeRTOS provides software timers, FreeRTOS software timers have a few limitations:

- Maximum resolution is equal to the RTOS tick period
- Timer callbacks are dispatched from a low-priority timer service (i.e., daemon) task. This task can be preempted by other tasks, leading to decreased precision and accuracy.

Although hardware timers are not subject to the limitations mentioned, they may not be as user-friendly. For instance, application components may require timer events to be triggered at specific future times, but hardware timers typically have only one “compare” value for interrupt generation. This necessitates the creation of an additional system on top of the hardware timer to keep track of pending events and ensure that callbacks are executed when the corresponding hardware interrupts occur.

The hardware timer interrupt’s priority is configured via the `CONFIG_ESP_TIMER_INTERRUPT_LEVEL` option (possible priorities being 1, 2, or 3). Raising the timer interrupt’s priority can reduce the timer processing delay caused by interrupt latency.

`esp_timer` set of APIs provides one-shot and periodic timers, microsecond time resolution, and 64-bit range.

Internally, `esp_timer` uses a 64-bit hardware timer. The exact hardware timer implementation used will depend on the target, where LAC timer is used for ESP32.

Timer callbacks can be dispatched by two methods:

- `ESP_TIMER_TASK`. Timer callbacks are dispatched from a high-priority `esp_timer` task. Because all the callbacks are dispatched from the same task, it is recommended to only do the minimal possible amount of work from the callback itself, posting an event to a lower-priority task using a queue instead.

- `ESP_TIMER_ISR`. Timer callbacks are dispatched directly from the timer interrupt handler. This method is useful for some simple callbacks which aim for lower latency.

Creating and starting a timer, and dispatching the callback takes some time. Therefore, there is a lower limit to the timeout value of one-shot `esp_timer`. If `esp_timer_start_once()` is called with a timeout value of less than 20 us, the callback will be dispatched only after approximately 20 us.

Periodic `esp_timer` also imposes a 50 us restriction on the minimal timer period. Periodic software timers with a period of less than 50 us are not practical since they would consume most of the CPU time. Consider using dedicated hardware peripherals or DMA features if you find that a timer with a small period is required.

Using `esp_timer` APIs

A single timer is represented by `esp_timer_handle_t` type. Each timer has a callback function associated with it. This callback function is called from the `esp_timer` task each time the timer elapses.

- To create a timer, call `esp_timer_create()`.
- To delete the timer when it is no longer needed, call `esp_timer_delete()`.

The timer can be started in one-shot mode or in periodic mode.

- To start the timer in one-shot mode, call `esp_timer_start_once()`, passing the time interval after which the callback should be called. When the callback gets called, the timer is considered to be stopped.
- To start the timer in periodic mode, call `esp_timer_start_periodic()`, passing the period with which the callback should be called. The timer keeps running until `esp_timer_stop()` is called.

Note that the timer must not be running when `esp_timer_start_once()` or `esp_timer_start_periodic()` is called. To restart a running timer, call `esp_timer_stop()` first, then call one of the start functions.
Callback Functions

Note: Keep the callback functions as short as possible. Otherwise, it will affect all timers.

Timer callbacks that are processed by the ESP_TIMER_ISR method should not call the context switch call \texttt{portYIELD_FROM_ISR()}. Instead, use the \texttt{esp_timer_isr_dispatch_need_yield()} function. The context switch will be done after all ISR dispatch timers have been processed if required by the system.

\textbf{esp_timer During Light-sleep}

During Light-sleep, the \texttt{esp_timer} counter stops and no callback functions are called. Instead, the time is counted by the RTC counter. Upon waking up, the system gets the difference between the counters and calls a function that advances the \texttt{esp_timer} counter. Since the counter has been advanced, the system starts calling callbacks that were not called during sleep. The number of callbacks depends on the duration of the sleep and the period of the timers. It can lead to the overflow of some queues. This only applies to periodic timers, since one-shot timers will be called once.

This behavior can be changed by calling \texttt{esp_timer_stop()} before sleeping. In some cases, this can be inconvenient, and instead of the stop function, you can use the \texttt{skip_unhandled_events} option during \texttt{esp_timer_create()}. When the \texttt{skip_unhandled_events} is true, if a periodic timer expires one or more times during Light-sleep, then only one callback is called on wake.

Using the \texttt{skip_unhandled_events} option with automatic Light-sleep (see \textit{Power Management APIs}) helps to reduce the power consumption of the system when it is in Light-sleep. The duration of Light-sleep is also in part determined by the next event occurs. Timers with \texttt{skip_unhandled_events} option will not wake up the system.

Handling Callbacks

\texttt{esp_timer} is designed to achieve a high-resolution and low-latency timer with the ability to handle delayed events. If the timer is late, then the callback will be called as soon as possible, and it will not be lost. In the worst case, when the timer has not been processed for more than one period (for periodic timers), the callbacks will be called one after the other without waiting for the set period. This can be bad for some applications, and the \texttt{skip_unhandled_events} option is introduced to eliminate this behavior. If \texttt{skip_unhandled_events} is set, then a periodic timer that has expired multiple times without being able to call the callback will still result in only one callback event once processing is possible.

Obtaining Current Time

\texttt{esp_timer} also provides a convenience function to obtain the time passed since start-up, with microsecond precision: \texttt{esp_timer_get_time()}. This function returns the number of microseconds since \texttt{esp_timer} was initialized, which usually happens shortly before \texttt{app_main} function is called.

Unlike \texttt{gettimeofday} function, values returned by \texttt{esp_timer_get_time()}:

- Start from zero after the chip wakes up from Deep-sleep
- Do not have timezone or DST adjustments applied

Application Example

The following example illustrates the usage of \texttt{esp_timer} APIs: system/esp_timer.
API Reference

Header File

- components/esp_timer/include/esp_timer.h

Functions

`esp_err_t esp_timer_early_init (void)`

Minimal initialization of esp_timer.

This function can be called very early in startup process, after this call only esp_timer_get_time function can be used.

**Note:** This function is called from startup code. Applications do not need to call this function before using other esp_timer APIs.

**Returns**

- ESP_OK on success

`esp_err_t esp_timer_init (void)`

Initialize esp_timer library.

This function will be called from startup code on every core if CONFIG_ESP_TIMER_ISR_AFFINITY_NO_AFFINITY is enabled, It allocates the timer ISR on MULTIPLE cores and creates the timer task which can be run on any core.

**Note:** This function is called from startup code. Applications do not need to call this function before using other esp_timer APIs. Before calling this function, esp_timer_early_init must be called by the startup code.

**Returns**

- ESP_OK on success
- ESP_ERR_NO_MEM if allocation has failed
- ESP_ERR_INVALID_STATE if already initialized
- other errors from interrupt allocator

`esp_err_t esp_timer_deinit (void)`

De-initialize esp_timer library.

**Note:** Normally this function should not be called from applications

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_STATE if not yet initialized

`esp_err_t esp_timer_create (const esp_timer_create_args_t *create_args, esp_timer_handle_t *out_handle)`

Create an esp_timer instance.

**Note:** When done using the timer, delete it with esp_timer_delete function.
Parameters

- **create_args** - Pointer to a structure with timer creation arguments. Not saved by the library, can be allocated on the stack.
- **out_handle** - Output, pointer to esp_timer_handle_t variable which will hold the created timer handle.

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if some of the create_args are not valid
- ESP_ERR_INVALID_STATE if esp_timer library is not initialized yet
- ESP_ERR_NO_MEM if memory allocation fails

```c
esp_err_t esp_timer_start_once(esp_timer_handle_t timer, uint64_t timeout_us)
```
Start one-shot timer.

Timer should not be running when this function is called.

Parameters

- **timer** - timer handle created using esp_timer_create
- **timeout_us** - timer timeout, in microseconds relative to the current moment

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is already running

```c
esp_err_t esp_timer_start_periodic(esp_timer_handle_t timer, uint64_t period)
```
Start a periodic timer.

Timer should not be running when this function is called. This function will start the timer which will trigger every `period` microseconds.

Parameters

- **timer** - timer handle created using esp_timer_create
- **period** - timer period, in microseconds

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is already running

```c
esp_err_t esp_timer_restart(esp_timer_handle_t timer, uint64_t timeout_us)
```
Restart a currently running timer.

If the given timer is a one-shot timer, the timer is restarted immediately and will timeout once in `timeout_us` microseconds. If the given timer is a periodic timer, the timer is restarted immediately with a new period of `timeout_us` microseconds.

Parameters

- **timer** - timer Handle created using esp_timer_create
- **timeout_us** - Timeout, in microseconds relative to the current time. In case of a periodic timer, also represents the new period.

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_INVALID_STATE if the timer is not running

```c
esp_err_t esp_timer_stop(esp_timer_handle_t timer)
```
Stop the timer.

This function stops the timer previously started using esp_timer_start_once or esp_timer_start_periodic.

Parameters **timer** - timer handle created using esp_timer_create

Returns

- ESP_OK on success
- ESP_ERR_INVALID_STATE if the timer is not running
**esp_err_t esp_timer_delete (esp_timer_handle_t timer)**

Delete an esp_timer instance.

The timer must be stopped before deleting. A one-shot timer which has expired does not need to be stopped.

**Parameters**
- timer - timer handle allocated using esp_timer_create

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_STATE if the timer is running

**int64_t esp_timer_get_time (void)**

Get time in microseconds since boot.

**Returns**
- number of microseconds since underlying timer has been started

**int64_t esp_timer_get_next_alarm (void)**

Get the timestamp when the next timeout is expected to occur.

**Returns**
- Timestamp of the nearest timer event, in microseconds. The timebase is the same as for the values returned by esp_timer_get_time.

**int64_t esp_timer_get_next_alarm_for_wake_up (void)**

Get the timestamp when the next timeout is expected to occur skipping those which have skip_unhandled_events flag.

**Returns**
- Timestamp of the nearest timer event, in microseconds. The timebase is the same as for the values returned by esp_timer_get_time.

**esp_err_t esp_timer_get_period (esp_timer_handle_t timer, uint64_t *period)**

Get the period of a timer.

This function fetches the timeout period of a timer.

**Parameters**
- timer - timer handle allocated using esp_timer_create
- period - memory to store the timer period value in microseconds

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the arguments are invalid

**esp_err_t esp_timer_get_expiry_time (esp_timer_handle_t timer, uint64_t *expiry)**

Get the expiry time of a one-shot timer.

This function fetches the expiry time of a one-shot timer.

**Parameters**
- timer - timer handle allocated using esp_timer_create
- expiry - memory to store the timeout value in microseconds

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if the arguments are invalid
- ESP_ERR_NOT_SUPPORTED if the timer type is periodic
**esp_err_t esp_timer_dump (FILE *stream)**

Dump the list of timers to a stream.

If CONFIG_ESP_TIMER_PROFILING option is enabled, this prints the list of all the existing timers. Otherwise, only the list active timers is printed.

The format is:

name period alarm times_armed times_triggered total_callback_run_time

where:

name — timer name (if CONFIG_ESP_TIMER_PROFILING is defined), or timer pointer period — period of timer, in microseconds, or 0 for one-shot timer alarm — time of the next alarm, in microseconds since boot, or 0 if the timer is not started

The following fields are printed if CONFIG_ESP_TIMER_PROFILING is defined:

times_armed — number of times the timer was armed via esp_timer_start_X times_triggered - number of times the callback was called total_callback_run_time - total time taken by callback to execute, across all calls

**Parameters**

- **stream** — stream (such as stdout) to dump the information to

**Returns**

- ESP_OK on success
- ESP_ERR_NO_MEM if can not allocate temporary buffer for the output

**void esp_timer_isr_dispatch_need_yield (void)**

Requests a context switch from a timer callback function.

This only works for a timer that has an ISR dispatch method. The context switch will be called after all ISR dispatch timers have been processed.

**bool esp_timer_is_active (esp_timer_handle_t timer)**

Returns status of a timer, active or not.

This function is used to identify if the timer is still active or not.

**Parameters**

- **timer** — timer handle created using esp_timer_create

**Returns**

- 1 if timer is still active
- 0 if timer is not active.

**esp_err_t esp_timer_new_etm_alarm_event (esp_etm_event_handle_t *out_event)**

Get the ETM event handle of esp_timer underlying alarm event.

**Parameters**

- **out_event** — [out] Returned ETM event handle

**Returns**

- ESP_OK Success
- ESP_ERR_INVALID_ARG Parameter error

---

**Note:** The created ETM event object can be deleted later by calling esp_etm_del_event

**Note:** The ETM event is generated by the underlying hardware &amp;#8212; systimer, therefore, if the esp_timer is not clocked by systimer, then no ETM event will be generated.

**Parameters**

- **out_event** — [out] Returned ETM event handle

**Returns**

- ESP_OK Success
- ESP_ERR_INVALID_ARG Parameter error

**Structures**

**struct esp_timer_create_args_t**

Timer configuration passed to esp_timer_create.
Chapter 2. API Reference

Public Members

`esp_timer_cb_t callback`
Function to call when timer expires.

`void *arg`
Argument to pass to the callback.

`esp_timer_dispatch_t dispatch_method`
Call the callback from task or from ISR.

`const char *name`
Timer name, used in esp_timer_dump function.

`bool skip_unhandled_events`
Skip unhandled events for periodic timers.

Type Definitions

typedef struct esp_timer *`esp_timer_handle_t`
Opaque type representing a single esp_timer.

typedef void (*`esp_timer_cb_t`)(void *arg)
Timer callback function type.

    Param arg  pointer to opaque user-specific data

Enumerations

enum `esp_timer_dispatch_t`
Method for dispatching timer callback.

    Values:

    enumerator `ESP_TIMER_TASK`
    Callback is called from timer task.

    enumerator `ESP_TIMER_MAX`
    Count of the methods for dispatching timer callback.

2.10.17 Internal and Unstable APIs

This section is listing some APIs that are internal or likely to be changed or removed in the next releases of ESP-IDF.

API Reference

Header File

* components/espr_rom/include/esp_rom_sys.h
**Chapter 2. API Reference**

**Functions**

```c
void esp_rom_software_reset_system (void)
    Software Reset digital core include RTC.
    It is not recommended to use this function in esp-idf, use esp_restart() instead.

void esp_rom_software_reset_cpu (int cpu_no)
    Software Reset cpu core.
    It is not recommended to use this function in esp-idf, use esp_restart() instead.
```

**Parameters**

- `cpu_no` : The CPU to reset, 0 for PRO CPU, 1 for APP CPU.

```c
int esp_rom_printf (const char* fmt, ...)
    Print formatted string to console device.
```

**Note:** float and long long data are not supported!

**Parameters**

- `fmt` : Format string
- `...` : Additional arguments, depending on the format string

**Returns**

- `int`: Total number of characters written on success; A negative number on failure.

```c
void esp_rom_delay_us (uint32_t us)
    Pauses execution for us microseconds.
```

**Parameters**

- `us` : Number of microseconds to pause

```c
void esp_rom_install_channel_putchar (int channel, void (*putc)(char c))
    esp_rom_printf can print message to different channels simultaneously. This function can help install the low
    level putc function for esp_rom_printf.
```

**Parameters**

- `channel` : Channel number (starting from 1)
- `putc` : Function pointer to the putc implementation. Set NULL can disconnect
  esp_rom_printf with putc.

```c
void esp_rom_install_uart_putchar (void)
    Install UART1 as the default console channel, equivalent to esp_rom_install_channel_putchar(1,
    esp_rom_uart_putchar)
```

```c
soc_reset_reason_t esp_rom_get_reset_reason (int cpu_no)
    Get reset reason of CPU.
```

**Parameters**

- `cpu_no` : CPU number

**Returns**

- `soc_reset_reason_t` : Reset reason code (see in soc/reset_reasons.h)

```c
void esp_rom_route_intr_matrix (int cpu_core, uint32_t periph_intr_id, uint32_t cpu_intr_num)
    Route peripheral interrupt sources to CPU’s interrupt port by matrix.
```

**Usually there’re 4 steps to use an interrupt:**

a. Route peripheral interrupt source to CPU. e.g. esp_rom_route_intr_matrix(0, 
ETS_WIFI_MAC_INTR_SOURCE, ETS_WMAC_INUM)

b. Set interrupt handler for CPU

c. Enable CPU interrupt

d. Enable peripheral interrupt

**Parameters**

- `cpu_core` : The CPU number, which the peripheral interrupt will inform to
- `periph_intr_id` : The peripheral interrupt source number
- `cpu_intr_num` : The CPU interrupt number
Chapter 2. API Reference

```c
uint32_t esp_rom_get_cpu_ticks_per_us(void)
Get the real CPU ticks per us.

Returns CPU ticks per us

void esp_rom_set_cpu_ticks_per_us(uint32_t ticks_per_us)
Set the real CPU tick rate.
```

**Note:** Call this function when CPU frequency is changed, otherwise the `esp_rom_delay_us` can be inaccurate.

**Parameters**

- `ticks_per_us` - CPU ticks per us

### 2.10.18 Inter-Processor Call

**Note:** The IPC is an Inter-Processor Call and NOT Inter-Process Communication as found on other operating systems.

**Overview**

Due to the dual core nature of the ESP32, there are instances where a certain callback must be run in the context of a particular CPU such as:

- When allocating an ISR to an interrupt source of a particular CPU (applies to freeing a particular CPU’s interrupt source as well).
- On particular chips (such as the ESP32), accessing memory that is exclusive to a particular CPU (such as RTC Fast Memory).
- Reading the registers/state of another CPU.

The IPC (Inter-Processor Call) feature allows a particular CPU (the calling CPU) to trigger the execution of a callback function on another CPU (the target CPU). The IPC feature allows execution of a callback function on the target CPU in either a task context, or a High Priority Interrupt context (see High-Level Interrupts for more details). Depending on the context that the callback function is executed in, different restrictions apply to the implementation of the callback function.

**IPC in Task Context**

The IPC feature implements callback execution in a task context by creating an IPC task for each CPU during application startup. When the calling CPU needs to execute a callback on the target CPU, the callback will execute in the context of the target CPU’s IPC task.

When using IPCs in a task context, users need to consider the following:

- **IPC callbacks should ideally be simple and short.** An **IPC callback should avoid attempting to block or yield.**
- **The IPC tasks are created at the highest possible priority (i.e., configMAX_PRIORITIES - 1) thus the callback should also run at that priority as a result. However, CONFIG_ESP_IPC_USES_CALLERS_PRIORITY** is enabled by default which will temporarily lower the priority of the target CPU’s IPC task to the calling CPU before executing the callback.
- **Depending on the complexity of the callback, users may need to configure the stack size of the IPC task via CONFIG_ESP_IPC_TASK_STACK_SIZE.**
- **The IPC feature is internally protected by a mutex. Therefore, simultaneous IPC calls from two or more calling CPUs will be handled on a first come first serve basis.**
**API Usage**  
Task Context IPC callbacks have the following restrictions:

- The callback must be of type `void func(void *arg)`
- The callback should avoid attempting to block or yield as this will result in the target CPU’s IPC task blocking or yielding.
- The callback must avoid changing any aspect of the IPC task (e.g., by calling `vTaskPrioritySet(NULL, x)`).

The IPC feature offers the API listed below to execute a callback in a task context on a target CPU. The API allows the calling CPU to block until the callback’s execution has completed, or return immediately once the callback’s execution has started.

- `esp_ipc_call()` will trigger an IPC call on the target CPU. This function will block until the target CPU’s IPC task begins execution of the callback.
- `esp_ipc_call_blocking()` will trigger an IPC on the target CPU. This function will block until the target CPU’s IPC task completes execution of the callback.

**IPC in ISR Context**

In some cases, we need to quickly obtain the state of another CPU such as in a core dump, GDB stub, various unit tests, and DPORT workaround. For such scenarios, the IPC feature supports execution of callbacks in a *High Priority Interrupt* context. The IPC feature implements the High Priority Interrupt context by reserving a High Priority Interrupt on each CPU for IPC usage. When a calling CPU needs to execute a callback on the target CPU, the callback will execute in the context of the High Priority Interrupt of the target CPU.

When using IPCs in High Priority Interrupt context, users need to consider the following:

- Since the callback is executed in a High Priority Interrupt context, the callback must be written entirely in assembly. See the API Usage below for more details regarding writing assembly callbacks.
- The priority of the reserved High Priority Interrupt is dependent on the `CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL` option.
- **When the callback executes:**
  - The calling CPU will disable interrupts of level 3 and lower
  - Although the priority of the reserved interrupt depends on `CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL`, during the execution IPC ISR callback, the target CPU will disable interrupts of level 5 and lower regardless of what `CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL` is set to.

**API Usage**  
High Priority Interrupt IPC callbacks have the following restrictions:

- The callback must be of type `void func(void *arg)` but implemented entirely in assembly
- The callback is invoked via the `CALLX0` instruction with register windowing disabled, thus the callback:
  - Must not call any register window related instructions (e.g., `entry` and `retw`).
  - Must not call other C functions as register windowing is disabled
- The callback should be placed in IRAM at a 4-byte aligned address
- (On invocation of/after returning from) the callback, the registers `a2`, `a3`, `a4` are (saved/restored) automatically thus:
  - `a2` will contain the `void *arg` of the callback
  - `a3/a4` are free to use as scratch registers

The IPC feature offers the API listed below to execute a callback in a High Priority Interrupt context.

- `esp_ipc_isr_asm_call()` will trigger an IPC call on the target CPU. This function will busy-wait until the target CPU begins execution of the callback.
- `esp_ipc_isr_asm_call_blocking()` will trigger an IPC call on the target CPU. This function will busy-wait until the target CPU completes execution of the callback.

The following code-blocks demonstrates a High Priority Interrupt IPC callback written in assembly that simply reads the target CPU’s cycle count.
Chapter 2. API Reference

```c
/* esp_test_ipc_isr_get_cycle_count_other_cpu(void *arg) */
// this function reads CCOUNT of the target CPU and stores it in arg.
// use only a2, a3 and a4 regs here.
.section .iram1, "ax"
.align 4
.global esp_test_ipc_isr_get_cycle_count_other_cpu
.type esp_test_ipc_isr_get_cycle_count_other_cpu, @function

// Args:
// a2 - void* arg
esp_test ipc_isr_get_cycle_count_other_cpu:
rsr.ccount a3
s32i a3, a2, 0
ret

unit32_t cycle_count;
esp_ipc_isr_asm_call_blocking{esp_test_ipc_isr_get_cycle_count_other_cpu, (void*)cycle_count};
```

**Note:** The number of scratch registers available for use is sufficient for most simple use cases. But if your callback requires more scratch registers, void *arg can point to a buffer that is used as a register save area. The callback can then save and restore more registers. See the system/ipc/ipc_isr.

**Note:** For more examples of High Priority Interrupt IPC callbacks, see components/esp_system/port/arch/xtensa/esp_ipc_isr_routines.S and components/esp_system/test/test_ipc_isr.S

The High Priority Interrupt IPC API also provides the following convenience functions that can stall/resume the target CPU. These API utilize the High Priority Interrupt IPC, but supply their own internal callbacks:

* esp_ipc_isr_stall_other_cpu() stalls the target CPU. The calling CPU disables interrupts of level 3 and lower while the target CPU will busy-wait with interrupts of level 5 and lower disabled. The target CPU will busy-wait until esp_ipc_isr_release_other_cpu() is called.
* esp_ipc_isr_release_other_cpu() resumes the target CPU.

**API Reference**

**Header File**

- components/esp_system/include/esp_ipc.h

**Functions**

*esp_err_t* esp_ipc_call (uint32_t cpu_id, esp_ipc_func_t func, void *arg)

Execute a callback on a given CPU.

Execute a given callback on a particular CPU. The callback must be of type “esp_ipc_func_t” and will be invoked in the context of the target CPU’s IPC task.

- This function will block the target CPU’s IPC task has begun execution of the callback
- If another IPC call is ongoing, this function will block until the ongoing IPC call completes
- The stack size of the IPC task can be configured via the CONFIG_ESP_IPC_TASK_STACK_SIZE option

**Note:** In single-core mode, returns ESP_ERR_INVALID_ARG for cpu_id 1.
### Parameters

- **cpu_id** [in] CPU where the given function should be executed (0 or 1)
- **func** [in] Pointer to a function of type `void func(void* arg)` to be executed
- **arg** [in] Arbitrary argument of type `void*` to be passed into the function

### Returns

- **ESP_ERR_INVALID_ARG** if `cpu_id` is invalid
- **ESP_ERR_INVALID_STATE** if the FreeRTOS scheduler is not running
- **ESP_OK** otherwise

```c
esp_err_t esp_ipc_call_blocking (uint32_t cpu_id, esp_ipc_func_t func, void *arg)
```

Execute a callback on a given CPU until and block until it completes.

This function is identical to `esp_ipc_call()` except that this function will block until the execution of the callback completes.

**Note:** In single-core mode, returns **ESP_ERR_INVALID_ARG** for `cpu_id` 1.

### Type Definitions

```c
typedef void (*esp_ipc_func_t)(void *arg)
```

IPC Callback.

A callback of this type should be provided as an argument when calling `esp_ipc_call()` or `esp_ipc_call_blocking()`.

### Header File

- `components/esp_system/include/esp_ipc_isr.h`

### Functions

```c
void esp_ipc_isr_asm_call (esp_ipc_isr_func_t func, void *arg)
```

Execute an assembly callback on the other CPU.

Execute a given callback on the other CPU in the context of a High Priority Interrupt.

- This function will busy-wait in a critical section until the other CPU has started execution of the callback
- The callback must be written in assembly, is invoked using a `CALLX0` instruction, and has a2, a3, a4 as scratch registers. See docs for more details

**Note:** This function is not available in single-core mode.

### Parameters

- **func** [in] Pointer to a function of type `void func(void* arg)` to be executed
- **arg** [in] Arbitrary argument of type `void*` to be passed into the function
**void esp_ipc_isr_asm_call_blocking (esp_ipc_isr_func_t func, void *arg)**

Execute an assembly callback on the other CPU and busy-wait until it completes.

This function is identical to `esp_ipc_isr_asm_call()` except that this function will busy-wait until the execution of the callback completes.

---

**Note:** This function is not available in single-core mode.

---

**Parameters**

- **func** [in] Pointer to a function of type `void func(void* arg)` to be executed
- **arg** [in] Arbitrary argument of type `void*` to be passed into the function

---

**void esp_ipc_isr_stall_other_cpu (void)**

Stall the other CPU.

This function will stall the other CPU. The other CPU is stalled by busy-waiting in the context of a High Priority Interrupt. The other CPU will not be resumed until `esp_ipc_isr_release_other_cpu()` is called.

- This function is internally implemented using IPC ISR
- This function is used for DPORT workaround.
- If the stall feature is paused using `esp_ipc_isr_stall_pause()`, this function will have no effect

---

**Note:** This function is not available in single-core mode.

---

**Note:** It is the caller’s responsibility to avoid deadlocking on spinlocks

---

**void esp_ipc_isr_release_other_cpu (void)**

Release the other CPU.

This function will release the other CPU that was previously stalled from calling `esp_ipc_isr_stall_other_cpu()`.

- This function is used for DPORT workaround.
- If the stall feature is paused using `esp_ipc_isr_stall_pause()`, this function will have no effect

---

**Note:** This function is not available in single-core mode.

---

**void esp_ipc_isr_stall_pause (void)**

Pause the CPU stall feature.

This function will pause the CPU stall feature. Once paused, calls to `esp_ipc_isr_stall_other_cpu()` and `esp_ipc_isr_release_other_cpu()` will have no effect. If a IPC ISR call is already in progress, this function will busy-wait until the call completes before pausing the CPU stall feature.

---

**void esp_ipc_isr_stall_abort (void)**

Abort a CPU stall.

This function will abort any stalling routine of the other CPU due to a previous call to `esp_ipc_isr_stall_other_cpu()`. This function aborts the stall in a non-recoverable manner, thus should only be called in case of a panic.

- This function is used in panic handling code
void esp_ipc_isr_stall_resume(void)
    Resume the CPU stall feature.
    This function will resume the CPU stall feature that was previously paused by calling esp_ipc_isr_stall_pause().
    Once resumed, calls to esp_ipc_isr_stall_other_cpu() and esp_ipc_isr_release_other_cpu() will have effect again.

Type Definitions
typedef void (*esp_ipc_isr_func_t)(void *arg)
    IPC ISR Callback.
    A callback of this type should be provided as an argument when calling esp_ipc_isr_asm_call() or
    esp_ipc_isr_asm_call_blocking().

2.10.19  Interrupt allocation

Overview

The ESP32 has two cores, with 32 interrupts each. Each interrupt has a certain priority level, most (but not all)
interrupts are connected to the interrupt mux.

Because there are more interrupt sources than interrupts, sometimes it makes sense to share an interrupt in multiple
drivers. The esp_intr_alloc() abstraction exists to hide all these implementation details.

A driver can allocate an interrupt for a certain peripheral by calling esp_intr_alloc() (or
esp_intr_alloc_intrstatus()). It can use the flags passed to this function to set the type of inter-
rupt allocated, specifying a particular level or trigger method. The interrupt allocation code will then find an
applicable interrupt, use the interrupt mux to hook it up to the peripheral, and install the given interrupt handler and
ISR to it.

This code presents two different types of interrupts, handled differently: shared interrupts and non-shared interrupts.
The simplest ones are non-shared interrupts: a separate interrupt is allocated per esp_intr_alloc() call and
this interrupt is solely used for the peripheral attached to it, with only one ISR that will get called. On the other
hand, shared interrupts can have multiple peripherals triggering them, with multiple ISRs being called when one of
the peripherals attached signals an interrupt. Thus, ISRs that are intended for shared interrupts should check the
interrupt status of the peripheral they service in order to check if any action is required.

Non-shared interrupts can be either level- or edge-triggered. Shared interrupts can only be level interrupts due to the
chance of missed interrupts when edge interrupts are used.

For example, let’s say DevA and DevB share an interrupt. DevB signals an interrupt, so INT line goes high. The
ISR handler calls code for DevA but does nothing. Then, ISR handler calls code for DevB, but while doing that,
DevA signals an interrupt. DevB’s ISR is done, it clears interrupt status for DevB and exits interrupt code. Now,
an interrupt for DevA is still pending, but because the INT line never went low, as DevA kept it high even when the
interrupt for DevB was cleared, the interrupt is never serviced.

Multicore issues

Peripherals that can generate interrupts can be divided in two types:

- External peripherals, within the ESP32 but outside the Xtensa cores themselves. Most ESP32 peripherals are
  of this type.
- Internal peripherals, part of the Xtensa CPU cores themselves.

Interrupt handling differs slightly between these two types of peripherals.
**Internal peripheral interrupts**  
Each Xtensa CPU core has its own set of six internal peripherals:

- Three timer comparators
- A performance monitor
- Two software interrupts.

Internal interrupt sources are defined in `esp_intr_alloc.h` as `ETS_INTERNAL_*_INTR_SOURCE`.

These peripherals can only be configured from the core they are associated with. When generating an interrupt, the interrupt they generate is hard-wired to their associated core; it’s not possible to have, for example, an internal timer comparator of one core generate an interrupt on another core. That is why these sources can only be managed using a task running on that specific core. Internal interrupt sources are still allocatable using `esp_intr_alloc()` as normal, but they cannot be shared and will always have a fixed interrupt level (namely, the one associated in hardware with the peripheral).

**External Peripheral Interrupts**  
The remaining interrupt sources are from external peripherals. These are defined in `soc/soc.h` as `ETS_*_INTR_SOURCE`.

Non-internal interrupt slots in both CPU cores are wired to an interrupt multiplexer, which can be used to route any external interrupt source to any of these interrupt slots.

- Allocating an external interrupt will always allocate it on the core that does the allocation.
- Freeing an external interrupt must always happen on the same core it was allocated on.
- Disabling and enabling external interrupts from another core is allowed.
- Multiple external interrupt sources can share an interrupt slot by passing `ESP_INTR_FLAG_SHARED` as a flag to `esp_intr_alloc()`.

Care should be taken when calling `esp_intr_alloc()` from a task which is not pinned to a core. During task switching, these tasks can migrate between cores. Therefore it is impossible to tell which CPU the interrupt is allocated on, which makes it difficult to free the interrupt handle and may also cause debugging difficulties. It is advised to use `xTaskCreatePinnedToCore()` with a specific CoreID argument to create tasks that will allocate interrupts. In the case of internal interrupt sources, this is required.

**IRAM-Safe Interrupt Handlers**

The `ESP_INTR_FLAG_IRAM` flag registers an interrupt handler that always runs from IRAM (and reads all its data from DRAM), and therefore does not need to be disabled during flash erase and write operations.

This is useful for interrupts which need a guaranteed minimum execution latency, as flash write and erase operations can be slow (erases can take tens or hundreds of milliseconds to complete).

It can also be useful to keep an interrupt handler in IRAM if it is called very frequently, to avoid flash cache misses. Refer to the *SPI flash API documentation* for more details.

**Multiple Handlers Sharing A Source**

Several handlers can be assigned to a same source, given that all handlers are allocated using the `ESP_INTR_FLAG_SHARED` flag. They will all be allocated to the interrupt, which the source is attached to, and called sequentially when the source is active. The handlers can be disabled and freed individually. The source is attached to the interrupt (enabled), if one or more handlers are enabled, otherwise detached. A handler will never be called when disabled, while its source may still be triggered if any one of its handler enabled.

Sources attached to non-shared interrupt do not support this feature.

Though the framework support this feature, you have to use it very carefully. There usually exist two ways to stop an interrupt from being triggered: disable the source or mask peripheral interrupt status. IDF only handles enabling and disabling of the source itself, leaving status and mask bits to be handled by users. Status bits shall either be masked before the handler responsible for it is disabled, either be masked and then properly handled in another enabled interrupt. Please note that leaving some status bits unhandled without masking them, while
disabling the handlers for them, will cause the interrupt(s) to be triggered indefinitely, resulting therefore in a system crash.

API Reference

Header File

- components/esp_hw_support/include/esp_intr_alloc.h

Functions

**esp_err_t esp_intr_mark_shared**(int intno, int cpu, bool is_in_iram)

Mark an interrupt as a shared interrupt.

This will mark a certain interrupt on the specified CPU as an interrupt that can be used to hook shared interrupt handlers to.

**Parameters**

- **intno** – The number of the interrupt (0-31)
- **cpu** – CPU on which the interrupt should be marked as shared (0 or 1)
- **is_in_iram** – Shared interrupt is for handlers that reside in IRAM and the int can be left enabled while the flash cache is disabled.

**Returns**

ESP_ERR_INVALID_ARG if cpu or intno is invalid ESP_OK otherwise

**esp_err_t esp_intr_reserve**(int intno, int cpu)

Reserve an interrupt to be used outside of this framework.

This will mark a certain interrupt on the specified CPU as reserved, not to be allocated for any reason.

**Parameters**

- **intno** – The number of the interrupt (0-31)
- **cpu** – CPU on which the interrupt should be marked as shared (0 or 1)

**Returns**

ESP_ERR_INVALID_ARG if cpu or intno is invalid ESP_OK otherwise

**esp_err_t esp_intr_alloc**(int source, int flags, intr_handler_t handler, void *arg, intr_handle_t *ret_handle)

Allocate an interrupt with the given parameters.

This finds an interrupt that matches the restrictions as given in the flags parameter, maps the given interrupt source to it and hooks up the given interrupt handler (with optional argument) as well. If needed, it can return a handle for the interrupt as well.

The interrupt will always be allocated on the core that runs this function.

If ESP_INTR_FLAG_IRAM flag is used, and handler address is not in IRAM or RTC_FAST_MEM, then ESP_ERR_INVALID_ARG is returned.

**Parameters**

- **source** – The interrupt source. One of the ETS_*_INTR_SOURCE interrupt mux sources, as defined in soc/soc.h, or one of the internal ETS_INTERNAL_*_INTR_SOURCE sources as defined in this header.
- **flags** – An ORed mask of the ESP_INTR_FLAG_* defines. These restrict the choice of interrupts that this routine can choose from. If this value is 0, it will default to allocating a non-shared interrupt of level 1, 2 or 3. If this is ESP_INTR_FLAG_SHARED, it will allocate a shared interrupt of level 1. Setting ESP_INTR_FLAG_INTRDISABLED will return from this function with the interrupt disabled.
- **handler** – The interrupt handler. Must be NULL when an interrupt of level >3 is requested, because these types of interrupts aren’t C-callable.
- **arg** – Optional argument for passed to the interrupt handler
- **ret_handle** – Pointer to an intr_handle_t to store a handle that can later be used to request details or free the interrupt. Can be NULL if no handle is required.

**Returns**

ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
ESP_ERR_NOT_FOUND No free interrupt found with the specified flags ESP_OK otherwise
Allocate an interrupt with the given parameters.

This essentially does the same as esp_intr_alloc, but allows specifying a register and mask combo. For shared interrupts, the handler is only called if a read from the specified register, ANDed with the mask, returns non-zero. By passing an interrupt status register address and a fitting mask, this can be used to accelerate interrupt handling in the case a shared interrupt is triggered; by checking the interrupt statuses first, the code can decide which ISRs can be skipped.

**Parameters**
- **source** – The interrupt source. One of the `ETS_*_INTR_SOURCE` interrupt mux sources, as defined in `soc/soc.h`, or one of the internal ETS_INTERNAL_*_INTR_SOURCE sources as defined in this header.
- **flags** – An ORred mask of the `ESP_INTR_FLAG_*` defines. These restrict the choice of interrupts that this routine can choose from. If this value is 0, it will default to allocating a non-shared interrupt of level 1, 2 or 3. If this is `ESP_INTR_FLAG_SHARED`, it will allocate a shared interrupt of level 1. Setting `ESP_INTR_FLAG_INTRDISABLED` will return from this function with the interrupt disabled.
- **intrstatusreg** – The address of an interrupt status register
- **intrstatusmask** – A mask. If a read of address intrstatusreg has any of the bits that are 1 in the mask set, the ISR will be called. If not, it will be skipped.
- **handler** – The interrupt handler. Must be NULL when an interrupt of level >3 is requested, because these types of interrupts aren’t C-callable.
- **arg** – Optional argument for passed to the interrupt handler
- **ret_handle** – Pointer to an intr_handle_t to store a handle that can later be used to request details or free the interrupt. Can be NULL if no handle is required.

**Returns**
- ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
- ESP_OK otherwise

---

Disable and free an interrupt.

Use an interrupt handle to disable the interrupt and release the resources associated with it. If the current core is not the core that registered this interrupt, this routine will be assigned to the core that allocated this interrupt, blocking and waiting until the resource is successfully released.

**Parameters**
- **handle** – The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

**Returns**
- ESP_ERR_INVALID_ARG the handle is NULL ESP_FAIL failed to release this handle ESP_OK otherwise

---

Get CPU number an interrupt is tied to.

**Parameters**
- **handle** – The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

**Returns**
- The core number where the interrupt is allocated

---

Get the allocated interrupt for a certain handle.

**Parameters**
- **handle** – The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

**Returns**
- The interrupt number
**esp_err_t esp_intr_disable(intr_handle_t handle)**

Disable the interrupt associated with the handle.

**Note:**

a. For local interrupts (ESP_INTERNAL_* sources), this function has to be called on the CPU the interrupt is allocated on. Other interrupts have no such restriction.

b. When several handlers sharing a same interrupt source, interrupt status bits, which are handled in the handler to be disabled, should be masked before the disabling, or handled in other enabled interrupts properly. Miss of interrupt status handling will cause infinite interrupt calls and finally system crash.

**Parameters**

- handle: The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

**Returns**

- ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
- ESP_OK otherwise

---

**esp_err_t esp_intr_enable(intr_handle_t handle)**

Enable the interrupt associated with the handle.

**Note:** For local interrupts (ESP_INTERNAL_* sources), this function has to be called on the CPU the interrupt is allocated on. Other interrupts have no such restriction.

**Parameters**

- handle: The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus

**Returns**

- ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
- ESP_OK otherwise

---

**esp_err_t esp_intr_set_in_iram(intr_handle_t handle, bool is_in_iram)**

Set the “in IRAM” status of the handler.

**Note:** Does not work on shared interrupts.

**Parameters**

- handle: The handle, as obtained by esp_intr_alloc or esp_intr_alloc_intrstatus
- is_in_iram: Whether the handler associated with this handle resides in IRAM. Handlers residing in IRAM can be called when cache is disabled.

**Returns**

- ESP_ERR_INVALID_ARG if the combination of arguments is invalid.
- ESP_OK otherwise

---

**void esp_intr_noniram_disable(void)**

Disable interrupts that aren’t specifically marked as running from IRAM.

**void esp_intr_noniram_enable(void)**

Re-enable interrupts disabled by esp_intr_noniram_disable.

**void esp_intr_enable_source(int inum)**

Enable the interrupt source based on its number

**Parameters**

- inum: interrupt number from 0 to 31

---

**void esp_intr_disable_source(int inum)**

Disable the interrupt source based on its number

**Parameters**

- inum: interrupt number from 0 to 31
static inline int esp_intr_flags_to_level (int flags)
Get the lowest interrupt level from the flags.

Parameters flags - The same flags that pass to esp_intr_alloc_intrstatus API

Macros

ESP_INTR_FLAG_LEVEL1
Interrupt allocation flags.
These flags can be used to specify which interrupt qualities the code calling esp_intr_alloc* needs. Accept a
Level 1 interrupt vector (lowest priority)

ESP_INTR_FLAG_LEVEL2
Accept a Level 2 interrupt vector.

ESP_INTR_FLAG_LEVEL3
Accept a Level 3 interrupt vector.

ESP_INTR_FLAG_LEVEL4
Accept a Level 4 interrupt vector.

ESP_INTR_FLAG_LEVEL5
Accept a Level 5 interrupt vector.

ESP_INTR_FLAG_LEVEL6
Accept a Level 6 interrupt vector.

ESP_INTR_FLAG_NMI
Accept a Level 7 interrupt vector (highest priority)

ESP_INTR_FLAG_SHARED
Interrupt can be shared between ISRs.

ESP_INTR_FLAG_EDGE
Edge-triggered interrupt.

ESP_INTR_FLAG_IRAM
ISR can be called if cache is disabled.

ESP_INTR_FLAG_INTRDISABLED
Return with this interrupt disabled.

ESP_INTR_FLAG_LOWMED
Low and medium prio interrupts. These can be handled in C.

ESP_INTR_FLAG_HIGH
High level interrupts. Need to be handled in assembly.

ESP_INTR_FLAG_LEVELMASK
Mask for all level flags.
ETS_INTERNAL_TIMER0_INTR_SOURCE
Platform timer 0 interrupt source.
The esp_intr_alloc* functions can allocate an int for all ETS_*_INTR_SOURCE interrupt sources that are routed through the interrupt mux. Apart from these sources, each core also has some internal sources that do not pass through the interrupt mux. To allocate an interrupt for these sources, pass these pseudo-sources to the functions.

ETSINTERNAL_TIMER1_INTR_SOURCE
Platform timer 1 interrupt source.

ETSINTERNAL_TIMER2_INTR_SOURCE
Platform timer 2 interrupt source.

ETSINTERNAL_SW0_INTR_SOURCE
Software int source 1.

ETSINTERNAL_SW1_INTR_SOURCE
Software int source 2.

ETSINTERNAL_PROFILING_INTR_SOURCE
Int source for profiling.

ETSINTERNAL_UNUSED_INTR_SOURCE
Interrupt is not assigned to any source.

ETSINTERNAL_INTR_SOURCE_OFF
Provides SystemView with positive IRQ IDs, otherwise scheduler events are not shown properly.

ESP_INTR_ENABLE (inum)
Enable interrupt by interrupt number

ESP_INTR_DISABLE (inum)
Disable interrupt by interrupt number

Type Definitions
typedef void (*intr_handler_t)(void *arg)
Function prototype for interrupt handler function
typedef struct intr_handle_data_t intr_handle_data_t
Interrupt handler associated data structure
typedef intr_handle_data_t *intr_handle_t
Handle to an interrupt handler

2.10.20 Logging library

Overview
The logging library provides two ways for setting log verbosity:

• At compile time: in menuconfig, set the verbosity level using the option CONFIG_LOG_DEFAULT_LEVEL.
• Optionally, also in menuconfig, set the maximum verbosity level using the option `CONFIG_LOG_MAXIMUM_LEVEL`. By default this is the same as the default level, but it can be set higher in order to compile more optional logs into the firmware.

• **At runtime:** all logs for verbosity levels lower than `CONFIG_LOG_DEFAULT_LEVEL` are enabled by default. The function `esp_log_level_set()` can be used to set a logging level on a per module basis. Modules are identified by their tags, which are human-readable ASCII zero-terminated strings.

There are the following verbosity levels:

- Error (lowest)
- Warning
- Info
- Debug
- Verbose (highest)

**Note:** The function `esp_log_level_set()` cannot set logging levels higher than specified by `CONFIG_LOG_MAXIMUM_LEVEL`. To increase log level for a specific file above this maximum at compile time, use the macro `LOG_LOCAL_LEVEL` (see the details below).

---

**How to use this library**

In each C file that uses logging functionality, define the `TAG` variable as shown below:

```c
static const char* TAG = "MyModule";
```

Then use one of the logging macros to produce output, e.g.:

```c
ESP_LOGW(TAG, "Baud rate error %.1f%%. Requested: %d baud, actual: %d baud", error_→.100, baud_req, baud_real);
```

Several macros are available for different verbosity levels:

- `ESP_LOGE` - error (lowest)
- `ESP_LOGW` - warning
- `ESP_LOGI` - info
- `ESP_LOGD` - debug
- `ESP_LOGV` - verbose (highest)

Additionally, there are `ESP_EARLY_LOGx` versions for each of these macros, e.g. `ESP_EARLY_LOGE`. These versions have to be used explicitly in the early startup code only, before heap allocator and syscalls have been initialized. Normal `ESP_LOGx` macros can also be used while compiling the bootloader, but they will fall back to the same implementation as `ESP_EARLY_LOGx` macros.

There are also `ESP_DRAM_LOGx` versions for each of these macros, e.g. `ESP_DRAM_LOGE`. These versions are used in some places where logging may occur with interrupts disabled or with flash cache inaccessible. Use of this macros should be as sparing as possible, as logging in these types of code should be avoided for performance reasons.

**Note:** Inside critical sections interrupts are disabled so it’s only possible to use `ESP_DRAM_LOGx` (preferred) or `ESP_EARLY_LOGx`. Even though it’s possible to log in these situations, it’s better if your program can be structured not to require it.

To override default verbosity level at file or component scope, define the `LOG_LOCAL_LEVEL` macro.

At file scope, define it before including `esp_log.h`, e.g.:

```c
#define LOG_LOCAL_LEVEL ESP_LOG_VERBOSE
#include "esp_log.h"
```

At component scope, define it in the component CMakeLists:
target_compile_definitions(${COMPONENT_LIB} PUBLIC "-DLOG_LOCAL_LEVEL=ESP_LOG_-VERBOSEx"

To configure logging output per module at runtime, add calls to the function `esp_log_level_set()` as follows:

```c
esp_log_level_set("*", ESP_LOG_ERROR); // set all components to ERROR level
esp_log_level_set("wifi", ESP_LOG_WARN); // enable WARN logs from WiFi stack
esp_log_level_set("dhcpc", ESP_LOG_INFO); // enable INFO logs from DHCP client
```

**Note:** The “DRAM” and “EARLY” log macro variants documented above do not support per module setting of log verbosity. These macros will always log at the “default” verbosity level, which can only be changed at runtime by calling `esp_log_level("*", level)`.

**Logging to Host via JTAG** By default, the logging library uses the `vprintf`-like function to write formatted output to the dedicated UART. By calling a simple API, all log output may be routed to JTAG instead, making logging several times faster. For details, please refer to Section **Logging to Host**.

**Application Example**

The logging library is commonly used by most esp-idf components and examples. For demonstration of log functionality, check ESP-IDF’s examples directory. The most relevant examples that deal with logging are the following:

- system/ota
- storage/sd_card
- protocols/https_request

**API Reference**

**Header File**

- components/log/include/esp_log.h

**Functions**

- `void esp_log_level_set (const char *tag, esp_log_level_t level)`
  
  Set log level for given tag.

  If logging for given component has already been enabled, changes previous setting.

  **Note:** Note that this function can not raise log level above the level set using `CONFIG_LOG_MAXIMUM_LEVEL` setting in menuconfig. To raise log level above the default one for a given file, define `LOG_LOCAL_LEVEL` to one of the `ESP_LOG_*` values, before including `esp_log.h` in this file.

  **Parameters**

  - `tag` – Tag of the log entries to enable. Must be a non-NULL zero terminated string. Value "*" resets log level for all tags to the given value.
  - `level` – Selects log level to enable. Only logs at this and lower verbosity levels will be shown.

- `esp_log_level_t esp_log_level_get (const char *tag)`
  
  Get log level for a given tag, can be used to avoid expensive log statements.

  **Parameters**

  - `tag` – Tag of the log to query current level. Must be a non-NULL zero terminated string.
Returns  The current log level for the given tag

```
vprintf_like_t esp_log_set_vprintf(vprintf_like_t func)
```

Set function used to output log entries.

By default, log output goes to UART0. This function can be used to redirect log output to some other destination, such as file or network. Returns the original log handler, which may be necessary to return output to the previous destination.

Note: Please note that function callback here must be re-entrant as it can be invoked in parallel from multiple thread context.

**Parameters**
- `func` – new Function used for output. Must have same signature as `vprintf`.
- `Returns`  – old Function used for output.

```
uint32_t esp_log_timestamp(void)
```

Function which returns timestamp to be used in log output.

This function is used in expansion of ESP_LOGx macros. In the 2nd stage bootloader, and at early application startup stage this function uses CPU cycle counter as time source. Later when FreeRTOS scheduler start running, it switches to FreeRTOS tick count.

For now, we ignore millisecond counter overflow.

**Returns**  –  timestamp, in milliseconds

```
char *esp_log_system_timestamp(void)
```

Function which returns system timestamp to be used in log output.

This function is used in expansion of ESP_LOGx macros to print the system time as “HH:MM:SS.sss”. The system time is initialized to 0 on startup, this can be set to the correct time with an SNTP sync, or manually with standard POSIX time functions.

Currently, this will not get used in logging from binary blobs (i.e. Wi-Fi & Bluetooth libraries), these will still print the RTOS tick time.

**Returns**  – timestamp, in “HH:MM:SS.sss”

```
uint32_t esp_log_early_timestamp(void)
```

Function which returns timestamp to be used in log output.

This function uses HW cycle counter and does not depend on OS, so it can be safely used after application crash.

**Returns**  – timestamp, in milliseconds

```
void esp_log_write(esp_log_level_t level, const char *tag, const char *format, ...)
```

Write message into the log.

This function is not intended to be used directly. Instead, use one of ESP_LOGE, ESP_LOGW, ESP_LOGI, ESP_LOGD, ESP_LOGV macros.

This function or these macros should not be used from an interrupt.

```
void esp_log_writev(esp_log_level_t level, const char *tag, const char *format, va_list args)
```

Write message into the log, va_list variant.

This function is provided to ease integration toward other logging framework, so that esp_log can be used as a log sink.

**See also:**
- esp_log_write()
Macros

**ESP_LOG_BUFFER_HEX_LEVEL (tag, buffer, buff_len, level)**

Log a buffer of hex bytes at specified level, separated into 16 bytes each line.

**Parameters**

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes
- **level** – level of the log

**ESP_LOG_BUFFER_CHAR_LEVEL (tag, buffer, buff_len, level)**

Log a buffer of characters at specified level, separated into 16 bytes each line. Buffer should contain only printable characters.

**Parameters**

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes
- **level** – level of the log

**ESP_LOG_BUFFER_HEXDUMP (tag, buffer, buff_len, level)**

Dump a buffer to the log at specified level.

The dump log shows just like the one below:

<table>
<thead>
<tr>
<th>W (195) log_example: 0x3ffb4280</th>
<th>45 53 50 33 32 20 69 73 20 67 72 65 61 74...</th>
</tr>
</thead>
<tbody>
<tr>
<td>→ 2c 20</td>
<td>ESP32 is great,</td>
</tr>
<tr>
<td>W (195) log_example: 0x3ffb4290</td>
<td>77 6f 72 6b 69 6e 67 20 61 6c 6f 6e 67 20...</td>
</tr>
<tr>
<td>→ 77 69</td>
<td>working along wi</td>
</tr>
<tr>
<td>W (205) log_example: 0x3ffb42a0</td>
<td>74 68 20 74 68 65 20 49 44 46 2e 00...</td>
</tr>
<tr>
<td>→</td>
<td>th the IDF...</td>
</tr>
</tbody>
</table>

It is highly recommended to use terminals with over 102 text width.

**Parameters**

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes
- **level** – level of the log

**ESP_LOG_BUFFER_HEX (tag, buffer, buff_len)**

Log a buffer of hex bytes at Info level.

See also:

esp_log_buffer_hex_level

**Parameters**

- **tag** – description tag
- **buffer** – Pointer to the buffer array
- **buff_len** – length of buffer in bytes

**ESP_LOG_BUFFER_CHAR (tag, buffer, buff_len)**

Log a buffer of characters at Info level. Buffer should contain only printable characters.

See also:

esp_log_buffer_char_level

**Parameters**

- **tag** – description tag
Chapter 2. API Reference

- **buffer** - Pointer to the buffer array
- **buff_len** - Length of buffer in bytes

**ESP_EARLY_LOGE**(tag, format, ...)
Macro to output logs in startup code, before heap allocator and syscalls have been initialized. Log at ESP_LOG_ERROR level.

See also:
printf, ESP_LOGE, ESP_DRAM_LOGE In the future, we want to become compatible with clang. Hence, we provide two versions of the following macros which are using variadic arguments. The first one is using the GNU extension ##__VA_ARGS__. The second one is using the C++20 feature VA_OPT(,). This allows users to compile their code with standard C++20 enabled instead of the GNU extension. Below C++20, we haven’t found any good alternative to using ##__VA_ARGS__.

**ESP_EARLY_LOGW**(tag, format, ...)
Macro to output logs in startup code at ESP_LOG_WARN level.

See also:
ESP_EARLY_LOGE, ESP_LOGE, printf

**ESP_EARLY_LOGI**(tag, format, ...)
Macro to output logs in startup code at ESP_LOG_INFO level.

See also:
ESP_EARLY_LOGE, ESP_LOGE, printf

**ESP_EARLY_LOGD**(tag, format, ...)
Macro to output logs in startup code at ESP_LOG_DEBUG level.

See also:
ESP_EARLY_LOGE, ESP_LOGE, printf

**ESP_EARLY_LOGV**(tag, format, ...)
Macro to output logs in startup code at ESP_LOG_VERBOSE level.

See also:
ESP_EARLY_LOGE, ESP_LOGE, printf

**_ESP_LOG_EARLY_ENABLED**(log_level)

**ESP_LOG_EARLY_IMPL**(tag, format, log_level, log_tag_letter, ...)

**ESP_LOGE**(tag, format, ...)

**ESP_LOGW**(tag, format, ...)

**ESP_LOGI**(tag, format, ...)

**ESP_LOGD**(tag, format, ...)

**ESP_LOGV**(tag, format, ...)
Chapter 2. API Reference

ESP_LOG_LEVEL (level, tag, format, ...)
runtime macro to output logs at a specified level.

See also:
printf

Parameters
• tag – tag of the log, which can be used to change the log level by esp_log_level_set at runtime.
• level – level of the output log.
• format – format of the output log. See printf
• ... – variables to be replaced into the log. See printf

ESP_LOG_LEVEL_LOCAL (level, tag, format, ...)
runtime macro to output logs at a specified level. Also check the level with LOG_LOCAL_LEVEL.

See also:
printf, ESP_LOG_LEVEL

ESP_DRAM_LOGE (tag, format, ...)
Macro to output logs when the cache is disabled. Log at ESP_LOG_ERROR level.

Similar to
Usage: ESP_DRAM_LOGE(DRAM_STR("my_tag"), "format", or ESP_DRAM_LOGE(TAG, "format", ...), where TAG is a char* that points to a str in the DRAM.

See also:
ESP_EARLY_LOGE, the log level cannot be changed per-tag, however esp_log_level_set("*", level) will set the default level which controls these log lines also.

See also:
esp_rom_printf, ESP_LOGE

Note: Unlike normal logging macros, it’s possible to use this macro when interrupts are disabled or inside an ISR.

Note: Placing log strings in DRAM reduces available DRAM, so only use when absolutely essential.

ESP_DRAM_LOGW (tag, format, ...)
macro to output logs when the cache is disabled at ESP_LOG_WARN level.

See also:
ESP_DRAM_LOGW, ESP_LOGW, esp_rom_printf
**ESP_DRAM_LOGI** (tag, format, ...)

Macro to output logs when the cache is disabled at ESP_LOG_INFO level.

**See also:**

ESP_DRAM_LOGI, ESP_LOGI, esp_rom_printf

**ESP_DRAM_LOGD** (tag, format, ...)

Macro to output logs when the cache is disabled at ESP_LOG_DEBUG level.

**See also:**

ESP_DRAM_LOGD, ESP_LOGD, esp_rom_printf

**ESP_DRAM_LOGV** (tag, format, ...)

Macro to output logs when the cache is disabled at ESP_LOG_VERBOSE level.

**See also:**

ESP_DRAM_LOGV, ESP_LOGV, esp_rom_printf

**Type Definitions**

typedef int (*vprintf_like_t)(const char*, va_list)

**Enumerations**

enum esp_log_level_t

Log level.

*Values:*

enumerator ESP_LOG_NONE

No log output

enumerator ESP_LOG_ERROR

Critical errors, software module cannot recover on its own

enumerator ESP_LOG_WARN

Error conditions from which recovery measures have been taken

enumerator ESP_LOG_INFO

Information messages which describe normal flow of events

enumerator ESP_LOG_DEBUG

Extra information which is not necessary for normal use (values, pointers, sizes, etc).

enumerator ESP_LOG_VERBOSE

Bigger chunks of debugging information, or frequent messages which can potentially flood the output.

### 2.10.21 Miscellaneous System APIs
Software Reset

To perform software reset of the chip, the `esp_restart()` function is provided. When the function is called, execution of the program stops, both CPUs are reset, the application is loaded by the bootloader and starts execution again.

Additionally, the `esp_register_shutdown_handler()` function can register a routine that will be automatically called before a restart (that is triggered by `esp_restart()`) occurs. This is similar to the functionality of `atexit` POSIX function.

Reset Reason

ESP-IDF applications can be started or restarted due to a variety of reasons. To get the last reset reason, call `esp_reset_reason()` function. See description of `esp_reset_reason_t` for the list of possible reset reasons.

Heap Memory

Two heap-memory-related functions are provided:

- `esp_get_free_heap_size()` returns the current size of free heap memory.
- `esp_get_minimum_free_heap_size()` returns the minimum size of free heap memory that has ever been available (i.e., the smallest size of free heap memory in the application’s lifetime).

Note that ESP-IDF supports multiple heaps with different capabilities. The functions mentioned in this section return the size of heap memory that can be allocated using the `malloc` family of functions. For further information about heap memory, see Heap Memory Allocation.

MAC Address

These APIs allow querying and customizing MAC addresses for different supported network interfaces (e.g., Wi-Fi, Bluetooth, Ethernet).

To fetch the MAC address for a specific network interface (e.g., Wi-Fi, Bluetooth, Ethernet), call the function `esp_read_mac()`.

In ESP-IDF, the MAC addresses for the various network interfaces are calculated from a single base MAC address. By default, the Espressif base MAC address is used. This base MAC address is pre-programmed into the ESP32 eFuse in the factory during production.

<table>
<thead>
<tr>
<th>Interface</th>
<th>MAC Address (4 universally administered, default)</th>
<th>MAC Address (2 universally administered)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wi-Fi Station</td>
<td>base_mac</td>
<td>base_mac</td>
</tr>
<tr>
<td>Wi-Fi SoftAP</td>
<td>base_mac, +1 to the last octet</td>
<td><code>Local MAC</code> (derived from Wi-Fi Station MAC)</td>
</tr>
<tr>
<td>Bluetooth</td>
<td>base_mac, +2 to the last octet</td>
<td>base_mac, +1 to the last octet</td>
</tr>
<tr>
<td>Ethernet</td>
<td>base_mac, +3 to the last octet</td>
<td><code>Local MAC</code> (derived from Bluetooth MAC)</td>
</tr>
</tbody>
</table>

Note: The configuration configures the number of universally administered MAC addresses that are provided by Espressif.

Custom Interface MAC Sometimes you may need to define custom MAC addresses that are not generated from the base MAC address. To set a custom interface MAC address, use the `esp_iface_mac_addr_set()` function. This function allows you to overwrite the MAC addresses of interfaces set (or not yet set) by the base MAC address.
Once a MAC address has been set for a particular interface, it will not be affected when the base MAC address is changed.

**Custom Base MAC** The default base MAC is pre-programmed by Espressif in eFuse BLK0. To set a custom base MAC instead, call the function `esp_iface_mac_addr_set()` with the `ESP_MAC_BASE` argument (or `esp_base_mac_addr_set()`) before initializing any network interfaces or calling the `esp_read_mac()` function. The custom MAC address can be stored in any supported storage device (e.g., flash, NVS).

The custom base MAC addresses should be allocated such that derived MAC addresses will not overlap. Based on the table above, users can configure the option `CONFIG_ESP32_UNIVERSAL_MAC_ADDRESSES` to set the number of valid universal MAC addresses that can be derived from the custom base MAC.

**Note:** It is also possible to call the function `esp_netif_set_mac()` to set the specific MAC used by a network interface after network initialization. But it is recommended to use the base MAC approach documented here to avoid the possibility of the original MAC address briefly appearing on the network before being changed.

**Custom MAC Address in eFuse** When reading custom MAC addresses from eFuse, ESP-IDF provides a helper function `esp__mac_get_custom()`. Users can also use `esp_read_mac()` with the `ESP_MAC_EFUSE_CUSTOM` argument. This loads the MAC address from eFuse BLK3. The `esp__mac_get_custom()` function assumes that the custom base MAC address is stored in the following format:

<table>
<thead>
<tr>
<th>Field</th>
<th># of bits</th>
<th>Range of bits</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>8</td>
<td>191:184</td>
<td>0: invalid, others →valid</td>
</tr>
<tr>
<td>Reserved</td>
<td>128</td>
<td>183:56</td>
<td></td>
</tr>
<tr>
<td>MAC address</td>
<td>48</td>
<td>55:8</td>
<td></td>
</tr>
<tr>
<td>MAC address CRC</td>
<td>8</td>
<td>7:0</td>
<td>CRC-8-CCITT, polynomial 0x07</td>
</tr>
</tbody>
</table>

**Note:** If the 3/4 coding scheme is enabled, all eFuse fields in this block must be burnt at the same time.

Once custom eFuse MAC address has been obtained (using `esp_efuse_mac_get_custom()` or `esp_read_mac()`), you need to set it as the base MAC address. There are two ways to do it:

1. Use an old API: call `esp_base_mac_addr_set()`.
2. Use a new API: call `esp_iface_mac_addr_set()` with the `ESP_MAC_BASE` argument.

**Local Versus Universal MAC Addresses** ESP32 comes pre-programmed with enough valid Espressif universally administered MAC addresses for all internal interfaces. The table above shows how to calculate and derive the MAC address for a specific interface according to the base MAC address.

When using a custom MAC address scheme, it is possible that not all interfaces can be assigned with a universally administered MAC address. In these cases, a locally administered MAC address is assigned. Note that these addresses are intended for use on a single local network only.

See [this article](#) for the definition of locally and universally administered MAC addresses.

Function `esp_derive_local_mac()` is called internally to derive a local MAC address from a universal MAC address. The process is as follows:

1. The U/L bit (bit value 0x2) is set in the first octet of the universal MAC address, creating a local MAC address.
2. If this bit is already set in the supplied universal MAC address (i.e., the supplied “universal” MAC address was in fact already a local MAC address), then the first octet of the local MAC address is XORed with 0x4.
Chapter 2. API Reference

Chip Version

`esp_chip_info()` function fills `esp_chip_info_t` structure with information about the chip. This includes the chip revision, number of CPU cores, and a bit mask of features enabled in the chip.

SDK Version

`esp_get_idf_version()` returns a string describing the ESP-IDF version which is used to compile the application. This is the same value as the one available through `IDF_VER` variable of the build system. The version string generally has the format of `git describe` output.

To get the version at build time, additional version macros are provided. They can be used to enable or disable parts of the program depending on the ESP-IDF version.

- `ESP_IDF_VERSION_MAJOR`, `ESP_IDF_VERSION_MINOR`, `ESP_IDF_VERSION_PATCH` are defined to integers representing major, minor, and patch version.
- `ESP_IDF_VERSION_VAL` and `ESP_IDF_VERSION` can be used when implementing version checks:

```c
#include "esp_idf_version.h"

#if ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)
    // enable functionality present in ESP-IDF v4.0
#endif
```

App Version

The application version is stored in `esp_app_desc_t` structure. It is located in DROM sector and has a fixed offset from the beginning of the binary file. The structure is located after `esp_image_header_t` and `esp_image_segment_header_t` structures. The type of the field version is string and it has a maximum length of 32 chars.

To set the version in your project manually, you need to set the `PROJECT_VER` variable in the `CMakeLists.txt` of your project. In application `CMakeLists.txt`, put set `set(PROJECT_VER "0.1.0.1")` before including project.cmake.

If the `CONFIG_APP_PROJECT_VER_FROM_CONFIG` option is set, the value of `CONFIG_APP_PROJECT_VER` will be used. Otherwise, if the `PROJECT_VER` variable is not set in the project, it will be retrieved either from the $PROJECT_PATH/version.txt file (if present) or using `git` command `git describe`. If neither is available, `PROJECT_VER` will be set to “1”. Application can make use of this by calling `esp_app_get_description()` or `esp_ota_get_partition_description()` functions.

API Reference

Header File

- components/esp_system/include/esp_system.h

Functions

`esp_err_t esp_register_shutdown_handler(shutdown_handler_t handle)`

Register shutdown handler.

This function allows you to register a handler that gets invoked before the application is restarted using esp_restart function.

**Parameters** handle – function to execute on restart

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_STATE if the handler has already been registered
- ESP_ERR_NO_MEM if no more shutdown handler slots are available

Submit Document Feedback
**esp_err_t esp_unregister_shutdown_handler (shutdown_handler_t handle)**

Unregister shutdown handler.

This function allows you to unregister a handler which was previously registered using esp_register_shutdown_handler function.

- ESP_OK on success
- ESP_ERR_INVALID_STATE if the given handler hasn’t been registered before

**void esp_restart (void)**

Restart PRO and APP CPUs.

This function can be called both from PRO and APP CPUs. After successful restart, CPU reset reason will be SW_CPU_RESET. Peripherals (except for Wi-Fi, BT, UART0, SPI1, and legacy timers) are not reset. This function does not return.

**esp_reset_reason_t esp_reset_reason (void)**

Get reason of last reset.

**Returns** See description of esp_reset_reason_t for explanation of each value.

**uint32_t esp_get_free_heap_size (void)**

Get the size of available heap.

**Note:** Note that the returned value may be larger than the maximum contiguous block which can be allocated.

**Returns** Available heap size, in bytes.

**uint32_t esp_get_free_internal_heap_size (void)**

Get the size of available internal heap.

**Note:** Note that the returned value may be larger than the maximum contiguous block which can be allocated.

**Returns** Available internal heap size, in bytes.

**uint32_t esp_get_minimum_free_heap_size (void)**

Get the minimum heap that has ever been available.

**Returns** Minimum free heap ever available

**void esp_system_abort (const char *details)**

Trigger a software abort.

**Parameters** details – Details that will be displayed during panic handling.

**Type Definitions**

typedef void (*shutdown_handler_t)(void)

Shutdown handler type

**Enumerations**

enum esp_reset_reason_t

Reset reasons.

**Values:**
enumerator **ESP_RST_UNKNOWN**
    Reset reason can not be determined.

enumerator **ESP_RST_POWERON**
    Reset due to power-on event.

enumerator **ESP_RST_EXT**
    Reset by external pin (not applicable for ESP32)

enumerator **ESP_RST_SW**
    Software reset via esp_restart.

enumerator **ESP_RST_PANIC**
    Software reset due to exception/panic.

enumerator **ESP_RST_INT_WDT**
    Reset (software or hardware) due to interrupt watchdog.

enumerator **ESP_RST_TASK_WDT**
    Reset due to task watchdog.

enumerator **ESP_RST_WDT**
    Reset due to other watchdogs.

enumerator **ESP_RST_DEEPSLEEP**
    Reset after exiting deep sleep mode.

enumerator **ESP_RST_BROWNOUT**
    Brownout reset (software or hardware)

enumerator **ESP_RST_SDIO**
    Reset over SDIO.

**Header File**

- components/esp_common/include/esp_idf_version.h

**Functions**

const char * **esp_get_idf_version** (void)
    Return full IDF version string, same as ‘git describe’ output.

**Note:** If you are printing the ESP-IDF version in a log file or other information, this function provides more information than using the numerical version macros. For example, numerical version macros don’t differentiate between development, pre-release and release versions, but the output of this function does.

**Returns** constant string from IDF_VER
Macros

**ESP_IDF_VERSION_MAJOR**
Major version number (X.x.x)

**ESP_IDF_VERSION_MINOR**
Minor version number (x.X.x)

**ESP_IDF_VERSION_PATCH**
Patch version number (x.x.X)

**ESP_IDF_VERSION_VAL** (major, minor, patch)
Macro to convert IDF version number into an integer
To be used in comparisons, such as ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)

**ESP_IDF_VERSION**
Current IDF version, as an integer
To be used in comparisons, such as ESP_IDF_VERSION >= ESP_IDF_VERSION_VAL(4, 0, 0)

Header File
- components/esp_hw_support/include/esp_mac.h

Functions

```c
esp_err_t esp_base_mac_addr_set (const uint8_t *mac)
```
Set base MAC address with the MAC address which is stored in BLK3 of EFUSE or external storage e.g. flash and EEPROM.
Base MAC address is used to generate the MAC addresses used by network interfaces.
If using a custom base MAC address, call this API before initializing any network interfaces. Refer to the ESP-IDF Programming Guide for details about how the Base MAC is used.

**Note:** Base MAC must be a unicast MAC (least significant bit of first byte must be zero).

**Note:** If not using a valid OUI, set the “locally administered” bit (bit value 0x02 in the first byte) to avoid collisions.

**Parameters**
- `mac` - base MAC address, length: 6 bytes. length: 6 bytes for MAC-48

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG If `mac` is NULL or is not a unicast MAC

```c
esp_err_t esp_base_mac_addr_get (uint8_t *mac)
```
Return base MAC address which is set using esp_base_mac_addr_set.

**Note:** If no custom Base MAC has been set, this returns the pre-programmed Espressif base MAC address.

**Parameters**
- `mac` - base MAC address, length: 6 bytes. length: 6 bytes for MAC-48

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG `mac` is NULL
- ESP_ERR_INVALID_MAC base MAC address has not been set
### esp_err_t esp_efuse_mac_get_custom (uint8_t *mac)

Return base MAC address which was previously written to BLK3 of EFUSE.

Base MAC address is used to generate the MAC addresses used by the networking interfaces. This API returns the custom base MAC address which was previously written to EFUSE BLK3 in a specified format.

Writing this EFUSE allows setting of a different (non-Espressif) base MAC address. It is also possible to store a custom base MAC address elsewhere, see esp_base_mac_addr_set() for details.

**Note:** This function is currently only supported on ESP32.

#### Parameters

- **mac**
  - Base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64 (used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)

#### Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG: mac is NULL
- ESP_ERR_INVALID_MAC: CUSTOM_MAC address has not been set, all zeros (for esp32-xx)
- ESP_ERR_INVALID_VERSION: An invalid MAC version field was read from BLK3 of EFUSE (for esp32)
- ESP_ERR_INVALID_CRC: An invalid MAC CRC was read from BLK3 of EFUSE (for esp32)

### esp_err_t esp_efuse_mac_get_default (uint8_t *mac)

Return base MAC address which is factory-programmed by Espressif in EFUSE.

#### Parameters

- **mac**
  - Base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64 (used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)

#### Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG: mac is NULL

### esp_err_t esp_read_mac (uint8_t *mac, esp_mac_type_t type)

Read base MAC address and set MAC address of the interface.

This function first get base MAC address using esp_base_mac_addr_get(). Then calculates the MAC address of the specific interface requested, refer to ESP-IDF Programming Guide for the algorithm.

The MAC address set by the esp_iface_mac_addr_set() function will not depend on the base MAC address.

#### Parameters

- **mac**
  - Base MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48 8 bytes for EUI-64 (used for IEEE 802.15.4, if CONFIG_SOC_IEEE802154_SUPPORTED=y)
- **type**
  - Type of MAC address to return

#### Returns

- ESP_OK on success

### esp_err_t esp_derive_local_mac (uint8_t *local_mac, const uint8_t *universal_mac)

Derive local MAC address from universal MAC address.

This function copies a universal MAC address and then sets the “locally administered” bit (bit 0x2) in the first octet, creating a locally administered MAC address.

If the universal MAC address argument is already a locally administered MAC address, then the first octet is XORed with 0x4 in order to create a different locally administered MAC address.

#### Parameters

- **local_mac**
  - Base MAC address, length: 6 bytes. length: 6 bytes for MAC-48
- **universal_mac**
  - Source universal MAC address, length: 6 bytes.

#### Returns

- ESP_OK on success

### esp_err_t esp_iface_mac_addr_set (const uint8_t *mac, esp_mac_type_t type)

Set custom MAC address of the interface. This function allows you to overwrite the MAC addresses of the interfaces set by the base MAC address.

#### Parameters
• **mac** - MAC address, length: 6 bytes/8 bytes. length: 6 bytes for MAC-48, 8 bytes for EUI-64 (used for ESP_MAC_IEEE802154 type, if CONFIG_SOC_IEEE802154_SUPPORTED=y)

• **type** - Type of MAC address

**Returns** ESP_OK on success

```c
size_t esp_mac_addr_len_get(esp_mac_type_t type)
```

Return the size of the MAC type in bytes.

If CONFIG_SOC_IEEE802154_SUPPORTED is set then for these types:

- ESP_MAC_IEEE802154 is 8 bytes.
- ESP_MAC_BASE, ESP_MAC_EFUSE_FACTORY and ESP_MAC_EFUSE_CUSTOM the MAC size is 6 bytes.
- ESP_MAC_EFUSE_EXT is 2 bytes. If CONFIG_SOC_IEEE802154_SUPPORTED is not set then for all types it returns 6 bytes.

**Parameters** type - Type of MAC address

**Returns** 0 MAC type not found (not supported) 6 bytes for MAC-48, 8 bytes for EUI-64.

**Macros**

- MAC2STR (a)
- MACSTR

**Enumerations**

```c
c enum esp_mac_type_t
```

**Values:**

- enumerator ESP_MAC_WIFI_STA
  - MAC for WiFi Station (6 bytes)
- enumerator ESP_MAC_WIFI_SOFTAP
  - MAC for WiFi Soft-AP (6 bytes)
- enumerator ESP_MAC_BT
  - MAC for Bluetooth (6 bytes)
- enumerator ESP_MAC_ETH
  - MAC for Ethernet (6 bytes)
- enumerator ESP_MAC_IEEE802154
  - if CONFIG_SOC_IEEE802154_SUPPORTED=y, MAC for IEEE802154 (8 bytes)
- enumerator ESP_MAC_BASE
  - Base MAC for that used for other MAC types (6 bytes)
- enumerator ESP_MAC_EFUSE_FACTORY
  - MAC_FACTORY eFuse which was burned by Espressif in production (6 bytes)
- enumerator ESP_MAC_EFUSE_CUSTOM
  - MAC_CUSTOM eFuse which was can be burned by customer (6 bytes)
enumerator **ESP_MAC_EFUSE_EXT**

if CONFIG_SOC_IEEE802154_SUPPORTED=y, MAC_EXT eFuse which is used as an extender for IEEE802154 MAC (2 bytes)

### Header File

- components/esp_hw_support/include/esp_chip_info.h

### Functions

```c
void esp_chip_info(esp_chip_info_t *out_info)
```

Fill an `esp_chip_info_t` structure with information about the chip.

**Parameters**

- `out_info` - [out] structure to be filled

### Structures

```c
struct esp_chip_info_t
```

The structure represents information about the chip.

### Public Members

```c
esp_chip_model_t model
```

chip model, one of `esp_chip_model_t`

```c
uint32_t features
```

bit mask of `CHIP_FEATURE_x` feature flags

```c
uint16_t revision
```

chip revision number (in format MXX; where M - wafer major version, XX - wafer minor version)

```c
uint8_t cores
```

number of CPU cores

### Macros

- **CHIP_FEATURE_EMB_FLASH**
  
  Chip has embedded flash memory.

- **CHIP_FEATURE_WIFI_BGN**
  
  Chip has 2.4GHz WiFi.

- **CHIP_FEATURE_BLE**
  
  Chip has Bluetooth LE.

- **CHIP_FEATURE_BT**
  
  Chip has Bluetooth Classic.

- **CHIP_FEATURE_IEEE802154**
  
  Chip has IEEE 802.15.4.
CHIP_FEATURE_EMB_PSRAM

Chip has embedded psram.

Enumerations

enum esp_chip_model_t

Chip models.

Values:

enumerator CHIP_ESP32

ESP32.

enumerator CHIP_ESP32S2

ESP32-S2.

enumerator CHIP_ESP32S3

ESP32-S3.

enumerator CHIP_ESP32C3

ESP32-C3.

enumerator CHIP_ESP32C2

ESP32-C2.

enumerator CHIP_ESP32C6

ESP32-C6.

enumerator CHIP_ESP32H2

ESP32-H2.

enumerator CHIP_POSIX_LINUX

The code is running on POSIX/Linux simulator.

Header File

- components/esp_hw_support/include/esp_cpu.h

Functions

void esp_cpu_stall (int core_id)

Stall a CPU core.

Parameters core_id - The core’s ID

void esp_cpu_unstall (int core_id)

Resume a previously stalled CPU core.

Parameters core_id - The core’s ID

void esp_cpu_reset (int core_id)

Reset a CPU core.

Parameters core_id - The core’s ID
void esp_cpu_wait_for_intr (void)
    // Wait for Interrupt.
    // This function causes the current CPU core to execute its Wait For Interrupt (WFI or equivalent) instruction.
    // After executing this function, the CPU core will stop execution until an interrupt occurs.

int esp_cpu_get_core_id (void)
    // Get the current core’s ID.
    // This function will return the ID of the current CPU (i.e., the CPU that calls this function).
    // Returns The current core’s ID [0..SOC_CPU_CORES_NUM - 1]

void *esp_cpu_get_sp (void)
    // Read the current stack pointer address.
    // Returns Stack pointer address

esp_cpu_cycle_count_t esp_cpu_get_cycle_count (void)
    // Get the current CPU core’s cycle count.
    // Each CPU core maintains an internal counter (i.e., cycle count) that increments every CPU clock cycle.
    // Returns Current CPU’s cycle count, 0 if not supported.

void esp_cpu_set_cycle_count (esp_cpu_cycle_count_t cycle_count)
    // Set the current CPU core’s cycle count.
    // Set the given value into the internal counter that increments every CPU clock cycle.
    // Parameters cycle_count - CPU cycle count

void *esp_cpu_pc_to_addr (uint32_t pc)
    // Convert a program counter (PC) value to address.
    // If the architecture does not store the true virtual address in the CPU’s PC or return addresses, this function
    // will convert the PC value to a virtual address. Otherwise, the PC is just returned
    // Parameters pc – PC value
    // Returns Virtual address

void esp_cpu_intr_get_desc (int core_id, int intr_num, esp_cpu_intr_desc_t *intr_desc_ret)
    // Get a CPU interrupt’s descriptor.
    // Each CPU interrupt has a descriptor describing the interrupt’s capabilities and restrictions. This function gets
    // the descriptor of a particular interrupt on a particular CPU.
    // Parameters
    //    * core_id –[in] The core’s ID
    //    * intr_num –[in] Interrupt number
    //    * intr_desc_ret –[out] The interrupt’s descriptor

bool esp_cpu_intr_has_handler (int intr_num)
    // Check if a particular interrupt already has a handler function.
    // Check if a particular interrupt on the current CPU already has a handler function assigned.
    // Note: This function simply checks if the IVT of the current CPU already has a handler assigned.
    // Parameters intr_num – Interrupt number (from 0 to 31)
Returns True if the interrupt has a handler function, false otherwise.

```c
void esp_cpu_intr_set_handler (int intr_num, esp_cpu_intr_handler_t handler, void *handler_arg)
```

Set the handler function of a particular interrupt.
Assign a handler function (i.e., ISR) to a particular interrupt on the current CPU.

**Note:** This function simply sets the handler function (in the IVT) and does not actually enable the interrupt.

**Parameters**
- `intr_num` - Interrupt number (from 0 to 31)
- `handler` - Handler function
- `handler_arg` - Argument passed to the handler function

```c
void *esp_cpu_intr_get_handler_arg (int intr_num)
```

Get a handler function’s argument of.

Get the argument of a previously assigned handler function on the current CPU.

**Parameters**
- `intr_num` - Interrupt number (from 0 to 31)

**Returns**
The argument passed to the handler function

```c
void esp_cpu_intr_enable (uint32_t intr_mask)
```

Enable particular interrupts on the current CPU.

**Parameters**
- `intr_mask` - Bitmask of the interrupts to enable

```c
void esp_cpu_intr_disable (uint32_t intr_mask)
```

Disable particular interrupts on the current CPU.

**Parameters**
- `intr_mask` - Bitmask of the interrupts to disable

```c
uint32_t esp_cpu_intr_get_enabled_mask (void)
```

Get the enabled interrupts on the current CPU.

**Returns**
Bitmask of the enabled interrupts

```c
void esp_cpu_intr_edge_ack (int intr_num)
```

Acknowledge an edge interrupt.

**Parameters**
- `intr_num` - Interrupt number (from 0 to 31)

```c
esp_err_t esp_cpu_set_breakpoint (int bp_num, const void *bp_addr)
```

Set and enable a hardware breakpoint on the current CPU.

**Note:** This function is meant to be called by the panic handler to set a breakpoint for an attached debugger during a panic.

**Note:** Overwrites previously set breakpoint with same breakpoint number.

**Parameters**
- `bp_num` - Hardware breakpoint number [0..SOC_CPU_BREAKPOINTS_NUM - 1]
- `bp_addr` - Address to set a breakpoint on

**Returns**
ESP_OK if breakpoint is set. Failure otherwise
### esp_err_t esp_cpu_clear_breakpoint (int bp_num)
Clear a hardware breakpoint on the current CPU.

**Note:** Clears a breakpoint regardless of whether it was previously set

**Parameters**
- **bp_num** – Hardware breakpoint number [0..SOC_CPU_BREAKPOINTS_NUM - 1]

**Returns**
- ESP_OK if breakpoint is cleared. Failure otherwise

### esp_err_t esp_cpu_set_watchpoint (int wp_num, const void* wp_addr, size_t size,
  esp_cpu_watchpoint_trigger_t trigger)
Set and enable a hardware watchpoint on the current CPU.

Set and enable a hardware watchpoint on the current CPU, specifying the memory range and trigger operation. Watchpoints will break/panic the CPU when the CPU accesses (according to the trigger type) on a certain memory range.

**Note:** Overwrites previously set watchpoint with same watchpoint number.

**Parameters**
- **wp_num** – Hardware watchpoint number [0..SOC_CPU_WATCHPOINTS_NUM-1]
- **wp_addr** – Watchpoint’s base address
- **size** – Size of the region to watch. Must be one of 2^n, with n in [0..6].
- **trigger** – Trigger type

**Returns**
- ESP_ERR_INVALID_ARG on invalid arg, ESP_OK otherwise

### esp_err_t esp_cpu_clear_watchpoint (int wp_num)
Clear a hardware watchpoint on the current CPU.

**Note:** Clears a watchpoint regardless of whether it was previously set

**Parameters**
- **wp_num** – Hardware watchpoint number [0..SOC_CPU_WATCHPOINTS_NUM - 1]

**Returns**
- ESP_OK if watchpoint was cleared. Failure otherwise.

### bool esp_cpu_dbgr_is_attached (void)
Check if the current CPU has a debugger attached.

**Returns**
- True if debugger is attached, false otherwise

### void esp_cpu_dbgr_break (void)
Trigger a call to the current CPU’s attached debugger.

### intptr_t esp_cpu_get_call_addr (intptr_t return_address)
Given the return address, calculate the address of the preceding call instruction. This is typically used to answer the question “where was the function called from?”.

**Parameters**
- **return_address** – The value of the return address register. Typically set to the value of __builtin_return_address(0).

**Returns**
- Address of the call instruction preceding the return address.

### bool esp_cpu_compare_and_set (volatile uint32_t *addr, uint32_t compare_value, uint32_t new_value)
Atomic compare-and-set operation.

**Parameters**
**Chapter 2. API Reference**

- **addr** - Address of atomic variable
- **compare_value** - Value to compare the atomic variable to
- **new_value** - New value to set the atomic variable to

**Returns** Whether the atomic variable was set or not

### Structures

**struct esp_cpu_intr_desc_t**

CPU interrupt descriptor.

Each particular CPU interrupt has an associated descriptor describing that particular interrupt’s characteristics. Call esp_cpu_intr_get_desc() to get the descriptors of a particular interrupt.

### Public Members

**int priority**

Priority of the interrupt if it has a fixed priority, (-1) if the priority is configurable.

**esp_cpu_intr_type_t type**

Whether the interrupt is an edge or level type interrupt, ESP_CPU_INTR_TYPE_NA if the type is configurable.

**uint32_t flags**

Flags indicating extra details.

### Macros

**ESP_CPU_INTR_DESC_FLAG_SPECIAL**

Interrupt descriptor flags of esp_cpu_intr_desc_t.

The interrupt is a special interrupt (e.g., a CPU timer interrupt)

**ESP_CPU_INTR_DESC_FLAG_RESVD**

The interrupt is reserved for internal use

### Type Definitions

typedef uint32_t **esp_cpu_cycle_count_t**

CPU cycle count type.

This data type represents the CPU’s clock cycle count.

typedef void (*esp_cpu_intr_handler_t)(void *arg)

CPU interrupt handler type.

### Enumerations

**enum esp_cpu_intr_type_t**

CPU interrupt type.

**Values:**

- **ESP_CPU_INTR_TYPE_LEVEL**
enumerator ESP_CPU_INTR_TYPE_EDGE

enumerator ESP_CPU_INTR_TYPE_NA

denum esp_cpu_watchpoint_trigger_t
CPU watchpoint trigger type.
Values:

enumerator ESP_CPU_WATCHPOINT_LOAD

enumerator ESP_CPU_WATCHPOINT_STORE

enumerator ESP_CPU_WATCHPOINT_ACCESS

Header File

- components/esp_app_format/include/esp_app_desc.h

Functions

cnst esp_app_desc_t *esp_app_get_description (void)
Return esp_app_desc structure. This structure includes app version.

Return description for running app.

int esp_app_get_elf_sha256 (char **dst, size_t size)
Fill the provided buffer with SHA256 of the ELF file, formatted as hexadecimal, null-terminated. If the buffer size is not sufficient to fit the entire SHA256 in hex plus a null terminator, the largest possible number of bytes will be written followed by a null.

Parameters

- dst - Destination buffer
- size - Size of the buffer

Returns Number of bytes written to dst (including null terminator)

Structures

struct esp_app_desc_t
Description about application.

Public Members

uint32_t magic_word
Magic word ESP_APP_DESC_MAGIC_WORD

uint32_t secure_version
Secure version

uint32_t reserv1[2]
reserv1
char version[32]
   Application version

char project_name[32]
   Project name

char time[16]
   Compile time

char date[16]
   Compile date

char idf_ver[32]
   Version IDF

uint8_t app_elf_sha256[32]
   sha256 of elf file

uint32_t reserv2[20]
   reserv2

Macros

ESP_APP_DESC_MAGIC_WORD
   The magic word for the esp_app_desc structure that is in DROM.

2.10.22 Over The Air Updates (OTA)

OTA Process Overview

The OTA update mechanism allows a device to update itself based on data received while the normal firmware is running (for example, over Wi-Fi or Bluetooth.)

OTA requires configuring the Partition Table of the device with at least two “OTA app slot” partitions (i.e. ota_0 and ota_1) and an “OTA Data Partition”.

The OTA operation functions write a new app firmware image to whichever OTA app slot that is currently not selected for booting. Once the image is verified, the OTA Data partition is updated to specify that this image should be used for the next boot.

OTA Data Partition

An OTA data partition (type data, subtype ota) must be included in the Partition Table of any project which uses the OTA functions.

For factory boot settings, the OTA data partition should contain no data (all bytes erased to 0xFF). In this case the esp-idf software bootloader will boot the factory app if it is present in the partition table. If no factory app is included in the partition table, the first available OTA slot (usually ota_0) is booted.

After the first OTA update, the OTA data partition is updated to specify which OTA app slot partition should be booted next.
The OTA data partition is two flash sectors (0x2000 bytes) in size, to prevent problems if there is a power failure while it is being written. Sectors are independently erased and written with matching data, and if they disagree a counter field is used to determine which sector was written more recently.

**App rollback**

The main purpose of the application rollback is to keep the device working after the update. This feature allows you to roll back to the previous working application in case a new application has critical errors. When the rollback process is enabled and an OTA update provides a new version of the app, one of three things can happen:

- The application works fine, `esp_ota_mark_app_valid_cancel_rollback()` marks the running application with the state `ESP_OTA_IMG_VALID`. There are no restrictions on booting this application.
- The application has critical errors and further work is not possible, a rollback to the previous application is required, `esp_ota_mark_app_invalid_rollback_and_reboot()` marks the running application with the state `ESP_OTA_IMG_INVALID` and reset. This application will not be selected by the bootloader for boot and will boot the previously working application.
- If the `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` option is set, and a reset occurs without calling either function then the application is rolled back.

**Note:** The state is not written to the binary image of the application but rather to the `otadata` partition. The partition contains a `ota_seq` counter which is a pointer to the slot (`ota_0, ota_1, …`) from which the application will be selected for boot.

**App OTA State** States control the process of selecting a boot app:

<table>
<thead>
<tr>
<th>States</th>
<th>Restriction of selecting a boot app in bootloader</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP_OTA_IMG.Valid</td>
<td>No restriction. Will be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG.Undef</td>
<td>No restriction. Will be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG.Invalid</td>
<td>Will not be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG.Aborted</td>
<td>Will not be selected.</td>
</tr>
<tr>
<td>ESP_OTA_IMG.New</td>
<td><code>CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE</code> option is set it will be selected only once. In bootloader the state immediately changes to <code>ESP_OTA_IMG_PENDING_VERIFY</code>.</td>
</tr>
<tr>
<td>ESP_OTA_IMG.PendingVerify</td>
<td><code>CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE</code> option is set it will not be selected, and the state will change to <code>ESP_OTA_IMG_ABORTED</code>.</td>
</tr>
</tbody>
</table>

If `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` option is not enabled (by default), then the use of the following functions `esp_ota_mark_app_valid_cancel_rollback()` and `esp_ota_mark_app_invalid_rollback_and_reboot()` are optional, and `ESP_OTA_IMG_NEW` and `ESP_OTA_IMG_PENDING_VERIFY` states are not used.

An option in Kconfig `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` allows you to track the first boot of a new application. In this case, the application must confirm its operability by calling `esp_ota_mark_app_valid_cancel_rollback()` function, otherwise the application will be rolled back upon reboot. It allows you to control the operability of the application during the boot phase. Thus, a new application has only one attempt to boot successfully.

**Rollback Process** The description of the rollback process when `CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE` option is enabled:

- The new application is successfully downloaded and `esp_ota_set_boot_partition()` function makes this partition bootable and sets the state `ESP_OTA_IMG_NEW`. This state means that the application is new and should be monitored for its first boot.
- Reboot `esp_restart()`.
• The bootloader checks for the ESP_OTA_IMG_PENDING_VERIFY state if it is set, then it will be written to ESP_OTA_IMG_ABORTED.
• The bootloader selects a new application to boot so that the state is not set as ESP_OTA_IMG_INVALID or ESP_OTA_IMG_ABORTED.
• The bootloader checks the selected application for ESP_OTA_IMG_NEW state if it is set, then it will be written to ESP_OTA_IMG_PENDING_VERIFY. This state means that the application requires confirmation of its operability, if this does not happen and a reboot occurs, this state will be overwritten to ESP_OTA_IMG_ABORTED (see above) and this application will no longer be able to start, i.e. there will be a rollback to the previous working application.
• A new application has started and should make a self-test.
• If the self-test has completed successfully, then you must call the function esp_ota_mark_app_valid_cancel_rollback() because the application is awaiting confirmation of operability (ESP_OTA_IMG_PENDING_VERIFY state).
• If the self-test fails then call esp_ota_mark_app_invalid_rollback_and_reboot() function to roll back to the previous working application, while the invalid application is set ESP_OTA_IMG_INVALID state.
• If the application has not been confirmed, the state remains ESP_OTA_IMG_PENDING_VERIFY, and the next boot it will be changed to ESP_OTA_IMG_ABORTED. That will prevent re-boot of this application. There will be a rollback to the previous working application.

Unexpected Reset  If a power loss or an unexpected crash occurs at the time of the first boot of a new application, it will roll back the application.

Recommendation: Perform the self-test procedure as quickly as possible, to prevent rollback due to power loss.

Only OTA partitions can be rolled back. Factory partition is not rolled back.

Booting invalid/aborted apps  Booting an application which was previously set to ESP_OTA_IMG_INVALID or ESP_OTA_IMG_ABORTED is possible:

• Get the last invalid application partition esp_ota_get_last_invalid_partition().
• Pass the received partition to esp_ota_set_boot_partition(), this will update the otadata.
• Restart esp_restart(). The bootloader will boot the specified application.

To determine if self-tests should be run during startup of an application, call the esp_ota_get_state_partition() function. If result is ESP_OTA_IMG_PENDING_VERIFY then self-testing and subsequent confirmation of operability is required.

Where the states are set  A brief description of where the states are set:

• ESP_OTA_IMG_VALID state is set by esp_ota_mark_app_valid_cancel_rollback() function.
• ESP_OTA_IMG_UNDEFINED state is set by esp_ota_set_boot_partition() function if CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is not enabled.
• ESP_OTA_IMG_NEW state is set by esp_ota_set_boot_partition() function if CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is enabled.
• ESP_OTA_IMG_INVALID state is set by esp_ota_mark_app_invalid_rollback_and_reboot() function.
• ESP_OTA_IMG_ABORTED state is set if there was no confirmation of the application operability and occurs reboots (if CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is enabled).
• ESP_OTA_IMG_PENDING_VERIFY state is set in a bootloader if CONFIG_BOOTLOADER_APP_ROLLBACK_ENABLE option is enabled and selected app has ESP_OTA_IMG_NEW state.

Anti-rollback

Anti-rollback prevents rollback to application with security version lower than one programmed in eFuse of chip.
This function works if set `CONFIG_BOOTLOADER_APPANTI_ROLLBACK` option. In the bootloader, when selecting a bootable application, an additional security version check is added which is on the chip and in the application image. The version in the bootable firmware must be greater than or equal to the version in the chip.

`CONFIG_BOOTLOADER_APPANTI_ROLLBACK` and `CONFIG_BOOTLOADER_APPROLLBACK_ENABLE` options are used together. In this case, rollback is possible only on the security version which is equal or higher than the version in the chip.

A typical anti-rollback scheme is

- New firmware released with the elimination of vulnerabilities with the previous version of security.
- After the developer makes sure that this firmware is working. He can increase the security version and release a new firmware.
- Download new application.
- To make it bootable, run the function `esp_ota_set_boot_partition()`. If the security version of the new application is smaller than the version in the chip, the new application will be erased. Update to new firmware is not possible.
- Reboot.
- In the bootloader, an application with a security version greater than or equal to the version in the chip will be selected. If otadata is in the initial state, and one firmware was loaded via a serial channel, whose secure version is higher than the chip, then the secure version of efuse will be immediately updated in the bootloader.
- New application booted. Then the application should perform diagnostics of the operation and if it is completed successfully, you should call `esp_ota_mark_app_valid_cancel_rollback()` function to mark the running application with the ESP_OTA_IMG_VALID state and update the secure version on chip. Note that if was called `esp_ota_mark_app_invalid_rollback_and_reboot()` function a rollback may not happen as the device may not have any bootable apps. It will then return ESP_ERR_OTA_ROLLBACK_FAILED error and stay in the ESP_OTA_IMG_PENDING_VERIFY state.
- The next update of app is possible if a running app is in the ESP_OTA_IMG_VALID state.

Recommendation:

If you want to avoid the download/erase overhead in case of the app from the server has security version lower than the running app, you have to get `new_app_info.secure_version` from the first package of an image and compare it with the secure version of efuse. Use `esp_efuse_check_secure_version(new_app_info.secure_version)` function if it is true then continue downloading otherwise abort.

```c
bool image_header_was_checked = false;
while (1) {
    int data_read = esp_http_client_read(client, ota_write_data, BUFFSIZE);
    ...
    if (data_read > 0) {
        if (!image_header_was_checked) {
            esp_app_desc_t new_app_info;
            if (data_read > sizeof(esp_image_header_t) + sizeof(esp_image_segment_header_t) + sizeof(esp_app_desc_t)) {
                // check current version with downloading
                if (esp_efuse_check_secure_version(new_app_info.secure_version) == false) {
                    ESP_LOGE(TAG, "This a new app can not be downloaded due to a secure version is lower than stored in efuse.");
                    http_cleanup(client);
                    task_fatal_error();
                }
                image_header_was_checked = true;
                esp_ota_begin(update_partition, OTA_SIZE_UNKNOWN, &update_handle);
            }
        }
        esp_ota_write(update_handle, (const void *)ota_write_data, data_read);
    }
}(continues on next page)```
Restrictions:

- The number of bits in the secure_version field is limited to 32 bits. This means that only 32 times you can do an anti-rollback. You can reduce the length of this efuse field using `CONFIG_BOOTLOADER_APP_SEC_VER_SIZE_EFUSE_FIELD` option.
- Anti-rollback works only if the encoding scheme for efuse is set to NONE.
- Factory and Test partitions are not supported in anti rollback scheme and hence partition table should not have partition with SubType set to factory or test.

security_version:

- In application image it is stored in esp_app_desc structure. The number is set `CONFIG_BOOTLOADER_APP_SECURE_VERSION`.
- In ESP32 it is stored in efuse EFUSE_BLK3_RDATA4_REG. (when a eFuse bit is programmed to 1, it can never be reverted to 0). The number of bits set in this register is the security_version from app.

Secure OTA Updates Without Secure boot

The verification of signed OTA updates can be performed even without enabling hardware secure boot. This can be achieved by setting `CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT` and `CONFIG_SECURE_SIGNED_ON_UPDATE_NO_SECURE_BOOT`

For more information refer to Signed App Verification Without Hardware Secure Boot

OTA Tool (otatool.py)

The component app_update provides a tool otatool.py for performing OTA partition-related operations on a target device. The following operations can be performed using the tool:

- read contents of otadata partition (read_otadata)
- erase otadata partition, effectively resetting device to factory app (erase_otadata)
- switch OTA partitions (switch_ota_partition)
- erasing OTA partition (erase_ota_partition)
- write to OTA partition (write_ota_partition)
- read contents of OTA partition (read_ota_partition)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool’s Python API and command-line interface, respectively.

Python API  Before anything else, make sure that the otatool module is imported.

```python
import sys
import os

idf_path = os.environ["IDF_PATH"]  # get value of IDF_PATH from environment
otatool_dir = os.path.join(idf_path, "components", "app_update")  # otatool.py...lives in $IDF_PATH/components/app_update

sys.path.append(otatool_dir)  # this enables Python to find otatool module
from otatool import *  # import all names inside otatool module
```

The starting point for using the tool’s Python API to do is create a OatoolTarget object:
# Create a partool.py target device connected on serial port /dev/ttyUSB1
target = OtapoolTarget("/dev/ttyUSB1")

The created object can now be used to perform operations on the target device:

```python
# Erase otadata, resetting the device to factory app
target.erase_otadata()

# Erase contents of OTA app slot 0
target.erase_ota_partition(0)

# Switch boot partition to that of app slot 1
target.switch_ota_partition(1)

# Read OTA partition 'ota_3' and save contents to a file named 'ota_3.bin'
target.read_ota_partition("ota_3", "ota_3.bin")
```

The OTA partition to operate on is specified using either the app slot number or the partition name.

More information on the Python API is available in the docstrings for the tool.

**Command-line Interface** The command-line interface of `otatool.py` has the following structure:

```
.otatool.py [command-args] [subcommand] [subcommand-args]
```

- `command-args` - these are arguments that are needed for executing the main...
- `subcommand` - this is the operation to be performed
- `subcommand-args` - these are arguments that are specific to the chosen operation

```bash
# Erase otadata, resetting the device to factory app
otatool.py --port "/dev/ttyUSB1" erase_otadata

# Erase contents of OTA app slot 0
otatool.py --port "/dev/ttyUSB1" erase_ota_partition --slot 0

# Switch boot partition to that of app slot 1
otatool.py --port "/dev/ttyUSB1" switch_ota_partition --slot 1

# Read OTA partition 'ota_3' and save contents to a file named 'ota_3.bin'
otatool.py --port "/dev/ttyUSB1" read_ota_partition --name=ota_3 --output=ota_3.bin
```

More information can be obtained by specifying `--help` as argument:

```
# Display possible subcommands and show main command argument descriptions
otatool.py --help

# Show descriptions for specific subcommand arguments
otatool.py [subcommand] --help
```

Application Example

End-to-end example of OTA firmware update workflow: system/ota.

API Reference

Header File

- components/app_update/include/esp_ota_ops.h

Functions

- \texttt{const esp_app_desc_t *esp_ota_get_app_description (void)}
  
  Return esp_app_desc structure. This structure includes app version.

  \textbf{Note:} This API is present for backward compatibility reasons. Alternative function with the same functionality is \texttt{esp_app_get_description}.

- \texttt{int esp_ota_get_app_elf_sha256 (char*dst,size_tsize)}
  
  Fill the provided buffer with SHA256 of the ELF file, formatted as hexadecimal, null-terminated. If the buffer size is not sufficient to fit the entire SHA256 in hex plus a null terminator, the largest possible number of bytes will be written followed by a null.

  \textbf{Note:} This API is present for backward compatibility reasons. Alternative function with the same functionality is \texttt{esp_app_get_elf_sha256}.

  \textbf{Parameters}
  
  - \texttt{dst} – Destination buffer
  - \texttt{size} – Size of the buffer

  \textbf{Returns} Number of bytes written to \texttt{dst} (including null terminator)

- \texttt{esp_err_t esp_ota_begin (const esp_partition_t *partition,size_timage_size, esp_ota_handle_t*out_handle)}
  
  Commence an OTA update writing to the specified partition.

  The specified partition is erased to the specified image size.

  If image size is not yet known, pass OTA_SIZE_UNKNOWN which will cause the entire partition to be erased.

  On success, this function allocates memory that remains in use until \texttt{esp_ota_end()} is called with the returned handle.

  \textbf{Note:} If the rollback option is enabled and the running application has the ESP_OTA_IMG_PENDING_VERIFY state then it will lead to the ESP_ERR_OTA_ROLLBACK_INVALID_STATE error. Confirm the running app before to run download a new app, use \texttt{esp_ota_mark_app_valid_cancel_rollback()} function for it (this should be done as early as possible when you first download a new application).

  \textbf{Parameters}
  
  - \texttt{partition} – Pointer to info for partition which will receive the OTA update. Required.
  - \texttt{image_size} – Size of new OTA app image. Partition will be erased in order to receive this size of image. If 0 or OTA_SIZE_UNKNOWN, the entire partition is erased.
• **out_handle** – On success, returns a handle which should be used for subsequent esp_ota_write() and esp_ota_end() calls.

**Returns**

- ESP_OK: OTA operation commenced successfully.
- ESP_ERR_INVALID_ARG: partition or out_handle arguments were NULL, or partition doesn’t point to an OTA app partition.
- ESP_ERR_NO_MEM: Cannot allocate memory for OTA operation.
- ESP_ERR_OTA_PARTITION_CONFLICT: Partition holds the currently running firmware, cannot update in place.
- ESP_ERR_NOT_FOUND: Partition argument not found in partition table.
- ESP_ERR_OTA_SELECT_INFO_INVALID: The OTA data partition contains invalid data.
- ESP_ERR_INVALID_SIZE: Partition doesn’t fit in configured flash size.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_ROLLBACK_INVALID_STATE: If the running app has not confirmed state. Before performing an update, the application must be valid.

```
esp_err_t esp_ota_write(esp_ota_handle_t handle, const void*data, size_t size)
```

Write OTA update data to partition.

This function can be called multiple times as data is received during the OTA operation. Data is written sequentially to the partition.

**Parameters**

- **handle** – Handle obtained from esp_ota_begin
- **data** – Data buffer to write
- **size** – Size of data buffer in bytes

**Returns**

- ESP_OK: Data was written to flash successfully.
- ESP_ERR_INVALID_ARG: handle is invalid.
- ESP_ERR_OTA_VALIDATE_FAILED: First byte of image contains invalid app image magic byte.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
- ESP_ERR_OTA_SELECT_INFO_INVALID: OTA data partition has invalid contents

```
esp_err_t esp_ota_write_with_offset(esp_ota_handle_t handle, const void*data, size_t size, uint32_t offset)
```

Write OTA update data to partition at an offset.

This function can write data in non-contiguous manner. If flash encryption is enabled, data should be 16 bytes aligned.

**Note:** While performing OTA, if the packets arrive out of order, esp_ota_write_with_offset() can be used to write data in non-contiguous manner. Use of esp_ota_write_with_offset() in combination with esp_ota_write() is not recommended.

**Parameters**

- **handle** – Handle obtained from esp_ota_begin
- **data** – Data buffer to write
- **size** – Size of data buffer in bytes
- **offset** – Offset in flash partition

**Returns**

- ESP_OK: Data was written to flash successfully.
- ESP_ERR_INVALID_ARG: handle is invalid.
- ESP_ERR_OTA_VALIDATE_FAILED: First byte of image contains invalid app image magic byte.
• ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash write failed.
• ESP_ERR_OTA_SELECT_INFO_INVALID: OTA data partition has invalid contents

`esp_err_t esp_ota_end (esp_ota_handle_t handle)`

Finish OTA update and validate newly written app image.

**Note:** After calling esp_ota_end(), the handle is no longer valid and any memory associated with it is freed (regardless of result).

**Parameters**
- handle – Handle obtained from esp_ota_begin().

**Returns**
- ESP_OK: Newly written OTA app image is valid.
- ESP_ERR_NOT_FOUND: OTA handle was not found.
- ESP_ERR_INVALID_ARG: Handle was never written to.
- ESP_ERR_OTA_VALIDATE_FAILED: OTA image is invalid (either not a valid app image, or - if secure boot is enabled - signature failed to verify.)
- ESP_ERR_INVALID_STATE: If flash encryption is enabled, this result indicates an internal error writing the final encrypted bytes to flash.

`esp_err_t esp_ota_abort (esp_ota_handle_t handle)`

Abort OTA update, free the handle and memory associated with it.

**Parameters**
- handle – obtained from esp_ota_begin().

**Returns**
- ESP_OK: Handle and its associated memory is freed successfully.
- ESP_ERR_NOT_FOUND: OTA handle was not found.

`esp_err_t esp_ota_set_boot_partition (const esp_partition_t *partition)`

Configure OTA data for a new boot partition.

**Note:** If this function returns ESP_OK, calling esp_restart() will boot the newly configured app partition.

**Parameters**
- partition – Pointer to info for partition containing app image to boot.

**Returns**
- ESP_OK: OTA data updated, next reboot will use specified partition.
- ESP_ERR_INVALID_ARG: partition argument was NULL or didn’t point to a valid OTA partition of type “app”.
- ESP_ERR_OTA_VALIDATE_FAILED: Partition contained invalid app image. Also returned if secure boot is enabled and signature validation failed.
- ESP_ERR_NOT_FOUND: OTA data partition not found.
- ESP_ERR_FLASH_OP_TIMEOUT or ESP_ERR_FLASH_OP_FAIL: Flash erase or write failed.

`const esp_partition_t *esp_ota_get_boot_partition (void)`

Get partition info of currently configured boot app.

If esp_ota_set_boot_partition() has been called, the partition which was set by that function will be returned.

If esp_ota_set_boot_partition() has not been called, the result is usually the same as esp_ota_get_running_partition(). The two results are not equal if the configured boot partition does not contain a valid app (meaning that the running partition will be an app that the bootloader chose via fallback).

If the OTA data partition is not present or not valid then the result is the first app partition found in the partition table. In priority order, this means: the factory app, the first OTA app slot, or the test app partition.
Note that there is no guarantee the returned partition is a valid app. Use esp_image_verify(ESP_IMAGE_VERIFY, ...) to verify if the returned partition contains a bootable image.

**Returns**  Pointer to info for partition structure, or NULL if partition table is invalid or a flash read operation failed. Any returned pointer is valid for the lifetime of the application.

```c
const esp_partition_t *esp_ota_get_running_partition (void)
```

Get partition info of currently running app.

This function is different to esp_ota_get_boot_partition() in that it ignores any change of selected boot partition caused by esp_ota_set_boot_partition(). Only the app whose code is currently running will have its partition information returned.

The partition returned by this function may also differ from esp_ota_get_boot_partition() if the configured boot partition is somehow invalid, and the bootloader fell back to a different app partition at boot.

**Returns**  Pointer to info for partition structure, or NULL if no partition is found or flash read operation failed. Returned pointer is valid for the lifetime of the application.

```c
const esp_partition_t *esp_ota_get_next_update_partition (const esp_partition_t *start_from)
```

Return the next OTA app partition which should be written with a new firmware. Call this function to find an OTA app partition which can be passed to esp_ota_begin().

Finds next partition round-robin, starting from the current running partition.

**Parameters**  
* start_from – If set, treat this partition info as describing the current running partition. Can be NULL, in which case esp_ota_get_running_partition() is used to find the currently running partition. The result of this function is never the same as this argument.

**Returns**  Pointer to info for partition which should be updated next. NULL result indicates invalid OTA data partition, or that no eligible OTA app slot partition was found.

```c
esp_err_t esp_ota_get_partition_description (const esp_partition_t *partition, esp_app_desc_t *app_desc)
```

Returns esp_app_desc structure for app partition. This structure includes app version.

**Parameters**  
* partition – [in] Pointer to app partition. (only app partition)  
* app_desc – [out] Structure of info about app.

**Returns**  
* ESP_OK Successful.  
* ESP_ERR_NOT_FOUND app_desc structure is not found. Magic word is incorrect.  
* ESP_ERR_NOT_SUPPORTED Partition is not application.  
* ESP_ERR_INVALID_ARG Arguments is NULL or if partition’s offset exceeds partition size.  
* ESP_ERR_INVALID_SIZE Read would go out of bounds of the partition.  
* or one of error codes from lower-level flash driver.

```c
uint8_t esp_ota_get_app_partition_count (void)
```

Returns number of ota partitions provided in partition table.

**Returns**  
* Number of OTA partitions

```c
esp_err_t esp_ota_mark_app_valid_cancel_rollback (void)
```

This function is called to indicate that the running app is working well.

**Returns**  
* ESP_OK: if successful.
This function is called to roll back to the previously workable app with reboot.

If rollback is successful then device will reset else API will return with error code. Checks applications on a flash drive that can be booted in case of rollback. If the flash does not have at least one app (except the running app) then rollback is not possible.

Returns
- ESP_FAIL: if not successful.
- ESP_ERR_OTA.Rollback_FAILED: The rollback is not possible due to flash does not have any apps.

const esp_partition_t *esp_ota_get_last_invalid_partition (void)

Returns last partition with invalid state (ESP.OTA_IMG.INVALID or ESP.OTA_IMG.ABORTED).

Returns partition.

esp_err_t esp_ota_get_state_partition (const esp_partition_t *partition, esp_ota_img_states_t *ota_state)

Returns state for given partition.

Parameters
- partition [in] Pointer to partition.
- ota_state [out] state of partition (if this partition has a record in otadata).

Returns
- ESP_OK: Successful.
- ESP_ERR_INVALID_ARG: partition or ota_state arguments were NULL.
- ESP_ERR_NOT_SUPPORTED: partition is not ota.
- ESP_ERR_NOT_FOUND: Partition table does not have otadata or state was not found for given partition.

esp_err_t esp_ota_erase_last_boot_app_partition (void)

Erase previous boot app partition and corresponding otadata select for this partition.

When current app is marked to as valid then you can erase previous app partition.

Returns
- ESP_OK: Successful, otherwise ESP.ERR.

bool esp_ota_check_rollback_is_possible (void)

Checks applications on the slots which can be booted in case of rollback.

These applications should be valid (marked in otadata as not UNDEFINED, INVALID or ABORTED and crc is good) and be able booted, and secure_version of app >= secure_version of efuse (if anti-rollback is enabled).

Returns
- True: Returns true if the slots have at least one app (except the running app).
- False: The rollback is not possible.

Macros

OTA_SIZE_UNKNOWN
Used for esp.ota_begin() if new image size is unknown

OTA_WITH_SEQUENTIAL_WRITES
Used for esp.ota_begin() if new image size is unknown and erase can be done in incremental manner (assuming write operation is in continuous sequence)

ESP_ERR.OTA_BASE
Base error code for ota_ops api
Chapter 2. API Reference

**ESP_ERR_OTA_PARTITION_CONFLICT**
Error if request was to write or erase the current running partition

**ESP_ERR_OTA_SELECT_INFO_INVALID**
Error if OTA data partition contains invalid content

**ESP_ERR_OTA_VALIDATE_FAILED**
Error if OTA app image is invalid

**ESP_ERR_OTA_SMALL_SEC_VER**
Error if the firmware has a secure version less than the running firmware.

**ESP_ERR_OTA_ROLLBACK_FAILED**
Error if flash does not have valid firmware in passive partition and hence rollback is not possible

**ESP_ERR_OTA_ROLLBACK_INVALID_STATE**
Error if current active firmware is still marked in pending validation state (ESP_OTA_IMG_PENDING_VERIFY), essentially first boot of firmware image post upgrade and hence firmware upgrade is not possible

**Type Definitions**

typedef uint32_t esp_ota_handle_t
Opaque handle for an application OTA update.

    esp_ota_begin() returns a handle which is then used for subsequent calls to esp_ota_write() and esp_ota_end().

**Debugging OTA Failure**

**2.10.23 Performance Monitor**

The Performance Monitor component provides APIs to use ESP32 internal performance counters to profile functions and applications.

**Application Example**

An example which combines performance monitor is provided in examples/system/perfmon directory. This example initializes the performance monitor structure and execute them with printing the statistics.

**High level API Reference**

**Header Files**

- perfmon/include/perfmon.h

**API Reference**

**Header File**

- components/perfmon/include/xtensa_perfmon_access.h
Fig. 41: How to Debug When OTA Fails (click to enlarge)
Functions

`esp_err_t xtensa_perfmon_init` (int id, uint16_t select, uint16_t mask, int kernelcnt, int tracelevel)
Init Performance Monitor.

Initialize performance monitor register with define values

**Parameters**
- `id` [in] performance counter number
- `select` [in] select value from PMCTRLx register
- `mask` [in] mask value from PMCTRLx register
- `kernelcnt` [in] kernelcnt value from PMCTRLx register
- `tracelevel` [in] tracelevel value from PMCTRLx register

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if one of the arguments is not correct

`esp_err_t xtensa_perfmon_reset` (int id)
Reset PM counter.

Reset PM counter. Writes 0 to the PMx register.

**Parameters** `id` [in] performance counter number

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if id out of range

`void xtensa_perfmon_start` (void)
Start PM counters.

Start all PM counters synchronously. Write 1 to the PGM register

`void xtensa_perfmon_stop` (void)
Stop PM counters.

Stop all PM counters synchronously. Write 0 to the PGM register

`uint32_t xtensa_perfmon_value` (int id)
Read PM counter.

Read value of defined PM counter.

**Parameters** `id` [in] performance counter number

**Returns**
- Performance counter value

`esp_err_t xtensa_perfmon_overflow` (int id)
Read PM overflow state.

Read overflow value of defined PM counter.

**Parameters** `id` [in] performance counter number

**Returns**
- ESP_OK if there is no overflow (overflow = 0)
- ESP_FAIL if overflow occur (overflow = 1)

`void xtensa_perfmon_dump` (void)
Dump PM values.

Dump all PM register to the console.

**Header File**
- components/perfmon/include/xtensa_perfmon_apis.h
Functions

```c
esp_err_t xtensa_perfmon_exec(const xtensa_perfmon_config_t *config)
```

Execute PM.

Execute performance counter for dedicated function with defined parameters

**Parameters**
- `config` - [in] pointer to the configuration structure

**Returns**
- ESP_OK if no errors
- ESP_ERR_INVALID_ARG if one of the required parameters not defined
- ESP_FAIL - counter overflow

```c
void xtensa_perfmon_view_cb(void *params, uint32_t select, uint32_t mask, uint32_t value)
```

Dump PM results.

Callback to dump perfmon result to a FILE* stream specified in perfmon_config_t::callback_params. If callback_params is set to NULL, will print to stdout

**Parameters**
- `params` - [in] used parameters passed from configuration (callback_params). This parameter expected as FILE* hanle, where data will be stored. If this parameter NULL, then data will be stored to the stdout.
- `select` - [in] select value for current counter
- `mask` - [in] mask value for current counter
- `value` - [in] counter value for current counter

Structures

```c
struct xtensa_perfmon_config
```

Performance monitor configuration structure.

Structure to configure performance counter to measure dedicated function

**Public Members**

```c
int repeat_count
```

how much times function will be called before the callback will be repeated

```c
float max_deviation
```

Difference between min and max counter number 0..1, 0 - no difference, 1 - not used

```c
void *call_params
```

This pointer will be passed to the call_function as a parameter

```c
void (*call_function)(void *params)
```

pointer to the function that have to be called

```c
void (*callback)(void *params, uint32_t select, uint32_t mask, uint32_t value)
```

pointer to the function that will be called with result parameters

```c
void *callback_params
```

parameter that will be passed to the callback

```c
int tracelevel
```

trace level for all counters. In case of negative value, the filter will be ignored. If it’s >=0, then the perfmon will count only when interrupt level > tracelevel. It’s useful to monitor interrupts.
typedef struct xtensa_perfmon_config xtensa_perfmon_config_t
   Performance monitor configuration structure.
   Structure to configure performance counter to measure dedicated function

2.10.24 Power Management

Overview

Power management algorithm included in ESP-IDF can adjust the advanced peripheral bus (APB) frequency, CPU frequency, and put the chip into light sleep mode to run an application at smallest possible power consumption, given the requirements of application components.

Application components can express their requirements by creating and acquiring power management locks.

For example:

• Driver for a peripheral clocked from APB can request the APB frequency to be set to 80 MHz while the peripheral is used.
• RTOS can request the CPU to run at the highest configured frequency while there are tasks ready to run.
• A peripheral driver may need interrupts to be enabled, which means it will have to request disabling light sleep.

Since requesting higher APB or CPU frequencies or disabling light sleep causes higher current consumption, please keep the usage of power management locks by components to a minimum.

Configuration

Power management can be enabled at compile time, using the option CONFIG_PM_ENABLE.

Enabling power management features comes at the cost of increased interrupt latency. Extra latency depends on a number of factors, such as the CPU frequency, single/dual core mode, whether or not frequency switch needs to be done. Minimum extra latency is 0.2 us (when the CPU frequency is 240 MHz and frequency scaling is not enabled). Maximum extra latency is 40 us (when frequency scaling is enabled, and a switch from 40 MHz to 80 MHz is performed on interrupt entry).

Dynamic frequency scaling (DFS) and automatic light sleep can be enabled in an application by calling the function esp_pm_configure(). Its argument is a structure defining the frequency scaling settings, esp_pm_config_t. In this structure, three fields need to be initialized:

• max_freq_mhz: Maximum CPU frequency in MHz, i.e., the frequency used when the ESP_PM_CPU_FREQ_MAX lock is acquired. This field will usually be set to the default CPU frequency.
• min_freq_mhz: Minimum CPU frequency in MHz, i.e., the frequency used when only the ESP_PM_APB_FREQ_MAX lock is acquired. This field can be set to the XTAL frequency value, or the XTAL frequency divided by an integer. Note that 10 MHz is the lowest frequency at which the default REF_TICK clock of 1 MHz can be generated.
• **light_sleep_enable**: Whether the system should automatically enter light sleep when no locks are acquired (true/false).

   Alternatively, if you enable the option `CONFIG_PM_DFS_INIT_AUTO` in menuconfig, the maximum CPU frequency will be determined by the `CONFIG_ESP_DEFAULT_CPU_FREQ_MHZ` setting, and the minimum CPU frequency will be locked to the XTAL frequency.

   **Note:** Automatic light sleep is based on FreeRTOS Tickless Idle functionality. If automatic light sleep is requested while the option `CONFIG_FREERTOS_USE_TICKLESS_IDLE` is not enabled in menuconfig, `esp_pm_configure()` will return the error `ESP_ERR_NOT_SUPPORTED`.

   **Note:** In light sleep, peripherals are clock gated, and interrupts (from GPIOs and internal peripherals) will not be generated. A wakeup source described in the *Sleep Modes* documentation can be used to trigger wakeup from the light sleep state.

For example, the EXT0 and EXT1 wakeup sources can be used to wake up the chip via a GPIO.

**Power Management Locks**

Applications have the ability to acquire/release locks in order to control the power management algorithm. When an application acquires a lock, the power management algorithm operation is restricted in a way described below. When the lock is released, such restrictions are removed.

Power management locks have acquire/release counters. If the lock has been acquired a number of times, it needs to be released the same number of times to remove associated restrictions.

ESP32 supports three types of locks described in the table below.

<table>
<thead>
<tr>
<th>Lock</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP_PM_CPU_FREQ_MAX</td>
<td>Requests CPU frequency to be at the maximum value set with <code>esp_pm_configure()</code>. For ESP32, this value can be set to 80 MHz, 160 MHz, or 240 MHz.</td>
</tr>
<tr>
<td>ESP_PM_APB_FREQ_MAX</td>
<td>Requests the APB frequency to be at the maximum supported value. For ESP32, this is 80 MHz.</td>
</tr>
<tr>
<td>ESP_PM_NO_LIGHT_SLEEP</td>
<td>Disables automatic switching to light sleep.</td>
</tr>
</tbody>
</table>

**ESP32 Power Management Algorithm**

The table below shows how CPU and APB frequencies will be switched if dynamic frequency scaling is enabled. You can specify the maximum CPU frequency with either `esp_pm_configure()` or `CONFIG_ESP_DEFAULT_CPU_FREQ_MHZ`. 
### Dynamic Frequency Scaling and Peripheral Drivers

When DFS is enabled, the APB frequency can be changed multiple times within a single RTOS tick. The APB frequency change does not affect the operation of some peripherals, while other peripherals may have issues. For example, Timer Group peripheral timers will keep counting, however, the speed at which they count will change proportionally to the APB frequency.

The following peripherals work normally even when the APB frequency is changing:

- **UART**: if REF_TICK or XTAL is used as a clock source. See `uart_config_t::source_clk`.
- **LED**: if REF_TICK is used as a clock source. See `ledc_timer_config()` function.
- **RMT**: if REF_TICK or XTAL is used as a clock source. See `rmt_config_t::flags` and macro `RMT_CHANNEL_FLAGS_AWARE_DFS`.
- **GPTimer**: if APB is used as the clock source. See `gptimer_config_t::clk_src`.
- **TSSENS**: XTAL or RTC_8M is used as a clock source. So, APB frequency changing will not influence it.

<table>
<thead>
<tr>
<th>Max CPU Frequency Set</th>
<th>Lock Acquisition</th>
<th>CPU and APB Frequencies</th>
</tr>
</thead>
</table>
| 240                   | Any of ESP_PM_CPU_FREQ_MAX or ESP_PM_APB_FREQ_MAX acquired | CPU: 240 MHz
                       |                   | APB: 80 MHz |
                       | None              | Min values for both frequencies set with `esp_pm_configure()` |
| 160                   | ESP_PM_CPU_FREQ_MAX acquired | CPU: 160 MHz
                       |                   | APB: 80 MHz |
                       | ESP_PM_APB_FREQ_MAX acquired, ESP_PM_CPU_FREQ_MAX not acquired | CPU: 80 MHz
                       |                   | APB: 80 MHz |
                       | None              | Min values for both frequencies set with `esp_pm_configure()` |
| 80                    | Any of ESP_PM_CPU_FREQ_MAX or ESP_PM_APB_FREQ_MAX acquired | CPU: 80 MHz
                       |                   | APB: 80 MHz |
                       | None              | Min values for both frequencies set with `esp_pm_configure()` |

If none of the locks are acquired, and light sleep is enabled in a call to `esp_pm_configure()`, the system will go into light sleep mode. The duration of light sleep will be determined by:

- FreeRTOS tasks blocked with finite timeouts
- Timers registered with High resolution timer APIs

Light sleep duration will be chosen to wake up the chip before the nearest event (task being unblocked, or timer elapses).

To skip unnecessary wake-up, you can consider initializing an esp_timer with the `skip_unhandled_events` option as true. Timers with this flag will not wake up the system and it helps to reduce consumption.
Currently, the following peripheral drivers are aware of DFS and will use the ESP_PM_APB_FREQ_MAX lock for the duration of the transaction:

- SPI master
- I2C
- I2S (If the APPLL clock is used, then it will use the ESP_PM_NO_LIGHT_SLEEP lock)
- SDMMC

The following drivers will hold the ESP_PM_APB_FREQ_MAX lock while the driver is enabled:

- **SPI slave**: between calls to `spi_slave_initialize()` and `spi_slave_free()`.
- **Ethernet**: between calls to `esp_eth_driver_install()` and `esp_eth_driver_uninstall()`.
- **WiFi**: between calls to `esp_wifi_start()` and `esp_wifi_stop()`. If modem sleep is enabled, the lock will be released for the periods of time when radio is disabled.
- **TWAI**: between calls to `twai_driver_install()` and `twai_driver_uninstall()` (only when the clock source is set to `TWAI_CLK_SRC_APB`).
- **Bluetooth**: between calls to `esp_bt_controller_enable()` and `esp_bt_controller_disable()`. If Bluetooth modem sleep is enabled, the ESP_PM_APB_FREQ_MAX lock will be released for the periods of time when radio is disabled. However the ESP_PM_NO_LIGHT_SLEEP lock will still be held, unless `CONFIG_BTDM_CTRL_LOW_POWER_CLOCK` option is set to “External 32kHz crystal”.

The following peripheral drivers are not aware of DFS yet. Applications need to acquire/release locks themselves, when necessary:

- PCNT
- Sigma-delta
- The legacy timer group driver
- MCPWM

**Light-sleep Peripheral Power Down**

**API Reference**

**Header File**

- `components/esp_pm/include/esp_pm.h`

**Functions**

`esp_err_t esp_pm_configure (const void *config)`

Set implementation-specific power management configuration.

- **Parameters** `config` - pointer to implementation-specific configuration structure (e.g. `esp_pm_config_esp32`)
- **Returns**
  - ESP_OK on success
  - ESP_ERR_INVALID_ARG if the configuration values are not correct
  - ESP_ERR_NOT_SUPPORTED if certain combination of values is not supported, or if `CONFIG_PM_ENABLE` is not enabled in sdkconfig

`esp_err_t esp_pm_get_configuration (void *config)`

Get implementation-specific power management configuration.

- **Parameters** `config` - pointer to implementation-specific configuration structure (e.g. `esp_pm_config_esp32`)
- **Returns**
  - ESP_OK on success
  - ESP_ERR_INVALID_ARG if the pointer is null
**esp_err_t esp_pm_lock_create** (esp_pm_lock_type_t lock_type, int arg, const char *name, esp_pm_lock_handle_t *out_handle)

Initialize a lock handle for certain power management parameter.

When lock is created, initially it is not taken. Call esp_pm_lock_acquire to take the lock.

This function must not be called from an ISR.

**Parameters**

- **lock_type** – Power management constraint which the lock should control
- **arg** – Argument, value depends on lock_type, see esp_pm_lock_type_t
- **name** – Arbitrary string identifying the lock (e.g. “wifi” or “spi”). Used by the esp_pm_dump_locks function to list existing locks. May be set to NULL. If not set to NULL, must point to a string which is valid for the lifetime of the lock.
- **out_handle** – [out] handle returned from this function. Use this handle when calling esp_pm_lock_delete, esp_pm_lock_acquire, esp_pm_lock_release. Must not be NULL.

**Returns**

- ESP_OK on success
- ESP_ERR_NO_MEM if the lock structure cannot be allocated
- ESP_ERR_INVALID_ARG if out_handle is NULL or type argument is not valid
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

**esp_err_t esp_pm_lock_acquire** (esp_pm_lock_handle_t handle)

Take a power management lock.

Once the lock is taken, power management algorithm will not switch to the mode specified in a call to esp_pm_lock_create, or any of the lower power modes (higher numeric values of ‘mode’).

The lock is recursive, in the sense that if esp_pm_lock_acquire is called a number of times, esp_pm_lock_release has to be called the same number of times in order to release the lock.

This function may be called from an ISR.

This function is not thread-safe w.r.t. calls to other esp_pm_lock_* functions for the same handle.

**Parameters** handle – handle obtained from esp_pm_lock_create function

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

**esp_err_t esp_pm_lock_release** (esp_pm_lock_handle_t handle)

Release the lock taken using esp_pm_lock_acquire.

Call to this functions removes power management restrictions placed when taking the lock.

Locks are recursive, so if esp_pm_lock_acquire is called a number of times, esp_pm_lock_release has to be called the same number of times in order to actually release the lock.

This function may be called from an ISR.

This function is not thread-safe w.r.t. calls to other esp_pm_lock_* functions for the same handle.

**Parameters** handle – handle obtained from esp_pm_lock_create function

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle is invalid
- ESP_ERR_NOT_SUPPORTED if lock is not acquired
- ESP_ERR_NOT_SUPPORTED if CONFIG_PM_ENABLE is not enabled in sdkconfig

**esp_err_t esp_pm_lock_delete** (esp_pm_lock_handle_t handle)

Delete a lock created using esp_pm_lock.

The lock must be released before calling this function.

This function must not be called from an ISR.
Parameters **handle** – handle obtained from `esp_pm_lock_create` function

Returns

- ESP_OK on success
- ESP_ERR_INVALID_ARG if the handle argument is NULL
- ESP_ERR_INVALID_STATE if the lock is still acquired
- ESP_ERR_NOT_SUPPORTED if `CONFIG_PM_ENABLE` is not enabled in `sdkconfig`

```c
esp_err_t esp_pm_dump_locks(FILE *stream)
```

Dump the list of all locks to stderr

This function dumps debugging information about locks created using `esp_pm_lock_create` to an output stream. This function must not be called from an ISR. If `esp_pm_lock_acquire/release` are called while this function is running, inconsistent results may be reported.

Parameters **stream** – stream to print information to; use stdout or stderr to print to the console; use `fmemopen/open_memstream` to print to a string buffer.

Returns

- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if `CONFIG_PM_ENABLE` is not enabled in `sdkconfig`

### Structures

```c
struct esp_pm_config_t
```

Power management config.

Pass a pointer to this structure as an argument to `esp_pm_configure` function.

### Public Members

```c
int max_freq_mhz
```

Maximum CPU frequency, in MHz

```c
int min_freq_mhz
```

Minimum CPU frequency to use when no locks are taken, in MHz

```c
bool light_sleep_enable
```

Enter light sleep when no locks are taken

### Type Definitions

```c
typedef esp_pm_config_t esp_pm_config_esp32_t
```

backward compatibility newer chips no longer require this typedef

```c
typedef esp_pm_config_t esp_pm_config_esp32s2_t
```

```c
typedef esp_pm_config_t esp_pm_config_esp32s3_t
```

```c
typedef esp_pm_config_t esp_pm_config_esp32c3_t
```

```c
typedef esp_pm_config_t esp_pm_config_esp32c2_t
```

```c
typedef esp_pm_config_t esp_pm_config_esp32c6_t
```
typedef struct esp_pm_lock *esp_pm_lock_handle_t

Opaque handle to the power management lock.

Enumerations

enum esp_pm_lock_type_t

Power management constraints.

Values:

generic

enumerator ESP_PM_CPU_FREQ_MAX

Require CPU frequency to be at the maximum value set via esp_pm_configure. Argument is unused and should be set to 0.

generic

enumerator ESP_PM_APB_FREQ_MAX

Require APB frequency to be at the maximum value supported by the chip. Argument is unused and should be set to 0.

generic

enumerator ESP_PM_NO_LIGHT_SLEEP

Prevent the system from going into light sleep. Argument is unused and should be set to 0.

2.10.25 POSIX Threads Support

Overview

ESP-IDF is based on FreeRTOS but offers a range of POSIX-compatible APIs that allow easy porting of third party code. This includes support for common parts of the POSIX Threads “pthreads” API.

POSIX Threads are implemented in ESP-IDF as wrappers around equivalent FreeRTOS features. The runtime memory or performance overhead of using the pthreads API is quite low, but not every feature available in either pthreads or FreeRTOS is available via the ESP-IDF pthreads support.

Pthreads can be used in ESP-IDF by including standard <pthread.h> header, which is included in the toolchain libc. An additional ESP-IDF specific header, esp_pthread.h, provides additional non-POSIX APIs for using some ESP-IDF features with pthreads.

C++ Standard Library implementations for std::thread, std::mutex, std::condition_variable, etc. are implemented using pthreads (via GCC libstdc++). Therefore, restrictions mentioned here also apply to the equivalent C++ standard library functionality.

RTOS Integration

Unlike many operating systems using POSIX Threads, ESP-IDF is a real-time operating system with a real-time scheduler. This means that a thread will only stop running if a higher priority task is ready to run, the thread blocks on an OS synchronization structure like a mutex, or the thread calls any of the functions sleep, vTaskDelay(), or usleep.

Note: If calling a standard libc or C++ sleep function, such as usleep defined in unistd.h, then the task will only block and yield the CPU if the sleep time is longer than one FreeRTOS tick period. If the time is shorter, the thread will busy-wait instead of yielding to another RTOS task.

By default, all POSIX Threads have the same RTOS priority, but it is possible to change this by calling a custom API.
Chapter 2. API Reference

Standard features

The following standard APIs are implemented in ESP-IDF.

Refer to standard POSIX Threads documentation, or pthread.h, for details about the standard arguments and behaviour of each function. Differences or limitations compared to the standard APIs are noted below.

Thread APIs

- **pthread_create()** - The `attr` argument is supported for setting stack size and detach state only. Other attribute fields are ignored. Unlike FreeRTOS task functions, the `start_routine` function is allowed to return. A "detached" type thread is automatically deleted if the function returns. The default "joinable" type thread will be suspended until `pthread_join()` is called on it.
  - `pthread_join()`
  - `pthread_detach()`
  - `pthread_exit()`
  - `sched_yield()`
  - `pthread_self()` - An assert will fail if this function is called from a FreeRTOS task which is not a `pthread`.
  - `pthread_equal()`

Thread Attributes

- **pthread_attr_init()**
  - `pthread_attr_destroy()` - This function does not need to free any resources and instead resets the `attr` structure to defaults (implementation is same as `pthread_attr_init()`).
- **`pthread_attr_getstacksize()`** / **`pthread_attr_setstacksize()`**
- **`pthread_attr_getdetachstate()`** / **`pthread_attr_setdetachstate()`**

Once

- `pthread_once()`

Static initializer constant `PTHREAD_ONCE_INIT` is supported.

**Note:** This function can be called from tasks created using either `pthread` or FreeRTOS APIs

Mutexes

POSIX Mutexes are implemented as FreeRTOS Mutex Semaphores (normal type for "fast" or "error check" mutexes, and Recursive type for "recursive" mutexes). This means that they have the same priority inheritance behaviour as mutexes created with `xSemaphoreCreateMutex()`.

- `pthread_mutex_init()`
- `pthread_mutex_destroy()`
- `pthread_mutex_lock()`
- `pthread_mutex_timedlock()`
- `pthread_mutex_unlock()`
- `pthread_mutexattr_init()`
- `pthread_mutexattr_destroy()`
- `pthread_mutexattr_gettype()` / `pthread_mutexattr_settype()`

Static initializer constant `PTHREAD_MUTEX_INITIALIZER` is supported, but the non-standard static initializer constants for other mutex types are not supported.

**Note:** These functions can be called from tasks created using either `pthread` or FreeRTOS APIs
Chapter 2. API Reference

Condition Variables

- `pthread_cond_init()` - The `attr` argument is not implemented and is ignored.
- `pthread_cond_destroy()`
- `pthread_cond_signal()`
- `pthread_cond_broadcast()`
- `pthread_cond_wait()`
- `pthread_cond_timedwait()`

Static initializer constant `PTHREAD_COND_INITIALIZER` is supported.

- The resolution of `pthread_cond_timedwait()` timeouts is the RTOS tick period (see `CONFIG_FREERTOS_HZ`). Timeouts may be delayed up to one tick period after the requested timeout.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs

Semaphores

In IDF, POSIX `unnamed` semaphores are implemented. The accessible API is described below. It implements semaphores as specified in the POSIX standard, unless specified otherwise.

- `sem_init()`
- `sem_destroy()`
- `sem_post()` – `pshared` is ignored. Semaphores can always be shared between FreeRTOS tasks.
- `sem_wait()`
- `sem_trywait()`
- `sem_timedwait()` – The time value passed by abstime will be rounded up to the next FreeRTOS tick. – The actual timeout will happen after the tick the time was rounded to and before the following tick. – It is possible, though unlikely, that the task is preempted directly after the timeout calculation, delaying the timeout of the following blocking operating system call by the duration of the preemption.
- `sem_getvalue()`

Read/Write Locks

- `pthread_rwlock_init()` - The `attr` argument is not implemented and is ignored.
- `pthread_rwlock_destroy()`
- `pthread_rwlock_rdlock()`
- `pthread_rwlock_wrlock()`
- `pthread_rwlock_unlock()`

Static initializer constant `PTHREAD_RWLOCK_INITIALIZER` is supported.

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs

Thread-Specific Data

- `pthread_key_create()` - The `destr_function` argument is supported and will be called if a thread function exits normally, calls `pthread_exit()`, or if the underlying task is deleted directly using the FreeRTOS function `vTaskDelete()`.
- `pthread_key_delete()`
- `pthread_setspecific()` / `pthread_getspecific()`

Note: These functions can be called from tasks created using either pthread or FreeRTOS APIs. When calling these functions from tasks created using FreeRTOS APIs, `CONFIG_FREERTOS_TLSP_DELETION_CALLBACKS` config
option must be enabled to ensure the thread-specific data is cleaned up before the task is deleted.

**Note:** There are other options for thread local storage in ESP-IDF, including options with higher performance. See [Thread Local Storage](#).

### Not Implemented

The `pthread.h` header is a standard header and includes additional APIs and features which are not implemented in ESP-IDF. These include:

- `pthread_cancel()` returns `ENOSYS` if called.
- `pthread_condattr_init()` returns `ENOSYS` if called.

Other POSIX Threads functions (not listed here) are not implemented and will produce either a compiler or a linker error if referenced from an ESP-IDF application. If you identify a useful API that you would like to see implemented in ESP-IDF, please open a feature request on GitHub <https://github.com/espressif/esp-idf/issues> with the details.

### ESP-IDF Extensions

The API `esp_pthread_set_cfg()` defined in the `esp_pthreads.h` header offers custom extensions to control how subsequent calls to `pthread_create()` will behave. Currently, the following configuration can be set:

- Default stack size of new threads, if not specified when calling `pthread_create()` (overrides `CONFIG_PTHREAD_TASK_STACK_SIZE_DEFAULT`).
- RTOS priority of new threads (overrides `CONFIG_PTHREAD_TASK_PRIO_DEFAULT`).
- Core affinity / core pinning of new threads (overrides `CONFIG_PTHREAD_TASK_CORE_DEFAULT`).
- FreeRTOS task name for new threads (overrides `CONFIG_PTHREAD_TASK_NAME_DEFAULT`).

This configuration is scoped to the calling thread (or FreeRTOS task), meaning that `esp_pthread_set_cfg()` can be called independently in different threads or tasks. If the `inherit_cfg` flag is set in the current configuration then any new thread created will inherit the creator’s configuration (if that thread calls `pthread_create()` recursively), otherwise the new thread will have the default configuration.

### Examples

- `system/pthread` demonstrates using the pthreads API to create threads
- `cxx/pthread` demonstrates using C++ Standard Library functions with threads

### API Reference

#### Header File

- `components/pthread/include/esp_pthread.h`

#### Functions

- `esp_pthread_cfg_t esp_pthread_get_default_config(void)`

  Creates a default pthread configuration based on the values set via menuconfig.

  **Returns** A default configuration structure.
**esp_err_t esp_pthread_set_cfg(const esp_pthread_cfg_t *cfg)**

Configure parameters for creating pthread.

This API allows you to configure how the subsequent pthread_create() call will behave. This call can be used to setup configuration parameters like stack size, priority, configuration inheritance etc.

If the ‘inherit’ flag in the configuration structure is enabled, then the same configuration is also inherited in the thread subtree.

**Note:** Passing non-NULL attributes to pthread_create() will override the stack_size parameter set using this API

**Parameters**
- `cfg`: The pthread config parameters

**Returns**
- ESP_OK if configuration was successfully set
- ESP_ERR_NO_MEM if out of memory
- ESP_ERR_INVALID_ARG if stack_size is less than PTHREAD_STACK_MIN

**esp_err_t esp_pthread_get_cfg(esp_pthread_cfg_t *p)**

Get current pthread creation configuration.

This will retrieve the current configuration that will be used for creating threads.

**Parameters**
- `p`: Pointer to the pthread config structure that will be updated with the currently configured parameters

**Returns**
- ESP_OK if the configuration was available
- ESP_ERR_NOT_FOUND if a configuration wasn’t previously set

**esp_err_t esp_pthread_init(void)**

Initialize pthread library.

### Structures

**struct esp_pthread_cfg_t**

pthread configuration structure that influences pthread creation

#### Public Members

- `size_t stack_size`
  
  The stack size of the pthread.

- `size_t prio`
  
  The thread’s priority.

- `bool inherit_cfg`
  
  Inherit this configuration further.

- `const char *thread_name`
  
  The thread name.

- `int pin_to_core`
  
  The core id to pin the thread to. Has the same value range as xCoreId argument of xTaskCreatePinnedToCore.
Chapter 2. API Reference

Macros

PTHREAD_STACK_MIN

2.10.26 Random Number Generation

ESP32 contains a hardware random number generator, values from it can be obtained using the APIs esp_random() and esp_fill_random().

The hardware RNG produces true random numbers under any of the following conditions:

- RF subsystem is enabled (i.e. Wi-Fi or Bluetooth are enabled).
- An internal entropy source has been enabled by calling bootloader_random_enable() and not yet disabled by calling bootloader_random_disable().
- While the ESP-IDF Second stage bootloader is running. This is because the default ESP-IDF bootloader implementation calls bootloader_random_enable() when the bootloader starts, and bootloader_random_disable() before executing the app.

When any of these conditions are true, samples of physical noise are continuously mixed into the internal hardware RNG state to provide entropy. Consult the ESP32 Technical Reference Manual > Random Number Generator (RNG) [PDF] chapter for more details.

If none of the above conditions are true, the output of the RNG should be considered pseudo-random only.

Startup

During startup, ESP-IDF bootloader temporarily enables a non-RF entropy source (internal reference voltage noise) that provides entropy for any first boot key generation. However, after the app starts executing then normally only pseudo-random numbers are available until Wi-Fi or Bluetooth are initialized.

To re-enable the entropy source temporarily during app startup, or for an application that does not use Wi-Fi or Bluetooth, call the function bootloader_random_enable() to re-enable the internal entropy source. The function bootloader_random_disable() must be called to disable the entropy source again before using ADC, I2S, Wi-Fi or Bluetooth.

Note: The entropy source enabled during the boot process by the ESP-IDF Second Stage Bootloader will seed the internal RNG state with some entropy. However, the internal hardware RNG state is not large enough to provide a continuous stream of true random numbers. This is why a continuous entropy source must be enabled whenever true random numbers are required.

Note: If an application requires a source of true random numbers but it is not possible to permanently enable a hardware entropy source, consider using a strong software DRBG implementation such as the mbedTLS CTR-DRBG or HMAC-DRBG, with an initial seed of entropy from hardware RNG true random numbers.

API Reference

Header File

- components/esp_hw_support/include/esp_random.h

Functions
**uint32_t esp_random (void)**

Get one random 32-bit word from hardware RNG.

If Wi-Fi or Bluetooth are enabled, this function returns true random numbers. In other situations, if true
random numbers are required then consult the ESP-IDF Programming Guide “Random Number Generation”
section for necessary prerequisites.

This function automatically busy-waits to ensure enough external entropy has been introduced into the hardware
RNG state, before returning a new random number. This delay is very short (always less than 100 CPU cycles).

**Returns** Random value between 0 and UINT32_MAX

**void esp_fill_random (void *buf, size_t len)**

Fill a buffer with random bytes from hardware RNG.

**Note:** This function is implemented via calls to esp_random(), so the same constraints apply.

**Parameters**

- **buf** – Pointer to buffer to fill with random numbers.
- **len** – Length of buffer in bytes

**Header File**

- components/bootloader_support/include/bootloader_random.h

**Functions**

**void bootloader_random_enable (void)**

Enable an entropy source for RNG if RF subsystem is disabled.

The exact internal entropy source mechanism depends on the chip in use but all SoCs use the SAR ADC
to continuously mix random bits (an internal noise reading) into the HWRNG. Consult the SoC Technical Reference Manual for more information.

Can also be called from app code, if true random numbers are required without initialized RF subsystem. This
might be the case in early startup code of the application when the RF subsystem has not started yet or if the
RF subsystem should not be enabled for power saving.

**Warning:** This function is not safe to use if any other subsystem is accessing the RF subsystem or the
ADC at the same time!

**void bootloader_random_disable (void)**

Disable entropy source for RNG.

Disables internal entropy source. Must be called after bootloader_random_enable() and before RF subsystem
features, ADC, or I2S (ESP32 only) are initialized.

Consult the ESP-IDF Programming Guide “Random Number Generation” section for details.

**void bootloader_fill_random (void *buffer, size_t length)**

Fill buffer with ‘length’ random bytes.

**Note:** If this function is being called from app code only, and never from the bootloader, then it’s better to
call esp_fill_random().
2.10.27 Sleep Modes

Overview

ESP32 contains the following power saving modes: Light-sleep, and Deep-sleep.

In Light-sleep mode, the digital peripherals, most of the RAM, and CPUs are clock-gated and their supply voltage is reduced. Upon exit from Light-sleep, the digital peripherals, RAM, and CPUs resume operation and their internal states are preserved.

In Deep-sleep mode, the CPUs, most of the RAM, and all digital peripherals that are clocked from APB_CLK are powered off. The only parts of the chip that remain powered on are:

- RTC controller
- ULP coprocessor
- RTC fast memory
- RTC slow memory

There are several wakeup sources in Deep-sleep and Light-sleep modes. These sources can also be combined so that the chip will wake up when any of the sources are triggered. Wakeup sources can be enabled using esp_sleep_enable_X_wakeup APIs and can be disabled using esp_sleep_disable_wakeup_source() API. Next section describes these APIs in detail. Wakeup sources can be configured at any moment before entering Light-sleep or Deep-sleep mode.

Additionally, the application can force specific powerdown modes for RTC peripherals and RTC memories using esp_sleep_pd_config() API.

Once wakeup sources are configured, the application can enter sleep mode using esp_light_sleep_start() or esp_deep_sleep_start() APIs. At this point, the hardware will be configured according to the requested wakeup sources, and the RTC controller will either power down or power off the CPUs and digital peripherals.

Wi-Fi/Bluetooth and Sleep Modes

In Deep-sleep and Light-sleep modes, the wireless peripherals are powered down. Before entering Deep-sleep or Light-sleep modes, the application must disable Wi-Fi and Bluetooth using the appropriate calls (i.e., esp_bluedroid_disable(), esp_bt_controller_disable(), esp_wifi_stop()). Wi-Fi and
Bluetooth connections will not be maintained in Deep-sleep or Light-sleep mode, even if these functions are not called.

If Wi-Fi/Bluetooth connections need to be maintained, enable Wi-Fi/Bluetooth Modem-sleep mode and automatic Light-sleep feature (see Power Management APIs). This will allow the system to wake up from sleep automatically when required by the Wi-Fi/Bluetooth driver, thereby maintaining the connection.

Wakeup Sources

**Timer** The RTC controller has a built-in timer which can be used to wake up the chip after a predefined amount of time. Time is specified at microsecond precision, but the actual resolution depends on the clock source selected for RTC SLOW_CLK.

For details on RTC clock options, see ESP32 Technical Reference Manual > ULP Coprocessor [PDF].

RTC peripherals or RTC memories don’t need to be powered on during sleep in this wakeup mode. `esp_sleep_enable_timer_wakeup()` function can be used to enable sleep wakeup using a timer.

**Touchpad** The RTC IO module contains the logic to trigger wakeup when a touch sensor interrupt occurs. To wakeup from a touch sensor interrupt, users need to configure the touch pad interrupt before the chip enters Deep-sleep or Light-sleep modes.

Revisions 0 and 1 of ESP32 only support this wakeup mode when RTC peripherals are not forced to be powered on (i.e., ESP_PD_DOMAIN_RTC_PERIPH should be set to ESP_PD_OPTION_AUTO).

`esp_sleep_enable_touchpad_wakeup()` function can be used to enable this wakeup source.

**External Wakeup (ext0)** The RTC IO module contains the logic to trigger wakeup when one of RTC GPIOs is set to a predefined logic level. RTC IO is part of the RTC peripherals power domain, so RTC peripherals will be kept powered on during Deep-sleep if this wakeup source is requested.

The RTC IO module is enabled in this mode, so internal pullup or pulldown resistors can also be used. They need to be configured by the application using `rtc_gpio_pullup_en()` and `rtc_gpio_pulldown_en()` functions before calling `esp_deep_sleep_start()`.

In revisions 0 and 1 of ESP32, this wakeup source is incompatible with ULP and touch wakeup sources. `esp_sleep_enable_ext0_wakeup()` function can be used to enable this wakeup source.

**Warning:** After waking up from sleep, the IO pad used for wakeup will be configured as RTC IO. Therefore, before using this pad as digital GPIO, users need to reconfigure it using `rtc_gpio_deinit()` function.

**External Wakeup (ext1)** The RTC controller contains the logic to trigger wakeup using multiple RTC GPIOs. One of the following two logic functions can be used to trigger wakeup:

- wake up if any of the selected pins is high (ESP_EXT1_WAKEUP_ANY_HIGH)
- wake up if all the selected pins are low (ESP_EXT1_WAKEUP_ALL_LOW)

This wakeup source is implemented by the RTC controller. As such, RTC peripherals and RTC memories can be powered down in this mode. However, if RTC peripherals are powered down, internal pullup and pulldown resistors will be disabled. To use internal pullup or pulldown resistors, request the RTC peripherals power domain to be kept on during sleep, and configure pullup/pulldown resistors using `rtc_gpio_` functions before entering sleep:

```c
esp_sleep_pd_config(ESP_PD_DOMAIN_RTC_PERIPH, ESP_PD_OPTION_ON);
rtc_gpio_pullup_dis(gpio_num);
rtc_gpio_pulldown_en(gpio_num);
```
Warning:

- To use the EXT1 wakeup, the IO pad(s) are configured as RTC IO. Therefore, before using these pads as
digital GPIOs, users need to reconfigure them by calling the `rtc_gpio_deinit()` function.
- If the RTC peripherals are configured to be powered down (which is by default), the wakeup IOs will be
set to the holding state before entering sleep. Therefore, after the chip wakes up from Light-sleep, please
call `rtc_gpio_hold_dis` to disable the hold function to perform any pin re-configuration. For Deep-sleep
wakeup, this is already being handled at the application startup stage.

`esp_sleep_enable_ext1_wakeup()` function can be used to enable this wakeup source.

**ULP Coprocessor Wakeup**    ULP coprocessor can run while the chip is in sleep mode, and may be used to poll
sensors, monitor ADC or touch sensor values, and wake up the chip when a specific event is detected. ULP copro-
cessor is part of the RTC peripherals power domain, and it runs the program stored in RTC slow memory. RTC slow
memory will be powered on during sleep if this wakeup mode is requested. RTC peripherals will be automatically
powered on before ULP coprocessor starts running the program; once the program stops running, RTC peripherals
are automatically powered down again.

Revisions 0 and 1 of ESP32 only support this wakeup mode when RTC peripherals are not forced to be powered on
(i.e., `ESP_PD_DOMAIN_RTC_PERIPH` should be set to `ESP_PD_OPTION_AUTO`).

`esp_sleep_enable_ulp_wakeup()` function can be used to enable this wakeup source.

**GPIO Wakeup (Light-sleep Only)** In addition to EXT0 and EXT1 wakeup sources described above, one more
method of wakeup from external inputs is available in Light-sleep mode. With this wakeup source, each pin can be
individually configured to trigger wakeup on high or low level using `gpio_wakeup_enable()` function. Unlike
EXT0 and EXT1 wakeup sources, which can only be used with RTC IOs, this wakeup source can be used with any
IO (RTC or digital).

`esp_sleep_enable_gpio_wakeup()` function can be used to enable this wakeup source.

```
Warning:    Before entering Light-sleep mode, check if any GPIO pin to be driven is part of the VDD_SDIO
power domain. If so, this power domain must be configured to remain ON during sleep.

For example, on ESP32-WROOM-32 board, GPIO16 and GPIO17 are linked to VDD_SDIO power domain. If
they are configured to remain high during Light-sleep, the power domain should be configured to remain powered
ON. This can be done with `esp_sleep_pd_config()`:

```esp_sleep_pd_config(ESP_PD_DOMAIN_VDDSDIO, ESP_PD_OPTION_ON);```

**UART Wakeup (Light-sleep Only)** When ESP32 receives UART input from external devices, it is often necessary
to wake up the chip when input data is available. The UART peripheral contains a feature which allows waking up
the chip from Light-sleep when a certain number of positive edges on RX pin are seen. This number of positive edges
can be set using `uart_set_wakeup_threshold()` function. Note that the character which triggers wakeup
(and any characters before it) will not be received by the UART after wakeup. This means that the external device
typically needs to send an extra character to the ESP32 to trigger wakeup before sending the data.

`esp_sleep_enable_uart_wakeup()` function can be used to enable this wakeup source.

**Power-down of RTC Peripherals and Memories**

By default, `esp_deep_sleep_start()` and `esp_light_sleep_start()` functions will power down all RTC power domains which are not needed by the enabled wakeup sources. To override this behaviour,
`esp_sleep_pd_config()` function is provided.
Note: in revision 0 of ESP32, RTC fast memory will always be kept enabled in Deep-sleep, so that the Deep-sleep stub can run after reset. This can be overridden, if the application doesn’t need clean reset behaviour after Deep-sleep.

If some variables in the program are placed into RTC slow memory (for example, using `RTC_DATA_ATTR` attribute), RTC slow memory will be kept powered on by default. This can be overridden using `esp_sleep_pd_config()` function, if desired.

### Power-down of Flash

By default, to avoid potential issues, `esp_light_sleep_start()` function will not power down flash. To be more specific, it takes time to power down the flash and during this period the system may be woken up, which then actually powers up the flash before this flash could be powered down completely. As a result, there is a chance that the flash may not work properly.

So, in theory, it’s ok if you only wake up the system after the flash is completely powered down. However, in reality, the flash power-down period can be hard to predict (for example, this period can be much longer when you add filter capacitors to the flash’s power supply circuit) and uncontrollable (for example, the asynchronous wake-up signals make the actual sleep time uncontrollable).

**Warning:** If a filter capacitor is added to your flash power supply circuit, please do everything possible to avoid powering down flash.

Therefore, it’s recommended not to power down flash when using ESP-IDF. For power-sensitive applications, it’s recommended to use Kconfig option `CONFIG_ESP_SLEEP_FLASH_LEAKAGE_WORKAROUND` to reduce the power consumption of the flash during light sleep, instead of powering down the flash.

It is worth mentioning that PSRAM has a similar Kconfig option `CONFIG_ESP_SLEEP_PSRAM_LEAKAGE_WORKAROUND`.

However, for those who have fully understood the risk and are still willing to power down the flash to further reduce the power consumption, please check the following mechanisms:

- Setting Kconfig option `CONFIG_ESP_SLEEP_POWER_DOWN_FLASH` only powers down the flash when the RTC timer is the only wake-up source and the sleep time is longer than the flash power-down period.
- Calling `esp_sleep_pd_config(ESP_PD_DOMAIN_VDDSDIO, ESP_PD_OPTION_OFF)` powers down flash when the RTC timer is not enabled as a wakeup source or the sleep time is longer than the flash power-down period.

**Note:**

- ESP-IDF does not provide any mechanism that can power down the flash in all conditions when light sleep.
- `esp_deep_sleep_start()` function will force power down flash regardless of user configuration.

### Entering Light-sleep

`esp_light_sleep_start()` function can be used to enter Light-sleep once wakeup sources are configured. It is also possible to enter Light-sleep with no wakeup sources configured. In this case, the chip will be in Light-sleep mode indefinitely until external reset is applied.

### Entering Deep-sleep

`esp_deep_sleep_start()` function can be used to enter Deep-sleep once wakeup sources are configured. It is also possible to enter Deep-sleep with no wakeup sources configured. In this case, the chip will be in Deep-sleep mode indefinitely until external reset is applied.
Chapter 2. API Reference

**Configuring IOs**

Some ESP32 IOs have internal pullups or pulldowns, which are enabled by default. If an external circuit drives this pin in Deep-sleep mode, current consumption may increase due to current flowing through these pullups and pulldowns. To isolate a pin to prevent extra current draw, call `rtc_gpio_isolate()` function.

For example, on ESP32-WROVER module, GPIO12 is pulled up externally, and it also has an internal pulldown in the ESP32 chip. This means that in Deep-sleep, some current will flow through these external and internal resistors, increasing Deep-sleep current above the minimal possible value.

Add the following code before `esp_deep_sleep_start()` to remove such extra current:

```c
rtc_gpio_isolate(GPIO_NUM_12);
```

**UART Output Handling**

Before entering sleep mode, `esp_deep_sleep_start()` will flush the contents of UART FIFOs. When entering Light-sleep mode using `esp_light_sleep_start()`, UART FIFOs will not be flushed. Instead, UART output will be suspended, and remaining characters in the FIFO will be sent out after wakeup from Light-sleep.

**Checking Sleep Wakeup Cause**

`esp_sleep_get_wakeup_cause()` function can be used to check which wakeup source has triggered wakeup from sleep mode.

For touchpad, it is possible to identify which touch pin has caused wakeup using `esp_sleep_get_touchpad_wakeup_status()` functions.

For ext1 wakeup sources, it is possible to identify which touch pin has caused wakeup using `esp_sleep_get_ext1_wakeup_status()` functions.

**Disable Sleep Wakeup Source**

Previously configured wakeup sources can be disabled later using `esp_sleep_disable_wakeup_source()` API. This function deactivates trigger for the given wakeup source. Additionally, it can disable all triggers if the argument is `ESP_SLEEP_WAKEUP_ALL`.

**Application Example**

- `protocols/sntp`: the implementation of basic functionality of Deep-sleep, where ESP module is periodically waken up to retrieve time from NTP server.
- `wifi/power_save`: the implementation of Wi-Fi Modem-sleep example.
- `bluetooth/nimble/power_save`: the implementation of Bluetooth Modem-sleep example.
- `system/deep_sleep`: the usage of various Deep-sleep wakeup triggers and ULP coprocessor programming.

**API Reference**

**Header File**

- `components/esp_hw_support/include/esp_sleep.h`
Chapter 2. API Reference

Functions

`esp_err_t esp_sleep_disable_wakeup_source(esp_sleep_source_t source)`

Disable wakeup source.

This function is used to deactivate wake up trigger for source defined as parameter of the function.

See docs/sleep-modes.rst for details.

**Note:** This function does not modify wake up configuration in RTC. It will be performed in esp_deep_sleep_start/esp_light_sleep_start function.

**Parameters**

- `source` -- number of source to disable of type esp_sleep_source_t

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_STATE if trigger was not active

`esp_err_t esp_sleep_enable_ulp_wakeup(void)`

Enable wakeup by ULP coprocessor.

**Note:** On ESP32, ULP wakeup source cannot be used when RTC_PERIPH power domain is forced, to be powered on (ESP_PD_OPTION_ON) or when ext0 wakeup source is used.

**Returns**

- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if additional current by touch (CONF_RTC_EXT_CRYST_ADDIT_CURRENT) is enabled.
- ESP_ERR_INVALID_STATE if ULP co-processor is not enabled or if wakeup triggers conflict

`esp_err_t esp_sleep_enable_timer_wakeup(uint64_t time_in_us)`

Enable wakeup by timer.

**Parameters**

- `time_in_us` -- time before wakeup, in microseconds

**Returns**

- ESP_OK on success
- ESP_ERR_INVALID_ARG if value is out of range (TBD)

`esp_err_t esp_sleep_enable_touchpad_wakeup(void)`

Enable wakeup by touch sensor.

**Note:** On ESP32, touch wakeup source can not be used when RTC_PERIPH power domain is forced to be powered on (ESP_PD_OPTION_ON) or when ext0 wakeup source is used.

**Note:** The FSM mode of the touch button should be configured as the timer trigger mode.

**Returns**

- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if additional current by touch (CONF_RTC_EXT_CRYST_ADDIT_CURRENT) is enabled.
- ESP_ERR_INVALID_STATE if wakeup triggers conflict
**Chapter 2. API Reference**

*touch_pad_t* `esp_sleep_get_touchpad_wakeup_status(void)`

Get the touch pad which caused wakeup.

If wakeup was caused by another source, this function will return TOUCH_PAD_MAX;

**Returns** touch pad which caused wakeup

*bool* `esp_sleep_is_valid_wakeup_gpio(gpio_num_t gpio_num)`

Returns true if a GPIO number is valid for use as wakeup source.

**Note:** For SoCs with RTC IO capability, this can be any valid RTC IO input pin.

**Parameters** `gpio_num` – Number of the GPIO to test for wakeup source capability  
**Returns** True if this GPIO number will be accepted as a sleep wakeup source.

*esp_err_t* `esp_sleep_enable_ext0_wakeup(gpio_num_t gpio_num, int level)`

Enable wakeup using a pin.

This function uses external wakeup feature of RTC_IO peripheral. It will work only if RTC peripherals are kept on during sleep.

This feature can monitor any pin which is an RTC IO. Once the pin transitions into the state given by level argument, the chip will be woken up.

**Note:** This function does not modify pin configuration. The pin is configured in esp_deep_sleep_start/esp_light_sleep_start, immediately before entering sleep mode.

**Note:** ESP32: ext0 wakeup source can not be used together with touch or ULP wakeup sources.

**Parameters**

- `gpio_num` – GPIO number used as wakeup source. Only GPIOs with the RTC functionality can be used. For different SoCs, the related GPIOs are:
  - ESP32: 0, 2, 4, 12-15, 25-27, 32-39;  
  - ESP32-S2: 0-21;  
  - ESP32-S3: 0-21.  
- `level` – input level which will trigger wakeup (0=low, 1=high)

**Returns**

- ESP_OK on success  
- ESP_ERR_INVALID_ARG if the selected GPIO is not an RTC GPIO, or the mode is invalid  
- ESP_ERR_INVALID_STATE if wakeup triggers conflict

*esp_err_t* `esp_sleep_enable_ext1_wakeup(uint64_t mask, esp_sleep_ext1_wakeup_mode_t mode)`

Enable wakeup using multiple pins.

This function uses external wakeup feature of RTC controller. It will work even if RTC peripherals are shut down during sleep.

This feature can monitor any number of pins which are in RTC IOs. Once any of the selected pins goes into the state given by mode argument, the chip will be woken up.

**Note:** This function does not modify pin configuration. The pins are configured in esp_deep_sleep_start/esp_light_sleep_start, immediately before entering sleep mode.
### Parameters
- **mask** - bit mask of GPIO numbers which will cause wakeup. Only GPIOs which have RTC functionality can be used in this bitmap. For different SoCs, the related GPIOs are:
  - ESP32: 0, 2, 4, 12-15, 25-27, 32-39;
  - ESP32-S2: 0-21;
  - ESP32-S3: 0-21.
- **mode** - select logic function used to determine wakeup condition:
  - ESP_EXT1_WAKEUP_ALL_LOW: wake up when all selected GPIOs are low
  - ESP_EXT1_WAKEUP_ANY_HIGH: wake up when any of the selected GPIOs is high

### Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if any of the selected GPIOs is not an RTC GPIO, or mode is invalid

```c
esp_err_t esp_sleep_enable_gpio_wakeup(void)
```

Enable wakeup from light sleep using GPIOs.

Each GPIO supports wakeup function, which can be triggered on either low level or high level. Unlike EXT0 and EXT1 wakeup sources, this method can be used both for all IOs: RTC IOs and digital IOs. It can only be used to wakeup from light sleep though.

To enable wakeup, first call gpio_wakeup_enable, specifying gpio number and wakeup level, for each GPIO which is used for wakeup. Then call this function to enable wakeup feature.

**Note:** On ESP32, GPIO wakeup source cannot be used together with touch or ULP wakeup sources.

### Returns
- ESP_OK on success
- ESP_ERR_INVALID_STATE if wakeup triggers conflict

```c
esp_err_t esp_sleep_enable_uart_wakeup(int uart_num)
```

Enable wakeup from light sleep using UART.

Use uart_set_wakeup_threshold function to configure UART wakeup threshold.

Wakeup from light sleep takes some time, so not every character sent to the UART can be received by the application.

**Note:** ESP32 does not support wakeup from UART2.

### Parameters
- **uart_num** - UART port to wake up from

### Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if wakeup from given UART is not supported

```c
esp_err_t esp_sleep_enable_bt_wakeup(void)
```

Enable wakeup by bluetooth.

### Returns
- ESP_OK on success
Chapter 2. API Reference

- ESP_ERR_NOT_SUPPORTED if wakeup from bluetooth is not supported

```c
esp_err_t esp_sleep_disable_bt_wakeup (void)
```
Disable wakeup by bluetooth.

**Returns**
- ESP_OK on success
- ESP_ERR_NOT_SUPPORTED if wakeup from bluetooth is not supported

```c
esp_err_t esp_sleep_enable_wifi_wakeup (void)
```
Enable wakeup by WiFi MAC.

**Returns**
- ESP_OK on success

```c
esp_err_t esp_sleep_disable_wifi_wakeup (void)
```
Disable wakeup by WiFi MAC.

**Returns**
- ESP_OK on success

```c
esp_err_t esp_sleep_enable_wifi_beacon_wakeup (void)
```
Enable beacon wakeup by WiFi MAC, it will wake up the system into modem state.

**Returns**
- ESP_OK on success

```c
esp_err_t esp_sleep_disable_wifi_beacon_wakeup (void)
```
Disable beacon wakeup by WiFi MAC.

**Returns**
- ESP_OK on success

```c
uint64_t esp_sleep_get_ext1_wakeup_status (void)
```
Get the bit mask of GPIOs which caused wakeup (ext1)

If wakeup was caused by another source, this function will return 0.

**Returns**
- Bit mask, if GPIOn caused wakeup, BIT(n) will be set

```c
esp_err_t esp_sleep_pd_config (esp_sleep_pd_domain_t domain, esp_sleep_pd_option_t option)
```
Set power down mode for an RTC power domain in sleep mode.

If not set using this API, all power domains default to ESP_PD_OPTION_AUTO.

**Parameters**
- `domain` - power domain to configure
- `option` - power down option (ESP_PD_OPTION_OFF, ESP_PD_OPTION_ON, or ESP_PD_OPTION_AUTO)

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if either of the arguments is out of range

```c
void esp_deep_sleep_start (void)
```
Enter deep sleep with the configured wakeup options.

This function does not return.

```c
esp_err_t esp_light_sleep_start (void)
```
Enter light sleep with the configured wakeup options.

**Returns**
- ESP_OK on success (returned after wakeup)
- ESP_ERR_SLEEP_REJECT sleep request is rejected(wakeup source set before the sleep request)
Chapter 2. API Reference

- ESP_ERR_SLEEP_TOO_SHORT_SLEEP_DURATION after deducting the sleep flow overhead, the final sleep duration is too short to cover the minimum sleep duration of the chip, when rtc timer wakeup source enabled

```c
void esp_deep_sleep (uint64_t time_in_us)
```

Enter deep-sleep mode.

The device will automatically wake up after the deep-sleep time. Upon waking up, the device calls deep sleep wake stub, and then proceeds to load application.

Call to this function is equivalent to a call to esp_deep_sleep_enable_timer_wakeup followed by a call to esp_deep_sleep_start.

**Parameters**

- `time_in_us` - deep-sleep time, unit: microsecond

```c
esp_err_t esp_deep_sleep_register_hook (esp_deep_sleep_cb_t new_dslp_cb)
```

Register a callback to be called from the deep sleep prepare.

**Warning:** deepsleep callbacks should without parameters, and MUST NOT, UNDER ANY CIRCUMSTANCES, CALL A FUNCTION THAT MIGHT BLOCK.

- **Parameters**
  - `new_dslp_cb` - Callback to be called

- **Returns**
  - ESP_OK: Callback registered to the deepsleep misc_modules_sleep_prepare
  - ESP_ERR_NO_MEM: No more hook space for register the callback

```c
void esp_deep_sleep_deregister_hook (esp_deep_sleep_cb_t old_dslp_cb)
```

Unregister an deepsleep callback.

**Parameters**

- `old_dslp_cb` - Callback to be unregistered

```c
esp_sleep_wakeup_cause_t esp_sleep_get_wakeup_cause ()
```

Get the wakeup source which caused wakeup from sleep.

**Returns**

cause of wake up from last sleep (deep sleep or light sleep)

```c
void esp_wake_deep_sleep ()
```

Default stub to run on wake from deep sleep.

- Allows for executing code immediately on wake from sleep, before the software bootloader or ESP-IDF app has started up.

This function is weak-linked, so you can implement your own version to run code immediately when the chip wakes from sleep.

See docs/deep-sleep-stub.rst for details.

```c
void esp_set_deep_sleep_wake_stub (esp_deep_sleep_wake_stub_fn_t new_stub)
```

Install a new stub at runtime to run on wake from deep sleep.

- If implementing esp_wake_deep_sleep() then it is not necessary to call this function.

However, it is possible to call this function to substitute a different deep sleep stub. Any function used as a deep sleep stub must be marked RTC_IRAM_ATTR, and must obey the same rules given for esp_wake_deep_sleep().

```c
void esp_set_deep_sleep_wake_stub_default_entry (void)
```

Set wake stub entry to default esp_wake_stub_entry

```c
esp_deep_sleep_wake_stub_fn_t esp_get_deep_sleep_wake_stub ()
```

Get current wake from deep sleep stub.

**Returns**

Return current wake from deep sleep stub, or NULL if no stub is installed.
void esp_default_wake_deep_sleep (void)
   The default esp-idf-provided esp_wake_deep_sleep() stub.
   See docs/deep-sleep-stub.rst for details.
void esp_deep_sleep_disable_rom_logging (void)
   Disable logging from the ROM code after deep sleep.
   Using LSB of RTC_STORE4.
void esp_sleep_config_gpio_isolate (void)
   Configure to isolate all GPIO pins in sleep state.
void esp_sleep_enable_gpio_switch (bool enable)
   Enable or disable GPIO pins status switching between slept status and waked status.

   Parameters enable – decide whether to switch status or not

Macros

ESP_PD_DOMAIN_RTC8M

Type Definitions

typedef void (*esp_deep_sleep_cb_t)(void)
typedef esp_sleep_source_t esp_sleep_wakeup_cause_t

typedef void (*esp_deep_sleep_wake_stub_fn_t)(void)
   Function type for stub to run on wake from sleep.

Enumerations

enum esp_sleep_ext1_wakeup_mode_t
   Logic function used for EXT1 wakeup mode.
   Values:

   enumerator ESP_EXT1_WAKEUP_ALL_LOW
      Wake the chip when all selected GPIOs go low.

   enumerator ESP_EXT1_WAKEUP_ANY_HIGH
      Wake the chip when any of the selected GPIOs go high.

enum esp_sleep_pd_domain_t
   Power domains which can be powered down in sleep mode.
   Values:

   enumerator ESP_PD_DOMAIN_RTC_PERIPH
      RTC IO, sensors and ULP co-processor.

   enumerator ESP_PD_DOMAIN_RTC_SLOW_MEM
      RTC slow memory.
Chapter 2. API Reference

enumerator `ESP_PD_DOMAIN_RTC_FAST_MEM`  
RTC fast memory.

enumerator `ESP_PD_DOMAIN_XTAL`  
XTAL oscillator.

enumerator `ESP_PD_DOMAIN_RC_FAST`  
Internal Fast oscillator.

enumerator `ESP_PD_DOMAIN_VDDSDIO`  
VDD_SDIO.

enumerator `ESP_PD_DOMAIN_MODEM`  
MODEM, includes WiFi, Bluetooth and IEEE802.15.4.

enumerator `ESP_PD_DOMAIN_MAX`  
Number of domains.

enum `esp_sleep_pd_option_t`  
Power down options.

Values:

enumerator `ESP_PD_OPTION_OFF`  
Power down the power domain in sleep mode.

enumerator `ESP_PD_OPTION_ON`  
Keep power domain enabled during sleep mode.

enumerator `ESP_PD_OPTION_AUTO`  
Keep power domain enabled in sleep mode, if it is needed by one of the wakeup options. Otherwise power it down.

enum `esp_sleep_source_t`  
Sleep wakeup cause.

Values:

enumerator `ESP_SLEEP_WAKEUP_UNDEFINED`  
In case of deep sleep, reset was not caused by exit from deep sleep.

enumerator `ESP_SLEEP_WAKEUP_ALL`  
Not a wakeup cause, used to disable all wakeup sources with esp_sleep_disable_wakeup_source.

enumerator `ESP_SLEEP_WAKEUP_EXT0`  
Wakeup caused by external signal using RTC_IO.

enumerator `ESP_SLEEP_WAKEUP_EXT1`  
Wakeup caused by external signal using RTC_CNTL.
enumerator ESP_SLEEP_WAKEUP_TIMER
  Wakeup caused by timer.

enumerator ESP_SLEEP_WAKEUP_TOUCHPAD
  Wakeup caused by touchpad.

enumerator ESP_SLEEP_WAKEUP_ULP
  Wakeup caused by ULP program.

enumerator ESP_SLEEP_WAKEUP_GPIO
  Wakeup caused by GPIO (light sleep only on ESP32, S2 and S3)

enumerator ESP_SLEEP_WAKEUP_UART
  Wakeup caused by UART (light sleep only)

enumerator ESP_SLEEP_WAKEUP_WIFI
  Wakeup caused by WIFI (light sleep only)

enumerator ESP_SLEEP_WAKEUP_COCPU
  Wakeup caused by COCPU int.

enumerator ESP_SLEEP_WAKEUP_COCPU_TRAP_TRIG
  Wakeup caused by COCPU crash.

enumerator ESP_SLEEP_WAKEUP_BT
  Wakeup caused by BT (light sleep only)

define esp_sleep_mode_t
  Sleep mode.

  Values:

  enumerator ESP_SLEEP_MODE_LIGHT_SLEEP
    light sleep mode

  enumerator ESP_SLEEP_MODE_DEEP_SLEEP
    deep sleep mode

  enum [anonymous]
  Values:

  enumerator ESP_ERR_SLEEP_REJECT

  enumerator ESP_ERR_SLEEP_TOO_SHORT_SLEEP_DURATION

2.10.28  SoC Capabilities

This section lists definitions of the ESP32’s SoC hardware capabilities. These definitions are commonly used in IDF to control which hardware dependent features are supported and thus compiled into the binary.
Chapter 2. API Reference

**Note:** These defines are currently not considered to be part of the public API, and may be changed at any time.

SOC_CLK_RC_FAST_D256_SUPPORTED

SOC_RTC_SLOW_CLK_SUPPORT_RC_FAST_D256

SOC_CLK_RC_FAST_SUPPORT_CALIBRATION

SOC_CLK_XTAL32K_SUPPORTED
  Support to connect an external low frequency crystal

SOC_SDMMC_USE_IOMUX

SOC_SDMMC_NUM_SLOTS

SOC_WIFI_WAPI_SUPPORT
  Support WAPI

SOC_WIFI_CSI_SUPPORT
  Support CSI
SOC_WIFI_MESH_SUPPORT
Support WIFI MESH

SOC_WIFI_SUPPORT_VARIABLE_BEACON_WINDOW
Support delta early time for rf phy on/off

SOC_WIFI_NAN_SUPPORT
Support WIFI Aware (NAN)

SOC_BLE_SUPPORTED
Support Bluetooth Low Energy hardware

SOC_BLE_MESH_SUPPORTED
Support BLE MESH

SOC_BT_CLASSIC_SUPPORTED
Support Bluetooth Classic hardware

SOC_BLE_DEVICE_PRIVACY_SUPPORTED
Support BLE device privacy mode

SOC_BLUFI_SUPPORTED
Support BLUFI

SOC_ULP_HAS_ADC

2.10.29 System Time

Overview

ESP32 uses two hardware timers for the purpose of keeping system time. System time can be kept by using either one or both of the hardware timers depending on the application’s purpose and accuracy requirements for system time. The two hardware timers are:

- **RTC timer**: This timer allows time keeping in various sleep modes, and can also persist time keeping across any resets (with the exception of power-on resets which reset the RTC timer). The frequency deviation depends on the RTC Timer Clock Sources and affects the accuracy only in sleep modes, in which case the time will be measured at 6.6667 μs resolution.

- **High-resolution timer**: This timer is not available in sleep modes and will not persist over a reset, but has greater accuracy. The timer uses the APB_CLK clock source (typically 80 MHz), which has a frequency deviation of less than ±10 ppm. Time will be measured at 1 μs resolution.

The possible combinations of hardware timers used to keep system time are listed below:

- RTC and high-resolution timer (default)
- RTC
- High-resolution timer
- None

It is recommended that users stick to the default option as it provides the highest accuracy. However, users can also select a different setting via the `CONFIG_NEWLIB_TIME_SYSCALL` configuration option.
RTC Timer Clock Sources

The RTC timer has the following clock sources:

- **Internal 150 kHz RC oscillator (default):** Features the lowest Deep-sleep current consumption and no dependence on any external components. However, the frequency stability of this clock source is affected by temperature fluctuations, so time may drift in both Deep-sleep and Light-sleep modes.
- **External 32 kHz crystal:** Requires a 32 kHz crystal to be connected to the 32K_XP and 32K_XN pins. This source provides a better frequency stability at the expense of a slightly higher (by 1 µA) Deep-sleep current consumption.
- **External 32 kHz oscillator at 32K_XN pin:** Allows using 32 kHz clock generated by an external circuit. The external clock signal must be connected to the 32K_XN pin. The amplitude should be less than 1.2 V for sine wave signal and less than 1 V for square wave signal. Common mode voltage should be in the range of 0.1 < Vcm < 0.5xVamp, where Vamp stands for signal amplitude. In this case, the 32K_XN pin cannot be used as a GPIO pin.
- **Internal 8.5 MHz oscillator, divided by 256 (~33 kHz):** Provides better frequency stability than the Internal 150 kHz RC oscillator at the expense of a higher (by 5 µA) Deep-sleep current consumption. It also does not require external components.

The choice depends on your requirements for system time accuracy and power consumption in sleep modes. To modify the RTC clock source, set `CONFIG_RTC_CLK_SRC` in project configuration.

More details about the wiring requirements for the external crystal or external oscillator, please refer to [ESP32 Hardware Design Guidelines](#).

**Get Current Time**

To get the current time, use the POSIX function `gettimeofday()`. Additionally, you can use the following standard C library functions to obtain time and manipulate it:

```c
#include <time.h>

struct tm *timeinfo;

time(&timeinfo);
```

To stop smooth time adjustment and update the current time immediately, use the POSIX function `settimeofday()`.

If you need to obtain time with one second resolution, use the following code snippet:

```c
#include <time.h>

time_t now;
char strftime_buf[64];

// Set timezone to China Standard Time
setenv("TZ", "CST-8", 1);
tzset();

localtime_r(&now, &timeinfo);
strftime(strftime_buf, sizeof(strftime_buf), "%c", &timeinfo);
ESP_LOGI(TAG, "The current date/time in Shanghai is: \%s", strftime_buf);
```
If you need to obtain time with one microsecond resolution, use the code snippet below:

```c
struct timeval tv_now;
gettimeofday(&tv_now, NULL);
int64_t time_us = (int64_t)tv_now.tv_sec * 1000000L + (int64_t)tv_now.tv_usec;
```

### SNTP Time Synchronization

To set the current time, you can use the POSIX functions `settimeofday()` and `adjtime()`. They are used internally in the lwIP SNTP library to set current time when a response from the NTP server is received. These functions can also be used separately from the lwIP SNTP library.

Some lwIP APIs, including SNTP functions, are not thread safe, so it is recommended to use `esp_netif component` when interacting with SNTP module.

To initialize a particular SNTP server and also start the SNTP service, simply create a default SNTP server configuration with a particular server name, then call `esp_netif_sntp_init()` to register that server and start the SNTP service.

```c
esp_sntp_config_t config = ESP_NETIF_SNTP_DEFAULT_CONFIG("pool.ntp.org");
esp_netif_sntp_init(&config);
```

This code automatically performs time synchronization once a reply from the SNTP server is received. Sometimes it is useful to wait until the time gets synchronized, `esp_netif_sntp_sync_wait()` can be used for this purpose:

```c
if (esp_netif_sntp_sync_wait(pdMS_TO_TICKS(10000)) != ESP_OK) {
    printf("Failed to update system time within 10s timeout\n");
}
```

To configure multiple NTP servers (or use more advanced settings, such as DHCP provided NTP servers), please refer to the detailed description of `SNTP API` in `esp_netif` documentation.

The lwIP SNTP library could work in one of the following sync modes:

- **SNTP_SYNC_MODE_IMMED** (default): Updates system time immediately upon receiving a response from the SNTP server after using `settimeofday()`.
- **SNTP_SYNC_MODE_SMOOTH**: Updates time smoothly by gradually reducing time error using the function `adjtime()`. If the difference between the SNTP response time and system time is more than 35 minutes, update system time immediately by using `settimeofday()`.

If you want to choose the `SNTP_SYNC_MODE_SMOOTH` mode, please set the `esp_sntp_config::smooth` to `true` in the SNTP configuration struct. Otherwise (and by default) the `SNTP_SYNC_MODE_IMMED` mode will be used.

For setting a callback function that is called when time gets synchronized, use the `esp_sntp_config::sync_cb` field in the configuration struct.

An application with this initialization code will periodically synchronize the time. The time synchronization period is determined by `CONFIG_LWIP_SNTP_UPDATE_DELAY` (the default value is one hour). To modify the variable, set `CONFIG_LWIP_SNTP_UPDATE_DELAY` in project configuration.

A code example that demonstrates the implementation of time synchronization based on the lwIP SNTP library is provided in the `protocols/sntp` directory.

Note that it’s also possible to use lwIP API directly, but care must be taken to thread safety. Here we list the thread-safe APIs:

- `sntp_set_time_sync_notification_cb()` can be used to set a callback function that will notify of the time synchronization process.
- `sntp_get_sync_status()` and `sntp_set_sync_status()` can be used to get/set time synchronization status.
- `sntp_set_sync_mode()` can be used to set the synchronization mode.
• `esp_sntp_setoperatingmode()` sets the preferred operating mode.:
  ```cpp
cpp
  enumerator: ESP_SNTP_OPMODE_POLL
  ```
  and `esp_sntp_init()` initializes SNTP module.
• `esp_sntp_setservername()` configures one SNTP server.

Timezones

To set the local timezone, use the following POSIX functions:

1. Call `setenv()` to set the `TZ` environment variable to the correct value based on the device location. The format of the time string is the same as described in the GNU libc documentation (although the implementation is different).
2. Call `tzset()` to update C library runtime data for the new timezone.

Once these steps are completed, call the standard C library function `localtime()`, and it will return the correct local time taking into account the timezone offset and daylight saving time.

Year 2036 and 2038 Overflow Issues

SNTP/NTP 2036 Overflow  SNTP/NTP timestamps are represented as 64-bit unsigned fixed point numbers, where the first 32 bits represent the integer part, and the last 32 bits represent the fractional part. The 64-bit unsigned fixed point number represents the number of seconds since 00:00 on 1st of January 1900, thus SNTP/NTP times will overflow in the year 2036.

To address this issue, lifetime of the SNTP/NTP timestamps has been extended by convention by using the MSB (bit 0 by convention) of the integer part to indicate time ranges between years 1968 to 2104 (see RFC2030 for more details). This convention is implemented in lwIP library SNTP module. Therefore SNTP-related functions in ESP-IDF are future-proof until year 2104.

Unix Time 2038 Overflow  Unix time (type `time_t`) was previously represented as a 32-bit signed integer, leading to an overflow in year 2038 (i.e., Y2K38 issue). To address the Y2K38 issue, ESP-IDF uses a 64-bit signed integer to represent `time_t` starting from release v5.0, thus deferring time_t overflow for another 292 billion years.

API Reference

Header File

```
• components/lwip/include/apps/esp_sntp.h
```

Functions

```c

void sntp_sync_time (struct timeval *tv)
```

This function updates the system time.

This is a weak-linked function. It is possible to replace all SNTP update functionality by placing a `sntp_sync_time()` function in the app firmware source. If the default implementation is used, calling `sntp_set_sync_mode()` allows the time synchronization mode to be changed to instant or smooth. If a callback function is registered via `sntp_set_time_sync_notification_cb()`, it will be called following time synchronization.

**Parameters**

`tv` – Time received from SNTP server.

```c

void sntp_set_sync_mode (sntp_sync_mode_t sync_mode)
```

Set the sync mode.

Modes allowed: `SNTP_SYNC_MODE_IMMED` and `SNTP_SYNC_MODE_SMOOTH`.

**Parameters**

`sync_mode` – Sync mode.
Chapter 2. API Reference

...
void esp_sntp_setservername (u8_t idx, const char *server)
    Sets SNTP hostname.

Parameters
    •  idx - Index of the server
    •  server - Name of the server

const char *esp_sntp_getservername (u8_t idx)
    Gets SNTP server name.

Parameters  idx - Index of the server
    Returns  Name of the server

const ip_addr_t *esp_sntp_getserver (u8_t idx)
    Get SNTP server IP.

Parameters  idx - Index of the server
    Returns  IP address of the server

bool esp_sntp_enabled (void)
    Checks if snntp is enabled.

    Returns  true if snntp module is enabled

static inline void sntp_setoperatingmode (u8_t operating_mode)
    if not build within lwip, provide translating inlines, that will warn about thread safety

static inline void sntp_servermode_dhcp (int set_servers_from_dhcp)

static inline void sntp_setservername (u8_t idx, const char *server)

static inline void sntp_init (void)

static inline const char *sntp_getservername (u8_t idx)

static inline const ip_addr_t *sntp_getserver (u8_t idx)

Macros

esp_sntp_sync_time
    Aliases for esp_snntp prefixed API (inherently thread safe)

esp_sntp_set_sync_mode

esp_sntp_get_sync_mode

esp_sntp_get_sync_status

esp_sntp_set_sync_status

esp_sntp_set_time_sync_notification_cb

esp_sntp_set_sync_interval

esp_sntp_get_sync_interval

esp_sntp_restart
SNTP_OPMODE_POLL

Type Definitions

typedef void (*sntp_sync_time_cb_t)(struct timeval *tv)

SNTP callback function for notifying about time sync event.

**Param** tv  Time received from SNTP server.

Enumerations

enum sntp_sync_mode_t

SNTP time update mode.

**Values:**

enumerator **SNTP_SYNC_MODE_IMMED**

Update system time immediately when receiving a response from the SNTP server.

enumerator **SNTP_SYNC_MODE_SMOOTH**

Smooth time updating. Time error is gradually reduced using adjtime function. If the difference between
SNTP response time and system time is large (more than 35 minutes) then update immediately.

enum sntp_sync_status_t

SNTP sync status.

**Values:**

enumerator **SNTP_SYNC_STATUS_RESET**

enumerator **SNTP_SYNC_STATUS_COMPLETED**

enumerator **SNTP_SYNC_STATUS_IN_PROGRESS**

enum esp_sntp_operatingmode_t

SNTP operating modes per lwip SNTP module.

**Values:**

enumerator **ESP_SNTP_OPMODE_LISTENONLY**

2.10.30 The himem allocation API

Overview

The ESP32 can access external SPI RAM transparently, so you can use it as normal memory in your program code. However, because the address space for external memory is limited in size, only the first 4MiB can be used as such. Access to the remaining memory is still possible, however this needs to go through a bankswitching scheme controlled by the himem API.
Specifically, what is implemented by the himem API is a bankswitching scheme. Hardware-wise, the 4MiB region for external SPI RAM is mapped into the CPU address space by a MMU, which maps a configurable 32K bank/page of external SPI RAM into each of the 32K pages in the 4MiB region accessed by the CPU. For external memories that are <=4MiB, this MMU is configured to unity mapping, effectively mapping each CPU address 1-to-1 to the external SPI RAM address.

In order to use the himem API, you have to enable it in the menuconfig using `CONFIG_SPIRAM_BANKSWITCH_ENABLE`, as well as set the amount of banks reserved for this in `CONFIG_SPIRAM_BANKSWITCH_RESERVE`. This decreases the amount of external memory allocated by functions like `malloc()`, but it allows you to use the himem api to map any of the remaining memory into the reserved banks.

The himem API is more-or-less an abstraction of the bankswitching scheme: it allows you to claim one or more banks of address space (called ‘regions’ in the API) as well as one or more of banks of memory to map into the ranges.

**Example**

An example doing a simple memory test of the high memory range is available in esp-idf: `system/hmem`

**API Reference**

**Header File**

- `components/esp_psram/include/esp32/himem.h`

**Functions**

`esp_err_t esp_himem_alloc(size_t size, esp_himem_handle_t *handle_out)`

Allocate a block in high memory.

**Parameters**

- `size` - Size of the to-be-allocated block, in bytes. Note that this needs to be a multiple of the external RAM mmu block size (32K).
- `handle_out` - [out] Handle to be returned

**Returns**

- `ESP_OK` if successful
- `ESP_ERR_NO_MEM` if out of memory
- `ESP_ERR_INVALID_SIZE` if size is not a multiple of 32K

`esp_err_t esp_himem_alloc_map_range(size_t size, esp_himem_rangehandle_t *handle_out)`

Allocate a memory region to map blocks into.

This allocates a contiguous CPU memory region that can be used to map blocks of physical memory into.

**Parameters**

- `size` - Size of the range to be allocated. Note this needs to be a multiple of the external RAM mmu block size (32K).
- `handle_out` - [out] Handle to be returned

**Returns**

- `ESP_OK` if successful
- `ESP_ERR_NO_MEM` if out of memory or address space
- `ESP_ERR_INVALID_SIZE` if size is not a multiple of 32K

`esp_err_t esp_himem_map(esp_himem_handle_t handle, esp_himem_rangehandle_t range, size_t ram_offset, size_t range_offset, size_t len, int flags, void **out_ptr)`

Map a block of high memory into the CPUs address space.

This effectively makes the block available for read/write operations.

**Note:** The region to be mapped needs to have offsets and sizes that are aligned to the SPI RAM MMU block size (32K)

**Parameters**
- **handle**: Handle to the block of memory, as given by `esp_himem_alloc`
- **range**: Range handle to map the memory in
- **ram_offset**: Offset into the block of physical memory of the block to map
- **range_offset**: Offset into the address range where the block will be mapped
- **len**: Length of region to map
- **flags**: One of `ESP_HIMEM_MAPFLAG_*`
- **out_ptr**: [out] Pointer to variable to store resulting memory pointer in

**Returns**
- `ESP_OK` if the memory could be mapped
  - `ESP_ERR_INVALID_ARG` if offset, range or len aren’t MMU-block-aligned (32K)
  - `ESP_ERR_INVALID_SIZE` if the offsets/lengths don’t fit in the allocated memory or range
  - `ESP_ERR_INVALID_STATE` if a block in the selected ram offset/length is already mapped, or if a block in the selected range offset/length already has a mapping.

### `esp_err_t esp_himem_free (esp_himem_handle_t handle)`

Free a block of physical memory.

This clears out the associated handle making the memory available for re-allocation again. This will only succeed if none of the memory blocks currently have a mapping.

**Parameters**
- **handle**: Handle to the block of memory, as given by `esp_himem_alloc`

**Returns**
- `ESP_OK` if the memory is successfully freed
  - `ESP_ERR_INVALID_ARG` if the handle still is (partially) mapped

### `esp_err_t esp_himem_free_map_range (esp_himem_rangehandle_t handle)`

Free a mapping range.

This clears out the associated handle making the range available for re-allocation again. This will only succeed if none of the range blocks currently are used for a mapping.

**Parameters**
- **handle**: Handle to the range block, as given by `esp_himem_alloc_map_range`

**Returns**
- `ESP_OK` if the memory is successfully freed
  - `ESP_ERR_INVALID_ARG` if the handle still is (partially) mapped to

### `esp_err_t esp_himem_unmap (esp_himem_rangehandle_t range, void *ptr, size_t len)`

Unmap a region.

**Parameters**
- **range**: Range handle
- **ptr**: Pointer returned by `esp_himem_map`
- **len**: Length of the block to be unmapped. Must be aligned to the SPI RAM MMU blocksize (32K)

**Returns**
- `ESP_OK` if the memory is successfully unmapped.
  - `ESP_ERR_INVALID_ARG` if ptr or len are invalid.

### `size_t esp_himem_get_phys_size (void)`

Get total amount of memory under control of himem API.

**Returns**
- Amount of memory, in bytes

### `size_t esp_himem_get_free_size (void)`

Get free amount of memory under control of himem API.

**Returns**
- Amount of free memory, in bytes

### `size_t esp_himem_reserved_area_size (void)`

Get amount of SPI memory address space needed for bankswitching.

**Note:** This is also weakly defined in `esp32/spiram.c` and returns 0 there, so if no other function in this file is used, no memory is reserved.

**Returns**
- Amount of reserved area, in bytes
Chapter 2. API Reference

Macros

ESP_HIMEM_BLKSZ

ESP_HIMEM_MAPFLAG_RO

Indicates that a mapping will only be read from. Note that this is unused for now.

Type Definitions

typedef struct esp_himem_ramdatal *esp_himem_handle_t

typedef struct esp_himem_rangedatal *esp_himem_rangehandle_t

2.10.31 ULP Coprocessor programming

The Ultra Low Power (ULP) coprocessor is a simple finite state machine (FSM) which is designed to perform measurements using the ADC, temperature sensor, and external I2C sensors, while the main processors are in deep sleep mode. The ULP coprocessor can access the RTC_SLOW_MEM memory region, and registers in the RTC_CNTL, RTC_IO, and SARADC peripherals. The ULP coprocessor uses fixed-width 32-bit instructions, 32-bit memory addressing, and has 4 general-purpose 16-bit registers. This coprocessor is referred to as ULP FSM in ESP-IDF.

Installing the Toolchain

The ULP FSM coprocessor code is written in assembly and compiled using the binutils-esp32ulp toolchain. If you have already set up ESP-IDF with CMake build system according to the Getting Started Guide, then the ULP FSM toolchain will already be installed.

Programming ULP FSM

The ULP FSM can be programmed using the supported instruction set. Alternatively, the ULP FSM coprocessor can also be programmed using C Macros on the main CPU. These two methods are described in the following section:

ESP32 ULP coprocessor instruction set

This document provides details about the instructions used by ESP32 ULP FSM coprocessor assembler.

ULP FSM coprocessor has 4 16-bit general purpose registers, labeled R0, R1, R2, R3. It also has an 8-bit counter register (stage_cnt) which can be used to implement loops. Stage count register is accessed using special instructions.

ULP coprocessor can access 8k bytes of RTC_SLOW_MEM memory region. Memory is addressed in 32-bit word units. It can also access peripheral registers in RTC_CNTL, RTC_IO, and SENS peripherals.

All instructions are 32-bit. Jump instructions, ALU instructions, peripheral register and memory access instructions are executed in 1 cycle. Instructions which work with peripherals (TSENS, ADC, I2C) take variable number of cycles, depending on peripheral operation.

The instruction syntax is case insensitive. Upper and lower case letters can be used and intermixed arbitrarily. This is true both for register names and instruction names.

Note about addressing

ESP32 ULP FSM coprocessor’s JUMP, ST, LD family of instructions expect the address argument to be expressed in the following way depending on the type of address argument used:

- When the address argument is presented as a label then the instruction expects the address to be expressed as 32-bit words.
- Consider the following example program:
entry:
  NOP
  NOP
  NOP
  NOP
loop:
  MOVE R1, loop
  JUMP R1

When this program is assembled and linked, address of label `loop` will be equal to 16 (expressed in bytes). However, `JUMP` instruction expects the address stored in register `R1` to be expressed in 32-bit words. To account for this common use case, the assembler will convert the address of label `loop` from bytes to words, when generating the `MOVE` instruction. Hence, the code generated code will be equivalent to:

```
0000  NOP
0004  NOP
0008  NOP
000c  NOP
0010  MOVE R1,  
0014  JUMP R1
```

- The other case is when the argument of `MOVE` instruction is not a label but a constant. In this case assembler will use the value as is, without any conversion:

```
.set val, 0x10
MOVE R1, val
```

In this case, value loaded into `R1` will be 0x10. However, when an immediate value is used as an offset in `LD` and `ST` instructions, the assembler considers the address argument in bytes and converts it to 32-bit words before executing the instruction:

```
ST R1, R2, 4  // offset = 4 bytes; Mem[R2 + 4 / 4] = R1
```

In this case, the value in `R1` is stored at the memory location pointed by `[R2 + offset / 4]`.

Consider the following code:

```
.global array
array:  .long  0
        .long  0
        .long  0
        .long  0

MOVE R1, array
MOVE R2, 0x1234
ST R2, R1, 0  // write value of R2 into the first array element,
              // i.e. array[0]

ST R2, R1, 4  // write value of R2 into the second array element
              // (4 byte offset), i.e. array[1]

ADD R1, R1, 2 // this increments address by 2 words (8 bytes)
ST R2, R1, 0  // write value of R2 into the third array element,
              // i.e. array[2]
```

**Note about instruction execution time** ULP coprocessor is clocked from `RTC_FAST_CLK`, which is normally derived from the internal 8MHz oscillator. Applications which need to know exact ULP clock frequency can calibrate it against the main XTAL clock:

```
#include "soc/rtc.h"

// calibrate 8M/256 clock against XTAL, get 8M/256 clock period
```

(continues on next page)
Chapter 2. API Reference

(continued from previous page)

```c
uint32_t rtc_8md256_period = rtc_clk_cal(RTC_CAL_8MD256, 100);
uint32_t rtc_fast_freq_hz = 1000000ULL * (1 << RTC_CLK_CAL_FRACT) * 256 / rtc_8md256_period;
```

ULP coprocessor needs certain number of clock cycles to fetch each instruction, plus certain number of cycles to execute it, depending on the instruction. See description of each instruction below for details on the execution time.

Instruction fetch time is:

- 2 clock cycles — for instructions following ALU and branch instructions.
- 4 clock cycles — in other cases.

Note that when accessing RTC memories and RTC registers, ULP coprocessor has lower priority than the main CPUs. This means that ULP coprocessor execution may be suspended while the main CPUs access same memory region as the ULP.

The detailed description of all instructions is presented below:

### NOP - no operation

**Syntax**

```
NOP
```

**Operands** None

**Cycles** 2 cycle to execute, 4 cycle to fetch next instruction

**Description** No operation is performed. Only the PC is incremented.

**Example**

```
1:  NOP
```

### ADD - Add to register

**Syntax**

```
ADD Rdst, Rsrc1, Rsrc2
ADD Rdst, Rsrc1, imm
```

**Operands**

- `Rdst` - Register R[0..3]
- `Rsrc1` - Register R[0..3]
- `Rsrc2` - Register R[0..3]
- `imm` - 16-bit signed value

**Cycles** 2 cycles to execute, 4 cycles to fetch next instruction

**Description** The instruction adds source register to another source register or to a 16-bit signed value and stores the result in the destination register.

**Examples**

```
1:   ADD R1, R2, R3    // R1 = R2 + R3
2:   Add R1, R2, 0x1234 // R1 = R2 + 0x1234
3:   .set value1, 0x03  // constant value1=0x03
    Add R1, R2, value1   // R1 = R2 + value1
4:   .global label      // declaration of variable label
    add R1, R2, label    // R1 = R2 + label
    label: nop           // definition of variable label
```

### SUB - Subtract from register

**Syntax**

```
SUB Rdst, Rsrc1, Rsrc2
SUB Rdst, Rsrc1, imm
```

---

Submit Document Feedback
Chapter 2. API Reference

Operands

- **Rdst** - Register R[0..3]
- **Rsrc1** - Register R[0..3]
- **Rsrc2** - Register R[0..3]
- **Imm** - 16-bit signed value

Cycles 2 cycles to execute, 4 cycles to fetch next instruction

Description The instruction subtracts the source register from another source register or subtracts a 16-bit signed value from a source register, and stores the result to the destination register.

Examples:

<table>
<thead>
<tr>
<th>Example</th>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SUB R1, R2, R3</td>
<td>R1 = R2 - R3</td>

**AND - Bitwise logical AND of two operands**

Syntax **AND** Rdst, Rsrc1, Rsrc2

**AND** Rdst, Rsrc1, imm

Operands

- **Rdst** - Register R[0..3]
- **Rsrc1** - Register R[0..3]
- **Rsrc2** - Register R[0..3]
- **Imm** - 16-bit signed value

Cycles 2 cycles to execute, 4 cycles to fetch next instruction

Description The instruction does a bitwise logical AND of a source register and another source register or a 16-bit signed value and stores the result to the destination register.

Examples:

<table>
<thead>
<tr>
<th>Example</th>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>AND R1, R2, R3</td>
<td>R1 = R2 &amp; R3</td>
</tr>
<tr>
<td>2</td>
<td>AND R1, R2, 0x1234</td>
<td>R1 = R2 &amp; 0x1234</td>
</tr>
<tr>
<td>3</td>
<td>.set value1, 0x03</td>
<td>constant value1=0x03</td>
</tr>
<tr>
<td></td>
<td>AND R1, R2, value1</td>
<td>R1 = R2 &amp; value1</td>
</tr>
<tr>
<td>4</td>
<td>.global label</td>
<td>declaration of variable label</td>
</tr>
<tr>
<td></td>
<td>AND R1, R2, label</td>
<td>R1 = R2 &amp; label</td>
</tr>
<tr>
<td></td>
<td>label: nop</td>
<td>definition of variable label</td>
</tr>
</tbody>
</table>

---

**OR - Bitwise logical OR of two operands**

Syntax **OR** Rdst, Rsrc1, Rsrc2

**OR** Rdst, Rsrc1, imm

Operands

- **Rdst** - Register R[0..3]
- **Rsrc1** - Register R[0..3]
- **Rsrc2** - Register R[0..3]
- **Imm** - 16-bit signed value

Cycles 2 cycles to execute, 4 cycles to fetch next instruction
Chapter 2. API Reference

Description The instruction does a bitwise logical OR of a source register and another source register or a 16-bit signed value and stores the result to the destination register.

Examples:

1: OR R1, R2, R3 // R1 = R2 || R3
2: OR R1, R2, 0x1234 // R1 = R2 || 0x1234
3: .set value1, 0x03 // constant value1=0x03
   OR R1, R2, value1 // R1 = R2 || value1
4: .global label // declaration of variable label
   OR R1, R2, label // R1 = R2 || label
   ...
   label: nop // definition of variable label

LSH - Logical Shift Left

Syntax LSH Rdst, Rscl, Rscre

Operands
- Rdst - Register R[0..3]
- Rscl - Register R[0..3]
- Rscre - Register R[0..3]
- Imm - 16-bit signed value

Cycles 2 cycles to execute, 4 cycles to fetch next instruction

Description The instruction does a logical shift to left of the source register by the number of bits from another source register or a 16-bit signed value and stores the result to the destination register.

Note: Shift operations which are greater than 15 bits will have an undefined result.

Examples:

1: LSH R1, R2, R3 // R1 = R2 << R3
2: LSH R1, R2, 0x03 // R1 = R2 << 0x03
3: .set value1, 0x03 // constant value1=0x03
   LSH R1, R2, value1 // R1 = R2 << value1
4: .global label // declaration of variable label
   LSH R1, R2, label // R1 = R2 << label
   ...
   label: nop // definition of variable label

RSH - Logical Shift Right

Syntax RSH Rdst, Rscl, Rscre

Operands Rdst - Register R[0..3] Rscl - Register R[0..3] Rscre - Register R[0..3] Imm - 16-bit signed value

Cycles 2 cycles to execute, 4 cycles to fetch next instruction

Description The instruction does a logical shift to right of a source register by the number of bits from another source register or a 16-bit signed value and stores the result to the destination register.

Note: Shift operations which are greater than 15 bits will have an undefined result.

Examples:
Chapter 2. API Reference

MOVE – Move to register

Syntax

MOVE Rdst, Rsrc
MOVE Rdst, imm

Operands

- **Rdst** – Register R[0..3]
- **Rsrc** – Register R[0..3]
- **Imm** – 16-bit signed value

Cycles

2 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction moves the value from the source register or a 16-bit signed value to the destination register.

Note:

Note that when a label is used as an immediate, the address of the label will be converted from bytes to words. This is because LD, ST, and JUMP instructions expect the address register value to be expressed in words rather than bytes. See the section **Note about addressing** for more details.

Examples:

1:    MOVE R1, R2          // R1 = R2
2:    MOVE R1, 0x03        // R1 = 0x03
3:    .set value1, 0x03    // constant value1=0x03
     RSH R1, R2, value1     // R1 = R2 >> value1
4:    .global label        // declaration of variable label
     MOV R1, R2, label      // R1 = R2 >> label
     label: nop             // definition of variable label

ST – Store data to the memory

Syntax

ST Rsrc, Rdst, offset

Operands

- **Rsrc** – Register R[0..3], holds the 16-bit value to store
- **Rdst** – Register R[0..3], address of the destination, in 32-bit words
- **Offset** – 13-bit signed value, offset in bytes

Cycles

4 cycles to execute, 4 cycles to fetch next instruction

Description

The instruction stores the 16-bit value of Rsrc to the lower half-word of memory with address Rdst+offset. The upper half-word is written with the current program counter (PC) (expressed in words, shifted left by 5 bits) OR’d with Rdst (0..3):

\[
\text{Mem}[(\text{Rdst} + \text{offset})/4][31:0] = (\text{PC}[10:0], 3'b0, \text{Rdst}, \text{Rsrc}[15:0])
\]

The application can use the higher 16 bits to determine which instruction in the ULP program has written any particular word into memory.
Note: Note that the offset specified in bytes is converted to a 32-bit word offset before execution. See the section Note about addressing for more details.

Examples:

1:    ST R1, R2, 0x12       // MEM[R2 + 0x12 / 4] = R1

2:    .data
      Addr1: .word 123        // Define label Addr1 16 bit
      .set offs, 0x00         // Define constant offs
      .text
      MOVE R1, 1              // R1 = 1
      MOVE R2, Addr1          // R2 = Addr1
      ST R1, R2, offs         // MEM[R2 + 0 / 4] = R1
                             // MEM[Addr1 + 0] will be 32'h600001

LD – Load data from the memory

Syntax  LD Rdst, Rs rc, offset

Operands
- Rdst – Register R[0..3], destination
- Rs rc – Register R[0..3], holds address of destination, in 32-bit words
- Offset – 13-bit signed value, offset in bytes

Cycles  4 cycles to execute, 4 cycles to fetch next instruction

Description The instruction loads the lower 16-bit half-word from memory with address [Rsrc + offset / 4] into the destination register Rdst:

Rdst[15:0] = Mem[Rsrc + offset / 4][15:0]

Note: Note that the offset specified in bytes is converted to a 32-bit word offset before execution. See the section Note about addressing for more details.

Examples:

1:    LD R1, R2, 0x12       // R1 = MEM[R2 + 0x12 / 4]

2:    .data
      Addr1: .word 123        // Define label Addr1 16 bit
      .set offs, 0x00         // Define constant offs
      .text
      MOVE R1, 1              // R1 = 1
      MOVE R2, Addr1          // R2 = Addr1 / 4 (address of label is
                             // converted into words)
      LD R1, R2, offs         // R1 = MEM[R2 + 0]
                             // R1 will be 123

JUMP – Jump to an absolute address

Syntax  JUMP Rdst

JUMP ImmAddr
JUMP Rdst, Condition
JUMP ImmAddr, Condition

Operands
- Rdst – Register R[0..3] containing address to jump to (expressed in 32-bit words)
- ImmAddr – 13 bits address (expressed in bytes), aligned to 4 bytes
- Condition:
Chapter 2. API Reference

– EQ – jump if last ALU operation result was zero
– OV – jump if last ALU has set overflow flag

**Cycles** 2 cycles to execute, 2 cycles to fetch next instruction

**Description** The instruction makes jump to the specified address. Jump can be either unconditional or based on an ALU flag.

**Examples:**

1: JUMP R1 // Jump to address in R1 (address in R1 is in 32-bit words)

2: JUMP 0x120, EQ // Jump to address 0x120 (in bytes) if ALU result is zero

3: JUMP label // Jump to label
   ...
   label: nop // Definition of label

4: .global label // Declaration of global label
   MOVE R1, label // R1 = label (value loaded into R1 is in words)
   JUMP R1 // Jump to label
   ...
   label: nop // Definition of label

**JUMPR – Jump to a relative offset (condition based on R0)**

**Syntax** JUMPR Step, Threshold, Condition

**Operands**
- **Step** – relative shift from current position, in bytes
- **Threshold** – threshold value for branch condition
- **Condition**:  
  - EQ (equal) – jump if value in R0 == threshold  
  - LT (less than) – jump if value in R0 < threshold  
  - LE (less or equal) – jump if value in R0 <= threshold  
  - GT (greater than) – jump if value in R0 > threshold  
  - GE (greater or equal) – jump if value in R0 >= threshold

**Cycles**

Conditions LT, GE, LE and GT: 2 cycles to execute, 2 cycles to fetch next instruction

Conditions LE and GT are implemented in the assembler using one JUMPR instruction:

```c
// JUMPR target, threshold, GT is implemented as:
JUMPR target, threshold+1, GE

// JUMPR target, threshold, LE is implemented as:
JUMPR target, threshold + 1, LT
```

Conditions EQ is implemented in the assembler using two JUMPR instructions:

```c
// JUMPR target, threshold, EQ is implemented as:
JUMPR next, threshold + 1, GE
JUMPR target, threshold, GE
next:
```

**Description** The instruction makes a jump to a relative address if condition is true. Condition is the result of comparison of R0 register value and the threshold value.
Examples:

```plaintext
1: pos: JUMPR 16, 20, GE // Jump to address (position + 16 bytes) if value in R0 >= 20

2: // Down counting loop using R0 register
   MOVE R0, 16 // load 16 into R0
   label: SUB R0, R0, 1 // R0--
   NOP // do something
   JUMPR label, 1, GE // jump to label if R0 >= 1
```

**JUMPS – Jump to a relative address (condition based on stage count)**

**Syntax** JUMPS Step, Threshold, Condition

**Operands**
- Step – relative shift from current position, in bytes
- Threshold – threshold value for branch condition
- **Condition**:
  - EQ (equal) – jump if value in stage_cnt == threshold
  - LT (less than) – jump if value in stage_cnt < threshold
  - LE (less or equal) – jump if value in stage_cnt <= threshold
  - GT (greater than) – jump if value in stage_cnt > threshold
  - GE (greater or equal) – jump if value in stage_cnt >= threshold

**Cycles**

Conditions LE, LT, GE: 2 cycles to execute, 2 cycles to fetch next instruction

Conditions EQ, GT are implemented in the assembler using two JUMPS instructions:

```plaintext
// JUMPS target, threshold, EQ is implemented as:

JUMPS next, threshold, LT
JUMPS target, threshold, LE

next:

// JUMPS target, threshold, GT is implemented as:

JUMPS next, threshold, LE
JUMPS target, threshold, GE

next:
```

Therefore the execution time will depend on the branches taken: either 2 cycles to execute + 2 cycles to fetch, or 4 cycles to execute + 4 cycles to fetch.

**Description** The instruction makes a jump to a relative address if condition is true. Condition is the result of comparison of count register value and threshold value.

**Examples:**

```plaintext
1: pos: JUMPS 16, 20, EQ // Jump to (position + 16 bytes) if stage_cnt <= 20

2: // Up counting loop using stage count register
   STAGE_RST // set stage_cnt to 0
   label: STAGE_INC 1 // stage_cnt++
   NOP // do something
   JUMPS label, 16, LT // jump to label if stage_cnt < 16
```

**STAGE_RST – Reset stage count register**

**Syntax** STAGE_RST
Operands  No operands
Description  The instruction sets the stage count register to 0
Cycles  2 cycles to execute, 4 cycles to fetch next instruction

Examples:

```
1:            STAGE_RST  // Reset stage count register
```

STAGE_INC – Increment stage count register

Syntax  STAGE_INC Value
Operands  
  - Value – 8 bits value
Cycles  2 cycles to execute, 4 cycles to fetch next instruction
Description  The instruction increments the stage count register by the given value.

Examples:

```
1:            STAGE_INC 10  // stage_cnt += 10
2:            // Up counting loop example:
    STAGE_RST  // set stage_cnt to 0
    label: STAGE_INC 1  // stage_cnt++
    NOP  // do something
    JUMPS label, 16, LT  // jump to label if stage_cnt < 16

3:            // Down counting loop example
    STAGE_RST  // set stage_cnt to 0
    STAGE_INC 16  // increment stage_cnt to 16
    label: STAGE_DEC 1  // stage_cnt--;
    NOP  // do something
    JUMPS label, 0, GT  // jump to label if stage_cnt > 0
```

STAGE_DEC – Decrement stage count register

Syntax  STAGE_DEC Value
Operands  
  - Value – 8 bits value
Cycles  2 cycles to execute, 4 cycles to fetch next instruction
Description  The instruction decrements the stage count register by the given value.

Examples:

```
1:            STAGE_DEC 10  // stage_cnt -= 10;
2:            // Down counting loop example
    STAGE_RST  // set stage_cnt to 0
    STAGE_INC 16  // increment stage_cnt to 16
    label: STAGE_DEC 1  // stage_cnt--;
    NOP  // do something
    JUMPS label, 0, GT  // jump to label if stage_cnt > 0
```

HALT – End the program

Syntax  HALT
Operands  No operands
Cycles  2 cycles to execute
Description  The instruction halts the ULP coprocessor and restarts the ULP wakeup timer, if it is enabled.

Examples:

```
1:            HALT  // Halt the coprocessor
```

WAKE – Wake up the chip

Syntax  WAKE
Operands  No operands
Cycles  2 cycles to execute, 4 cycles to fetch next instruction
Description  The instruction sends an interrupt from the ULP coprocessor to the RTC controller.
   • If the SoC is in deep sleep mode, and ULP wakeup is enabled, this causes the SoC to wake up.
   • If the SoC is not in deep sleep mode, and ULP interrupt bit (RTC_CNTL_ULP_CP_INT_ENA) is set in RTC_CNTL_INT_ENA_REG register, RTC interrupt will be triggered.

Note:  Note that before using WAKE instruction, ULP program may need to wait until RTC controller is ready to wake up the main CPU. This is indicated using RTC_CNTL_RDY_FOR_WAKEUP bit of RTC_CNTL_LOW_POWER_ST_REG register. If WAKE instruction is executed while RTC_CNTL_RDY_FOR_WAKEUP is zero, it has no effect (wake up does not occur). If the WAKE instruction is intended to be used while the main CPU is not in sleep mode then the RTC_CNTL_MAIN_STATE_IN_IDLE (bit 27) of RTC_CNTL_LOW_POWER_ST_REG can be used to check whether main CPU is in normal mode or sleep mode.

Examples:

1:  is_rdy_for_wakeup:         // Read RTC_CNTL_RDY_FOR_WAKEUP bit
   READ_RTC_FIELD(RTC_CNTL_LOW_POWER_ST_REG, RTC_CNTL_RDY_FOR_WAKEUP)
   AND r0, r0, 1
   JUMP is_rdy_for_wakeup, eq  // Retry until the bit is set
   WAKE  // Trigger wake up
   REG_WR 0x006, 24, 24, 0  // Stop ULP timer (clear RTC_CNTL_ULP_CP_SLP_TIMER_EN)
   HALT  // Stop the ULP program
   // After these instructions, SoC will wake up,
   // and ULP will not run again until started by the main program.

1:  check_wakeup:               // Read RTC_CNTL_RDY_FOR_WAKEUP and RTC_CNTL_MAIN_STATE_IN_IDLE bit
   READ_RTC_REG(RTC_CNTL_LOW_POWER_ST_REG, 27, 1)
   MOVE r1, r0
   // Copy result in to r1
   READ_RTC_FIELD(RTC_CNTL_LOW_POWER_ST_REG, RTC_CNTL_RDY_FOR_WAKEUP)
   OR r0, r0, r1
   JUMP check_wakeup, eq  // Retry until either of the bit are set
   WAKE  // Trigger wake up
   HALT  // Stop the ULP program

SLEEP --set ULP wakeup timer period
Syntax  SLEEP sleep_reg
Operands  • sleep_reg = 0..4, selects one of SENS_ULP_CP_SLEEP_CYCx_REG registers.
Cycles  2 cycles to execute, 4 cycles to fetch next instruction
Description  The instruction selects which of the SENS_ULP_CP_SLEEP_CYCx_REG (x = 0..4) register values is to be used by the ULP wakeup timer as wakeup period. By default, the value from SENS_ULP_CP_SLEEP_CYC0_REG is used.

Examples:

1:  SLEEP 1  // Use period set in SENS_ULP_CP_SLEEP_CYC1_REG

2:  .set sleep_reg, 4  // Set constant
    SLEEP sleep_reg  // Use period set in SENS_ULP_CP_SLEEP_CYC4_REG

WAIT --wait some number of cycles
Syntax  WAIT Cycles
Operands
- **Cycles** — number of cycles for wait

**Cycles** 2 + Cycles cycles to execute, 4 cycles to fetch next instruction

**Description** The instruction delays for given number of cycles.

**Examples:**

```
1: WAIT 10  // Do nothing for 10 cycles
2: .set wait_cnt, 10 // Set a constant
    WAIT wait_cnt // wait for 10 cycles
```

---

**ADC** — do measurement with ADC

**Syntax**

- ADC Rdst, Sar_sel, Mux
- ADC Rdst, Sar_sel, Mux, 0 — deprecated form

**Operands**

- **Rdst** — Destination Register R[0..3], result will be stored to this register
- **Sar_sel** — Select ADC: 0 = SARADC1, 1 = SARADC2
- **Mux** - Enable ADC channel. Channel number is [Mux-1]. If the user passes Mux value 1, then ADC channel 0 gets used.

**Cycles** 23 + max(1, SAR_AMP_WAIT1) + max(1, SAR_AMP_WAIT2) + max(1, SAR_AMP_WAIT3) + SARx_SAMPLE_CYCLE + SARx_SAMPLE_BIT cycles to execute, 4 cycles to fetch next instruction

**Description** The instruction makes measurements from ADC.

**Examples:**

```
.. only:: esp32

1: ADC R1, 0, 1 // Measure value using ADC1 channel 0 and store result into R1
```

---

**I2C_RD** — read single byte from I2C slave

**Syntax**

- I2C_RD Sub_addr, High, Low, Slave_sel

**Operands**

- **Sub_addr** — Address within the I2C slave to read.
- **High, Low** — Define range of bits to read. Bits outside of [High, Low] range are masked.
- **Slave_sel** — Index of I2C slave address to use.

**Cycles** Execution time mostly depends on I2C communication time. 4 cycles to fetch next instruction.

**Description** I2C_RD instruction reads one byte from I2C slave with index Slave_sel. Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == Slave_sel. 8 bits of read result is stored into R0 register.

**Examples:**

```
1: I2C_RD 0x10, 7, 0, 0 // Read byte from sub-address 0x10 of... 
    ->slave with address set in SENS_I2C_SLAVE_ADDR0
```

---

**I2C_WR** — write single byte to I2C slave

**Syntax**

- I2C_WR Sub_addr, Value, High, Low, Slave_sel

**Operands**

- **Sub_addr** — Address within the I2C slave to write.
- **Value** — 8-bit value to be written.
- **High, Low** — Define range of bits to write. Bits outside of [High, Low] range are masked.
Chapter 2. API Reference

• Slave_sel - Index of I2C slave address to use.

Cycles  Execution time mostly depends on I2C communication time. 4 cycles to fetch next instruction.

Description  I2C_WR instruction writes one byte to I2C slave with index Slave_sel. Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == Slave_sel.

Examples:

```
1:  I2C_WR  0x20, 0x33, 7, 0, 1  // Write byte 0x33 to sub-address...
    ~0x20 of slave with address set in SENS_I2C_SLAVE_ADDR1.
```

REG_RD – read from peripheral register

Syntax  REG_RD Addr, High, Low

Operands
• Addr – Register address, in 32-bit words
• High – Register end bit number
• Low – Register start bit number

Cycles  4 cycles to execute, 4 cycles to fetch next instruction

Description  The instruction reads up to 16 bits from a peripheral register into a general purpose register: R0 = REG[Addr][High:Low].

This instruction can access registers in RTC_CNTL, RTC_IO, SENS, and RTC_I2C peripherals. Address of the register, as seen from the ULP, can be calculated from the address of the same register on the DPORT bus as follows:

```
addr_ulp = (addr_dport - DR_REG_RTCCNTL_BASE) / 4
```

Examples:

```
1:  REG_RD  0x120, 7, 4  // load 4 bits: R0 = {12'b0, REG[0x120][7:4]}
```

REG_WR – write to peripheral register

Syntax  REG_WR Addr, High, Low, Data

Operands
• Addr – Register address, in 32-bit words.
• High – Register end bit number
• Low – Register start bit number
• Data – Value to write, 8 bits

Cycles  8 cycles to execute, 4 cycles to fetch next instruction

Description  The instruction writes up to 8 bits from an immediate data value into a peripheral register: REG[Addr][High:Low] = data.

This instruction can access registers in RTC_CNTL, RTC_IO, SENS, and RTC_I2C peripherals. Address of the register, as seen from the ULP, can be calculated from the address of the same register on the DPORT bus as follows:

```
addr_ulp = (addr_dport - DR_REG_RTCCNTL_BASE) / 4
```

Examples:

```
1:  REG_WR  0x120, 7, 0, 0x10  // set 8 bits: REG[0x120][7:0] = 0x10
```

Convenience macros for peripheral registers access  ULP source files are passed through C preprocessor before the assembler. This allows certain macros to be used to facilitate access to peripheral registers.

Some existing macros are defined in soc/soc_ulp.h header file. These macros allow access to the fields of peripheral registers by their names. Peripheral registers names which can be used with these macros are the ones
defined in soc/rtc_cntl_reg.h, soc/rtc_io_reg.h, soc/sens_reg.h, and soc/rtc_i2c_reg.h.

**READ_RTC_REG(rtc_reg, low_bit, bit_width)**  Read up to 16 bits from rtc_reg[low_bit + bit_width - 1 : low_bit] into R0. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/rtc_cntl_reg.h"
/* Read 16 lower bits of RTC_CNTL_TIME0_REG into R0 */
READ_RTC_REG(RTC_CNTL_TIME0_REG, 0, 16)
```

**READ_RTC_FIELD(rtc_reg, field)**  Read from a field in rtc_reg into R0, up to 16 bits. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/sens_reg.h"
/* Read 8-bit SENS_TSENS_OUT field of SENS_SAR_SLAVE_ADDR3_REG into R0 */
READ_RTC_FIELD(SENS_SAR_SLAVE_ADDR3_REG, SENS_TSENS_OUT)
```

**WRITE_RTC_REG(rtc_reg, low_bit, bit_width, value)**  Write immediate value into rtc_reg[low_bit + bit_width - 1 : low_bit], bit_width <= 8. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/rtc_io_reg.h"
/* Set BIT(2) of RTC_GPIO_OUT_DATA_W1TS field in RTC_GPIO_OUT_W1TS_REG */
WRITE_RTC_REG(RTC_GPIO_OUT_W1TS_REG, RTC_GPIO_OUT_DATA_W1TS_S + 2, 1, 1)
```

**WRITE_RTC_FIELD(rtc_reg, field, value)**  Write immediate value into a field in rtc_reg, up to 8 bits. For example:

```c
#include "soc/soc_ulp.h"
#include "soc/rtc_cntl_reg.h"
/* Set RTC_CNTL_ULP_CP_SLP_TIMER_EN field of RTC_CNTL_STATE0_REG to 0 */
WRITE_RTC_FIELD(RTC_CNTL_STATE0_REG, RTC_CNTL_ULP_CP_SLP_TIMER_EN, 0)
```

**Programming ULP FSM coprocessor using C macros (legacy)**  In addition to the existing binutils port for the ESP32 ULP coprocessor, it is possible to generate programs for the ULP FSM coprocessor by embedding assembly-like macros into an ESP32 application. Here is an example how this can be done:

```c
const ulp_insn_t program[] = {
    I_MOVI(R3, 16),       // R3 <- 16
    I_LD(R0, R3, 0),     // R0 <- RTC_SLOW_MEM[R3 + 0]
    I_LD(R1, R3, 1),     // R1 <- RTC_SLOW_MEM[R3 + 1]
    I_ADDR(R2, R0, R1),  // R2 <- R0 + R1
    I_ST(R2, R3, 2),     // R2 -> RTC_SLOW_MEM[R2 + 2]
    I_HALT()
};
size_t load_addr = 0;
size_t size = sizeof(program)/sizeof(ulp_insn_t);
ulp_process_macros_and_load(load_addr, program, ssize);
ulp_run(load_addr);
```

The program array is an array of ulp_insn_t, i.e. ULP coprocessor instructions. Each I_XXX preprocessor define translates into a single 32-bit instruction. Arguments of these preprocessor defines can be register numbers (R0 – R3) and literal constants. See the API reference section at the end of this guide for descriptions of instructions and arguments they take.

**Note:** Because some of the instruction macros expand to inline function calls, defining such array in global scope will cause the compiler to produce an “initializer element is not constant” error. To fix this error, move the definition
of instructions array into local scope.

**Note:** Load, store and move instructions use addresses expressed in **32-bit words**. Address 0 corresponds to the first word of RTC_SLOW_MEM. This is different to how address arguments are handled in assembly code of the same instructions. See the section **Note about addressing** for more details for reference.

To generate branch instructions, special M_ preprocessor defines are used. M_LABEL define can be used to define a branch target. Label identifier is a 16-bit integer. M_Bxxx defines can be used to generate branch instructions with target set to a particular label.

Implementation note: these M_ preprocessor defines will be translated into two ulp_insn_t values: one is a token value which contains label number, and the other is the actual instruction. ulp_process_macros_and_load function resolves the label number to the address, modifies the branch instruction to use the correct address, and removes the extra ulp_insn_t token which contains the label number.

Here is an example of using labels and branches:

```c
const ulp_insn_t program[] = {
    I_MOVI(R0, 34),       // R0 <- 34
    M_LABEL(1),            // label_1
    I_MOVI(R1, 32),        // R1 <- 32
    I_LD(R1, R1, 0),       // R1 <- RTC_SLOW_MEM[R1]
    M_MOVI(R2, 33),        // R2 <- 33
    I_LD(R2, R2, 0),       // R2 <- RTC_SLOW_MEM[R2]
    I_SUBR(R3, R1, R2),    // R3 <- R1 - R2
    I_ST(R3, R0, 0),       // R3 -> RTC_SLOW_MEM[R0 + 0]
    M_ADDI(R0, R0, 1),     // R0++
    M_BL(1, 64),           // if (R0 < 64) goto label_1
    I_HALT(),
};
RTC_SLOW_MEM[32] = 42;
RTC_SLOW_MEM[33] = 18;
size_t load_addr = 0;
size_t size = sizeof(program)/sizeof(ulp_insn_t);
ulp_process_macros_and_load(load_addr, program, &size);
ulp_run(load_addr);
```

## API Reference

### Header File

- `components/ulp/fsm/include/esp32/ulp.h`

### Functions

**static inline** uint32_t **SOC_REG_TO_ULP_PERIPH_SEL**( uint32_t reg)

Map SoC peripheral register to periph_sel field of RD_REG and WR_REG instructions.

- **Parameters reg** - peripheral register in RTC_CNTL_, RTC_IO_, SENS_, RTC_I2C peripherals.
- **Returns** periph_sel value for the peripheral to which this register belongs.

### Unions

**union ulp_insn**

> #include <ulp.h> Instruction format structure.
Chapter 2. API Reference

All ULP instructions are 32 bit long. This union contains field layouts used by all of the supported instructions. This union also includes a special “macro” instruction layout. This is not a real instruction which can be executed by the CPU. It acts as a token which is removed from the program by the ulp_process_macros_and_load function.

These structures are not intended to be used directly. Preprocessor definitions provided below fill the fields of these structure with the right arguments.

**Public Members**

```c
uint32_t cycles
    Number of cycles to sleep
    TBD, cycles used for measurement

uint32_t unused
    Unused

uint32_t opcode
    Opcode (OPCODE_DELAY)
    Opcode (OPCODE_ST)
    Opcode (OPCODE_LD)
    Opcode (OPCODE_HALT)
    Opcode (OPCODE_BRANCH)
    Opcode (OPCODE_ALU)
    Opcode (OPCODE_WR_REG)
    Opcode (OPCODE_RD_REG)
    Opcode (OPCODE_ADC)
    Opcode (OPCODE_TSENS)
    Opcode (OPCODE_I2C)
    Opcode (OPCODE_END)
    Opcode (OPCODE_MACRO)

struct ulp_insn::[anonymous] delay
    Format of DELAY instruction

uint32_t dreg
    Register which contains data to store
    Register where the data should be loaded to
    Register which contains target PC, expressed in words (used if .reg == 1)
    Destination register
    Register where to store ADC result
    Register where to store temperature measurement result
    Destination register (for SUB_OPCODE_MACRO_LABELPC) >
```
uint32_t sreg
    Register which contains address in RTC memory (expressed in words)
    Register with operand A

uint32_t unused1
    Unused

uint32_t offset
    Offset to add to sreg
    Absolute value of target PC offset w.r.t. current PC, expressed in words

uint32_t unused2
    Unused

uint32_t sub_opcode
    Sub opcode (SUB_OPCODE_ST)
    Sub opcode (SUB_OPCODE_BX)
    Sub opcode (SUB_OPCODE_B)
    Sub opcode (SUB_OPCODE_BS)
    Sub opcode (SUB_OPCODE_ALU_REG)
    Sub opcode (SUB_OPCODE_ALU_CNT)
    Sub opcode (SUB_OPCODE_ALU_IMM)
    Sub opcode (SUB_OPCODE_WAKEUP)
    Sub opcode (SUB_OPCODE_SLEEP)
    SUB_OPCODE_MACRO_LABEL or SUB_OPCODE_MACRO_BRANCH or SUB_OPCODE_MACRO_LABELPC

struct ulp_insn::[anonymous] st
    Format of ST instruction

struct ulp_insn::[anonymous] ld
    Format of LD instruction

struct ulpInsn::[anonymous] halt
    Format of HALT instruction

uint32_t addr
    Target PC, expressed in words (used if .reg == 0)
    Address within either RTC_CNTL, RTC_IO, or SARADC

uint32_t reg
    Target PC in register (1) or immediate (0)

uint32_t type
    Jump condition (BX_JUMP_TYPE_xxx)
struct \textit{ulp_insn}::[anonymous] \textbf{bx}

Format of BRANCH instruction (absolute address)

\textbf{uint32_t \textit{imm}}

Immediate value to compare against
Immediate value of operand
Immediate value of operand B

\textbf{uint32_t \textit{cmp}}

Comparison to perform: B\_CMP\_L or B\_CMP\_GE
Comparison to perform: JUMPS\_LT, JUMPS\_GE or JUMPS\_LE

\textbf{uint32_t \textit{sign}}

Sign of target PC offset: 0: positive, 1: negative

struct \textit{ulp_insn}::[anonymous] \textbf{b}

Format of BRANCH instruction (relative address, conditional on R0)

struct \textit{ulp_insn}::[anonymous] \textbf{bs}

Format of BRANCH instruction (relative address, conditional on the stage counter)

\textbf{uint32_t \textit{treg}}

Register with operand B

\textbf{uint32_t \textit{sel}}

Operation to perform, one of ALU\_SEL\_xxx
Operation to perform, one of ALU\_SEL\_Sxxx

struct \textit{ulp_insn}::[anonymous] \textbf{alu\_reg}

Format of ALU instruction (both sources are registers)

struct \textit{ulp_insn}::[anonymous] \textbf{alu\_reg\_s}

Format of ALU instruction (stage counter and an immediate)

struct \textit{ulp_insn}::[anonymous] \textbf{alu\_imm}

Format of ALU instruction (one source is an immediate)

\textbf{uint32_t \textit{periph\_sel}}

Select peripheral: RTC\_CNTL (0), RTC\_IO(1), SARADC(2)

\textbf{uint32_t \textit{data}}

8 bits of data to write
8 bits of data for write operation

\textbf{uint32_t \textit{low}}

Low bit
uint32_t high
   High bit

struct ulp_insn::[anonymous] wr_reg
   Format of WR_REG instruction

struct ulp_insn::[anonymous] rd_reg
   Format of RD_REG instruction

uint32_t mux
   Select SARADC pad (mux + 1)

uint32_t sar_sel
   Select SARADC0 (0) or SARADC1 (1)

struct ulp_insn::[anonymous] adc
   Format of ADC instruction

uint32_t wait_delay
   Cycles to wait after measurement is done

uint32_t reserved
   Reserved, set to 0

struct ulpInsn::[anonymous] tsens
   Format of TSENS instruction

uint32_t i2c_addr
   I2C slave address

uint32_t low_bits
   low bit of range for write operation (lower bits are masked)

uint32_t high_bits
   high bit of range for write operation (higher bits are masked)

uint32_t i2c_sel
   index of slave address register [7:0]

uint32_t rw
   Write (1) or read (0)

struct ulp_insn::[anonymous] i2c
   Format of I2C instruction

uint32_t wakeup
   Set to 1 to wake up chip
struct ulp_insn::[anonymous] end
   Format of END instruction with wakeup

uint32_t cycle_sel
   Select which one of SARADC_ULP_CP_SLEEP_CYCx_REG to get the sleep duration from

struct ulp_insn::[anonymous] sleep
   Format of END instruction with sleep

uint32_t label
   Label number

struct ulp_insn::[anonymous] macro
   Format of tokens used by MACROs

uint32_t instruction
   Encoded instruction for ULP coprocessor

**Macros**

R0
   general purpose register 0

R1
   general purpose register 1

R2
   general purpose register 2

R3
   general purpose register 3

**OPCODE_WR_REG**
   Instruction: write peripheral register (RTC_CNTL/RTC_IO/SARADC)

**OPCODE_RD_REG**
   Instruction: read peripheral register (RTC_CNTL/RTC_IO/SARADC)

**RD_REG_PERIPH_RTC_CNTL**
   Identifier of RTC_CNTL peripheral for RD_REG and WR_REG instructions

**RD_REG_PERIPH_RTC_IO**
   Identifier of RTC_IO peripheral for RD_REG and WR_REG instructions

**RD_REG_PERIPH_SENS**
   Identifier of SARADC peripheral for RD_REG and WR_REG instructions

**RD_REG_PERIPH_RTC_I2C**
   Identifier of RTC_I2C peripheral for RD_REG and WR_REG instructions
Chapter 2. API Reference

**OPCODE_I2C**
Instruction: read/write I2C

**SUB_OPCODE_I2C_RD**
I2C read

**SUB_OPCODE_I2C_WR**
I2C write

**OPCODE_DELAY**
Instruction: delay (nop) for a given number of cycles

**OPCODE_ADC**
Instruction: SAR ADC measurement

**OPCODE_ST**
Instruction: store indirect to RTC memory

**SUB_OPCODE_ST**
Store 32 bits, 16 MSBs contain PC, 16 LSBs contain value from source register

**OPCODE_ALU**
Arithmetic instructions

**SUB_OPCODE_ALU_REG**
Arithmetic instruction, both source values are in register

**SUB_OPCODE_ALU_IMM**
Arithmetic instruction, one source value is an immediate

**SUB_OPCODE_ALU_CNT**
Arithmetic instruction, stage counter and an immediate

**ALU_SEL_ADD**
Addition

**ALU_SEL_SUB**
Subtraction

**ALU_SEL_AND**
Logical AND

**ALU_SEL_OR**
Logical OR

**ALU_SEL_MOV**
Copy value (immediate to destination register or source register to destination register)
**ALU_SEL_LSH**  
Shift left by given number of bits

**ALU_SEL_RSH**  
Shift right by given number of bits

**ALU_SEL_SINC**  
Increment the stage counter

**ALU_SEL_SDEC**  
Decrement the stage counter

**ALU_SEL_SRST**  
Reset the stage counter

**OPCODE_BRANCH**  
Branch instructions

**SUB_OPCODE_BX**  
Branch to absolute PC (immediate or in register)

**SUB_OPCODE_BR**  
Branch to relative PC, conditional on R0

**SUB_OPCODE_BS**  
Branch to relative PC, conditional on the stage counter

**BX_JUMP_TYPE_DIRECT**  
Unconditional jump

**BX_JUMP_TYPEZERO**  
Branch if last ALU result is zero

**BX_JUMP_TYPE_OVF**  
Branch if last ALU operation caused and overflow

**SUB_OPCODE_B**  
Branch to a relative offset

**B_CMP_L**  
Branch if R0 is less than an immediate

**B_CMP_GE**  
Branch if R0 is greater than or equal to an immediate

**JUMPS_LT**  
Branch if the stage counter <
**JUMPS_GE**

Branch if the stage counter >=

**JUMPS_LE**

Branch if the stage counter <=

**OPCODE_END**

Stop executing the program

**SUB_OPCODE_END**

Stop executing the program and optionally wake up the chip

**SUB_OPCODE_SLEEP**

Stop executing the program and run it again after selected interval

**OPCODE_TSENS**

Instruction: temperature sensor measurement. Poor accuracy, not recommended for most use-cases

**OPCODE_HALT**

Halt the coprocessor

**OPCODE_LD**

Indirect load lower 16 bits from RTC memory

**OPCODE_MACRO**

Not a real opcode. Used to identify labels and branches in the program

**SUB_OPCODE_MACRO_LABEL**

Label macro

**SUB_OPCODE_MACRO_BRANCH**

Branch macro

**SUB_OPCODE_MACRO_LABELPC**

Label pointer macro

**I_DELAY**(cycles_)

Delay (nop) for a given number of cycles

**I_HALT()**

Halt the coprocessor.

This instruction halts the coprocessor, but keeps ULP timer active. As such, ULP program will be restarted again by timer. To stop the program and prevent the timer from restarting the program, use I_END(0) instruction.

**I_WR_REG**(reg, low_bit, high_bit, val)

Write literal value to a peripheral register

reg[high_bit : low_bit] = val This instruction can access RTC_CNTL_, RTC_IO_, SENS_, and RTC_I2C peripheral registers.
Chapter 2. API Reference

I_RD_REG (reg, low_bit, high_bit)
Read from peripheral register into R0

R0 = reg[high_bit : low_bit] This instruction can access RTC_CNTL_, RTC_IO_, SENS_, and RTC_I2C
peripheral registers.

I_WR_REG_BIT (reg, shift, val)
Set or clear a bit in the peripheral register.

Sets bit (1 << shift) of register reg to value val. This instruction can access RTC_CNTL_, RTC_IO_, SENS_,
and RTC_I2C peripheral registers.

I_WAKE ()
Wake the SoC from deep sleep.

This instruction initiates wake up from deep sleep. Use esp_deep_sleep_enable_ulp_wakeup to enable deep
sleep wakeup triggered by the ULP before going into deep sleep. Note that ULP program will still keep running
until the I_HALT instruction, and it will still be restarted by timer at regular intervals, even when the SoC is
woken up.

To stop the ULP program, use I_HALT instruction.

To disable the timer which start ULP program, use I_END() instruction. I_END instruction clears the
RTC_CNTL_ULP_CP_SLP_TIMER_EN_S bit of RTC_CNTL_STATE0_REG register, which controls the
ULP timer.

I_END ()
Stop ULP program timer.

This is a convenience macro which disables the ULP program timer. Once this instruction is used, ULP
program will not be restarted anymore until ulp_run function is called.

ULP program will continue running after this instruction. To stop the currently running program, use
I_HALT().

I_SLEEP_CYCLE_SEL (timer_idx)
Select the time interval used to run ULP program.

This instructions selects which of the SENS_SLEEP_CYCLES_Sx registers’ value is used by the ULP pro-
gram timer. When the ULP program stops at I_HALT instruction, ULP program timer start counting. When
the counter reaches the value of the selected SENS_SLEEP_CYCLES_Sx register, ULP program start run-
ging again from the start address (passed to the ulp_run function). There are 5 SENS_SLEEP_CYCLES_Sx
registers, so 0 <= timer_idx < 5.

By default, SENS_SLEEP_CYCLES_S0 register is used by the ULP program timer.

I_TSENS (reg_dest, delay)
Perform temperature sensor measurement and store it into reg_dest.

Delay can be set between 1 and ((1 << 14) - 1). Higher values give higher measurement resolution.

I_ADC (reg_dest, adc_idx, pad_idx)
Perform ADC measurement and store result in reg_dest.

adc_idx selects ADC (0 or 1). pad_idx selects ADC pad (0 - 7).

I_ST (reg_val, reg_addr, offset_)
Store value from register reg_val into RTC memory.

The value is written to an offset calculated by adding value of reg_addr register and offset_field (this offset is
expressed in 32-bit words). 32 bits written to RTC memory are built as follows:

• bits [31:21] hold the PC of current instruction, expressed in 32-bit words
• bits [20:18] = 3’b0
• bits [17:16] reg_addr (0..3)
• bits [15:0] are assigned the contents of reg_val
Chapter 2. API Reference

```
RTC_SLOW_MEM[addr + offset_] = { insn_PC[10:0], 3'b0, reg_addr, reg_val[15:0] }

I_LD (reg_dest, reg_addr, offset_)
Load value from RTC memory into reg_dest register.
Loads 16 LSBS from RTC memory word given by the sum of value in reg_addr and value of offset_.

I_BL (pc_offset, imm_value)
Branch relative if R0 less than immediate value.

I_BGE (pc_offset, imm_value)
Branch relative if R0 greater or equal than immediate value.

I_BXR (reg_pc)
Unconditional branch to absolute PC, address in register.

I_BXI (imm_pc)
Unconditional branch to absolute PC, immediate address.

I_BXZR (reg_pc)
Branch to absolute PC if ALU result is zero, address in register.

I_BXZI (imm_pc)
Branch to absolute PC if ALU result is zero, immediate address.

I_BXFR (reg_pc)
Branch to absolute PC if ALU overflow, address in register.

I_BXFI (imm_pc)
Branch to absolute PC if ALU overflow, immediate address.

I_ADDR (reg_dest, reg_src1, reg_src2)
Addition: dest = src1 + src2

I_SUBR (reg_dest, reg_src1, reg_src2)
Subtraction: dest = src1 - src2

I_ANDR (reg_dest, reg_src1, reg_src2)
Logical AND: dest = src1 & src2

I_ORR (reg_dest, reg_src1, reg_src2)
Logical OR: dest = src1 | src2

I_MOVR (reg_dest, reg_src)
Copy: dest = src

I_LSHR (reg_dest, reg_src, reg_shift)
Logical shift left: dest = src << shift
```
I_RSHR (reg_dest, reg_src, reg_shift)
   Logical shift right: dest = src >> shift

I_ADDI (reg_dest, reg_src, imm_)
   Add register and an immediate value: dest = src + imm

I_SUBI (reg_dest, reg_src, imm_)
   Subtract register and an immediate value: dest = src - imm

I_ANDI (reg_dest, reg_src, imm_)
   Logical AND register and an immediate value: dest = src & imm

I_ORI (reg_dest, reg_src, imm_)
   Logical OR register and an immediate value: dest = src | imm

I_MOVI (reg_dest, imm_)
   Copy an immediate value into register: dest = imm

I_LSHI (reg_dest, reg_src, imm_)
   Logical shift left register value by an immediate: dest = src << imm

I_RSHI (reg_dest, reg_src, imm_)
   Logical shift right register value by an immediate: dest = val >> imm

M_LABEL (label_num)
   Define a label with number label_num.
   This is a macro which doesn’t generate a real instruction. The token generated by this macro is removed by ulp_process_macros_and_load function. Label defined using this macro can be used in branch macros defined below.

M_BRANCH (label_num)
   Token macro used by M_B and M_BX macros. Not to be used directly.

M_LABELPC (label_num)
   Token macro used by M_MOVL macro. Not to be used directly.

M_MOVL (reg_dest, label_num)
   Macro: Move the program counter at the given label into the register. This address can then be used with I_BXR, I_BXZR, I_BXFR, etc.
   This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BL (label_num, imm_value)
   Macro: branch to label label_num if R0 is less than immediate value.
   This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BGE (label_num, imm_value)
   Macro: branch to label label_num if R0 is greater or equal than immediate value
   This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BX (label_num)
   Macro: unconditional branch to label
   This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.
M_BXZ (label_num)
Macro: branch to label if ALU result is zero
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BXF (label_num)
Macro: branch to label if ALU overflow
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

I_STAGE_INC (imm_)
Increment the stage counter by immediate value

I_STAGE_DEC (imm_)
Decrement the stage counter by immediate value

I_STAGE_RST ()
Reset the stage counter

M_BSLT (label_num, imm_value)
Macro: branch to label if the stage counter is less than immediate value
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BSGE (label_num, imm_value)
Macro: branch to label if the stage counter is greater than or equal to immediate value
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BSLE (label_num, imm_value)
Macro: branch to label if the stage counter is less than or equal to immediate value
This macro generates two ulp_insn_t values separated by a comma, and should be used when defining contents of ulp_insn_t arrays. First value is not a real instruction; it is a token which is removed by ulp_process_macros_and_load function.

M_BSEQ (label_num, imm_value)
Macro: branch to label if the stage counter is equal to immediate value. Implemented using two JUMPS instructions: JUMPS next, imm_value, LT JUMPS label_num, imm_value, LE
This macro generates three ulp_insn_t values separated by commas, and should be used when defining contents of ulp_insn_t arrays. Second value is not a real instruction; it is a token which is removed by ulp_process Macros_and_load function.

M_BSGT (label_num, imm_value)
Macro: branch to label if the stage counter is greater than immediate value. Implemented using two instructions: JUMPS next, imm_value, LE JUMPS label_num, imm_value, GE
This macro generates three ulp_insn_t values separated by commas, and should be used when defining contents of ulp_insn_t arrays. Second value is not a real instruction; it is a token which is removed by ulp_process Macros_and_load function.

I_JUMPS (pc_offset, imm_value, comp_type)
Branch relative if (stage counter [comp_type] [imm_value]) evaluates to true.
pc_offset is expressed in words, and can be from -127 to 127 imm_value is an 8-bit value to compare the stage counter against comp_type is the type of comparison to perform: JUMPS_LT (<), JUMPS_GE (>=) or JUMPS_LE (<=)

**I_I2C_RW** (sub_addr, val, low_bit, high_bit, slave_sel, rw_bit)

Perform an I2C transaction with a slave device. I_I2C_READ and I_I2C_WRITE are provided for convenience, instead of using this directly.

Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == slave_sel. For read operations, 8 bits of read result is stored into R0 register. For write operations, val will be written to sub_addr at [high_bit:low_bit]. Bits outside of this range are masked.

**I_I2C_READ** (slave_sel, sub_addr)

Read a byte from the sub address of an I2C slave, and store the result in R0.

Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == slave_sel.

**I_I2C_WRITE** (slave_sel, sub_addr, val)

Write a byte to the sub address of an I2C slave.

Slave address (in 7-bit format) has to be set in advance into SENS_I2C_SLAVE_ADDRx register field, where x == slave_sel.

### Compiling the ULP Code

To compile the ULP FSM code as part of the component, the following steps must be taken:

1. The ULP FSM code, written in assembly, must be added to one or more files with .S extension. These files must be placed into a separate directory inside the component directory, for instance, ulp/

   **Note:** When registering the component (via `idf_component_register`), this directory should **not** be added to the SRC_DIRS argument. The logic behind this is that the ESP-IDF build system will compile files found in SRC_DIRS based on their extensions. For .S files, xtensa-esp32-elf-as assembler is used. This is not desirable for ULP FSM assembly files, so the easiest way to achieve the distinction is by placing ULP FSM assembly files into a separate directory. The ULP FSM assembly source files should also be added to SRCS for the same reason. See the step below for how to properly add ULP FSM assembly source files.

2. Call `ulp_embed_binary` from the component CMakeLists.txt after registration. For example:

   ```
   ...
   idf_component_register()

   set(ulp_app_name ulp_${COMPONENT_NAME})
   set(ulp_s_sources ulp/ulp_assembly_source_file.S)
   set(ulp_exp_dep_srcs "ulp_c-source_file.c")
   ulp_embed_binary(${ulp_app_name} "${ulp_s_sources}" "${ulp_exp_dep_srcs}")
   ```

   The first argument to `ulp_embed_binary` specifies the ULP FSM binary name. The name specified here will also be used by other generated artifacts such as the ELF file, map file, header file and linker export file. The second argument specifies the ULP FSM assembly source files. Finally, the third argument specifies the list of component source files which include the header file to be generated. This list is needed to build the dependencies correctly and ensure that the generated header file will be created before any of these files are compiled. See the section below for the concept of generated header files for ULP applications.

3. Build the application as usual (e.g. `idf.py app`). Inside, the build system will take the following steps to build ULP FSM program:

   1. **Run each assembly file** (foo.S) **through the C preprocessor.** This step generates the preprocessed assembly files (foo.ulp.S) in the component build directory. This step also generates dependency files (foo.ulp.d).
2. **Run preprocessed assembly sources through the assembler.** This produces object (foo.ulp.o) and listing (foo.ulp.lst) files. Listing files are generated for debugging purposes and are not used at later stages of the build process.

3. **Run the linker script template through the C preprocessor.** The template is located in components/ulp/ld directory.

4. **Link the object files into an output ELF file** (ulp_app_name.elf). The Map file (ulp_app_name.map) generated at this stage may be useful for debugging purposes.

5. **Dump the contents of the ELF file into a binary** (ulp_app_name.bin) which can then be embedded into the application.

6. **Generate a list of global symbols** (ulp_app_name.sym) in the ELF file using esp32ulp-elf-nm.

7. **Create an LD export script and a header file** (ulp_app_name.ld and ulp_app_name.h) containing the symbols from ulp_app_name.sym. This is done using the esp32ulp_mapgen.py utility.

8. **Add the generated binary to the list of binary files** to be embedded into the application.

### Accessing the ULP FSM Program Variables

Global symbols defined in the ULP FSM program may be used inside the main program.

For example, the ULP FSM program may define a variable `measurement_count` which will define the number of ADC measurements the program needs to make before waking up the chip from deep sleep:

```asm
.global measurement_count
measurement_count:    .long 0

// later, use measurement_count
move r3, measurement_count
ld r3, r3, 0
```

The main program needs to initialize this variable before the ULP program is started. The build system makes this possible by generating the `${ULP_APP_NAME}.h` and `${ULP_APP_NAME}.ld` files which define the global symbols present in the ULP program. Each global symbol defined in the ULP program is included in these files and are prefixed with `ulp_`.

The header file contains the declaration of the symbol:

```c
extern uint32_t ulp_measurement_count;
```

Note that all symbols (variables, arrays, functions) are declared as `uint32_t`. For functions and arrays, take the address of the symbol and cast it to the appropriate type.

The generated linker script file defines the locations of symbols in RTC_SLOW_MEM:

```ini
PROVIDE ( ulp_measurement_count = 0x50000060 );
```

To access the ULP program variables from the main program, the generated header file should be included using an `#include` statement. This will allow the ULP program variables to be accessed as regular variables:

```c
#include "ulp_app_name.h"

// later
void init_ulp_vars() {
    ulp_measurement_count = 64;
}
```

Note that the ULP FSM program can only use the lower 16 bits of each 32-bit word in RTC memory, because the registers are 16-bit, and there is no instruction to load from the high part of the word. Likewise, the ULP store instruction writes register values into the lower 16 bits of the 32-bit word in RTC memory. The upper 16 bits are written with a value which depends on the address of the store instruction, thus when reading variables written by the ULP coprocessor, the main application needs to mask the upper 16 bits, e.g.:
Starting the ULP FSM Program

To run a ULP FSM program, the main application needs to load the ULP program into RTC memory using the \texttt{ulp_load_binary()} function, and then start it using the \texttt{ulp_run()} function.

Note that the Enable Ultra Low Power (ULP) Coprocessor option must be enabled in menuconfig to work with ULP. To select the type of ULP to be used, the ULP Co-processor type option must be set. To reserve memory for the ULP, the RTC slow memory reserved for coprocessor option must be set to a value big enough to store ULP code and data. If the application components contain multiple ULP programs, then the size of the RTC memory must be sufficient to hold the largest one.

Each ULP program is embedded into the ESP-IDF application as a binary blob. The application can reference this blob and load it in the following way (suppose ULP\_APP\_NAME was defined to \texttt{ulp_app_name}):

```c
extern const uint8_t bin_start[] asm("_binary_ulp_app_name_bin_start");
extern const uint8_t bin_end[] asm("_binary_ulp_app_name_bin_end");

void start_ulp_program() {
    ESP_ERROR_CHECK( ulp_load_binary(
        0 // load address, set to 0 when using default linker scripts
        bin_start,
        (bin_end - bin_start) / sizeof(uint32_t)) );
}
```

Once the program is loaded into RTC memory, the application can start it by passing the address of the entry point to the \texttt{ulp_run} function:

```c
ESP_ERROR_CHECK( ulp_run(&ulp_entry - RTC_SLOW_MEM) );
```

Declaration of the entry point symbol comes from the generated header file mentioned above, \$\{ULP\_APP\_NAME\}.h. In the assembly source of the ULP FSM application, this symbol must be marked as \texttt{.global}:

```assembly
.global entry
entry:
    // code starts here
```

ESP32 ULP program flow

ESP32 ULP coprocessor is started by a timer. The timer is started once \texttt{ulp_run()} is called. The timer counts a number of RTC\_SLOW\_CLK ticks (by default, produced by an internal 150 kHz RC oscillator). The number of ticks is set using SENS\_ULP\_CP\_SLEEP\_CYCx\_REG registers (x = 0..4). When starting the ULP for the first time, SENS\_ULP\_CP\_SLEEP\_CYC0\_REG will be used to set the number of timer ticks. Later the ULP program can select another SENS\_ULP\_CP\_SLEEP\_CYCx\_REG register using sleep instruction.

The application can set ULP timer period values (SENS\_ULP\_CP\_SLEEP\_CYCx\_REG, x = 0..4) using \texttt{ulp_set_wakeup_period} function.

Once the timer counts the number of ticks set in the selected SENS\_ULP\_CP\_SLEEP\_CYCx\_REG register, ULP coprocessor powers up and starts running the program from the entry point set in the call to \texttt{ulp_run()}.

The program runs until it encounters a \texttt{halt} instruction or an illegal instruction. Once the program halts the ULP coprocessor powers down and the timer is started again.

To disable the timer (effectively preventing the ULP program from running again), clear the RTC\_CNTL\_ULP\_CP\_SLP\_TIMER\_EN bit in the RTC\_CNTL\_STATE0\_REG register. This can be done both from ULP code and from the main program.
Chapter 2. API Reference

Application Examples

- ULP FSM Coprocessor counts pulses on an IO while main CPU is in deep sleep: `system/ulp_fsm/ulp`
- ULP FSM Coprocessor polls ADC in while main CPU is in deep sleep: `system/ulp_fsm/ulp_adc`

API Reference

Header File

- `components/ulp/ulp_fsm/include/ulp_fsm_common.h`

Functions

`esp_err_t ulp_isr_register (intr_handler_t fn, void *arg)`

Register ULP wakeup signal ISR.

**Parameters**
- `fn` - ISR callback function
- `arg` - ISR callback function arguments

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if callback function is NULL
- ESP_ERR_NO_MEM if heap memory cannot be allocated for the interrupt

`esp_err_t ulp_isr_deregister (intr_handler_t fn, void *arg)`

Deregister ULP wakeup signal ISR.

**Parameters**
- `fn` - ISR callback function
- `arg` - ISR callback function arguments

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if callback function is NULL
- ESP_ERR_INVALID_STATE if a handler matching both callback function and its arguments isn’t registered

`esp_err_t ulp_process_macros_and_load (uint32_t load_addr, const ulp_insn_t *program, size_t *psize)`

Resolve all macro references in a program and load it into RTC memory.

**Parameters**
- `load_addr` - address where the program should be loaded, expressed in 32-bit words
- `program` - ulp_insn_t array with the program
- `psize` - size of the program, expressed in 32-bit words

**Returns**
- ESP_OK on success
- ESP_ERR_NO_MEM if auxiliary temporary structure cannot be allocated
- one of ESP_ERR_ULP_xxx if program is not valid or cannot be loaded

`esp_err_t ulp_load_binary (uint32_t load_addr, const uint8_t *program_binary, size_t program_size)`

Load ULP program binary into RTC memory.

ULP program binary should have the following format (all values little-endian):

a. MAGIC, (value 0x00706c75, 4 bytes)
b. TEXT_OFFSET, offset of .text section from binary start (2 bytes)
c. TEXT_SIZE, size of .text section (2 bytes)
Chapter 2. API Reference

d. DATA_SIZE, size of .data section (2 bytes)
e. BSS_SIZE, size of .bss section (2 bytes)
f. (TEXT_OFFSET - 12) bytes of arbitrary data (will not be loaded into RTC memory)
g. .text section
h. .data section

Linker script in components/ulp/ld/esp32.ulp.ld produces ELF files which correspond to this format. This linker script produces binaries with load_addr == 0.

Parameters
- load_addr – address where the program should be loaded, expressed in 32-bit words
- program_binary – pointer to program binary
- program_size – size of the program binary

Returns
- ESP_OK on success
- ESP_ERR_INVALID_ARG if load_addr is out of range
- ESP_ERR_INVALID_SIZE if program_size doesn’t match (TEXT_OFFSET + TEXT_SIZE + DATA_SIZE)
- ESP_ERR_NOT_SUPPORTED if the magic number is incorrect

```c
esp_err_t ulp_run(uint32_t entry_point)
```

Run the program loaded into RTC memory.

Parameters entry_point – entry point, expressed in 32-bit words

Returns ESP_OK on success

Macros

ESP_ERR_ulp_BASE
Offset for ULP-related error codes

ESP_ERR_ulp_SIZE_TOO_BIG
Program doesn’t fit into RTC memory reserved for the ULP

ESP_ERR_ulp_INVALID_LOAD_ADDR
Load address is outside of RTC memory reserved for the ULP

ESP_ERR_ulp_DUPLICATE_LABEL
More than one label with the same number was defined

ESP_ERR_ulp_UNDEFINED_LABEL
Branch instructions references an undefined label

ESP_ERR_ulp_BRANCH_OUT_OF_RANGE
Branch target is out of range of B instruction (try replacing with BX)

Type Definitions

typedef union ulp_insn ulp_insn_t

Header File
- components/ulp/ulp_common/include/ulp_common.h
### Functions

**esp_err_t ulp_set_wakeup_period(size_t period_index, uint32_t period_us)**

Set one of ULP wakeup period values.

ULP coprocessor starts running the program when the wakeuptimer counts up to a given value (called period). There are 5 period values which can be programmed into SENS_ULP_CP_SLEEP_CYCx_REG registers, x = 0..4 for ESP32, and one period value which can be programmed into RTC_CNTL_ULP_CP_TIMER_1_REG register for ESP32-S2/S3. By default, for ESP32, wakeuptimer will use the period set into SENS_ULP_CP_SLEEP_CYC0_REG, i.e. period number 0. ULP program code can use SLEEP instruction to select which of the SENS_ULP_CP_SLEEP_CYCx_REG should be used for subsequent wakeups.

However, please note that SLEEP instruction issued (from ULP program) while the system is in deep sleep mode does not have effect, and sleep cycle count 0 is used.

For ESP32-S2/S3 the SLEEP instruction not exist. Instead a WAKE instruction will be used.

**Note:** The ULP FSM requires two clock cycles to wakeup before being able to run the program. Then additional 16 cycles are reserved after wakeup waiting until the 8M clock is stable. The FSM also requires two more clock cycles to go to sleep after the program execution is halted. The minimum wakeuptime period that may be set up for the ULP is equal to the total number of cycles spent on the above internal tasks. For a default configuration of the ULP running at 150kHz it makes about 133us.

**Parameters**
- `period_index` – Wakeup period setting number (0 - 4)
- `period_us` – Wakeup period, us

**Returns**
- ESP_OK on success
- ESP_ERR_INVALID_ARG if period_index is out of range

**void ulp_timer_stop(void)**

Stop the ULP timer.

**Note:** This will stop the ULP from waking up if halted, but will not abort any program currently executing on the ULP.

**void ulp_timer_resume(void)**

Resume the ULP timer.

**Note:** This will resume an already configured timer, but does no other configuration

### Header File

- components/ulp/ulp_common/include/esp32/ulp_common_defs.h

### Macros

**RTC SLOW_MEM**

RTC slow memory, 8k size

### 2.10.32 Watchdogs
Overview

The ESP-IDF has support for multiple types of watchdogs, with the two main ones being: The Interrupt Watchdog Timer and the Task Watchdog Timer (TWDT). The Interrupt Watchdog Timer and the TWDT can both be enabled using Project Configuration Menu, however the TWDT can also be enabled during runtime. The Interrupt Watchdog is responsible for detecting instances where FreeRTOS task switching is blocked for a prolonged period of time. The TWDT is responsible for detecting instances of tasks running without yielding for a prolonged period.

ESP-IDF has support for the following types of watchdog timers:

- Interrupt Watchdog Timer (IWDT)
- Task Watchdog Timer (TWDT)

The various watchdog timers can be enabled using the Project Configuration Menu. However, the TWDT can also be enabled during runtime.

Interrupt Watchdog Timer (IWDT)

The purpose of the IWDT is to ensure that interrupt service routines (ISRs) are not blocked from running for a prolonged period of time (i.e., the IWDT timeout period). Blocking ISRs from running in a timely manner is undesirable as it can increases ISR latency, and also prevents task switching (as task switching is executed form an ISR). The things that can block ISRs from running include:

- Disabling interrupts
- Critical Sections (also disables interrupts)
- Other same/higher priority ISRs (will block same/lower priority ISRs from running it completes execution)

The IWDT utilizes the watchdog timer in Timer Group 1 as its underlying hardware timer and leverages the FreeRTOS tick interrupt on each CPU to feed the watchdog timer. If the tick interrupt on a particular CPU is not run at within the IWDT timeout period, it is indicative that something is blocking ISRs from being run on that CPU (see the list of reasons above).

When the IWDT times out, the default action is to invoke the panic handler and display the panic reason as Interrupt wdt timeout on CPU0 or Interrupt wdt timeout on CPU1 (as applicable). Depending on the panic handler’s configured behavior (see CONFIG_ESP_SYSTEM_PANIC), users can then debug the source of the IWDT timeout (via the backtrace, OpenOCD, gdbstub etc) or simply reset the chip (which may be preferred in a production environment).

If for whatever reason the panic handler is unable to run after an IWDT timeout, the IWDT has a secondary timeout that will hard-reset the chip (i.e., a system reset).

Configuration

- The IWDT is enabled by default via the CONFIG_ESP_INT_WDT option.
- The IWDT’s timeout is configured by setting the CONFIG_ESP_INT_WDT_TIMEOUT_MS option.
  - Note that the default timeout is higher if PSRAM support is enabled, as a critical section or interrupt routine that accesses a large amount of PSRAM will take longer to complete in some circumstances.
  - The timeout should always at least twice longer than the period between FreeRTOS ticks (see CONFIG_FREERTOS_HZ).

Tuning  If you find the IWDT timeout is triggered because an interrupt or critical section is running longer than the timeout period, consider rewriting the code:

- Critical sections should be made as short as possible. Any non-critical code/computation should be placed outside the critical section.
- Interrupt handlers should also perform the minimum possible amount of computation. Users can consider deferring any computation to a task by having the ISR push data to a task using queues.
Neither critical sections or interrupt handlers should ever block waiting for another event to occur. If changing the code to reduce the processing time is not possible or desirable, it’s possible to increase the `CONFIG_ESP_INT_WDT_TIMEOUT_MS` setting instead.

**Task Watchdog Timer (TWDT)**

The Task Watchdog Timer (TWDT) is used to monitor particular tasks, ensuring that they are able to execute within a given timeout period. The TWDT primarily watches the Idle Tasks of each CPU, however any task can subscribe to be watched by the TWDT. By watching the Idle Tasks of each CPU, the TWDT can detect instances of tasks running for a prolonged period of time without yielding. This can be an indicator of poorly written code that spinloops on a peripheral, or a task that is stuck in an infinite loop.

The TWDT is built around the Hardware Watchdog Timer in Timer Group 0. When a timeout occurs, an interrupt is triggered. Users can define the function `esp_task_wdt_isr_user_handler` in the user code, in order to receive the timeout event and extend the default behavior.

**Usage**

The following functions can be used to watch tasks using the TWDT:

- `esp_task_wdt_init()` to initialize the TWDT and subscribe the idle tasks.
- `esp_task_wdt_add()` subscribes other tasks to the TWDT.
- Once subscribed, `esp_task_wdt_reset()` should be called from the task to feed the TWDT.
- `esp_task_wdt_delete()` unsubscribes a previously subscribed task
- `esp_task_wdt_deinit()` unsubscribes the idle tasks and deinitializes the TWDT

In the case where applications need to watch at a more granular level (i.e., ensure that a particular functions/stub/code-path is called), the TWDT allows subscription of “users”.

- `esp_task_wdt_add_user()` to subscribe an arbitrary user of the TWDT. This function will return a user handle to the added user.
- `esp_task_wdt_reset_user()` must be called using the user handle in order to prevent a TWDT timeout.
- `esp_task_wdt_delete_user()` unsubscribes an arbitrary user of the TWDT.

**Configuration**

The default timeout period for the TWDT is set using config item `CONFIG_ESP_TASK_WDT_TIMEOUT_S`. This should be set to at least as long as you expect any single task will need to monopolize the CPU (for example, if you expect the app will do a long intensive calculation and should not yield to other tasks). It is also possible to change this timeout at runtime by calling `esp_task_wdt_init()`.

**Note:** Erasing large flash areas can be time consuming and can cause a task to run continuously, thus triggering a TWDT timeout. The following two methods can be used to avoid this:

- Increase `CONFIG_ESP_TASK_WDT_TIMEOUT_S` in menuconfig for a larger watchdog timeout period.
- You can also call `esp_task_wdt_init()` to increase the watchdog timeout period before erasing a large flash area.

For more information, you can refer to SPI Flash.

The following config options control TWDT configuration. They are all enabled by default:

- `CONFIG_ESP_TASK_WDT_EN` - enables TWDT feature. If this option is disabled, TWDT cannot be used, even if initialized at runtime.
- `CONFIG_ESP_TASK_WDT_INIT` - the TWDT is initialized automatically during startup. If this option is disabled, it is still possible to initialize the Task WDT at runtime by calling `esp_task_wdt_init()`.
- `CONFIG_ESP_TASK_WDT_CHECK_IDLE_TASK_CPU0` - CPU0 Idle task is subscribed to the TWDT during startup. If this option is disabled, it is still possible to subscribe the idle task by calling `esp_task_wdt_init()` again.
Chapter 2. API Reference

- **CONFIG_ESP_TASK_WDT_CHECK_IDLE_TASK_CPU1** - CPU1 Idle task is subscribed to the TWDT during startup.

**Note:** On a TWDT timeout the default behaviour is to simply print a warning and a backtrace before continuing running the app. If you want a timeout to cause a panic and a system reset then this can be configured through **CONFIG_ESP_TASK_WDT_PANIC**.

**JTAG & Watchdogs**

While debugging using OpenOCD, the CPUs will be halted every time a breakpoint is reached. However if the watchdog timers continue to run when a breakpoint is encountered, they will eventually trigger a reset making it very difficult to debug code. Therefore OpenOCD will disable the hardware timers of both the interrupt and task watchdogs at every breakpoint. Moreover, OpenOCD will not reenable them upon leaving the breakpoint. This means that interrupt watchdog and task watchdog functionality will essentially be disabled. No warnings or panics from either watchdogs will be generated when the ESP32 is connected to OpenOCD via JTAG.

**API Reference**

**Task Watchdog** A full example using the Task Watchdog is available in esp-idf: `system/task_watchdog`

**Header File**

- components/esp_system/include/esp_task_wdt.h

**Functions**

```c
esp_err_t esp_task_wdt_init(const esp_task_wdt_config_t *config)
```

Initializes the Task Watchdog Timer (TWDT).

This function configures and initializes the TWDT. This function will subscribe the idle tasks if configured to do so. For other tasks, users can subscribe them using `esp_task_wdt_add()` or `esp_task_wdt_add_user()`. This function won’t start the timer if no task have been registered yet.

**Note:** `esp_task_wdt_init()` must only be called after the scheduler is started. Moreover, it must not be called by multiple tasks simultaneously.

**Parameters**

- `config` - [in] Configuration structure

**Returns**

- ESP_OK: Initialization was successful
- ESP_ERR_INVALID_STATE: Already initialized
- Other: Failed to initialize TWDT

```c
esp_err_t esp_task_wdt_reconfigure(const esp_task_wdt_config_t *config)
```

Reconfigures the Task Watchdog Timer (TWDT).

The function reconfigures the running TWDT. It must already be initialized when this function is called.

**Note:** `esp_task_wdt_reconfigure()` must not be called by multiple tasks simultaneously.

**Parameters**

- `config` - [in] Configuration structure

**Returns**

- ESP_OK: Reconfiguring was successful
- ESP_ERR_INVALID_STATE: TWDT not initialized yet
Chapter 2. API Reference

- Other: Failed to initialize TWDT

`esp_err_t esp_task_wdt_deinit (void)`

Deinitialize the Task Watchdog Timer (TWDT)

This function will deinitialize the TWDT, and unsubscribe any idle tasks. Calling this function whilst other tasks are still subscribed to the TWDT, or when the TWDT is already deinitialized, will result in an error code being returned.

**Note:** `esp_task_wdt_deinit()` must not be called by multiple tasks simultaneously.

**Returns**
- ESP_OK: TWDT successfully deinitialized
- Other: Failed to deinitialize TWDT

`esp_err_t esp_task_wdt_add (TaskHandle_t task_handle)`

Subscribe a task to the Task Watchdog Timer (TWDT)

This function subscribes a task to the TWDT. Each subscribed task must periodically call `esp_task_wdt_reset()` to prevent the TWDT from elapsing its timeout period. Failure to do so will result in a TWDT timeout.

**Parameters**
- task_handle – Handle of the task. Input NULL to subscribe the current running task to the TWDT

**Returns**
- ESP_OK: Successfully subscribed the task to the TWDT
- Other: Failed to subscribe task

`esp_err_t esp_task_wdt_add_user (const char* user_name, esp_task_wdt_user_handle_t* user_handle_ret)`

Subscribe a user to the Task Watchdog Timer (TWDT)

This function subscribes a user to the TWDT. A user of the TWDT is usually a function that needs to run periodically. Each subscribed user must periodically call `esp_task_wdt_reset_user()` to prevent the TWDT from elapsing its timeout period. Failure to do so will result in a TWDT timeout.

**Parameters**
- user_name – [in] String to identify the user
- user_handle_ret – [out] Handle of the user

**Returns**
- ESP_OK: Successfully subscribed the user to the TWDT
- Other: Failed to subscribe user

`esp_err_t esp_task_wdt_reset (void)`

Reset the Task Watchdog Timer (TWDT) on behalf of the currently running task.

This function will reset the TWDT on behalf of the currently running task. Each subscribed task must periodically call this function to prevent the TWDT from timing out. If one or more subscribed tasks fail to reset the TWDT on their own behalf, a TWDT timeout will occur.

**Returns**
- ESP_OK: Successfully reset the TWDT on behalf of the currently running task
- Other: Failed to reset

`esp_err_t esp_task_wdt_reset_user (esp_task_wdt_user_handle_t user_handle)`

Reset the Task Watchdog Timer (TWDT) on behalf of a user.

This function will reset the TWDT on behalf of a user. Each subscribed user must periodically call this function to prevent the TWDT from timing out. If one or more subscribed users fail to reset the TWDT on their own behalf, a TWDT timeout will occur.

**Parameters**
- user_handle – [in] User handle
• ESP_OK: Successfully reset the TWDT on behalf of the user
• Other: Failed to reset

`esp_err_t esp_task_wdt_delete(TaskHandle_t task_handle)`

Unsubscribes a task from the Task Watchdog Timer (TWDT)

This function will unsubscribe a task from the TWDT. After being unsubscribed, the task should no longer call `esp_task_wdt_reset()`.

**Parameters**
- `task_handle` [in] Handle of the task. Input NULL to unsubscribe the current running task.

**Returns**
- ESP_OK: Successfully unsubscribed the task from the TWDT
- Other: Failed to unsubscribe task

`esp_err_t esp_task_wdt_delete_user(esp_task_wdt_user_handle_t user_handle)`

Unsubscribes a user from the Task Watchdog Timer (TWDT)

This function will unsubscribe a user from the TWDT. After being unsubscribed, the user should no longer call `esp_task_wdt_reset_user()`.

**Parameters**
- `user_handle` [in] User handle

**Returns**
- ESP_OK: Successfully unsubscribed the user from the TWDT
- Other: Failed to unsubscribe user

`esp_err_t esp_task_wdt_status(TaskHandle_t task_handle)`

Query whether a task is subscribed to the Task Watchdog Timer (TWDT)

This function will query whether a task is currently subscribed to the TWDT, or whether the TWDT is initialized.

**Parameters**
- `task_handle` [in] Handle of the task. Input NULL to query the current running task.

**Returns**
- ESP_OK: The task is currently subscribed to the TWDT
- ESP_ERR_NOT_FOUND: The task is not subscribed
- ESP_ERR_INVALID_STATE: TWDT was never initialized

`void esp_task_wdt_isr_user_handler(void)`

User ISR callback placeholder.

This function is called by `task_wdt_isr` function (ISR for when TWDT times out). It can be defined in user code to handle TWDT events.

**Note:** It has the same limitations as the interrupt function. Do not use ESP_LOGx functions inside.

**Structures**

`struct esp_task_wdt_config_t`

Task Watchdog Timer (TWDT) configuration structure.

**Public Members**

`uint32_t timeout_ms`

TWDT timeout duration in milliseconds
uint32_t **idle_core_mask**

Mask of the cores who’s idle task should be subscribed on initialization

bool **trigger_panic**

Trigger panic when timeout occurs

**Type Definitions**

typedef struct esp_task_wdt_user_handle_s *esp_task_wdt_user_handle_t

Task Watchdog Timer (TWDT) user handle.

Code examples for this API section are provided in the system directory of ESP-IDF examples.

API Guides

4.1 Application Level Tracing library

4.1.1 Overview

ESP-IDF provides a useful feature for program behavior analysis: application level tracing. It is implemented in the corresponding library and can be enabled in menuconfig. This feature allows to transfer arbitrary data between host and ESP32 via JTAG, UART, or USB interfaces with small overhead on program execution. It is possible to use JTAG and UART interfaces simultaneously. The UART interface is mostly used for connection with SEGGER SystemView tool (see SystemView).

Developers can use this library to send application-specific state of execution to the host and receive commands or other types of information from the opposite direction at runtime. The main use cases of this library are:

1. Collecting application-specific data. See Application Specific Tracing.
2. Lightweight logging to the host. See Logging to Host.

Tracing components used when working over JTAG interface are shown in the figure below.

4.1.2 Modes of Operation

The library supports two modes of operation:

**Post-mortem mode**: This is the default mode. The mode does not need interaction with the host side. In this mode, tracing module does not check whether the host has read all the data from HW UP BUFFER, but directly overwrites old data with the new ones. This mode is useful when only the latest trace data is interesting to the user, e.g., for analyzing program’s behavior just before the crash. The host can read the data later on upon user request, e.g., via special OpenOCD command in case of working via JTAG interface.

**Streaming mode**: Tracing module enters this mode when the host connects to ESP32. In this mode, before writing new data to HW UP BUFFER, the tracing module checks that whether there is enough space in it and if necessary, waits for the host to read data and free enough memory. Maximum waiting time is controlled via timeout values passed by users to corresponding API routines. So when application tries to write data to the trace buffer using the finite value of the maximum waiting time, it is possible that this data will be dropped. This is especially true for tracing from time critical code (ISRs, OS scheduler code, etc.) where infinite timeouts can lead to system malfunction. In order to avoid loss of such critical data, developers can enable additional data buffering via menuconfig option.
**CONFIG_APPTRACE_PENDING_DATA_SIZE_MAX.** This macro specifies the size of data which can be buffered in above conditions. The option can also help to overcome situation when data transfer to the host is temporarily slowed down, e.g., due to USB bus congestions. But it will not help when the average bitrate of the trace data stream exceeds the hardware interface capabilities.

### 4.1.3 Configuration Options and Dependencies

Using of this feature depends on two components:

1. **Host side:** Application tracing is done over JTAG, so it needs OpenOCD to be set up and running on host machine. For instructions on how to set it up, please see [JTAG Debugging](#) for details.

2. **Target side:** Application tracing functionality can be enabled in menuconfig. Please go to Component config > Application Level Tracing menu, which allows selecting destination for the trace data (hardware interface for transport: JTAG or/and UART). Choosing any of the destinations automatically enables the `CONFIG_APPTRACE_ENABLE` option. For UART interfaces, users have to define baud rate, TX and RX pins numbers, and additional UART-related parameters.

**Note:** In order to achieve higher data rates and minimize the number of dropped packets, it is recommended to optimize the setting of JTAG clock frequency, so that it is at maximum and still provides stable operation of JTAG. See [Optimize JTAG Speed](#).

There are two additional menuconfig options not mentioned above:

1. **Threshold for flushing last trace data to host on panic (CONFIG_APPTRACE_POSTMORTEM_FLUSH_THRESH).** This option is necessary due to the nature of working over JTAG. In this mode, trace data is exposed to the host in 16 KB blocks. In post-mortem mode, when one block is filled, it is exposed to the host and the previous one becomes unavailable. In other words, the trace data is overwritten in 16 KB granularity. On panic, the latest data from the current input block is exposed to the host and the host can read them for post-analysis. System panic may occur when a very small amount of data are not exposed to the host yet. In this case, the previous 16 KB of collected data will be lost and the host will see the latest, but very small piece of the trace.
It can be insufficient to diagnose the problem. This menuconfig option allows avoiding such situations. It controls the threshold for flushing data in case of panic. For example, users can decide that it needs no less than 512 bytes of the recent trace data, so if there is less then 512 bytes of pending data at the moment of panic, they will not be flushed and will not overwrite the previous 16 KB. The option is only meaningful in post-mortem mode and when working over JTAG.

2. **Timeout for flushing last trace data to host on panic** ([CONFIG_APPTRACE_ONPANIC_HOST_FLUSH_TMO]). The option is only meaningful in streaming mode and it controls the maximum time that the tracing module will wait for the host to read the last data in case of panic.

3. **UART RX/TX ring buffer size** ([CONFIG_APPTRACE_UART_TX_BUFF_SIZE]). The size of the buffer depends on the amount of data transferred through the UART.

4. **UART TX message size** ([CONFIG_APPTRACE_UART_TX_MSG_SIZE]). The maximum size of the single message to transfer.

### 4.1.4 How to Use This Library

This library provides APIs for transferring arbitrary data between the host and ESP32. When enabled in menuconfig, the target application tracing module is initialized automatically at the system startup, so all what the user needs to do is to call corresponding APIs to send, receive or flush the data.

#### Application Specific Tracing

In general, users should decide what type of data should be transferred in every direction and how these data must be interpreted (processed). The following steps must be performed to transfer data between the target and the host:

1. On the target side, users should implement algorithms for writing trace data to the host. Piece of code below shows an example on how to do this.

```c
#include "esp_app_trace.h"
...
char buf[] = "Hello World!";
esp_err_t res = esp_apptrace_write(ESP_APPTRACE_DEST_TRAX, buf, strlen(buf), ESP_APPTRACE_TMO_INFINITE);
if (res != ESP_OK) {
    ESP_LOGE(TAG, "Failed to write data to host!");
    return res;
}
```

esp_apptrace_write() function uses memcpy to copy user data to the internal buffer. In some cases, it can be more optimal to use esp_apptrace_buffer_get() and esp_apptrace_buffer_put() functions. They allow developers to allocate buffer and fill it themselves. The following piece of code shows how to do this.

```c
#include "esp_app_trace.h"
...
int number = 10;
char *ptr = (char *)esp_apptrace_buffer_get(ESP_APPTRACE_DEST_TRAX, 32, 100/*tmo in us*/);
if (ptr == NULL) {
    ESP_LOGE(TAG, "Failed to get buffer!");
    return ESP_FAIL;
}
sprintf(ptr, "Here is the number %d", number);
esp_err_t res = esp_apptrace_buffer_put(ESP_APPTRACE_DEST_TRAX, ptr, 100/*tmo in us*/);
if (res != ESP_OK) {
    /* in case of error host tracing tool (e.g., OpenOCD) will report incomplete user buffer */
    ESP_LOGE(TAG, "Failed to put buffer!");
    return res;
}
```
Also according to his needs, the user may want to receive data from the host. Piece of code below shows an example on how to do this.

```c
#include "esp_app_trace.h"
...
char buf[32];
char down_buf[32];
size_t sz = sizeof(buf);

/* config down buffer */
esp_apptrace_down_buffer_config(down_buf, sizeof(down_buf));
/* check for incoming data and read them if any */
esp_err_t res = esp_apptrace_read(ESP_APPTRACE_DEST_TRAX, buf, &sz, 0/
~*do not wait*/);
if (res != ESP_OK) {
    ESP_LOGE(TAG, "Failed to read data from host!");
    return res;
}
if (sz > 0) {
    /* we have data, process them */
    ...
}
```

`esp_apptrace_read()` function uses `memcpy` to copy host data to user buffer. In some cases, it can be more optimal to use `esp_apptrace_down_buffer_get()` and `esp_apptrace_down_buffer_put()` functions. They allow developers to occupy chunk of read buffer and process it in-place. The following piece of code shows how to do this.

```c
#include "esp_app_trace.h"
...
char down_buf[32];
uint32_t *number;
size_t sz = 32;

/* config down buffer */
esp_apptrace_down_buffer_config(down_buf, sizeof(down_buf));
char *ptr = (char *)esp_apptrace_down_buffer_get(ESP_APPTRACE_DEST_TRAX, &sz, 100/*tmo in us*/);
if (ptr == NULL) {
    ESP_LOGE(TAG, "Failed to get buffer!");
    return ESP_FAIL;
}
if (sz > 4) {
    number = (uint32_t *)ptr;
    printf("Here is the number %d", *number);
} else {
    printf("No data");
}
esp_err_t res = esp_apptrace_down_buffer_put(ESP_APPTRACE_DEST_TRAX,--ptr, 100/*tmo in us*/);
if (res != ESP_OK) {
    /* in case of error host tracing tool (e.g., OpenOCD) will report--incomplete user buffer */
    ESP_LOGE(TAG, "Failed to put buffer!");
    return res;
}
```

2. The next step is to build the program image and download it to the target as described in the Getting Started Guide.
3. Run OpenOCD (see JTAG Debugging).
4. Connect to OpenOCD telnet server. It can be done using the following command in terminal `telnet <oocd_host> 4444`. If telnet session is opened on the same machine which runs OpenOCD, you can use localhost as <oocd_host> in the command above.
5. Start trace data collection using special OpenOCD command. This command will transfer tracing data and redirect them to the specified file or socket (currently only files are supported as trace data destination). For description of the corresponding commands, see OpenOCD Application Level Tracing Commands.

6. The final step is to process received data. Since the format of data is defined by users, the processing stage is out of the scope of this document. Good starting points for data processor are python scripts in $IDF_PATH/tools/esp_app_trace: apptrace_proc.py (used for feature tests) and logtrace_proc.py (see more details in section Logging to Host).

OpenOCD Application Level Tracing Commands  HW UP BUFFER is shared between user data blocks and the filling of the allocated memory is performed on behalf of the API caller (in task or ISR context). In multithreading environment, it can happen that the task/ISR which fills the buffer is preempted by another high priority task/ISR. So it is possible that the user data preparation process is not completed at the moment when that chunk is read by the host. To handle such conditions, the tracing module prepends all user data chunks with header which contains the allocated user buffer size (2 bytes) and the length of the actually written data (2 bytes). So the total length of the header is 4 bytes. OpenOCD command which reads trace data reports error when it reads incomplete user data chunk, but in any case, it puts the contents of the whole user chunk (including unfilled area) to the output file. Below is the description of available OpenOCD application tracing commands.

Note: Currently, OpenOCD does not provide commands to send arbitrary user data to the target.

Command usage:

```
esp aptrace [start <options>] | [stop] | [status] | [dump <cores_num> <outfile>]
```

Sub-commands:

- **start** Start tracing (continuous streaming).
- **stop** Stop tracing.
- **status** Get tracing status.
- **dump** Dump all data from (post-mortem dump).

Start command syntax:

```
start <outfile> [poll_period [trace_size [stop_tmo [wait4halt [skip_size]]]]]
```

- **outfile** Path to file to save data from both CPUs. This argument should have the following format: file:///path/to/file.
- **poll_period** Data polling period (in ms) for available trace data. If greater than 0, then command runs in non-blocking mode. By default, 1 ms.
- **trace_size** Maximum size of data to collect (in bytes). Tracing is stopped after specified amount of data is received. By default, -1 (trace size stop trigger is disabled).
- **stop_tmo** Idle timeout (in sec). Tracing is stopped if there is no data for specified period of time. By default, -1 (disable this stop trigger). Optionally set it to value longer than longest pause between tracing commands from target.
- **wait4halt** If 0, start tracing immediately, otherwise command waits for the target to be halted (after reset, by breakpoint etc.) and then automatically resumes it and starts tracing. By default, 0.
- **skip_size** Number of bytes to skip at the start. By default, 0.

Note: If poll_period is 0, OpenOCD telnet command line will not be available until tracing is stopped. You must stop it manually by resetting the board or pressing Ctrl+C in OpenOCD window (not one with the telnet session). Another option is to set trace_size and wait until this size of data is collected. At this point, tracing stops automatically.

Command usage examples:
1. Collect 2048 bytes of tracing data to the file `trace.log`. The file will be saved in the `openocd-esp32` directory.

   ```
   esp aptrace start file://trace.log 1 2048 5 0 0
   ```

   The tracing data will be retrieved and saved in non-blocking mode. This process will stop automatically after 2048 bytes are collected, or if no data are available for more than 5 seconds.

   **Note:** Tracing data is buffered before it is made available to OpenOCD. If you see “Data timeout!” message, then it is likely that the target is not sending enough data to empty the buffer to OpenOCD before the timeout. Either increase the timeout or use the function `esp_aptrace_flush()` to flush the data on specific intervals.

2. Retrieve tracing data indefinitely in non-blocking mode.

   ```
   esp aptrace start file://trace.log 1 -1 -1 0 0
   ```

   There is no limitation on the size of collected data and there is no data timeout set. This process may be stopped by issuing `esp aptrace stop` command on OpenOCD telnet prompt, or by pressing Ctrl+C in OpenOCD window.

3. Retrieve tracing data and save them indefinitely.

   ```
   esp aptrace start file://trace.log 0 -1 -1 0 0
   ```

   OpenOCD telnet command line prompt will not be available until tracing is stopped. To stop tracing, press Ctrl+C in the OpenOCD window.

4. Wait for the target to be halted. Then resume the target’s operation and start data retrieval. Stop after collecting 2048 bytes of data:

   ```
   esp aptrace start file://trace.log 0 2048 -1 1 0
   ```

   To configure tracing immediately after reset, use the OpenOCD `reset halt` command.

**Logging to Host**

ESP-IDF implements a useful feature: logging to the host via application level tracing library. This is a kind of semihosting when all `ESP_LOGx` calls send strings to be printed to the host instead of UART. This can be useful because “printing to host” eliminates some steps performed when logging to UART. Most part of the work is done on the host.

By default, ESP-IDF’s logging library uses `vprintf`-like function to write formatted output to dedicated UART. In general, it involves the following steps:

1. Format string is parsed to obtain type of each argument.
2. According to its type, every argument is converted to string representation.
3. Format string combined with converted arguments is sent to UART.

Though the implementation of the `vprintf`-like function can be optimized to a certain level, all steps above have to be performed in any case and every step takes some time (especially item 3). So it frequently occurs that with additional log added to the program to identify the problem, the program behavior is changed and the problem cannot be reproduced. And in the worst cases, the program cannot work normally at all and ends up with an error or even hangs.

Possible ways to overcome this problem are to use higher UART bitrates (or another faster interface) and/or to move string formatting procedure to the host.

The application level tracing feature can be used to transfer log information to the host using `esp_aptrace_vprintf` function. This function does not perform full parsing of the format string and arguments. Instead, it just calculates the number of arguments passed and sends them along with the format string address to the host. On the host, log data is processed and printed out by a special Python script.

**Limitations** Current implementation of logging over JTAG has some limitations:
1. No support for tracing from ESP_EARLY_LOGx macros.
2. No support for printf arguments whose size exceeds 4 bytes (e.g., double and uint64_t).
3. Only strings from the .rodata section are supported as format strings and arguments.
4. The maximum number of printf arguments is 256.

How To Use It  In order to use logging via trace module, users need to perform the following steps:
1. On the target side, the special vprintf-like function esp_apptrace_vprintf() needs to be installed. It sends log data to the host. An example is esp_log_set_vprintf(esp_apptrace_vprintf);. To send log data to UART again, use esp_log_set_vprintf(vprintf);.
2. Follow instructions in items 2-5 in Application Specific Tracing.
3. To print out collected log records, run the following command in terminal: $IDF_PATH/tools/esp_app_trace/logtrace_proc.py /path/to/trace/file /path/to/program/elf/file.

Log Trace Processor Command Options  Command usage:
logtrace_proc.py [-h] [--no-errors] <trace_file> <elf_file>

Positional arguments:
trace_file  Path to log trace file.
elf_file  Path to program ELF file.

Optional arguments:
-h, --help  Show this help message and exit.
--no-errors, -n  Do not print errors.

System Behavior Analysis with SEGGER SystemView

Another useful ESP-IDF feature built on top of application tracing library is the system level tracing which produces traces compatible with SEGGER SystemView tool (see SystemView). SEGGER SystemView is a real-time recording and visualization tool that allows to analyze runtime behavior of an application. It is possible to view events in real-time through the UART interface.

How To Use It  Support for this feature is enabled by Component config > Application Level Tracing > FreeRTOS SystemView Tracing (CONFIG_APPTRACE_SV_ENABLE) menuconfig option. There are several other options enabled under the same menu:
1. SystemView destination. Select the destination interface: JTAG or UART. In case of UART, it will be possible to connect SystemView application to the ESP32 directly and receive data in real-time.
2. ESP32 timer to use as SystemView timestamp source: (CONFIG_APPTRACE_SV_TS_SOURCE) selects the source of timestamps for SystemView events. In the single core mode, timestamps are generated using ESP32 internal cycle counter running at maximum 240 Mhz (~4 ns granularity). In the dual-core mode, external timer working at 40 Mhz is used, so the timestamp granularity is 25 ns.
3. Individually enabled or disabled collection of SystemView events (CONFIG_APPTRACE_SV_EVT_XXX):
   • Trace Buffer Overflow Event
   • ISR Enter Event
   • ISR Exit Event
   • ISR Exit to Scheduler Event
   • Task Start Execution Event
   • Task Stop Execution Event
   • Task Start Ready State Event
   • Task Stop Ready State Event
   • Task Create Event
   • Task Terminate Event
   • System Idle Event
   • Timer Enter Event
Chapter 4. API Guides

- Timer Exit Event

ESP-IDF has all the code required to produce SystemView compatible traces, so users can just configure necessary project options (see above), build, download the image to target, and use OpenOCD to collect data as described in the previous sections.

4. Select Pro or App CPU in menuconfig options Component config > Application Level Tracing > FreeRTOS SystemView Tracing to trace over the UART interface in real-time.

OpenOCD SystemView Tracing Command Options

Command usage:

```
esp sysview [start <options>] | [stop] | [status]
```

Sub-commands:

- **start** Start tracing (continuous streaming).
- **stop** Stop tracing.
- **status** Get tracing status.

Start command syntax:

```
start <outfile1> [outfile2] [poll_period [trace_size [stop_tmo]]]
```

- **outfile1** Path to file to save data from PRO CPU. This argument should have the following format: file:// path/to/file.
- **outfile2** Path to file to save data from APP CPU. This argument should have the following format: file:// path/to/file.
- **poll_period** Data polling period (in ms) for available trace data. If greater than 0, then command runs in non-blocking mode. By default, 1 ms.
- **trace_size** Maximum size of data to collect (in bytes). Tracing is stopped after specified amount of data is received. By default, -1 (trace size stop trigger is disabled).
- **stop_tmo** Idle timeout (in sec). Tracing is stopped if there is no data for specified period of time. By default, -1 (disable this stop trigger).

Note: If **poll_period** is 0, OpenOCD telnet command line will not be available until tracing is stopped. You must stop it manually by resetting the board or pressing Ctrl+C in the OpenOCD window (not the one with the telnet session). Another option is to set **trace_size** and wait until this size of data is collected. At this point, tracing stops automatically.

Command usage examples:

1. Collect SystemView tracing data to files `pro-cpu.SVDat` and `app-cpu.SVDat`. The files will be saved in openocd-esp32 directory.

   ```
   esp sysview start file://pro-cpu.SVDat file://app-cpu.SVDat
   ```

   The tracing data will be retrieved and saved in non-blocking mode. To stop this process, enter `esp sysview stop` command on OpenOCD telnet prompt, optionally pressing Ctrl+C in the OpenOCD window.

2. Retrieve tracing data and save them indefinitely.

   ```
   esp sysview start file://pro-cpu.SVDat file://app-cpu.SVDat 0 -1 -1
   ```

   OpenOCD telnet command line prompt will not be available until tracing is stopped. To stop tracing, press Ctrl+C in the OpenOCD window.

Data Visualization After trace data are collected, users can use a special tool to visualize the results and inspect behavior of the program.

Unfortunately, SystemView does not support tracing from multiple cores. So when tracing from ESP32 with JTAG interfaces in the dual-core mode, two files are generated: one for PRO CPU and another for APP CPU. Users can load each file into separate instances of the tool. For tracing over UART, users can select Component config
Chapter 4. API Guides

> Application Level Tracing > FreeRTOS SystemView Tracing in menuconfig Pro or App to choose which CPU has to be traced.

It is uneasy and awkward to analyze data for every core in separate instance of the tool. Fortunately, there is an Eclipse plugin called Impulse which can load several trace files, thus making it possible to inspect events from both cores in one view. Also, this plugin has no limitation of 1,000,000 events as compared to the free version of SystemView.

Good instructions on how to install, configure, and visualize data in Impulse from one core can be found here.

Note: ESP-IDF uses its own mapping for SystemView FreeRTOS events IDs, so users need to replace the original file mapping $SYSVIEW_INSTALL_DIR/Description/SYSVIEW_FreeRTOS.txt with $IDF_PATH/tools/esp_app_trace/SYSVIEW_FreeRTOS.txt. Also, contents of that IDF-specific file should be used when configuring SystemView serializer using the above link.

Configure Impulse for Dual Core Traces  After installing Impulse and ensuring that it can successfully load trace files for each core in separate tabs, users can add special Multi Adapter port and load both files into one view. To do this, users need to do the following steps in Eclipse:

1. Open the Signal Ports view. Go to Windows > Show View > Other menu. Find the Signal Ports view in Impulse folder and double-click it.
2. In the Signal Ports view, right-click Ports and select Add > New Multi Adapter Port.
3. In the open dialog box, click Add and select New Pipe/File.
4. In the open dialog box, select SystemView Serializer as Serializer and set path to PRO CPU trace file. Click OK.
5. Repeat the steps 3-4 for APP CPU trace file.
6. Double-click the created port. View for this port should open.
7. Click the Start/Stop Streaming button. Data should be loaded.
8. Use the Zoom Out, Zoom In and Zoom Fit buttons to inspect data.
9. For settings measurement cursors and other features, please see Impulse documentation.

Note: If you have problems with visualization (no data is shown or strange behaviors of zoom action are observed), you can try to delete current signal hierarchy and double-click on the necessary file or port. Eclipse will ask you to create a new signal hierarchy.

Gcov (Source Code Coverage)

Basics of Gcov and Gcovr  Source code coverage is data indicating the count and frequency of every program execution path that has been taken within a program’s runtime. Gcov is a GCC tool that, when used in concert with the compiler, can generate log files indicating the execution count of each line of a source file. The Gcovr tool is a utility for managing Gcov and generating summarized code coverage results.

Generally, using Gcov to compile and run programs on the host will undergo these steps:

1. Compile the source code using GCC with the --coverage option enabled. This will cause the compiler to generate a .gcno notes files during compilation. The notes files contain information to reconstruct execution path block graphs and map each block to source code line numbers. Each source file compiled with the --coverage option should have their own .gcno file of the same name (e.g., a main.c will generate a main.gcno when compiled).
2. Execute the program. During execution, the program should generate .gcda data files. These data files contain the counts of the number of times an execution path was taken. The program will generate a .gcda file for each source file compiled with the --coverage option (e.g., main.c will generate a main.gcda).
3. Gcov or Gcovr can be used to generate a code coverage report for each source file in the form of a .gcov file, whilst Gcovr will generate a coverage report in HTML format.
Gcov and Gcovr in ESP-IDF  Using Gcov in ESP-IDF is complicated due to the fact that the program is running remotely from the host (i.e., on the target). The code coverage data (i.e., the .gcda files) is initially stored on the target itself. OpenOCD is then used to dump the code coverage data from the target to the host via JTAG during runtime. Using Gcov in ESP-IDF can be split into the following steps.

1. Setting Up a Project for Gcov
2. Dumping Code Coverage Data
3. Generating Coverage Report

Setting Up a Project for Gcov

Compiler Option  In order to obtain code coverage data in a project, one or more source files within the project must be compiled with the --coverage option. In ESP-IDF, this can be achieved at the component level or the individual source file level:

- To cause all source files in a component to be compiled with the --coverage option, you can add target_compile_options(${COMPONENT_LIB} PRIVATE --coverage) to the CMakeLists.txt file of the component.
- To cause a select number of source files (e.g., source1.c and source2.c) in the same component to be compiled with the --coverage option, you can add set_source_files_properties(source1.c source2.c PROPERTIES COMPILER_FLAGS --coverage) to the CMakeLists.txt file of the component.

When a source file is compiled with the --coverage option (e.g., gcov_example.c), the compiler will generate the gcov_example.gcno file in the project’s build directory. Project Configuration  Before building a project with source code coverage, make sure that the following project configuration options are enabled by running idf.py menuconfig.

- Enable the application tracing module by selecting Trace Memory for the CONFIG_APPTRACE_DESTINATION1 option.
- Enable Gcov to the host via the CONFIG_APPTRACE_GCOV_ENABLE.

Dumping Code Coverage Data  Once a project has been compiled with the --coverage option and flashed onto the target, code coverage data will be stored internally on the target (i.e., in trace memory) whilst the application runs. The process of transferring code coverage data from the target to the host is known as dumping.

The dumping of coverage data is done via OpenOCD (see JTAG Debugging on how to setup and run OpenOCD). A dump is triggered by issuing commands to OpenOCD, therefore a telnet session to OpenOCD must be opened to issue such commands (run telnet localhost 4444). Note that GDB could be used instead of telnet to issue commands to OpenOCD, however all commands issued from GDB will need to be prefixed as mon <oocd_command>.

When the target dumps code coverage data, the .gcda files are stored in the project’s build directory. For example, if gcov_example_main.c of the main component is compiled with the --coverage option, then dumping the code coverage data would generate a gcov_example_main.gcda in build/esp-idf/main/CMakeFiles/__idf_main.dir/gcov_example_main.c.gcda. Note that the .gcno files produced during compilation are also placed in the same directory.

The dumping of code coverage data can be done multiple times throughout an application’s lifetime. Each dump will simply update the .gcda file with the newest code coverage information. Code coverage data is accumulative, thus the newest data will contain the total execution count of each code path over the application’s entire lifetime.

ESP-IDF supports two methods of dumping code coverage data form the target to the host:

- Instant Run-Time Dumpgit
- Hard-coded Dump
**Instant Run-Time Dump** An Instant Run-Time Dump is triggered by calling the ESP32 `gcov` OpenOCD command (via a telnet session). Once called, OpenOCD will immediately preempt the ESP32’s current state and execute a built-in ESP-IDF Gcov debug stub function. The debug stub function will handle the dumping of data to the host. Upon completion, the ESP32 will resume its current state.

**Hard-coded Dump** A Hard-coded Dump is triggered by the application itself by calling `esp_gcov_dump()` from somewhere within the application. When called, the application will halt and wait for OpenOCD to connect and retrieve the code coverage data. Once `esp_gcov_dump()` is called, the host must execute the `esp gcov dump` OpenOCD command (via a telnet session). The `esp gcov dump` command will cause OpenOCD to connect to the ESP32, retrieve the code coverage data, then disconnect from the ESP32, thus allowing the application to resume. Hard-coded Dumps can also be triggered multiple times throughout an application’s lifetime.

Hard-coded dumps are useful if code coverage data is required at certain points during an application’s lifetime by placing `esp_gcov_dump()` where necessary (e.g., after application initialization, during each iteration of an application’s main loop).

GDB can be used to set a breakpoint on `esp_gcov_dump()`, then call `mon esp gcov dump` automatically via the use a gdbinit script (see Using GDB from Command Line).

The following GDB script will add a breakpoint at `esp_gcov_dump()`, then call the `mon esp gcov dump` OpenOCD command.

```
b esp_gcov_dump
commands
mon esp gcov dump
end
```

**Note:** Note that all OpenOCD commands should be invoked in GDB as: `mon <oocd_command>`.

**Generating Coverage Report** Once the code coverage data has been dumped, the `.gcno`, `.gcda` and the source files can be used to generate a code coverage report. A code coverage report is simply a report indicating the number of times each line in a source file has been executed.

Both Gcov and Gcovr can be used to generate code coverage reports. Gcov is provided along with the Xtensa toolchain, whilst Gcovr may need to be installed separately. For details on how to use Gcov or Gcovr, refer to Gcov documentation and Gcovr documentation.

**Adding Gcovr Build Target to Project** To make report generation more convenient, users can define additional build targets in their projects such that the report generation can be done with a single build command.

Add the following lines to the CMakeLists.txt file of your project:

```
include($ENV{IDF_PATH}/tools/cmake/gcov.cmake)
idf_create_coverage_report(${CMAKE_CURRENT_BINARY_DIR}/coverage_report)
idf_clean_coverage_report(${CMAKE_CURRENT_BINARY_DIR}/coverage_report)
```

The following commands can now be used:

- `cmake --build build/ --target gcovr-report` will generate an HTML coverage report in `$BUILD_DIR_BASE)/coverage_report/html` directory.
- `cmake --build build/ --target cov-data-clean` will remove all coverage data files.

### 4.2 Application Startup Flow

This note explains various steps which happen before `app_main` function of an ESP-IDF application is called.
The high level view of startup process is as follows:

1. **First stage bootloader** in ROM loads second-stage bootloader image to RAM (IRAM & DRAM) from flash offset 0x1000.
2. **Second stage bootloader** loads partition table and main app image from flash. Main app incorporates both RAM segments and read-only segments mapped via flash cache.
3. **Application startup** executes. At this point the second CPU and RTOS scheduler are started.

This process is explained in detail in the following sections.

### 4.2.1 First stage bootloader

After SoC reset, PRO CPU will start running immediately, executing reset vector code, while APP CPU will be held in reset. During startup process, PRO CPU does all the initialization. APP CPU reset is de-asserted in the `call_start_cpu0` function of application startup code. Reset vector code is located in the mask ROM of the ESP32 chip and cannot be modified.

Startup code called from the reset vector determines the boot mode by checking `GPIO_STRAP_REG` register for bootstrap pin states. Depending on the reset reason, the following takes place:

1. Reset from deep sleep: if the value in `RTC_CNTL_STORE6_REG` is non-zero, and CRC value of RTC memory in `RTC_CNTL_STORE7_REG` is valid, use `RTC_CNTL_STORE6_REG` as an entry point address and jump immediately to it. If `RTC_CNTL_STORE6_REG` is zero, or `RTC_CNTL_STORE7_REG` contains invalid CRC, or once the code called via `RTC_CNTL_STORE6_REG` returns, proceed with boot as if it was a power-on reset. **Note:** to run customized code at this point, a deep sleep stub mechanism is provided. Please see deep sleep documentation for this.
2. For power-on reset, software SoC reset, and watchdog SoC reset: check the `GPIO_STRAP_REG` register if a custom bootmode (such as UART Download Mode) is requested. If this is the case, this custom loader mode is executed from ROM. Otherwise, proceed with boot as if it was due to software CPU reset. Consult ESP32 datasheet for a description of SoC boot modes and how to execute them.
3. For software CPU reset and watchdog CPU reset: configure SPI flash based on EFUSE values, and attempt to load the code from flash. This step is described in more detail in the next paragraphs.

**Note:** During normal boot modes the RTC watchdog is enabled when this happens, so if the process is interrupted or stalled then the watchdog will reset the SOC automatically and repeat the boot process. This may cause the SoC to strap into a new boot mode, if the strapping GPIOs have changed.

Second stage bootloader binary image is loaded from flash starting at address 0x1000. If **Secure Boot** is in use then the first 4 KB sector of flash is used to store secure boot IV and digest of the bootloader image. Otherwise, this sector is unused.

### 4.2.2 Second stage bootloader

In ESP-IDF, the binary image which resides at offset 0x1000 in flash is the second stage bootloader. Second stage bootloader source code is available in `components/bootloader` directory of ESP-IDF. Second stage bootloader is used in ESP-IDF to add flexibility to flash layout (using partition tables), and allow for various flows associated with flash encryption, secure boot, and over-the-air updates (OTA) to take place.

When the first stage bootloader is finished checking and loading the second stage bootloader, it jumps to the second stage bootloader entry point found in the binary image header.

Second stage bootloader reads the partition table found by default at offset 0x8000 (**configurable value**). See partition tables documentation for more information. The bootloader finds factory and OTA app partitions. If OTA app partitions are found in the partition table, the bootloader consults the `otadata` partition to determine which one should be booted. See **Over The Air Updates (OTA)** for more information.

For a full description of the configuration options available for the ESP-IDF bootloader, see **Bootloader**.
For the selected partition, second stage bootloader reads the binary image from flash one segment at a time:

- For segments with load addresses in internal **IRAM (Instruction RAM)** or **DRAM (Data RAM)**, the contents are copied from flash to the load address.
- For segments which have load addresses in **DROM (data stored in flash)** or **IROM (code executed from flash)** regions, the flash MMU is configured to provide the correct mapping from the flash to the load address.

Note that the second stage bootloader configures flash MMU for both PRO and APP CPUs, but it only enables flash MMU for PRO CPU. Reason for this is that second stage bootloader code is loaded into the memory region used by APP CPU cache. The duty of enabling cache for APP CPU is passed on to the application.

Once all segments are processed - meaning code is loaded and flash MMU is set up, second stage bootloader verifies the integrity of the application and then jumps to the application entry point found in the binary image header.

### 4.2.3 Application startup

Application startup covers everything that happens after the app starts executing and before the `app_main` function starts running inside the main task. This is split into three stages:

- Port initialization of hardware and basic C runtime environment.
- System initialization of software services and FreeRTOS.
- Running the main task and calling `app_main`.

**Note:** Understanding all stages of ESP-IDF app initialization is often not necessary. To understand initialization from the application developer’s perspective only, skip forward to *Running the main task*.

#### Port Initialization

ESP-IDF application entry point is `call_start_cpu0` function found in components/esp_system/port/cpu_start.c. This function is executed by the second stage bootloader, and never returns.

This port-layer initialization function initializes the basic C Runtime Environment ( “CRT” ) and performs initial configuration of the SoC’s internal hardware:

- Reconfigure CPU exceptions for the app (allowing app interrupt handlers to run, and causing **Fatal Errors** to be handled using the options configured for the app rather than the simpler error handler provided by ROM).
- If the option `CONFIG_BOOTLOADER_WDT_ENABLE` is not set then the RTC watchdog timer is disabled.
- Initialize internal memory (data & bss).
- Finish configuring the MMU cache.
- Enable PSRAM if configured.
- Set the CPU clocks to the frequencies configured for the project.
- Reconfigure the main SPI flash based on the app header settings (necessary for compatibility with bootloader versions before ESP-IDF V4.0, see **Bootloader Compatibility**).
- If the app is configured to run on multiple cores, start the other core and wait for it to initialize as well (inside the similar “port layer” initialization function `call_start_cpu1`).

Once `call_start_cpu0` completes running, it calls the “system layer” initialization function `start_cpu0` found in components/esp_system/startup.c. Other cores will also complete port-layer initialization and call `start_other_cores` found in the same file.

#### System Initialization

The main system initialization function is `start_cpu0`. By default, this function is weak-linked to the function `start_cpu0_default`. This means that it’s possible to override this function to add some additional initialization steps.

The primary system initialization stage includes:
• Log information about this application (project name, App Version, etc.) if default log level enables this.
• Initialize the heap allocator (before this point all allocations must be static or on the stack).
• Initialize newlib component syscalls and time functions.
• Configure the brownout detector.
• Setup libc stdin, stdout, and stderr according to the serial console configuration.
• Perform any security-related checks, including burning efuses that should be burned for this configuration (including disabling ROM download mode on ESP32 V3, CONFIG_ESP32_DISABLE_BASIC_ROM_CONSOLE).
• Initialize SPI flash API support.
• Call global C++ constructors and any C functions marked with __attribute__((constructor)).

Secondary system initialization allows individual components to be initialized. If a component has an initialization function annotated with the ESP_SYSTEM_INIT_FN macro, it will be called as part of secondary initialization. Component initialization functions have priorities assigned to them to ensure the desired initialization order. The priorities are documented in esp_system/system_init_fn.txt and ESP_SYSTEM_INIT_FN definition in source code are checked against this file.

Running the main task

After all other components are initialized, the main task is created and the FreeRTOS scheduler starts running.

After doing some more initialization tasks (that require the scheduler to have started), the main task runs the application-provided function app_main in the firmware.

The main task that runs app_main has a fixed RTOS priority (one higher than the minimum) and a configurable stack size.

The main task core affinity is also configurable: CONFIG_ESP_MAIN_TASK_AFFINITY.

Unlike normal FreeRTOS tasks (or embedded C main functions), the app_main task is allowed to return. If this happens, the task is cleaned up and the system will continue running with other RTOS tasks scheduled normally. Therefore, it is possible to implement app_main as either a function that creates other application tasks and then returns, or as a main application task itself.

Second core startup

A similar but simpler startup process happens on the APP CPU:

When running system initialization, the code on PRO CPU sets the entry point for APP CPU, de-asserts APP CPU reset, and waits for a global flag to be set by the code running on APP CPU, indicating that it has started. Once this is done, APP CPU jumps to call_start_cpu1 function in components/esp_system/port/cpu_start.c.

While PRO CPU does initialization in start_cpu0 function, APP CPU runs start_cpu_other_cores function. Similar to start_cpu0, this function is weak-linked and defaults to the start_cpu_other_cores_default function but can be replaced with a different function by the application.

The start_cpu_other_cores_default function does some core-specific system initialization and then waits for the PRO CPU to start the FreeRTOS scheduler, at which point it executes esp_startup_start_app_other_cores which is another weak-linked function defaulting to esp_startup_start_app_other_cores_default.

By default esp_startup_start_app_other_cores_default does nothing but spin in a busy-waiting loop until the scheduler of the PRO CPU triggers an interrupt to start the RTOS scheduler on the APP CPU.

4.3 BluFi
4.3.1 Overview

The BluFi for ESP32 is a Wi-Fi network configuration function via Bluetooth channel. It provides a secure protocol to pass Wi-Fi configuration and credentials to ESP32. Using this information, ESP32 can then connect to an AP or establish a SoftAP.

Fragmenting, data encryption, and checksum verification in the BluFi layer are the key elements of this process.

You can customize symmetric encryption, asymmetric encryption, and checksum support customization. Here we use the DH algorithm for key negotiation, 128-AES algorithm for data encryption, and CRC16 algorithm for checksum verification.

4.3.2 The BluFi Flow

The BluFi networking flow includes the configuration of the SoftAP and Station.

The following uses Station as an example to illustrate the core parts of the procedure, including broadcast, connection, service discovery, negotiation of the shared key, data transmission, and connection status backhaul.

1. Set the ESP32 into GATT Server mode and then it will send broadcasts with specific advertising data. You can customize this broadcast as needed, which is not a part of the BluFi Profile.
2. Use the App installed on the mobile phone to search for this particular broadcast. The mobile phone will connect to ESP32 as the GATT Client once the broadcast is confirmed. The App used during this part is up to you.
3. After the GATT connection is successfully established, the mobile phone will send a data frame for key negotiation to ESP32 (see the section The Frame Formats Defined in BluFi for details).
4. After ESP32 receives the data frame of key negotiation, it will parse the content according to the user-defined negotiation method.
5. The mobile phone works with ESP32 for key negotiation using the encryption algorithms, such as DH, RSA, or ECC.
6. After the negotiation process is completed, the mobile phone will send a control frame for security-mode setup to ESP32.
7. When receiving this control frame, ESP32 will be able to encrypt and decrypt the communication data using the shared key and the security configuration.
8. The mobile phone sends the data frame defined in the section of The Frame Formats Defined in BluFi, with the Wi-Fi configuration information to ESP32, including SSID, password, etc.
9. The mobile phone sends a control frame of Wi-Fi connection request to ESP32. When receiving this control frame, ESP32 will regard the communication of essential information as done and get ready to connect to the Wi-Fi.
10. After connecting to the Wi-Fi, ESP32 will send a control frame of Wi-Fi connection status report to the mobile phone. At this point, the networking procedure is completed.

Note:

1. After ESP32 receives the control frame of security-mode configuration, it will execute the operations in accordance with the defined security mode.
2. The data lengths before and after symmetric encryption/decryption must stay the same. It also supports in-place encryption and decryption.

4.3.3 The Flow Chart of BluFi

4.3.4 The Frame Formats Defined in BluFi

The frame formats for the communication between the mobile phone App and ESP32 are defined as follows:

The frame format with no fragment:
Fig. 2: BluFi Flow Chart
If the frag frame bit in the Frame Control field is enabled, there would be a 2-byte Total Content Length field in the Data field. This Total Content Length field indicates the length of the remaining part of the frame and also tells the remote how much memory needs to be allocated.

The frame format with fragments:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value (Byte)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type (Least Significant Bit)</td>
<td>1</td>
</tr>
<tr>
<td>Frame Control (Frag)</td>
<td>1</td>
</tr>
<tr>
<td>Sequence Number</td>
<td>1</td>
</tr>
<tr>
<td>Data Length</td>
<td>1</td>
</tr>
<tr>
<td>Data</td>
<td>${\text{Data Length}}$</td>
</tr>
<tr>
<td>CheckSum (Most Significant Bit)</td>
<td>2</td>
</tr>
</tbody>
</table>

Normally, the control frame does not contain data bits, except for ACK Frame.

The format of ACK Frame:

<table>
<thead>
<tr>
<th>Field</th>
<th>Value (Byte)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type - ACK (Least Significant Bit)</td>
<td>1</td>
</tr>
<tr>
<td>Frame Control</td>
<td>1</td>
</tr>
<tr>
<td>Sequence Number</td>
<td>1</td>
</tr>
<tr>
<td>Data Length</td>
<td>1</td>
</tr>
<tr>
<td>Data</td>
<td>Acked Sequence Number: 2</td>
</tr>
<tr>
<td>CheckSum (Most Significant Bit)</td>
<td>2</td>
</tr>
</tbody>
</table>

1. Type
   Type field takes 1 byte and is divided into Type and Subtype. Type uses the lower two bits, indicating whether the frame is a data frame or a control frame. Subtype uses the upper six bits, indicating the specific meaning of this data frame or control frame.
   • The control frame is not encrypted for the time being and supports to be verified.
   • The data frame supports to be encrypted and verified.

1.1 Control Frame (Binary: 0x0b 00)
### Control Frame

<table>
<thead>
<tr>
<th>Control Frame</th>
<th>Implication</th>
<th>Explanation</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0 (b'000000)</td>
<td>ACK</td>

</tr>
<tr>
<td>0x10-0x80</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

3. Sequence Number

The **Sequence Number** field is the field for sequence control. When a frame is sent, the value of this field is automatically incremented by 1 regardless of the type of frame, which prevents Replay Attack. The sequence would be cleared after each reconnection.

4. Data Length

The **Data Length** field indicates the length of the data field, which does not include CheckSum.

5. Data

Content of the **Data** field can be different according to various values of Type or Subtype. Please refer to the table above.

6. CheckSum

The **CheckSum** field takes two bytes, which is used to check “sequence + data length + clear text data”.

### 4.3.5 The Security Implementation of ESP32

1. Securing Data

To ensure that the transmission of the Wi-Fi SSID and password is secure, the message needs to be encrypted using symmetric encryption algorithms, such as AES, DES, and so on. Before using symmetric encryption algorithms, the devices are required to negotiate (or generate) a shared key using an asymmetric encryption algorithm (DH, RSA, ECC, etc).

2. Ensuring Data Integrity
To ensure data integrity, you need to add a checksum algorithm, such as SHA1, MD5, CRC, etc.

3. **Securing Identity (Signature)**
   
   Algorithm like RSA can be used to secure identity. But for DH, it needs other algorithms as an companion for signature.

4. **Replay Attack Prevention**
   
   It is added to the Sequence Number field and used during the checksum verification.
   
   For the coding of ESP32, you can determine and develop the security processing, such as key negotiation. The mobile application sends the negotiation data to ESP32, and then the data will be sent to the application layer for processing. If the application layer does not process it, you can use the DH encryption algorithm provided by BluFi to negotiate the key.
   
   The application layer needs to register several security-related functions to BluFi:

```c
typedef void (*esp_blufi_negotiate_data_handler_t)(uint8_t *data, int len, uint8_t *output_data, int *output_len, bool *need_free)
```

This function is for ESP32 to receive normal data during negotiation. After processing is completed, the data will be transmitted using `Output_data` and `Output_len`.

BluFi will send `output_data` from `Negotiate_data_handler` after `Negotiate_data_handler` is called.

Here are two `*`, which means the length of the data to be emitted is unknown. Therefore, it requires the function to allocate itself (malloc) or point to the global variable to inform whether the memory needs to be freed by `NEED_FREE`.

```c
typedef int (*esp_blufi_encrypt_func_t)(uint8_t iv8, uint8_t *crypt_data, int _crypt_len)
```

The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as a 8-bit of IV.

```c
typedef int (*esp_blufi_decrypt_func_t)(uint8_t iv8, uint8_t *crypt_data, int _crypt_len)
```

The data to be encrypted and decrypted must be in the same length. The IV8 is an 8-bit sequence value of frames, which can be used as an 8-bit of IV.

```c
typedef uint16_t (*esp_blufi_checksum_func_t)(uint8_t iv8, uint8_t *data, int len)
```

This function is used to compute CheckSum and return a value of CheckSum. BluFi uses the returned value to compare the CheckSum of the frame.

### 4.3.6 GATT Related Instructions

**UUID**

- BluFi Service UUID: 0xFFFF, 16 bit
- BluFi (the mobile -> ESP32): 0xFF01, writable
- BluFi (ESP32 -> the mobile phone): 0xFF02, readable and callable

### 4.4 Bootloader

The ESP-IDF Software Bootloader performs the following functions:

1. Minimal initial configuration of internal modules;
2. Initialize *Flash Encryption* and/or *Secure* features, if configured;
3. Select the application partition to boot, based on the partition table and ota_data (if any);
4. Load this image to RAM (IRAM & DRAM) and transfer management to the image that was just loaded. Bootloader is located at the address 0x1000 in the flash.

For a full description of the startup process including the ESP-IDF bootloader, see Application Startup Flow.

4.4.1 Bootloader Compatibility

It is recommended to update to newer versions of ESP-IDF: when they are released. The OTA (over the air) update process can flash new apps in the field but cannot flash a new bootloader. For this reason, the bootloader supports booting apps built from newer versions of ESP-IDF.

The bootloader does not support booting apps from older versions of ESP-IDF. When updating ESP-IDF manually on an existing product that might need to downgrade the app to an older version, keep using the older ESP-IDF bootloader binary as well.

**Note:** If testing an OTA update for an existing product in production, always test it using the same ESP-IDF bootloader binary that is deployed in production.

**Before ESP-IDF V2.1**

Bootloaders built from very old versions of ESP-IDF (before ESP-IDF V2.1) perform less hardware configuration than newer versions. When using a bootloader from these early ESP-IDF versions and building a new app, enable the config option `CONFIG_APP_COMPATIBLE_PRE_V2_1_BOOTLOADERS`.

**Before ESP-IDF V3.1**

Bootloaders built from versions of ESP-IDF before V3.1 do not support MD5 checksums in the partition table binary. When using a bootloader from these ESP-IDF versions and building a new app, enable the config option `CONFIG_APP_COMPATIBLE_PRE_V3_1_BOOTLOADERS`.

**Before ESP-IDF V5.1**

Bootloaders built from versions of ESP-IDF prior to V5.1 do not support `CONFIG_ESP_SYSTEM_ESP32_SRAM1_REGION_AS_IRAM`. When using a bootloader from these ESP-IDF versions and building a new app you should not use this option.

**SPI Flash Configuration**

Each ESP-IDF application or bootloader .bin file contains a header with `CONFIG_ESPTOOLPY_FLASHMODE`, `CONFIG_ESPTOOLPY_FLASHFREQ`, `CONFIG_ESPTOOLPY_FLASHSIZE` embedded in it. These are used to configure the SPI flash during boot.

The First stage bootloader in ROM reads the Second stage bootloader header information from flash and uses this information to load the rest of the Second stage bootloader from flash. However, at this time the system clock speed is lower than configured and not all flash modes are supported. When the Second stage bootloader then runs, it will reconfigure the flash using values read from the currently selected app binary’s header (and NOT from the Second stage bootloader header). This allows an OTA update to change the SPI flash settings in use.

Bootloaders prior to ESP-IDF V4.0 used the bootloader’s own header to configure the SPI flash, meaning these values could not be changed in an update. To maintain compatibility with older bootloaders, the app re-initializes the flash settings during app startup using the configuration found in the app header.
### 4.4.2 Log Level

The default bootloader log level is “Info”. By setting the `CONFIG_BOOTLOADER_LOG_LEVEL` option, it’s possible to increase or decrease this level. This log level is separate from the log level used in the app (see Logging library).

Reducing bootloader log verbosity can improve the overall project boot time by a small amount.

### 4.4.3 Factory Reset

Sometimes it is desirable to have a way for the device to fall back to a known-good state, in case of some problem with an update.

To roll back to the original “factory” device configuration and clear any user settings, configure the config item `CONFIG_BOOTLOADER_FACTORY_RESET` in the bootloader.

The factory reset mechanism allows the device to be factory reset in two ways:

- Clear one or more data partitions. The `CONFIG_BOOTLOADER_DATA_FACTORY_RESET` option allows users to specify which data partitions will be erased when the factory reset is executed.
  - Users can specify the names of partitions as a comma-delimited list with optional spaces for readability. (Like this: `nvs, phy_init, nvs_custom`).
  - Make sure that the names of partitions specified in the option are the same as those found in the partition table. Partitions of type “app” cannot be specified here.
- Boot from “factory” app partition. Enabling the `CONFIG_BOOTLOADER_OTA_DATA_ERASE` option will cause the device to boot from the default “factory” app partition after a factory reset (or if there is no factory app partition in the partition table then the default ota app partition is selected instead). This reset process involves erasing the OTA data partition which holds the currently selected OTA partition slot. The “factory” app partition slot (if it exists) is never updated via OTA, so resetting to this allows reverting to a “known good” firmware application.

Either or both of these configuration options can be enabled independently.

In addition, the following configuration options control the reset condition:

- `CONFIG_BOOTLOADER_NUM_PIN_FACTORY_RESET` - The input GPIO number used to trigger a factory reset. This GPIO must be pulled low or high (configurable) on reset to trigger this.
- `CONFIG_BOOTLOADER_HOLD_TIME_GPIO` - this is hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.
- `CONFIG_BOOTLOADER_FACTORY_RESET_PIN_LEVEL` - configure whether a factory reset should trigger on a high or low level of the GPIO. If the GPIO has an internal pullup then this is enabled before the pin is sampled, consult the ESP32 datasheet for details on pin internal pullups.

If an application needs to know if the factory reset has occurred, users can call the function `bootloader_common_get_rtc_retain_mem_factory_reset_state()`.

- If the status is read as true, the function will return the status, indicating that the factory reset has occurred. The function then resets the status to false for subsequent factory reset judgement.
- If the status is read as false, the function will return the status, indicating that the factory reset has not occurred, or the memory where this status is stored is invalid.

Note that this feature reserves some RTC FAST memory (the same size as the `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` feature).

### 4.4.4 Boot from Test Firmware

It’s possible to write a special firmware app for testing in production, and boot this firmware when needed. The project partition table will need a dedicated app partition entry for this testing app, type `app` and subtype `test` (see Partition Tables).
Implementing a dedicated test app firmware requires creating a totally separate ESP-IDF project for the test app (each project in ESP-IDF only builds one app). The test app can be developed and tested independently of the main project, and then integrated at production testing time as a pre-compiled .bin file which is flashed to the address of the main project’s test app partition.

To support this functionality in the main project’s bootloader, set the configuration item `CONFIG_BOOTLOADER_APP_TEST` and configure the following two items:

- `CONFIG_BOOTLOADER_NUM_PIN_APP_TEST` - GPIO number to boot TEST partition. The selected GPIO will be configured as an input with internal pull-up enabled. To trigger a test app, this GPIO must be pulled low on reset.
  
  Once the GPIO input is released (allowing it to be pulled up) and the device has been rebooted, the normally configured application will boot (factory or any OTA app partition slot).

- `CONFIG_BOOTLOADER_HOLD_TIME_GPIO` - this is hold time of GPIO for reset/test mode (by default 5 seconds). The GPIO must be held low continuously for this period of time after reset before a factory reset or test partition boot (as applicable) is performed.

### 4.4.5 Rollback

Rollback and anti-rollback features must be configured in the bootloader as well.

Consult the App rollback and Anti-rollback sections in the OTA API reference document.

### 4.4.6 Watchdog

By default, the hardware RTC Watchdog timer remains running while the bootloader is running and will automatically reset the chip if no app has successfully started after 9 seconds.

- The timeout period can be adjusted by setting `CONFIG_BOOTLOADER_WDT_TIME_MS` and recompiling the bootloader.
- The app’s behaviour can be adjusted so the RTC Watchdog remains enabled after app startup. The Watchdog would need to be explicitly reset (i.e., fed) by the app to avoid a reset. To do this, set the `CONFIG_BOOTLOADER_WDT_DISABLE_IN_USER_CODE` option, modify the app as needed, and then recompile the app.
- The RTC Watchdog can be disabled in the bootloader by disabling the `CONFIG_BOOTLOADER_WDT_ENABLE` setting and recompiling the bootloader. This is not recommended.

### 4.4.7 Bootloader Size

When enabling additional bootloader functions, including Flash Encryption or Secure Boot, and especially if setting a high `CONFIG_BOOTLOADER_LOG_LEVEL` level, then it is important to monitor the bootloader .bin file’s size.

When using the default `CONFIG_PARTITION_TABLE_OFFSET` value 0x8000, the size limit is 0x8000 bytes.

If the bootloader binary is too large, then the bootloader build will fail with an error “Bootloader binary size [...] is too large for partition table offset”. If the bootloader binary is flashed anyhow then the ESP32 will fail to boot - errors will be logged about either invalid partition table or invalid bootloader checksum.

Options to work around this are:

- Set bootloader compiler optimization back to “Size” if it has been changed from this default value.
- Reduce bootloader log level. Setting log level to Warning, Error or None all significantly reduce the final binary size (but may make it harder to debug).
- Set `CONFIG_PARTITION_TABLE_OFFSET` to a higher value than 0x8000, to place the partition table later in the flash. This increases the space available for the bootloader. If the partition table CSV file contains explicit partition offsets, they will need changing so no partition has an offset lower than `CONFIG_PARTITION_TABLE_OFFSET + 0x1000`. (This includes the default partition CSV files supplied with ESP-IDF.)
4.4.8 Fast Boot from Deep-Sleep

The bootloader has the `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` option which allows the wake-up time from Deep-sleep to be reduced (useful for reducing power consumption). This option is available when `CONFIG_SECURE_BOOT` option is disabled. Reduction of time is achieved due to the lack of image verification. During the first boot, the bootloader stores the address of the application being launched in the RTC FAST memory. And during the awakening, this address is used for booting without any checks, thus fast loading is achieved.

4.4.9 Custom Bootloader

The current bootloader implementation allows a project to extend it or modify it. There are two ways of doing it: by implementing hooks or by overriding it. Both ways are presented in `custom_bootloader` folder in ESP-IDF examples:

- `bootloader_hooks` which presents how to connect some hooks to the bootloader initialization
- `bootloader_override` which presents how to override the bootloader implementation

In the bootloader space, you cannot use the drivers and functions from other components. If necessary, then the required functionality should be placed in the project’s `bootloader_components` directory (note that this will increase its size).

If the bootloader grows too large then it can collide with the partition table, which is flashed at offset 0x8000 by default. Increase the `partition table offset` value to place the partition table later in the flash. This increases the space available for the bootloader.

4.5 Build System

This document explains the implementation of the ESP-IDF build system and the concept of “components”. Read this document if you want to know how to organize and build a new ESP-IDF project or component.

4.5.1 Overview

An ESP-IDF project can be seen as an amalgamation of a number of components. For example, for a web server that shows the current humidity, there could be:

- The ESP-IDF base libraries (libc, ROM bindings, etc)
- The Wi-Fi drivers
- A TCP/IP stack
- The FreeRTOS operating system
- A web server
- A driver for the humidity sensor
- Main code tying it all together

ESP-IDF makes these components explicit and configurable. To do that, when a project is compiled, the build system will look up all the components in the ESP-IDF directories, the project directories and (optionally) in additional custom component directories. It then allows the user to configure the ESP-IDF project using a text-based menu system to customize each component. After the components in the project are configured, the build system will compile the project.
Chapter 4. API Guides

Concepts

• A “project” is a directory that contains all the files and configuration to build a single “app” (executable), as well as additional supporting elements such as a partition table, data/filesystem partitions, and a bootloader.
• “Project configuration” is held in a single file called sdkconfig in the root directory of the project. This configuration file is modified via idf.py menuconfig to customize the configuration of the project. A single project contains exactly one project configuration.
• An “app” is an executable that is built by ESP-IDF. A single project will usually build two apps - a “project app” (the main executable, i.e., your custom firmware) and a “bootloader app” (the initial bootloader program which launches the project app).
• “Components” are modular pieces of standalone code that are compiled into static libraries (.a files) and linked to an app. Some are provided by ESP-IDF itself, others may be sourced from other places.
• “Target” is the hardware for which an application is built. A full list of supported targets in your version of ESP-IDF can be seen by running idf.py –list-targets.

Some things are not part of the project:

• “ESP-IDF” is not part of the project. Instead, it is standalone, and linked to the project via the IDF_PATH environment variable which holds the path of the esp-idf directory. This allows the IDF framework to be decoupled from your project.
• The toolchain for compilation is not part of the project. The toolchain should be installed in the system command PATH.

4.5.2 Using the Build System

idf.py

The idf.py command-line tool provides a front-end for easily managing your project builds. It manages the following tools:

• CMake, which configures the project to be built
• Ninja which builds the project
• esptool.py for flashing the target.

You can read more about configuring the build system using idf.py here.

Using CMake Directly

idf.py is a wrapper around CMake for convenience. However, you can also invoke CMake directly if you prefer.

When idf.py does something, it prints each command that it runs for easy reference. For example, the idf.py build command is the same as running these commands in a bash shell (or similar commands for Windows Command Prompt):

```
mkdir -p build
cd build
cmake .. -G Ninja  # or 'Unix Makefiles'
ninja
```

In the above list, the cmake command configures the project and generates build files for use with the final build tool. In this case, the final build tool is Ninja: running ninja actually builds the project.

It’s not necessary to run cmake more than once. After the first build, you only need to run ninja each time. ninja will automatically re-invoke cmake if the project needs reconfiguration.

If using CMake with ninja or make, there are also targets for more of the idf.py sub-commands. For example, running make menuconfig or ninja menuconfig in the build directory will work the same as idf.py menuconfig.
Chapter 4. API Guides

Note: If you’re already familiar with CMake, you may find the ESP-IDF CMake-based build system unusual because it wraps a lot of CMake’s functionality to reduce boilerplate. See writing pure CMake components for some information about writing more “CMake style” components.

**Flashing with Ninja or Make**  It’s possible to build and flash directly from ninja or make by running a target like:
ninja flash

Or:
make app-flash

Available targets are: flash, app-flash (app only), bootloader-flash (bootloader only).

When flashing this way, optionally set the ESPPORT and ESPBAUD environment variables to specify the serial port and baud rate. You can set environment variables in your operating system or IDE project. Alternatively, set them directly on the command line:

```
ESPPORT=/dev/ttyUSB0 ninja flash
```

Note: Providing environment variables at the start of the command like this is Bash shell Syntax. It will work on Linux and macOS. It won’t work when using Windows Command Prompt, but it will work when using Bash-like shells on Windows.

Or:

```
make -j3 app-flash ESPPORT=COM4 ESPBAUD=2000000
```

Note: Providing variables at the end of the command line is make syntax, and works for make on all platforms.

**Using CMake in an IDE**

You can also use an IDE with CMake integration. The IDE will want to know the path to the project’s CMakeLists.txt file. IDEs with CMake integration often provide their own build tools (CMake calls these “generators”) to build the source files as part of the IDE.

When adding custom non-build steps like “flash” to the IDE, it is recommended to execute idf.py for these “special” commands.

For more detailed information about integrating ESP-IDF with CMake into an IDE, see Build System Metadata.

**Setting up the Python Interpreter**

ESP-IDF works well with Python version 3.7+.

idf.py and other Python scripts will run with the default Python interpreter, i.e. python. You can switch to a different one like python3 $IDF_PATH/tools/idf.py ... or you can set up a shell alias or another script to simplify the command.

If using CMake directly, running cmake -D PYTHON=python3 ... will cause CMake to override the default Python interpreter.

If using an IDE with CMake, setting the PYTHON value as a CMake cache override in the IDE UI will override the default Python interpreter.
To manage the Python version more generally via the command line, check out the tools pyenv or virtualenv. These let you change the default Python version.

### 4.5.3 Example Project

An example project directory tree might look like this:

```
- myProject/
  - CMakeLists.txt
  - sdkconfig
    - components/
      - component1/
        - CMakeLists.txt
        - Kconfig
        - src1.c
      - component2/
        - CMakeLists.txt
        - Kconfig
        - src1.c
      - include/
        - component2.h
    - main/
      - CMakeLists.txt
      - src1.c
      - src2.c
  - build/
```

This example “myProject” contains the following elements:

- A top-level project CMakeLists.txt file. This is the primary file which CMake uses to learn how to build the project; and may set project-wide CMake variables. It includes the file /tools/cmake/project.cmake which implements the rest of the build system. Finally, it sets the project name and defines the project.
- “sdkconfig” project configuration file. This file is created/updated when idf.py menuconfig runs, and holds the configuration for all of the components in the project (including ESP-IDF itself). The “sdkconfig” file may or may not be added to the source control system of the project.
- Optional “components” directory contains components that are part of the project. A project does not have to contain custom components of this kind, but it can be useful for structuring reusable code or including third-party components that aren’t part of ESP-IDF. Alternatively, EXTRA_COMPONENT_DIRS can be set in the top-level CMakeLists.txt to look for components in other places.
- “main” directory is a special component that contains source code for the project itself. “main” is a default name, the CMake variable COMPONENT_DIRS includes this component but you can modify this variable. See the renaming main section for more info. If you have a lot of source files in your project, we recommend grouping most into components instead of putting them all in “main”.
- “build” directory is where the build output is created. This directory is created by idf.py if it doesn’t already exist. CMake configures the project and generates interim build files in this directory. Then, after the main build process is run, this directory will also contain interim object files and libraries as well as final binary output files. This directory is usually not added to source control or distributed with the project source code.

Component directories each contain a component CMakeLists.txt file. This file contains variable definitions to control the build process of the component, and its integration into the overall project. See Component CMakeLists Files for more details.

Each component may also include a Kconfig file defining the component configuration options that can be set via menuconfig. Some components may also include Kconfig.projbuild and project_include.cmake files, which are special files for overriding parts of the project.

### 4.5.4 Project CMakeLists File

Each project has a single top-level CMakeLists.txt file that contains build settings for the entire project. By default, the project CMakeLists can be quite minimal.
Minimal Example CMakeLists

Minimal project:

```cmake
cmake_minimum_required(VERSION 3.16)
include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)
```

Mandatory Parts

The inclusion of these three lines, in the order shown above, is necessary for every project:

- `cmake_minimum_required(VERSION 3.16)` tells CMake the minimum version that is required to build the project. ESP-IDF is designed to work with CMake 3.16 or newer. This line must be the first line in the CMakeLists.txt file.
- `include($ENV{IDF_PATH}/tools/cmake/project.cmake)` pulls in the rest of the CMake functionality to configure the project, discover all the components, etc.
- `project(myProject)` creates the project itself, and specifies the project name. The project name is used for the final binary output files of the app - ie myProject.elf, myProject.bin. Only one project can be defined per CMakeLists file.

Optional Project Variables

These variables all have default values that can be overridden for custom behavior. Look in /tools/cmake/project.cmake for all of the implementation details.

- `COMPONENT_DIRS`: Directories to search for components. Defaults to IDF_PATH/components, PROJECT_DIR/components, and EXTRA_COMPONENT_DIRS. Override this variable if you don’t want to search for components in these places.
- `EXTRA_COMPONENT_DIRS`: Optional list of additional directories to search for components. Paths can be relative to the project directory, or absolute.
- `COMPONENTS`: A list of component names to build into the project. Defaults to all components found in the COMPONENT_DIRS directories. Use this variable to “trim down” the project for faster build times. Note that any component which “requires” another component via the REQUIRE or PRIV_REQUIRES arguments on component registration will automatically have it added to this list, so the COMPONENTS list can be very short.

Any paths in these variables can be absolute paths, or set relative to the project directory.

To set these variables, use the `cmake set command` ie `set(VARIABLE "VALUE")`. The set() commands should be placed after the `cmake_minimum(...)` line but before the `include(...)` line.

Renaming main Component

The build system provides special treatment to the main component. It is a component that gets automatically added to the build provided that it is in the expected location, PROJECT_DIR/main. All other components in the build are also added as its dependencies, saving the user from hunting down dependencies and providing a build that works right out of the box. Renaming the main component causes the loss of these behind-the-scenes heavy lifting, requiring the user to specify the location of the newly renamed component and manually specify its dependencies. Specifically, the steps to renaming main are as follows:

1. Rename main directory.
2. Set EXTRA_COMPONENT_DIRS in the project CMakeLists.txt to include the renamed main directory.
3. Specify the dependencies in the renamed component’s CMakeLists.txt file via REQUIRE or PRIV_REQUIRES arguments on component registration.
Overriding Default Build Specifications

The build sets some global build specifications (compile flags, definitions, etc.) that gets used in compiling all sources from all components.

For example, one of the default build specifications set is the compile option `-Wextra`. Suppose a user wants to use override this with `-Wno-extra`, it should be done after `project()`:

```cmake
cmake_minimum_required(VERSION 3.16)
include($ENV{IDF_PATH}/tools/cmake/project.cmake)
project(myProject)
idf_build_set_property(COMPILE_OPTIONS "-Wno-error" APPEND)
```

This ensures that the compile options set by the user won’t be overridden by the default build specifications, since the latter are set inside `project()`.

4.5.5 Component CMakeLists Files

Each project contains one or more components. Components can be part of ESP-IDF, part of the project’s own components directory, or added from custom component directories (see above).

A component is any directory in the `COMPONENT_DIRS` list which contains a `CMakeLists.txt` file.

Searching for Components

The list of directories in `COMPONENT_DIRS` is searched for the project’s components. Directories in this list can either be components themselves (ie they contain a `CMakeLists.txt` file), or they can be top-level directories whose sub-directories are components.

When CMake runs to configure the project, it logs the components included in the build. This list can be useful for debugging the inclusion/exclusion of certain components.

Multiple Components with the Same Name

When ESP-IDF is collecting all the components to compile, it will do this in the order specified by `COMPONENT_DIRS`; by default, this means ESP-IDF’s internal components first (`IDF_PATH/components`), then any components in directories specified in `EXTRA_COMPONENT_DIRS`, and finally the project’s components (`PROJECT_DIR/components`). If two or more of these directories contain component sub-directories with the same name, the component in the last place searched is used. This allows, for example, overriding ESP-IDF components with a modified version by copying that component from the ESP-IDF components directory to the project components directory and then modifying it there. If used in this way, the ESP-IDF directory itself can remain untouched.

Note: If a component is overridden in an existing project by moving it to a new location, the project will not automatically see the new component path. Run `idf.py reconfigure` (or delete the project build folder) and then build again.

Minimal Component CMakeLists

The minimal component `CMakeLists.txt` file simply registers the component to the build system using `idf_component_register`:

```cmake
idf_component_register(SRCS "foo.c" "bar.c"
INCLUDE_DIRS "include"
REQUIRES mbedtls)
```
Chapter 4. API Guides

- **SRCS** is a list of source files (*.c, *.cpp, *.cc, *.S). These source files will be compiled into the component library.
- **INCLUDE_DIRS** is a list of directories to add to the global include search path for any component which requires this component, and also the main source files.
- **REQUIRES** is not actually required, but it is very often required to declare what other components this component will use. See component requirements.

A library with the name of the component will be built and linked to the final app.

Directories are usually specified relative to the CMakeLists.txt file itself, although they can be absolute.

There are other arguments that can be passed to `idf_component_register`. These arguments are discussed here.

See example component requirements and example component CMakeLists for more complete component CMakeLists.txt examples.

### Preset Component Variables

The following component-specific variables are available for use inside component CMakeLists, but should not be modified:

- **COMPONENT_DIR**: The component directory. Evaluates to the absolute path of the directory containing CMakeLists.txt. The component path cannot contain spaces. This is the same as the `CMAKE_CURRENT_SOURCE_DIR` variable.
- **COMPONENT_NAME**: Name of the component. Same as the name of the component directory.
- **COMPONENT_ALIAS**: Alias of the library created internally by the build system for the component.
- **COMPONENT_LIB**: Name of the library created internally by the build system for the component.

The following variables are set at the project level, but available for use in component CMakeLists:

- **CONFIG_***: Each value in the project configuration has a corresponding variable available in cmake. All names begin with `CONFIG_`. More information here.
- **ESP_PLATFORM**: Set to 1 when the CMake file is processed within the ESP-IDF build system.

### Build/Project Variables

The following are some project/build variables that are available as build properties and whose values can be queried using `idf_build_get_property` from the component CMakeLists.txt:

- **PROJECT_NAME**: Name of the project, as set in project CMakeLists.txt file.
- **PROJECT_DIR**: Absolute path of the project directory containing the project CMakeLists. Same as the `CMAKE_SOURCE_DIR` variable.
- **COMPONENTS**: Names of all components that are included in this build, formatted as a semicolon-delimited CMake list.
- **IDF_VER**: Git version of ESP-IDF (produced by `git describe`)  
  **IDF_VERSION_MAJOR**, **IDF_VERSION_MINOR**, **IDF_VERSION_PATCH**: Components of ESP-IDF version, to be used in conditional expressions. Note that this information is less precise than that provided by `IDF_VER` variable. v4.0-dev-, v4.0-beta1, v4.0-rc1 and v4.0 will all have the same values of `IDF_VERSION_*` variables, but different `IDF_VER` values.
- **IDF_TARGET**: Name of the target for which the project is being built.
- **PROJECT_VERSION**: Project version.
  - If `CONFIG_APP_PROJECT_VER_FROM_CONFIG` option is set, the value of `CONFIG_APP_PROJECT_VER` will be used.
  - Else, if `PROJECT_VER` variable is set in project CMakeLists.txt file, its value will be used.
  - Else, if the `PROJECT_DIR/version.txt` exists, its contents will be used as `PROJECT_VER`.
  - Else, if the project is located inside a Git repository, the output of `git description` will be used.
  - Otherwise, `PROJECT_VER` will be “1”.
- **EXTRA_PARTITION_SUBTYPES**: CMake list of extra partition subtypes. Each subtype description is a comma-separated string with `type_name, subtype_name, numeric_value` format. Components may add new subtypes by appending them to this list.
Chapter 4. API Guides

Other build properties are listed here.

Controlling Component Compilation

To pass compiler options when compiling source files belonging to a particular component, use the `target_compile_options` function:

```cmake
target_compile_options(${COMPONENT_LIB} PRIVATE -Wno-unused-variable)
```

To apply the compilation flags to a single source file, use the CMake `set_source_files_properties` command:

```cmake
set_source_files_properties(mysrc.c
  PROPERTIES COMPILER_FLAGS
  -Wno-unused-variable)
```

This can be useful if there is upstream code that emits warnings.

When using these commands, place them after the call to `idf_component_register` in the component CMakeLists file.

4.5.6 Component Configuration

Each component can also have a Kconfig file, alongside CMakeLists.txt. This contains configuration settings to add to the configuration menu for this component.

These settings are found under the “Component Settings” menu when menuconfig is run.

To create a component Kconfig file, it is easiest to start with one of the Kconfig files distributed with ESP-IDF.

For an example, see Adding conditional configuration.

4.5.7 Preprocessor Definitions

The ESP-IDF build system adds the following C preprocessor definitions on the command line:

- `ESP_PLATFORM`: Can be used to detect that build happens within ESP-IDF.
- `IDF_VER`: Defined to a git version string. E.g. `v2.0` for a tagged release or `v1.0-275-g0efaa4f` for an arbitrary commit.

4.5.8 Component Requirements

When compiling each component, the ESP-IDF build system recursively evaluates its dependencies. This means each component needs to declare the components that it depends on (“requires”).

When Writing a Component

```cmake
idadm_component_register(...) REQUIREES mbedtls PRIV_REQUIRES console spiffs)
```

- `REQUIRES` should be set to all components whose header files are #included from the `public` header files of this component.
- `PRIV_REQUIRES` should be set to all components whose header files are #included from any source files in this component, unless already listed in `REQUIRES`. Also, any component which is required to be linked in order for this component to function correctly.
• The values of REQUIRES and PRIV_REQUIRES should not depend on any configuration choices (CON-FIG_XXX macros). This is because requirements are expanded before the configuration is loaded. Other component variables (like include paths or source files) can depend on configuration choices.

• Not setting either or both REQUIRES variables is fine. If the component has no requirements except for the Common component requirements needed for RTOS, libc, etc.

If a component only supports some target chips (values of IDF_TARGET) then it can specify REQUIRED_IDF_TARGETS in the idf_component_register call to express these requirements. In this case, the build system will generate an error if the component is included in the build, but does not support the selected target.

**Note:** In CMake terms, REQUIRES & PRIV_REQUIRES are approximate wrappers around the CMake functions target_link_libraries(... PUBLIC ...) and target_link_libraries(... PRIVATE ...).

### Example of Component Requirements

Imagine there is a car component, which uses the engine component, which uses the spark_plug component:

```
- autoProject/
  - CMakeLists.txt
  - components/ - car/ - CMakeLists.txt
    - car.c
    - car.h
  - engine/ - CMakeLists.txt
    - engine.c
    - include/ - engine.h
  - spark_plug/ - CMakeLists.txt
    - spark_plug.c
    - spark_plug.h
```

**Car Component**  The car.h header file is the public interface for the car component. This header includes engine.h directly because it uses some declarations from this header:

```c
/* car.h */
#include "engine.h"

#ifdef ENGINE_IS_HYBRID
#define CAR_MODEL "Hybrid"
#endif
```

And car.c includes car.h as well:

```c
/* car.c */
#include "car.h"
```

This means the car/CMakeLists.txt file needs to declare that car requires engine:

```c
idf_component_register(SRCS "car.c"
  INCLUDE_DIRS "."
  REQUIRES engine)
```

• SRCS gives the list of source files in the car component.
• INCLUDE_DIRS gives the list of public include directories for this component. Because the public interface is car.h, the directory containing car.h is listed here.
• REQUIRES gives the list of components required by the public interface of this component. Because car.h is a public header and includes a header from engine, we include engine here. This makes sure that any other component which includes car.h will be able to recursively include the required engine.h also.
Engine Component The engine component also has a public header file include/engine.h, but this header is simpler:

```c
/* engine.h */
#define ENGINE_IS_HYBRID

void engine_start(void);
```

The implementation is in engine.c:

```c
/* engine.c */
#include "engine.h"
#include "spark_plug.h"
...
```

In this component, engine depends on spark_plug but this is a private dependency. spark_plug.h is needed to compile engine.c, but not needed to include engine.h.

This means that the engine/CMakeLists.txt file can use PRIV_REQUIRES:

```c
idf_component_register(SRCS "engine.c"
    INCLUDE_DIRS "include"
    PRIV_REQUIRES spark_plug)
```

As a result, source files in the car component don’t need the spark_plug include directories added to their compiler search path. This can speed up compilation, and stops compiler command lines from becoming longer than necessary.

Spark Plug Component The spark_plug component doesn’t depend on anything else. It has a public header file spark_plug.h, but this doesn’t include headers from any other components.

This means that the spark_plug/CMakeLists.txt file doesn’t need any REQUIRES or PRIV_REQUIRES clauses:

```c
idf_component_register(SRCS "spark_plug.c"
    INCLUDE_DIRS ".")
```

Source File Include Directories

Each component’s source file is compiled with these include path directories, as specified in the passed arguments to idf_component_register:

```c
idf_component_register(...) INCLUDE_DIRS "include"
    PRIV_INCLUDE_DIRS "other")
```

- The current component’s INCLUDE_DIRS and PRIV_INCLUDE_DIRS.
- The INCLUDE_DIRS belonging to all other components listed in the REQUIRES and PRIV_REQUIRES parameters (ie all the current component’s public and private dependencies).
- Recursively, all of the INCLUDE_DIRS of those components REQUIRES lists (ie all public dependencies of this component’s dependencies, recursively expanded).

Main Component Requirements

The component named main is special because it automatically requires all other components in the build. So it’s not necessary to pass REQUIRES or PRIV_REQUIRES to this component. See renaming main for a description of what needs to be changed if no longer using the main component.
# Chapter 4. API Guides

## Common Component Requirements

To avoid duplication, every component automatically requires some “common” IDF components even if they are not mentioned explicitly. Headers from these components can always be included.

The list of common components is: cxx, newlib, freertos, esp_hw_support, heap, log, soc, hal, esp_rom, esp_common, esp_system, xtensa/riscv.

## Including Components in the Build

- By default, every component is included in the build.
- If you set the COMPONENTS variable to a minimal list of components used directly by your project, then the build will expand to also include required components. The full list of components will be:
  - Components mentioned explicitly in COMPONENTS.
  - Those components’ requirements (evaluated recursively).
  - The “common” components that every component depends on.
- Setting COMPONENTS to the minimal list of required components can significantly reduce compile times.

## Circular Dependencies

It’s possible for a project to contain Component A that requires (REQUIRES or PRIV_REQUIRES) Component B, and Component B that requires Component A. This is known as a dependency cycle or a circular dependency.

CMake will usually handle circular dependencies automatically by repeating the component library names twice on the linker command line. However, this strategy doesn’t always work, and the build may fail with a linker error about “Undefined reference to …”, referencing a symbol defined by one of the components inside the circular dependency. This is particularly likely if there is a large circular dependency, i.e. A->B->C->D->A.

The best solution is to restructure the components to remove the circular dependency. In most cases, a software architecture without circular dependencies has desirable properties of modularity and clean layering and will be more maintainable in the long term. However, removing circular dependencies is not always possible.

To bypass a linker error caused by a circular dependency, the simplest workaround is to increase the CMake LINK_INTERFACE_MULTIPLICITY property of one of the component libraries. This causes CMake to repeat this library and its dependencies more than two times on the linker command line.

For example:

```cmake
set_property(TARGET ${COMPONENT_LIB} APPEND PROPERTY LINK_INTERFACE_MULTIPLICITY 3)
```

- This line should be placed after idf_component_register in the component CMakeLists.txt file.
- If possible, place this line in the component that creates the circular dependency by depending on a lot of other components. However, the line can be placed inside any component that is part of the cycle. Choosing the component that owns the source file shown in the linker error message, or the component that defines the symbol(s) mentioned in the linker error message, is a good place to start.
- Usually increasing the value to 3 (default is 2) is enough, but if this doesn’t work then try increasing the number further.
- Adding this option will make the linker command line longer, and the linking stage slower.

**Advanced Workaround: Undefined Symbols**

If only one or two symbols are causing a circular dependency, and all other dependencies are linear, then there is an alternative method to avoid linker errors: Specify the specific symbols required for the “reverse” dependency as undefined symbols at link time.

For example, if component A depends on component B but component B also needs to reference `reverse_ops` from component A (but nothing else), then you can add a line like the following to the component B CMakeLists.txt to resolve the cycle at link time:

```cmake
# This symbol is provided by 'Component A' at link time
target_link_libraries(${COMPONENT_LIB} INTERFACE "-u reverse_ops")
```
• The -u argument means that the linker will always include this symbol in the link, regardless of dependency ordering.
• This line should be placed after idf_component_register in the component CMakeLists.txt file.
• If ‘Component B’ doesn’t need to access any headers of ‘Component A’, only link to a few symbol(s), then this line can be used instead of any REQUIRES from B to A. This further simplifies the component structure in the build system.

See the target_link_libraries documentation for more information about this CMake function.

Requirements in the Build System Implementation

• Very early in the CMake configuration process, the script expand_requirements.cmake is run. This script does a partial evaluation of all component CMakeLists.txt files and builds a graph of component requirements (this graph may have cycles). The graph is used to generate a file component_depends.cmake in the build directory.
• The main CMake process then includes this file and uses it to determine the list of components to include in the build (internal BUILD_COMPONENTS variable). The BUILD_COMPONENTS variable is sorted so dependencies are listed first, however, as the component dependency graph has cycles this cannot be guaranteed for all components. The order should be deterministic given the same set of components and component dependencies.
• The value of BUILD_COMPONENTS is logged by CMake as “Component names: “
• Configuration is then evaluated for the components included in the build.
• Each component is included in the build normally and the CMakeLists.txt file is evaluated again to add the component libraries to the build.

Component Dependency Order The order of components in the BUILD_COMPONENTS variable determines other orderings during the build:

• Order that project_include.cmake files are included in the project.
• Order that the list of header paths is generated for compilation (via -I argument). (Note that for a given component’s source files, only that component’s dependency’s header paths are passed to the compiler.)

Adding Link-Time Dependencies The ESP-IDF CMake helper function idf_component_add_link_dependency adds a link-only dependency between one component and another. In almost all cases, it is better to use the PRIV_REQUIRES feature in idf_component_register to create a dependency. However, in some cases, it’s necessary to add the link-time dependency of another component to this component, i.e., the reverse order to PRIV_REQUIRES (for example: Overriding Default Chip Drivers).

To make another component depend on this component at link time:

```
idf_component_add_link_dependency(FROM other_component)
```

Place this line after the line with idf_component_register.

It’s also possible to specify both components by name:

```
idf_component_add_link_dependency(FROM other_component TO that_component)
```

4.5.9 Overriding Parts of the Project

project_include.cmake

For components that have build requirements that must be evaluated before any component CMakeLists files are evaluated, you can create a file called project_include.cmake in the component directory. This CMake file is included when project.cmake is evaluating the entire project.

project_include.cmake files are used inside ESP-IDF, for defining project-wide build features such as esptool.py command line arguments and the bootloader “special app”.
Unlike component CMakeLists.txt files, when including a project_include.cmake file the current source directory (CMAKE_CURRENT_SOURCE_DIR and working directory) is the project directory. Use the variable COMPONENT_DIR for the absolute directory of the component.

Note that project_include.cmake isn’t necessary for the most common component uses, such as adding include directories to the project, or LDFLAGS to the final linking step. These values can be customized via the CMakeLists.txt file itself. See Optional Project Variables for details.

project_include.cmake files are included in the order given in BUILD_COMPONENTS variable (as logged by CMake). This means that a component’s project_include.cmake file will be included after it’s all dependencies’ project_include.cmake files, unless both components are part of a dependency cycle. This is important if a project_include.cmake file relies on variables set by another component. See also above.

Take great care when setting variables or targets in a project_include.cmake file. As the values are included in the top-level project CMake pass, they can influence or break functionality across all components!

KConfig.projbuild

This is an equivalent to project_include.cmake for Component Configuration KConfig files. If you want to include configuration options at the top level of menuconfig, rather than inside the “Component Configuration” sub-menu, then these can be defined in the KConfig.projbuild file alongside the CMakeLists.txt file.

Take care when adding configuration values in this file, as they will be included across the entire project configuration. Where possible, it’s generally better to create a KConfig file for Component Configuration.

project_include.cmake files are used inside ESP-IDF, for defining project-wide build features such as esptool.py command line arguments and the bootloader “special app”.

Wrappers to Redefine or Extend Existing Functions

Thanks to the linker’s wrap feature, it is possible to redefine or extend the behavior of an existing ESP-IDF function. To do so, you will need to provide the following CMake declaration in your project’s CMakeLists.txt file:

```
target_link_libraries(${COMPONENT_LIB} INTERFACE "-Wl,--wrap=function_to_redefine")
```

Where function_to_redefine is the name of the function to redefine or extend. This option will let the linker replace all the calls to function_to_redefine functions in the binary libraries with calls to __wrap_function_to_redefine function. Thus, you must define this new symbol in your application.

The linker will provide a new symbol named __real_function_to_redefine which points to the former implementation of the function to redefine. It can be called from the new implementation, making it an extension of the former one.

This mechanism is shown in the example build_system/wrappers. Check examples/build_system/wrappers/README.md for more details.

4.5.10 Configuration-Only Components

Special components which contain no source files, only Kconfig.projbuild and KConfig, can have a one-line CMakeLists.txt file which calls the function idf_component_register() with no arguments specified. This function will include the component in the project build, but no library will be built and no header files will be added to any included paths.

4.5.11 Debugging CMake

For full details about CMake and CMake commands, see the CMake v3.16 documentation.

Some tips for debugging the ESP-IDF CMake-based build system:
• When CMake runs, it prints quite a lot of diagnostic information including lists of components and component paths.
• Running `cmake -DDEBUG=1` will produce more verbose diagnostic output from the IDF build system.
• Running `cmake` with the `--trace` or `--trace-expand` options will give a lot of information about control flow. See the `cmake` command line documentation.

When included from a project CMakeLists file, the `project.cmake` file defines some utility modules and global variables and then sets `IDF_PATH` if it was not set in the system environment.

It also defines an overridden custom version of the built-in CMake `project` function. This function is overridden to add all of the ESP-IDF specific project functionality.

### Warning On Undefined Variables

By default, the function of warnings on undefined variables is disabled.

To enable this function, we can pass the `--warn-uninitialized` flag to CMake or pass the `--cmake-warn-uninitialized` flag to `idf.py` so it will print a warning if an undefined variable is referenced in the build. This can be very useful to find buggy CMake files.

Browse the `/tools/cmake/project.cmake` file and supporting functions in `/tools/cmake/` for more details.

### 4.5.12 Example Component CMakeLists

Because the build environment tries to set reasonable defaults that will work most of the time, component `CMakeLists.txt` can be very small or even empty (see Minimal Component CMakeLists). However, overriding `preset_component_variables` is usually required for some functionality.

Here are some more advanced examples of component CMakeLists files.

#### Adding Conditional Configuration

The configuration system can be used to conditionally compile some files depending on the options selected in the project configuration.

Kconfig:

```bash
config FOO_ENABLE_BAR
  bool "Enable the BAR feature."
  help
    This enables the BAR feature of the FOO component.
```

CMakeLists.txt:

```bash
set(srcs "foo.c" "more_foo.c")
if(CONFIG_FOO_ENABLE_BAR)
  list(APPEND srcs "bar.c")
endif()

idf_component_register(SRCS "${srcs}"
  ...)
```

This example makes use of the CMake `if` function and `list APPEND` function.

This can also be used to select or stub out an implementation, as such:

Kconfig:
config ENABLE_LCD_OUTPUT
    bool "Enable LCD output."
    help
        Select this if your board has an LCD.
config ENABLE_LCD_CONSOLE
    bool "Output console text to LCD"
    depends on ENABLE_LCD_OUTPUT
    help
        Select this to output debugging output to the LCD
config ENABLE_LCD_PLOT
    bool "Output temperature plots to LCD"
    depends on ENABLE_LCD_OUTPUT
    help
        Select this to output temperature plots

CMakeLists.txt:

if (CONFIG_ENABLE_LCD_OUTPUT)
    set(srcs lcd-real.c lcd-spi.c)
else()
    set(srcs lcd-dummy.c)
endif()

# We need font if either console or plot is enabled
if (CONFIG_ENABLE_LCD_CONSOLE OR CONFIG_ENABLE_LCD_PLOT)
    list(APPEND srcs "font.c")
endif()

idf_component_register(SRCS "${srcs}"
    ...
)

Conditions Which Depend on the Target

The current target is available to CMake files via IDF_TARGET variable.

In addition to that, if target xyz is used (IDF_TARGET=xyz), then Kconfig variable CONFIG_IDF_TARGET_XYZ will be set.

Note that component dependencies may depend on IDF_TARGET variable, but not on Kconfig variables. Also one can not use Kconfig variables in include statements in CMake files, but IDF_TARGET can be used in such context.

Source Code Generation

Some components will have a situation where a source file isn’t supplied with the component itself but has to be generated from another file. Say our component has a header file that consists of the converted binary data of a BMP file, converted using a hypothetical tool called bmp2h. The header file is then included in as C source file called graphics_lib.c:

add_custom_command(OUTPUT logo.h
    COMMAND bmp2h -i ${COMPONENT_DIR}/logo.bmp -o log.h
    DEPENDS ${COMPONENT_DIR}/logo.bmp
    VERBATIM)

add_custom_target(logo DEPENDS logo.h)
add_dependencies(${COMPONENT_LIB} logo)

set_property(DIRECTORY "${COMPONENT_DIR}" APPEND PROPERTY
    ADDITIONAL_CLEAN_FILES logo.h)
This answer is adapted from the CMake FAQ entry, which contains some other examples that will also work with ESP-IDF builds.

In this example, logo.h will be generated in the current directory (the build directory) while logo.bmp comes with the component and resides under the component path. Because logo.h is a generated file, it should be cleaned when the project is cleaned. For this reason, it is added to the ADDITIONAL_CLEAN_FILES property.

**Note:** If generating files as part of the project CMakeLists.txt file, not a component CMakeLists.txt, then use build property PROJECT_DIR instead of ${COMPONENT_DIR} and ${PROJECT_NAME}.elf instead of ${COMPONENT_LIB}.)

If a a source file from another component included logo.h, then add_dependencies would need to be called to add a dependency between the two components, to ensure that the component source files were always compiled in the correct order.

### Embedding Binary Data

Sometimes you have a file with some binary or text data that you’d like to make available to your component, but you don’t want to reformat the file as a C source.

You can specify argument EMBED_FILES in the component registration, giving space-delimited names of the files to embed:

```
idf_component_register(...)  
    EMBED_FILES server_root_cert.der
```

Or if the file is a string, you can use the variable EMBED_TXTFILES. This will embed the contents of the text file as a null-terminated string:

```
idf_component_register(...)  
    EMBED_TXTFILES server_root_cert.pem
```

The file’s contents will be added to the .rodata section in flash, and are available via symbol names as follows:

```c
extern const uint8_t server_root_cert_pem_start[] asm("_binary_server_root_cert_\n\n pem_start");
extern const uint8_t server_root_cert_pem_end[] asm("_binary_server_root_cert_\n\n pem_end");
```

The names are generated from the full name of the file, as given in EMBED_FILES. Characters /, ., etc. are replaced with underscores. The _binary prefix in the symbol name is added by objcopy and is the same for both text and binary files.

To embed a file into a project, rather than a component, you can call the function target_add_binary_data like this:

```
target_add_binary_data(myproject.elf "main/data.bin" TEXT)
```

Place this line after the project() line in your project CMakeLists.txt file. Replace myproject.elf with your project name. The final argument can be TEXT to embed a null-terminated string, or BINARY to embed the content as-is.

For an example of using this technique, see the “main” component of the file_serving example protocols/http_server/file_serving/main/CMakeLists.txt - two files are loaded at build time and linked into the firmware.

It is also possible to embed a generated file:

```
add_custom_command(OUTPUT my_processed_file.bin  
    COMMAND my_process_file_cmd my_unprocessed_file.bin)
target_add_binary_data(my_target "my_processed_file.bin" BINARY)
```
In the example above, my\_processed\_file.bin is generated from my\_unprocessed\_file.bin through some command my\_process\_file\_cmd, then embedded into the target.

To specify a dependence on a target, use the DEPENDS argument:

```
add_custom_target(my_process COMMAND ...) target_add_binary_data(my_target "my_embed_file.bin" BINARY DEPENDS my_process)
```

The DEPENDS argument to target_add_binary_data ensures that the target executes first.

**Code and Data Placements**

ESP-IDF has a feature called linker script generation that enables components to define where its code and data will be placed in memory through linker fragment files. These files are processed by the build system, and is used to augment the linker script used for linking app binary. See *Linker Script Generation* for a quick start guide as well as a detailed discussion of the mechanism.

**Fully Overriding the Component Build Process**

Obviously, there are cases where all these recipes are insufficient for a certain component, for example when the component is basically a wrapper around another third-party component not originally intended to be compiled under this build system. In that case, it’s possible to forgo the ESP-IDF build system entirely by using a CMake feature called *ExternalProject*. Example component CMakeLists:

```
# External build process for quirc, runs in source dir and
# produces libquirc.a
externalproject_add(quirc_build
    PREFIX ${COMPONENT_DIR}
    SOURCE_DIR ${COMPONENT_DIR}/quirc
    CONFIGURE_COMMAND ""
    BUILD_IN_SOURCE 1
    BUILD_COMMAND make CC=${CMAKE_C_COMPILER} libquirc.a
    INSTALL_COMMAND ""
)

# Add libquirc.a to the build process
add_library(quirc STATIC IMPORTED GLOBAL)
add_dependencies(quirc quirc_build)

set_target_properties(quirc PROPERTIES IMPORTED_LOCATION
    ${COMPONENT_DIR}/quirc/libquirc.a)
set_target_properties(quirc PROPERTIES INTERFACE_INCLUDE_DIRECTORIES
    ${COMPONENT_DIR}/quirc/lib)
set_directory_properties( PROPERTIES ADDITIONAL_CLEAN_FILES
    "${COMPONENT_DIR}/quirc/libquirc.a")
```

(The above CMakeLists.txt can be used to create a component named quirc that builds the quirc project using its own Makefile.)

- `externalproject_add` defines an external build system.
  - `SOURCE_DIR`, `CONFIGURE_COMMAND`, `BUILD_COMMAND` and `INSTALL_COMMAND` should always be set. `CONFIGURE_COMMAND` can be set to an empty string if the build system has no “configure” step. `INSTALL_COMMAND` will generally be empty for ESP-IDF builds.
  - Setting `BUILD_IN_SOURCE` means the build directory is the same as the source directory. Otherwise, you can set `BUILD_DIR`.
  - Consult the *ExternalProject* documentation for more details about `externalproject_add()`
- The second set of commands adds a library target, which points to the “imported” library file built by the external system. Some properties need to be set in order to add include directories and tell CMake where this file is.

Submit Document Feedback
Finally, the generated library is added to ADDITIONAL_CLEAN_FILES. This means `make clean` will delete this library. (Note that the other object files from the build won’t be deleted.)

**Note:** When using an external build process with PSRAM, remember to add `-mfix-esp32-psram-cache-issue` to the C compiler arguments. See `CONFIG_SPIRAM_CACHE_WORKAROUND` for details of this flag.

### External Project Dependencies and Clean Builds

CMake has some unusual behavior around external project builds:

- **ADDITIONAL_CLEAN_FILES** only works when “make” or “ninja” is used as the build system. If an IDE build system is used, it won’t delete these files when cleaning.
- However, the ExternalProject configure & build commands will always be re-run after a clean is run.
- Therefore, there are two alternative recommended ways to configure the external build command:
  1. Have the external BUILD_COMMAND run a full clean compile of all sources. The build command will be run if any of the dependencies passed to `externalproject_add` with DEPENDS have changed, or if this is a clean build (i.e., any of `idf.py clean`, `ninja clean`, or `make clean` was run.)
  2. Have the external BUILD_COMMAND be an incremental build command. Pass the parameter BUILD_ALWAYS 1 to `externalproject_add`. This means the external project will be built each time a build is run, regardless of dependencies. This is only recommended if the external project has correct incremental build behavior, and doesn’t take too long to run.

The best of these approaches for building an external project will depend on the project itself, its build system, and whether you anticipate needing to frequently recompile the project.

### 4.5.13 Custom Sdkconfig Defaults

For example projects or other projects where you don’t want to specify a full sdkconfig configuration, but you do want to override some key values from the ESP-IDF defaults, it is possible to create a file `sdkconfig.defaults` in the project directory. This file will be used when creating a new config from scratch, or when any new config value hasn’t yet been set in the `sdkconfig` file.

To override the name of this file or to specify multiple files, set the `SDKCONFIG_DEFAULTS` environment variable or set `SDKCONFIG_DEFAULTS` in top-level `CMakeLists.txt`. File names that are not specified as full paths are resolved relative to current project’s directory.

When specifying multiple files, use a semicolon as the list separator. Files listed first will be applied first. If a particular key is defined in multiple files, the definition in the latter file will override definitions from former files.

Some of the IDF examples include a `sdkconfig.ci` file. This is part of the continuous integration (CI) test framework and is ignored by the normal build process.

### Target-dependent Sdkconfig Defaults

In addition to `sdkconfig.defaults` file, build system will also load defaults from `sdkconfig.defaults.TARGET_NAME` file, where TARGET_NAME is the value of IDF_TARGET. For example, for esp32 target, default settings will be taken from `sdkconfig.defaults` first, and then from `sdkconfig.defaults.esp32`.

If `SDKCONFIG_DEFAULTS` is used to override the name of defaults file/files, the name of target-specific defaults file will be derived from `SDKCONFIG_DEFAULTS` value/values using the rule above. When there are multiple files in `SDKCONFIG_DEFAULTS`, target-specific file will be applied right after the file bringing it in, before all latter files in `SDKCONFIG_DEFAULTS`.

For example, if `SDKCONFIG_DEFAULTS"sdkconfig.defaults;sdkconfig_devkit1", and there is a file `sdkconfig.defaults.esp32` in the same folder, then the files will be applied in the following order: (1) `sdkconfig.defaults` (2) `sdkconfig.defaults.esp32` (3) `sdkconfig_devkit1`. 
4.5.14 Flash Arguments

There are some scenarios that we want to flash the target board without IDF. For this case we want to save the built binaries, esptool.py and esptool write flash arguments. It’s simple to write a script to save binaries and esptool.py.

After running a project build, the build directory contains binary output files (.bin files) for the project and also the following flashing data files:

- `flash_project_args` contains arguments to flash the entire project (app, bootloader, partition table, PHY data if this is configured).
- `flash_app_args` contains arguments to flash only the app.
- `flash_bootloader_args` contains arguments to flash only the bootloader.

You can pass any of these flasher argument files to esptool.py as follows:

```python
python esptool.py --chip esp32 write_flash @build/flash_project_args
```

Alternatively, it is possible to manually copy the parameters from the argument file and pass them on the command line.

The build directory also contains a generated file `flasher_args.json` which contains project flash information, in JSON format. This file is used by idf.py and can also be used by other tools which need information about the project build.

4.5.15 Building the Bootloader

The bootloader is a special “subproject” inside `/components/bootloader/subproject`. It has its own project CMakeLists.txt file and builds separate .ELF and .BIN files to the main project. However, it shares its configuration and build directory with the main project.

The subproject is inserted as an external project from the top-level project, by the file `/components/bootloader/project_include.cmake`. The main build process runs CMake for the subproject, which includes discovering components (a subset of the main components) and generating a bootloader-specific config (derived from the main sdkconfig).

4.5.16 Writing Pure CMake Components

The ESP-IDF build system “wraps” CMake with the concept of “components”, and helper functions to automatically integrate these components into a project build.

However, underneath the concept of “components” is a full CMake build system. It is also possible to make a component which is pure CMake.

Here is an example minimal “pure CMake” component CMakeLists file for a component named `json`:

```cmake
add_library(json STATIC
  cJSON/cJSON.c
  cJSON/cJSON_Utils.c)
target_include_directories(json PUBLIC cJSON)
```

- This is actually an equivalent declaration to the IDF `json` component `/components/json/CMakeLists.txt`.
- This file is quite simple as there are not a lot of source files. For components with a large number of files, the globbing behavior of ESP-IDF’s component logic can make the component CMakeLists style simpler.
- Any time a component adds a library target with the component name, the ESP-IDF build system will automatically add this to the build, expose public include directories, etc. If a component wants to add a library target with a different name, dependencies will need to be added manually via CMake commands.
4.5.17 Using Third-Party CMake Projects with Components

CMake is used for a lot of open-source C and C++ projects — code that users can tap into for their applications. One of the benefits of having a CMake build system is the ability to import these third-party projects, sometimes even without modification! This allows for users to be able to get functionality that may not yet be provided by a component, or use another library for the same functionality.

Importing a library might look like this for a hypothetical library foo to be used in the main component:

```cmake
# Register the component
idf_component_register(...)

# Set values of hypothetical variables that control the build of `foo`
set(FOO_BUILD_STATIC OFF)
set(FOO_BUILD_TESTS OFF)

# Create and import the library targets
add_subdirectory(foo)

# Publicly link `foo` to `main` component
target_link_libraries(main PUBLIC foo)
```

For an actual example, take a look at `build_system/cmake/import_lib`. Take note that what needs to be done in order to import the library may vary. It is recommended to read up on the library’s documentation for instructions on how to import it from other projects. Studying the library’s CMakeLists.txt and build structure can also be helpful.

It is also possible to wrap a third-party library to be used as a component in this manner. For example, the mbedtls component is a wrapper for Espressif’s fork of mbedtls. See its component CMakeLists.txt.

The CMake variable ESP_PLATFORM is set to 1 whenever the ESP-IDF build system is being used. Tests such as if (ESP_PLATFORM) can be used in generic CMake code if special IDF-specific logic is required.

Using ESP-IDF Components from External Libraries

The above example assumes that the external library foo (or tinyxml in the case of the import_lib example) doesn’t need to use any ESP-IDF APIs apart from common APIs such as libc, libstdc++, etc. If the external library needs to use APIs provided by other ESP-IDF components, this needs to be specified in the external CMakeLists.txt file by adding a dependency on the library target idf::<componentname>.

For example, in the foo/CMakeLists.txt file:

```cmake
add_library(foo bar.c fizz.cpp buzz.cpp)

if(ESP_PLATFORM)
    # On ESP-IDF, bar.c needs to include esp_flash.h from the spi_flash component
    target_link_libraries(foo PRIVATE idf::spi_flash)
endif()
```

4.5.18 Using Prebuilt Libraries with Components

Another possibility is that you have a prebuilt static library (.a file), built by some other build process.

The ESP-IDF build system provides a utility function add_prebuilt_library for users to be able to easily import and use prebuilt libraries:

```cmake
add_prebuilt_library(target_name lib_path [REQUIRES req1 req2 ...] [PRIV_REQUIRES_ req1 req2 ...])
```

where:

- **target_name** - name that can be used to reference the imported library, such as when linking to other targets
Chapter 4. API Guides

- `lib_path` - path to prebuilt library; may be an absolute or relative path to the component directory

Optional arguments `REQUIRES` and `PRIV_REQUIRES` specify dependency on other components. These have the same meaning as the arguments for `idf_component_register`.

Take note that the prebuilt library must have been compiled for the same target as the consuming project. Configuration relevant to the prebuilt library must also match. If not paid attention to, these two factors may contribute to subtle bugs in the app.

For an example, take a look at `build_system/cmake/import_prebuilt`.

### 4.5.19 Using ESP-IDF in Custom CMake Projects

ESP-IDF provides a template CMake project for easily creating an application. However, in some instances the user might already have an existing CMake project or may want to create a custom one. In these cases it is desirable to be able to consume IDF components as libraries to be linked to the user’s targets (libraries/executables).

It is possible to do so by using the build system APIs provided by `tools/cmake/idf.cmake`. For example:

```cmake
cmake_minimum_required(VERSION 3.16)
project(my_custom_app C)

# Include CMake file that provides ESP-IDF CMake build system APIs.
include(${ENV{IDF_PATH}}/tools/cmake/idf.cmake)

# Include ESP-IDF components in the build, may be thought as an equivalent of
# add_subdirectory() but with some additional processing and magic for ESP-IDF
# specific build processes.
idf_build_process(esp32)

# Create the project executable and plainly link the newlib component to it using
# its alias, idf::newlib.
add_executable(${CMAKE_PROJECT_NAME}.elf main.c)
target_link_libraries(${CMAKE_PROJECT_NAME}.elf idf::newlib)

# Let the build system know what the project executable is to attach more targets,
# --dependencies, etc.
idf_build_executable(${CMAKE_PROJECT_NAME}.elf)
```

The example in `build_system/cmake/idf_as_lib` demonstrates the creation of an application equivalent to `hello world` application using a custom CMake project.

**Note:** The IDF build system can only set compiler flags for source files that it builds. When an external CMake-Lists.txt file is used and PSRAM is enabled, remember to add `-mfix-esp32-psram-cache-issue` to the C compiler arguments. See `CONFIG_SPIRAM_CACHE_WORKAROUND` for details of this flag.

### 4.5.20 ESP-IDF CMake Build System API

**idf-build-commands**

```cmake
idf_build_get_property(var property [GENERATOR_EXPRESSION])
```

Retrieve a build property `property` and store it in `var` accessible from the current scope. Specifying `GENERATOR_EXPRESSION` will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.
Chapter 4. API Guides

**idf_build_set_property** *(property val [APPEND])*

Set a build property `property` with value `val`. Specifying **APPEND** will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

**idf_build_component** *(component_dir)*

Present a directory `component_dir` that contains a component to the build system. Relative paths are converted to absolute paths with respect to current directory. All calls to this command must be performed before **idf_build_process**. This command does not guarantee that the component will be processed during build (see the COMPONENTS argument description for **idf_build_process**)

**idf_build_process** *(target [PROJECT_DIR project_dir] [PROJECT_VER project_ver] [PROJECT_NAME project_name] [SDKCONFIG sdkconfig] [SDKCONFIG_DEFAULTS sdkconfig_defaults] [BUILD_DIR build_dir] [COMPONENTS component1 component2 ...])*

Performs the bulk of the behind-the-scenes magic for including ESP-IDF components such as component configuration, libraries creation, dependency expansion and resolution. Among these functions, perhaps the most important from a user’s perspective is the libraries creation by calling each component’s `idf_component_register`. This command creates the libraries for each component, which are accessible using aliases in the form `idf::component_name`. These aliases can be used to link the components to the user’s own targets, either libraries or executables.

The call requires the target chip to be specified with `target` argument. Optional arguments for the call include:

- **PROJECT_DIR** - directory of the project; defaults to CMAKE_SOURCE_DIR
- **PROJECT_NAME** - name of the project; defaults to CMAKE_PROJECT_NAME
- **PROJECT_VER** - version/revision of the project; defaults to “1”
- **SDKCONFIG** - output path of generated sdkconfig file; defaults to PROJECT_DIR/sdkconfig or CMAKE_SOURCE_DIR/sdkconfig depending if PROJECT_DIR is set
- **SDKCONFIG_DEFAULTS** - list of files containing default config to use in the build (list must contain full paths); defaults to empty. For each value `filename` in the list, the config from file `filename.target`, if it exists, is also loaded.
- **BUILD_DIR** - directory to place ESP-IDF build-related artifacts, such as generated binaries, text files, components; defaults to CMAKE_BINARY_DIR
- **COMPONENTS** - select components to process among the components known by the build system (added via `idf_build_component`). This argument is used to trim the build. Other components are automatically added if they are required in the dependency chain, i.e. the public and private requirements of the components in this list are automatically added, and in turn the public and private requirements of those requirements, so on and so forth. If not specified, all components known to the build system are processed.

**idf_build_executable** *(executable)*

Specify the executable `executable` for ESP-IDF build. This attaches additional targets such as dependencies related to flashing, generating additional binary files, etc. Should be called after **idf_build_process**.

**idf_build_get_config** *(var config [GENERATOR_EXPRESSION])*

Get the value of the specified config. Much like build properties, specifying **GENERATOR_EXPRESSION** will retrieve the generator expression string for that config, instead of the actual value, which can be used with CMake commands that support generator expressions. Actual config values are only known after call to **idf_build_process**, however.
idf-build-properties

These are properties that describe the build. Values of build properties can be retrieved by using the build command idf_build_get_property. For example, to get the Python interpreter used for the build:

```
idf_build_get_property(python PYTHON)
message(STATUS "The Python interpreter is: ${python}")
```

- **BUILD_DIR** - build directory; set from idf_build_process BUILD_DIR argument
- **BUILD_COMPONENTS** - list of components included in the build; set by idf_build_process
- **BUILD_COMPONENT_ALIASES** - list of library alias of components included in the build; set by idf_build_process
- **C_COMPILE_OPTIONS** - compile options applied to all components’ C source files
- **COMPILE_OPTIONS** - compile options applied to all components’ source files, regardless of it being C or C++
- **COMPILE_DEFINITIONS** - compile definitions applied to all component source files
- **DEPENDENCIES_LOCK** - lock file path used in component manager. The default value is dependencies.lock under the project path.
- **EXECUTABLE** - project executable; set by call to idf_build_executable
- **EXECUTABLE_NAME** - name of project executable without extension; set by call to idf_build_executable
- **EXECUTABLE_DIR** - path containing the output executable
- **IDF_COMPONENT_MANAGER** - the component manager is enabled by default, but if this property is set to 0 it was disabled by the IDF_COMPONENT_MANAGER environment variable
- **IDF_PATH** - ESP-IDF path; set from IDF_PATH environment variable, if not, inferred from the location of idf.cmake
- **IDF_TARGET** - target chip for the build; set from the required target argument for idf_build_process
- **IDF_VER** - ESP-IDF version; set from either a version file or the Git revision of the IDF_PATH repository
- **INCLUDE_DIRECTORIES** - include directories for all component source files
- **KCONFIGS** - list of Kconfig files found in components in build; set by idf_build_process
- **KCONFIG_PROJBUILDS** - list of Kconfig.projbuild files found in components in build; set by idf_build_process
- **PROJECT_NAME** - name of the project; set from idf_build_process PROJECT_NAME argument
- **PROJECT_DIR** - directory of the project; set from idf_build_process PROJECT_DIR argument
- **PROJECT_VER** - version of the project; set from idf_build_process PROJECT_VER argument
- **PYTHON** - Python interpreter used for the build; set from PYTHON environment variable if available, if not “python” is used
- **SDKCONFIG** - full path to output config file; set from idf_build_process SDKCONFIG argument
- **SDKCONFIG_DEFAULTS** - list of files containing default config to use in the build; set from idf_build_process SDKCONFIG_DEFAULTS argument
- **SDKCONFIG_HEADER** - full path to C/C++ header file containing component configuration; set by idf_build_process
- **SDKCONFIG_CMAKE** - full path to CMake file containing component configuration; set by idf_build_process
- **SDKCONFIG_JSON** - full path to JSON file containing component configuration; set by idf_build_process
- **SDKCONFIG_JSON_MENUS** - full path to JSON file containing config menus; set by idf_build_process

idf-component-commands

Retrieve a specified component’s component property, property and store it in var accessible from the current scope. Specifying **GENERATOR_EXPRESSION** will retrieve the generator expression string for that property, instead of the actual value, which can be used with CMake commands that support generator expressions.
idf_component_set_property(component property val [APPEND])

Set a specified component’s component property, property with value val. Specifying APPEND will append the specified value to the current value of the property. If the property does not previously exist or it is currently empty, the specified value becomes the first element/member instead.

idf_component_register([[SRCS src1 src2 ...] | [[SRC_DIRS dir1 dir2 ...] [EXCLUDE_\-_SRCS src1 src2 ...]])

[INCLUDE_DIRS dir1 dir2 ...]
[PRIV_INCLUDE_DIRS dir1 dir2 ...]
[REQUIRES component1 component2 ...]
[PRIV_REQUIRES component1 component2 ...]
[LDFRAGMENTS ldfragment1 ldfragment2 ...]
[REQUIRED_IDF_TARGETS target1 target2 ...]
[EMBED_FILES file1 file2 ...]
[EMBED_TXTFILES file1 file2 ...]
[KCONFIG kconfig]
[KCONFIG_PROJBUILD kconfig_projbuild]
[WHOLE_ARCHIVE])

Register a component to the build system. Much like the project() CMake command, this should be called from the component’s CMakeLists.txt directly (not through a function or macro) and is recommended to be called before any other command. Here are some guidelines on what commands can not be called before idf_component_register:

- commands that are not valid in CMake script mode
- custom commands defined in project/include.cmake
- build system API commands except idf_build_get_property; although consider whether the property may not have been set yet

Commands that set and operate on variables are generally okay to call before idf_component_register.

The arguments for idf_component_register include:

- SRCS - component source files used for creating a static library for the component; if not specified, component is a treated as a config-only component and an interface library is created instead.
- SRC_DIRS, EXCLUDE_SRCS - used to glob source files (.c, .cpp, .S) by specifying directories, instead of specifying source files manually via SRCS. Note that this is subject to the limitations of globbing in CMake. Source files specified in EXCLUDE_SRCS are removed from the globbed files.
- INCLUDE_DIRS - paths, relative to the component directory, which will be added to the include search path for all other components which require the current component
- PRIV_INCLUDE_DIRS - directory paths, must be relative to the component directory, which will be added to the include search path for this component’s source files only
- REQUIRES - public component requirements for the component
- PRIV_REQUIRES - private component requirements for the component; ignored on config-only components
- LDFRAGMENTS - component linker fragment files
- REQUIRED_IDF_TARGETS - specify the only target the component supports
- KCONFIG - override the default Kconfig file
- KCONFIG_PROJBUILD - override the default Kconfig projbuild file
- WHOLE_ARCHIVE - if specified, the component library is surrounded by -Wl,--whole-archive, -Wl,--no-whole-archive when linked. This has the same effect as setting WHOLE_ARCHIVE component property.

The following are used for embedding data into the component, and is considered as source files when determining if a component is config-only. This means that even if the component does not specify source files, a static library is still created internally for the component if it specifies either:

- EMBED_FILES - binary files to be embedded in the component
- EMBED_TXTFILES - text files to be embedded in the component
### idf-component-properties

These are properties that describe a component. Values of component properties can be retrieved by using the build command `idf_component_get_property`. For example, to get the directory of the freertos component:

```c
idf_component_get_property(dir freertos COMPONENT_DIR)
message(STATUS "The 'freertos' component directory is: ${dir}")
```

- **COMPONENT_ALIAS** - alias for COMPONENT_LIB used for linking the component to external targets; set by `idf_build_component` and alias library itself is created by `idf_component_register`
- **COMPONENT_DIR** - component directory; set by `idf_build_component`
- **COMPONENT_OVERRIDEN_DIR** - contains the directory of the original component if this component over-rides another component
- **COMPONENT_LIB** - name for created component static/interface library; set by `idf_build_component` and library itself is created by `idf_component_register`
- **COMPONENT_NAME** - name of the component; set by `idf_build_component` based on the component directory name
- **COMPONENT_TYPE** - type of the component, whether LIBRARY or CONFIG_ONLY. A component is of type LIBRARY if it specifies source files or embeds a file
- **EMBED_FILES** - list of files to embed in component; set from `idf_component_register EMBED_FILES` argument
- **EMBED_TXTFILES** - list of text files to embed in component; set from `idf_component_register EMBED_TXTFILES` argument
- **INCLUDE_DIRS** - list of component include directories; set from `idf_component_register INCLUDE_DIRS` argument
- **KCONFIG** - component Kconfig file; set by `idf_build_component`
- **KCONFIG_PROJBUILD** - component Kconfig.projbuild; set by `idf_build_component`
- **LDFFRAGMENTS** - list of component linker fragment files; set from `idf_component_register LDFFRAGMENTS` argument
- **MANAGED_PRIV_REQUIRES** - list of private component dependencies added by the IDF component manager from dependencies in `idf_component.yml` manifest file
- **MANAGED_REQUIRES** - list of public component dependencies added by the IDF component manager from dependencies in `idf_component.yml` manifest file
- **PRIV_INCLUDE_DIRS** - list of component private include directories; set from `idf_component_register PRIV_INCLUDE_DIRS` on components of type LIBRARY
- **PRIV_REQUIRES** - list of private component dependencies; set from value of `idf_component_register PRIV_REQUIRES` argument and dependencies in `idf_component.yml` manifest file
- **REQUIRED_IDF_TARGETS** - list of targets the component supports; set from `idf_component_register EMBED_TXTFILES` argument
- **REQUIRES** - list of public component dependencies; set from value of `idf_component_register REQUIRES` argument and dependencies in `idf_component.yml` manifest file
- **SRCS** - list of component source files; set from `SRCS` or `SRC_DIRS/EXCLUDE_SRCS` argument of `idf_component_register`
- **WHOLE_ARCHIVE** - if this property is set to TRUE (or any boolean “true” CMake value: 1, ON, YES, Y), the component library is surrounded by `-Wl,--whole-archive, -Wl,--no-whole-archive` when linked. This can be used to force the linker to include every object file into the executable, even if the object file doesn’t resolve any references from the rest of the application. This is commonly used when a component contains plugins or modules which rely on link-time registration. This property is FALSE by default. It can be set to TRUE from the component CMakeLists.txt file.

#### 4.5.21 File Globbing & Incremental Builds

The preferred way to include source files in an ESP-IDF component is to list them manually via `SRCS` argument to `idf_component_register`: 
This preference reflects the CMake best practice of manually listing source files. This could, however, be inconvenient when there are lots of source files to add to the build. The ESP-IDF build system provides an alternative way for specifying source files using SRC_DIRS:

```
idf_component_register(SRC_DIRS library platform ...
```

This uses globbing behind the scenes to find source files in the specified directories. Be aware, however, that if a new source file is added and this method is used, then CMake won’t know to automatically re-run and this file won’t be added to the build.

The trade-off is acceptable when you’re adding the file yourself, because you can trigger a clean build or run `idf.py reconfigure` to manually re-run CMake. However, the problem gets harder when you share your project with others who may check out a new version using a source control tool like Git…

For components which are part of ESP-IDF, we use a third party Git CMake integration module (`/tools/cmake/third_party/GetGitRevisionDescription.cmake`) which automatically re-runs CMake any time the repository commit changes. This means if you check out a new ESP-IDF version, CMake will automatically re-run.

For project components (not part of ESP-IDF), there are a few different options:

- If keeping your project file in Git, ESP-IDF will automatically track the Git revision and re-run CMake if the revision changes.
- If some components are kept in a third git repository (not the project repository or ESP-IDF repository), you can add a call to the `git_describe` function in a component CMakeLists file in order to automatically trigger re-runs of CMake when the Git revision changes.
- If not using Git, remember to manually run `idf.py reconfigure` whenever a source file may change.
- To avoid this problem entirely, use SRC_DIRS argument to `idf_component_register` to list all source files in project components.

The best option will depend on your particular project and its users.

### 4.5.22 Build System Metadata

For integration into IDEs and other build systems, when CMake runs the build process generates a number of metadata files in the `build/` directory. To regenerate these files, run `cmake` or `idf.py reconfigure` (or any other `idf.py` build command).

- `compile_commands.json` is a standard format JSON file which describes every source file which is compiled in the project. A CMake feature generates this file, and many IDEs know how to parse it.
- `project_description.json` contains some general information about the ESP-IDF project, configured paths, etc.
- `flasher_args.json` contains `esptool.py` arguments to flash the project’s binary files. There are also `flash_*_args` files which can be used directly with `esptool.py`. See Flash arguments.
- `CMakeCache.txt` is the CMake cache file which contains other information about the CMake process, toolchain, etc.
- `config/sdkconfig.json` is a JSON-formatted version of the project configuration values.
- `config/kconfig_menus.json` is a JSON-formatted version of the menus shown in menuconfig, for use in external IDE UIs.

### JSON Configuration Server

A tool called `kconfserver` is provided to allow IDEs to easily integrate with the configuration system logic. `kconfserver` is designed to run in the background and interact with a calling process by reading and writing JSON over process stdin & stdout.
You can run `kconfserver` from a project via `idf.py confserver` or `ninja kconfserver`, or a similar target triggered from a different build generator.

For more information about `kconfserver`, see the `esp-idf-kconfig` documentation.

4.5.23 Build System Internals

Build Scripts

The list files for the ESP-IDF build system reside in `/tools/cmake`. The modules which implement core build system functionality are as follows:

- **build.cmake** - Build related commands i.e. build initialization, retrieving/setting build properties, build processing.
- **component.cmake** - Component related commands i.e. adding components, retrieving/setting component properties, registering components.
- **kconfig.cmake** - Generation of configuration files (sdkconfig, sdkconfig.h, sdkconfig.cmake, etc.) from Kconfig files.
- **ldgen.cmake** - Generation of final linker script from linker fragment files.
- **target.cmake** - Setting build target and toolchain file.
- **utilities.cmake** - Miscellaneous helper commands.

Aside from these files, there are two other important CMake scripts in `/tools/cmake`:

- **idf.cmake** - Sets up the build and includes the core modules listed above. Included in CMake projects in order to access ESP-IDF build system functionality.
- **project.cmake** - Includes `idf.cmake` and provides a custom `project()` command that takes care of all the heavy lifting of building an executable. Included in the top-level CMakeLists.txt of standard ESP-IDF projects.

The rest of the files in `/tools/cmake` are support or third-party scripts used in the build process.

Build Process

This section describes the standard ESP-IDF application build process. The build process can be broken down roughly into four phases:

![ESP-IDF Build System Process](image.png)

**Initialization**  This phase sets up necessary parameters for the build.

- **Upon inclusion of `idf.cmake` in `project.cmake`, the following steps are performed:**
  - Set `IDF_PATH` from environment variable or inferred from path to `project.cmake` included in the top-level CMakeLists.txt.
  - Add `tools/cmake` to `CMAKE_MODULE_PATH` and include core modules plus the various helper/third-party scripts.
  - Set build tools/executables such as default Python interpreter.
  - Get ESP-IDF git revision and store as `IDF_VER`.
  - Set global build specifications i.e. compile options, compile definitions, include directories for all components in the build.
  - Add components in `components` to the build.
- **The initial part of the custom `project()` command performs the following steps:**
– Set IDF_TARGET from environment variable or CMake cache and the corresponding CMAKE_TOOLCHAIN_FILE to be used.
– Add components in EXTRA_COMPONENT_DIRS to the build.
– Prepare arguments for calling command idf_build_process() from variables such as COMPONENTS/EXCLUDE_COMPONENTS, SDKCONFIG, SDKCONFIG_DEFAULTS.

The call to idf_build_process() command marks the end of this phase.

Enumeration

This phase builds a final list of components to be processed in the build, and is performed in the first half of idf_build_process().

• Retrieve each component’s public and private requirements. A child process is created which executes each component’s CMakeLists.txt in script mode. The values of idf_component_register REQUIRES and PRIV_REQUIRES argument is returned to the parent build process. This is called early expansion. The variable CMAKE_BUILD_EARLY_EXPANSION is defined during this step.
• Recursively include components based on public and private requirements.

Processing

This phase processes the components in the build, and is the second half of idf_build_process().

• Load project configuration from sdkconfig file and generate an sdkconfig.cmake and sdkconfig.h header. These define configuration variables/macros that are accessible from the build scripts and C/C++ source/header files, respectively.
• Include each component’s project_include.cmake.
• Add each component as a subdirectory, processing its CMakeLists.txt. The component CMakeLists.txt calls the registration command, idf_component_register which adds source files, include directories, creates component library, links dependencies, etc.

Finalization

This phase is everything after idf_build_process().

• Create executable and link the component libraries to it.
• Generate project metadata files such as project_description.json and display relevant information about the project built.

Browse /tools/cmake/project.cmake for more details.

4.5.24 Migrating from ESP-IDF GNU Make System

Some aspects of the CMake-based ESP-IDF build system are very similar to the older GNU Make-based system. The developer needs to provide values the include directories, source files etc. There is a syntactical difference, however, as the developer needs to pass these as arguments to the registration command, idf_component_register.

Automatic Conversion Tool

An automatic project conversion tool is available in tools/cmake/convert_to_cmake.py in ESP-IDF v4.x releases. The script was removed in v5.0 because of its make build system dependency.
**No Longer Available in CMake**

Some features are significantly different or removed in the CMake-based system. The following variables no longer exist in the CMake-based build system:

- **COMPONENT_BUILD_DIR**: Use `CMAKE_CURRENT_BINARY_DIR` instead.
- **COMPONENT_LIBRARY**: Defaulted to `(COMPONENT_NAME).a`, but the library name could be overridden by the component. The name of the component library can no longer be overridden by the component.
- **CC, LD, AR, OBJCOPY**: Full paths to each tool from the gcc xtensa cross-toolchain. Use `CMAKE_C_COMPILER`, `CMAKE_C_LINK_EXECUTABLE`, `CMAKE_OBJCOPY`, etc instead. See [Full list here](#).
- **HOSTCC, HOSTLD, HOSTAR**: Full names of each tool from the host native toolchain. These are no longer provided, external projects should detect any required host toolchain manually.
- **COMPONENT_ADD_IDFLAGS**: Used to override linker flags. Use the CMake `target_link_libraries` command instead.
- **COMPONENT_ADD_LINKER_DEPS**: List of files that linking should depend on. `target_link_libraries` will usually infer these dependencies automatically. For linker scripts, use the provided custom CMake function `target_linker_scripts`.
- **COMPONENT_SUBMODULES**: No longer used, the build system will automatically enumerate all submodules in the ESP-IDF repository.
- **COMPONENT_EXTRA_INCLUDES**: Used to be an alternative to `COMPONENT_PRIV_INCLUDEDIRS` for absolute paths. Use `PRIV_INCLUDE_DIRS` argument to `idf_component_register` for all cases now (can be relative or absolute).
- **COMPONENT_OBJS**: Previously, component sources could be specified as a list of object files. Now they can be specified as a list of source files via `SRCS` argument to `idf_component_register`.
- **COMPONENT_OBJEXCLUDE**: Has been replaced with `EXCLUDE_SRCS` argument to `idf_component_register`. Specify source files (as absolute paths or relative to component directory), instead.
- **COMPONENT_EXTRA_CLEAN**: Set property `ADDITIONAL_CLEAN_FILES` instead but note CMake has some restrictions around this functionality.
- **COMPONENT_OWNBUILDTARGET & COMPONENT_OWNCLEANTARGET**: Use CMake `ExternalProject` instead. See [Fully Overriding the Component Build Process](#) for full details.
- **COMPONENT_CONFIGONLY**: Call `idf_component_register` without any arguments instead. See [Configuration-Only Components](#).
- **CFLAGS, CPPFLAGS, CXXFLAGS**: Use equivalent CMake commands instead. See [Controlling Component Compilation](#).

**No Default Values**

Unlike in the legacy Make-based build system, the following have no default values:

- **Source directories** (`COMPONENT_SRCDIRS` variable in Make, `SRC_DIRS` argument to `idf_component_register` in CMake)
- **Include directories** (`COMPONENT_ADD_INCLUDEDIRS` variable in Make, `INCLUDE_DIRS` argument to `idf_component_register` in CMake)

**No Longer Necessary**

- In the legacy Make-based build system, it is required to also set `COMPONENT_SRCDIRS` if `COMPONENT_SRCS` is set. In CMake, the equivalent is not necessary i.e. specifying `SRC_DIRS` to `idf_component_register` if `SRCS` is also specified (in fact, `SRCS` is ignored if `SRC_DIRS` is specified).

**Flashing from Make**

`make flash` and similar targets still work to build and flash. However, project `sdkconfig` no longer specifies serial port and baud rate. Environment variables can be used to override these. See [Flashing with Ninja or Make](#) for more details.
Chapter 4. API Guides

4.6 RF Coexistence

4.6.1 Overview

ESP32 has only one 2.4 GHz ISM band RF module, which is shared by Bluetooth (BT & BLE) and Wi-Fi, so Bluetooth can’t receive or transmit data while Wi-Fi is receiving or transmitting data and vice versa. Under such circumstances, ESP32 uses the time-division multiplexing method to receive and transmit packets.

4.6.2 Supported Coexistence Scenario for ESP32

4.6.3 Coexistence Mechanism and Policy

Coexistence Mechanism

The RF resource allocation mechanism is based on priority. As shown below, both Bluetooth module and Wi-Fi module request RF resources from the coexistence module, and the coexistence module decides who will use the RF resource based on their priority.
Coexistence Policy

Coexistence Period and Time Slice  Wi-Fi, BT, and BLE have their fixed time slice to use the RF. A coexistence period is divided into 3 time slices in the order of Wi-Fi, BT, and BLE. In the Wi-Fi slice, Wi-Fi’s request to the coexistence arbitration module will have higher priority. Similarly, BT/ BLE can enjoy higher priority at their own time slices. The duration of the coexistence period and the proportion of each time slice are divided into four categories according to the Wi-Fi status:

1) IDLE status: the coexistence of BT and BLE is controlled by Bluetooth module.
2) CONNECTED status: the coexistence period starts at the Target Beacon Transmission Time (TBTT) and is more than 100 ms.
3) SCAN status: Wi-Fi slice and coexistence period are longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.
4) CONNECTING status: Wi-Fi slice is longer than in the CONNECTED status. To ensure Bluetooth performance, the Bluetooth time slice will also be adjusted accordingly.

According to the coexistence logic, different coexistence periods and time slice strategies will be selected based on the Wi-Fi and Bluetooth usage scenarios. A Coexistence policy corresponding to a certain usage scenarios is called a “coexistence scheme”. For example, the scenario of Wi-Fi CONNECTED and BLE CONNECTED has a corresponding coexistence scheme. In this scheme, the time slices of Wi-Fi and BLE in a coexistence period each account for 50%. The time allocation is shown in the following figure:

Dynamic Priority  The coexistence module assigns different priorities to different status of Wi-Fi and Bluetooth. And the priority for each status is dynamic. For example, in every N BLE Advertising events, there is always one event with high priority. If a high-priority BLE Advertising event occurs within the Wi-Fi time slice, the right to use the RF may be preempted by BLE.
**Wi-Fi Connectionless Modules Coexistence** To some extent, some combinations of connectionless power-saving parameters *Window* and *Interval* would lead to extra Wi-Fi priority request out of Wi-Fi time slice. It’s for obtaining RF resources at coexistence for customized parameters, while leading to impact on Bluetooth performance.

If connectionless power-saving parameters are configured with default values, the coexistence module would perform in stable mode and the behaviour above would not happen. So please configure Wi-Fi connectionless power-saving parameters to default values unless you have plenty of coexistence performance tests for customized parameters.

Please refer to *connectionless module power save* to get more detail.

### 4.6.4 How to Use the Coexistence Feature

**Coexistence API**

For most coexistence cases, ESP32 will switch the coexistence status automatically without calling API. However, ESP32 provides two APIs for the coexistence of BLE MESH and Wi-Fi. When the status of BLE MESH changes, call *esp_coex_status_bit_clear* to clear the previous status first and then call *esp_coex_status_bit_set* to set the current status.

**BLE MESH Coexistence Status** As the firmware of Wi-Fi and Bluetooth are not aware of the current scenario of the upper layer application, some coexistence schemes require application code to call the coexistence API to take effect. The application layer needs to pass the working status of BLE MESH to the coexistence module for selecting the coexistence scheme.

- ESP_COEX_BLE_ST_MESH_CONFIG: network is provisioning
- ESP_COEX_BLE_ST_MESH_TRAFFIC: data is transmitting
- ESP_COEX_BLE_ST_MESH_STANDBY: in idle status with no significant data interaction

**Coexistence API Error Codes**

All coexistence APIs have custom return values, i.e. error codes. These error codes can be categorized as:

- No error. For example, the return value ESP_OK signifies the API returned successfully.
- Recoverable errors. For example, the return value ESP_ERR_INVALID_ARG signifies API parameter errors.

### Setting Coexistence Compile-time Options

- After writing the coexistence program, you must check `CONFIG_ESP_COEX_SW_COEXIST_ENABLE` option through menuconfig to open coexistence configuration on software, otherwise the coexistence function mentioned above cannot be used.
- To ensure better communication performance of Wi-Fi and Bluetooth in the case of coexistence, run the task of the Wi-Fi protocol stack, the task of the Bluetooth Controller and Host protocol stack on different CPUs. You can use `CONFIG_BTDM_CTRL_PINNED_TO_CORE_CHOICE` and `CONFIG_BT_BLUEDROID_PINNED_TO_CORE_CHOICE` (or `CONFIG_BT_NIMBLE_PINNED_TO_CORE_CHOICE`) to put the tasks of the Bluetooth controller and the host protocol stack on the same CPU, and then use `CONFIG_ESP_WIFI_TASK_CORE_ID` to place the task of the Wi-Fi protocol stack on another CPU.
- In the case of coexistence, BLE SCAN may be interrupted by Wi-Fi and Wi-Fi releases RF resources before the end of the current BLE scan window. In order to make BLE acquire RF resources again within the current scan window, you can check the FULL SCAN configuration option through `CONFIG_BTDM_CTRL_FULL_SCAN_SUPPORTED`.
- You can reduce the memory consumption by configuring the following options on menuconfig.
  1) `CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY`: enable the configuration of dynamic memory for Bluetooth protocol stack.
  2) `CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM`: reduce the number of Wi-Fi static RX buffers.
3) **CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM**: reduce the number of Wi-Fi dynamic RX buffers.
4) **CONFIG_ESP_WIFI_TX_BUFFER**: enable the configuration of dynamic allocation TX buffers.
5) **CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM**: reduce the number of Wi-Fi dynamic TX buffers.
6) **CONFIG_ESP_WIFI_TX_BA_WIN**: reduce the number of Wi-Fi Block Ack TX windows.
7) **CONFIG_ESP_WIFI_RX_BA_WIN**: reduce the number of Wi-Fi Block Ack RX windows.
8) **CONFIG_ESP_WIFI_MGMT_SBUF_NUM**: reduce the number of Wi-Fi Management Short Buffer.
9) **CONFIG_ESP_WIFI_RX_IRAM_OPT**: turning off this configuration option will reduce the IRAM memory by approximately 17 KB.
10) **CONFIG_LWIP_TCP_SND_BUF_DEFAULT**: reduce the default TX buffer size for TCP sockets.
11) **CONFIG_LWIP_TCP_WND_DEFAULT**: reduce the default size of the RX window for TCP sockets.
12) **CONFIG_LWIP_TCP_RECVMBOX_SIZE**: reduce the size of the TCP receive mailbox.
13) **CONFIG_LWIP_UDP_RECVMBOX_SIZE**: reduce the size of the UDP receive mailbox.
14) **CONFIG_LWIP_TCPIP_RECVMBOX_SIZE**: reduce the size of TCPIP task receive mailbox.

**Note**: Since the coexistence configuration option depends on the Bluetooth configuration option, please turn on the Bluetooth configuration option first before configuring the coexistence feature in the Wi-Fi configuration option.

## 4.7 Core Dump

### 4.7.1 Overview

ESP-IDF provides support to generate core dumps on unrecoverable software errors. This useful technique allows post-mortem analysis of software state at the moment of failure. Upon the crash system enters panic state, prints some information and halts or reboots depending configuration. User can choose to generate core dump in order to analyse the reason of failure on PC later on. Core dump contains snapshots of all tasks in the system at the moment of failure. Snapshots include tasks control blocks (TCB) and stacks. So it is possible to find out what task, at what instruction (line of code) and what callstack of that task lead to the crash. It is also possible dumping variables content on demand if previously attributed accordingly. ESP-IDF provides special commands to help users to retrieve and analyse core dumps:

- `idf.py coredump-info`: prints crashed task’s registers, callstack, list of available tasks in the system, memory regions and contents of memory stored in core dump (TCBs and stacks)
- `idf.py coredump-debug`: creates core dump ELF file and runs GDB debug session with this file. User can examine memory, variables and tasks states manually. Note that since not all memory is saved in core dump only values of variables allocated on stack will be meaningful.

For more information about core dump internals see the - [Core dump internals](#)

### 4.7.2 Configurations

There are a number of core dump related configuration options which user can choose in project configuration menu (`idf.py menuconfig`).

**Core dump data destination** (Components -> Core dump -> Data destination)

- Save core dump to Flash (Flash)
- Print core dump to UART (UART)
- Disable core dump generation (None)

**Core dump data format** (Components -> Core dump -> Core dump data format)

- ELF format (Executable and Linkable Format file for core dump)
- Binary format (Basic binary format for core dump)

The ELF format contains extended features and allow to save more information about broken tasks and crashed software but it requires more space in the flash memory. This format of core dump is
recommended for new software designs and is flexible enough to extend saved information for future revisions.

The Binary format is kept for compatibility reasons, it uses less space in the memory to keep data and provides better performance.

Core dump data integrity check (Components -> Core dump -> Core dump data integrity check)

- Use CRC32 for core dump integrity verification
- Use SHA256 for core dump integrity verification (only work in ELF format)

The CRC32 option provides better calculation performance and consumes less memory for storage.

The SHA256 hash algorithm provides greater probability of detecting corruption than a CRC32 with multiple bit errors.

Maximum number of tasks snapshots in core dump (Components -> Core dump -> Maximum number of tasks)

Delay before core dump is printed to UART (Components -> Core dump -> Delay before print to UART)

The value is in ms.

Handling of UART core dumps in IDF Monitor (Components -> Core dump -> Delay before print to UART)

The value is base64 encoded.

- Decode and show summary (info_corefile)
- Don’t decode

Reserved stack size (Components -> Core dump -> Reserved stack size)

Size of the memory to be reserved for core dump stack. If 0 core dump process will run on the stack of crashed task/ISR, otherwise special stack will be allocated. To ensure that core dump itself will not overflow task/ISR stack set this to the value above 800.

4.7.3 Save core dump to flash

When this option is selected core dumps are saved to special partition on flash. When using default partition table files which are provided with ESP-IDF it automatically allocates necessary space on flash, But if user wants to use its own layout file together with core dump feature it should define separate partition for core dump as it is shown below:

```
# Name, Type, SubType, Offset, Size
# Note: if you have increased the bootloader size, make sure to update the offsets...
# to avoid overlap
nvs, data, nvs, 0x9000, 0x6000
phy_init, data, phy, 0xf000, 0x1000
factory, app, factory, 0x10000, 1M
coredump, data, coredump,, 64K
```

Important: If Flash Encryption is enabled on the device then please add encrypted flag to the coredump partition:

```
coredump, data, coredump,, 64K, encrypted
```

There are no special requirements for partition name. It can be chosen according to the user application needs, but partition type should be ‘data’ and sub-type should be ‘coredump’. Also when choosing partition size note that core dump data structure introduces constant overhead of 20 bytes and per-task overhead of 12 bytes. This overhead does not include size of TCB and stack for every task. So partition size should be at least 20 + max tasks number x (12 + TCB size + max task stack size) bytes.

The example of generic command to analyze core dump from flash is:
4.7.4 Print core dump to UART

When this option is selected base64-encoded core dumps are printed on UART upon system panic. In this case user should save core dump text body to some file manually and then run the following command:

```
idf.py coredump-info -c </path/to/saved/base64/text>
```

or

```
idf.py coredump-debug -c </path/to/saved/base64/text>
```

Base64-encoded body of core dump will be between the following header and footer:

```
----------------------------- CORE DUMP START -----------------------------
<body of base64-encoded core dump, save it to file on disk>
----------------------------- CORE DUMP END -----------------------------
```

The **CORE DUMP START** and **CORE DUMP END** lines must not be included in core dump text file.

4.7.5 ROM Functions in Backtraces

It is possible situation that at the moment of crash some tasks or/and crashed task itself have one or more ROM functions in their callstacks. Since ROM is not part of the program ELF it will be impossible for GDB to parse such callstacks, because it tries to analyse functions’ prologues to accomplish that. In that case callstack printing will be broken with error message at the first ROM function. To overcome this issue, ROM ELF provided by Espressif is loaded automatically based on the target and its revision. More details about ROM ELFs can be found [here](#).

4.7.6 Dumping variables on demand

Sometimes you want to read the last value of a variable to understand the root cause of a crash. Core dump supports retrieving variable data over GDB by attributing special notations declared variables.

**Supported notations and RAM regions**

- **COREDUMP_DRAM_ATTR** places variable into DRAM area which will be included into dump.
- **COREDUMP_RTCATTR** places variable into RTC area which will be included into dump.
- **COREDUMP_RTC_FAST_ATTR** places variable into RTC_FAST area which will be included into dump.

**Example**

1. In **Project Configuration Menu**, enable **COREDUMP TO FLASH**, then save and exit.
2. In your project, create a global variable in DRAM area as such as:

   ```c
   // uint8_t global_var;
   COREDUMP_DRAM_ATTR uint8_t global_var;
   ```

3. In main application, set the variable to any value and `assert(0)` to cause a crash.
global_var = 25;
assert(0);

4. Build, flash and run the application on a target device and wait for the dumping information.
5. Run the command below to start core dumping in GDB, where PORT is the device USB port:

idf.py coredump-debug

6. In GDB shell, type `p global_var` to get the variable content:

```
(gdb) p global_var
$1 = 25 '\031'
```

### 4.7.7 Running `idf.py coredump-info` and `idf.py coredump-debug`

`idf.py coredump-info --help` and `idf.py coredump-debug --help` commands can be used to get more details on usage.

### Related Documents

**Anatomy of core dump image**  Core dump component can be configured to use old legacy binary format or the new ELF one. The ELF format is recommended for new designs. It provides more information about the CPU and memory state of a program at the moment when panic handler is entered. The memory state embeds a snapshot of all tasks mapped in the memory space of the program. The CPU state contains register values when the core dump has been generated. Core dump file uses a subset of the ELF structures to register these information. Loadable ELF segments are used for the memory state of the process while ELF notes (ELF.PT_NOTE) are used for process metadata (pid, registers, signal, …). Especially, the CPU status is stored in a note with a special name and type (CORE, NT_PRSTATUS type).

Here is an overview of coredump layout:

Note: The format of image file showed on the above pictures represents current version of image and can be changed in future releases.

**Overview of implementation**  The figure below describes some basic aspects related to implementation of core dump:

Note: The diagram above hide some details and represents current implementation of the core dump and can be changed later.

### 4.8 C++ Support

ESP-IDF is primarily written in C and provides C APIs. However, ESP-IDF supports development of applications in C++. This document covers various topics relevant to C++ development.

The following C++ features are supported:

- Exception handling
- C++ language standard
- Runtime Type Information (RTTI)
- Thread Local Storage (thread_local keyword)
- All C++ features implemented by GCC, except for some limitations. See GCC documentation for details on features implemented by GCC.
Fig. 6: Core dump ELF image format

Fig. 7: Core dump binary image format
4.8.1 esp-idf-cxx Component

esp-idf-cxx component provides higher-level C++ APIs for some of the ESP-IDF features. This component is available from the IDF Component Registry.

4.8.2 C++ language standard

By default, ESP-IDF compiles C++ code with C++23 language standard with GNU extensions (-std=gnu++23).

To compile the source code of a certain component using a different language standard, set the desired compiler flag in the component CMakeLists.txt file:

```cmake
idf_component_register(
    ...
)'
target_compile_options(${COMPONENT_LIB} PRIVATE -std=gnu++11)
```

Use PUBLIC instead of PRIVATE if the public header files of the component also need to be compiled with the same language standard.

4.8.3 Multithreading

C++ threads, mutexes, and condition variables are supported. C++ threads are built on top of pthreads, which in turn wrap FreeRTOS tasks.

See cxx/pthread for an example of creating threads in C++.
4.8.4 Exception handling

Support for C++ Exceptions in ESP-IDF is disabled by default, but can be enabled using the `CONFIG_COMPILER_CXX_EXCEPTIONS` option.

If an exception is thrown, but there is no catch block, the program will be terminated by the abort function, and the backtrace will be printed. See Fatal Errors for more information about backtraces.

C++ Exceptions should only be used for exceptional cases, something happening unexpectedly and that is quite rare, e.g. an event that happens less frequently than 1 every 100 times. Do not use them for control flow (see also the section about resource usage below)! For more information on how to use C++ Exceptions, see the ISO C++ FAQ and CPP Core Guidelines.

See cxx/exceptions for an example of C++ exception handling.

C++ Exception Handling and Resource Usage

Enabling exception handling normally increases application binary size by a few KB.

Additionally, it may be necessary to reserve some amount of RAM for exception emergency pool. Memory from this pool will be used if it is not possible to allocate exception object from the heap. The amount of memory in the emergency pool can be set using the `CONFIG_COMPILER_CXX_EXCEPTIONS_EMG_POOL_SIZE` variable. Some additional stack memory (around 200 bytes) will also be used if and only if a C++ Exception is actually thrown, because it requires calling some functions from the top of the stack to initiate exception handling.

The run time of code using C++ exceptions depends on what actually happens at run time. If no exception is thrown, the code tends to be somewhat faster since there is no need to check error codes. If an exception is thrown, the run time of the code that handles exceptions will be orders of magnitude slower than code returning an error code. This increase may or may not be significant, however, in the entire application, in particular if the error handling requires additional action, such as a user input or messaging to a cloud. But exception-throwing code should never be used in real-time critical code paths.

4.8.5 Runtime Type Information (RTTI)

Support for RTTI is disabled by default, but can be enabled using `CONFIG_COMPILER_CXX_RTTI` option.

Enabling this option compiles all C++ files with RTTI support enabled, which allows using `dynamic_cast` conversion and `typeid` operator. Enabling this option typically increases the binary size by tens of KB.

See cxx/rtti for an example of using RTTI in ESP-IDF.

4.8.6 Developing in C++

The following sections provide tips on developing ESP-IDF applications in C++.

Combining C and C++ code

When part of the application is developed in C and part in C++, it is important to understand the concept of language linkage.

In order for a C++ function to be callable from C code, it has to be both declared and defined with C linkage (extern "C"):

```c
// declaration in the header file:
#ifdef __cplusplus
extern "C" { 
#endif
#endif
```

(continues on next page)
In order for a C function to be callable from C++, it has to be declared with C linkage:

```c
// declaration in the header file:
#ifdef __cplusplus
extern "C"
#endif
void my_c_func(void);

#ifdef __cplusplus
}  //endif
#endif

// definition in a .c file:
void my_c_func(void) {
    // ...
}
```

**Defining app_main in C++**

ESP-IDF expects the application entry point, `app_main`, to be defined with C linkage. When `app_main` is defined in a .cpp source file, it has to be designated as `extern "C"`:

```c
extern "C" void app_main()
{
}
```

**Designated initializers**

Many of the ESP-IDF components use *configuration structures* as arguments to the initialization functions. ESP-IDF examples written in C routinely use designated initializers to fill these structures in a readable and a maintainable way. C and C++ languages have different rules with regards to the designated initializers. For example, C++ language version C++23, currently the default in ESP-IDF, does not support out-of-order designated initialization, nested designated initialization, mixing of designated initializers and regular initializers, and designated initialization of arrays. Therefore, when porting ESP-IDF C examples to C++, some changes to the structure initializers may be necessary. See the C++ aggregate initialization reference for more details.

**iostream**

iostream functionality is supported in ESP-IDF, with a couple of caveats:

1. Normally ESP-IDF build process eliminates the unused code. However in the case of iostreams, simply including `<iostream>` header in one of the source files significantly increases the binary size (by about 200 kB).
2. By default, ESP-IDF uses a simple non-blocking implementation of the standard input stream (stdin). To get the usual behavior of \( \text{stdin} \), the application has to initialize the UART driver and enable the blocking mode as shown in common_components/protocol_examples_common/stdin_out.c.

### 4.8.7 Limitations

- Linker script generator doesn’t support function level placements for functions with C++ linkage.
- Various section attributes (such as `IRAM_ATTR`) are ignored when used with template functions.
- Vtables are placed into Flash and are not accessible when the flash cache is disabled. Therefore, virtual function calls should be avoided in *IRAM-safe interrupt handlers*. Placement of Vtables cannot be adjusted using the linker script generator, yet.
- C++ filesystem (\( \text{std::filesystem} \)) features are not supported.

### 4.8.8 What to Avoid

Do not use `setjmp/longjmp` in C++! `longjmp` blindly jumps up the stack without calling any destructors, easily introducing undefined behavior and memory leaks. Use C++ exceptions instead, they will guarantee correctly calling destructors. If you cannot use C++ exceptions, use alternatives (except `setjmp/longjmp` themselves) such as simple return codes.

### 4.9 Deep Sleep Wake Stubs

ESP32 supports running a “deep sleep wake stub” when coming out of deep sleep. This function runs immediately as soon as the chip wakes up - before any normal initialisation, bootloader, or ESP-IDF code has run. After the wake stub runs, the SoC can go back to sleep or continue to start ESP-IDF normally.

Deep sleep wake stub code is loaded into “RTC Fast Memory” and any data which it uses must also be loaded into RTC memory. RTC memory regions hold their contents during deep sleep.

#### 4.9.1 Rules for Wake Stubs

Wake stub code must be carefully written:

- As the SoC has freshly woken from sleep, most of the peripherals are in reset states. The SPI flash is unmapped.
- The wake stub code can only call functions implemented in ROM or loaded into RTC Fast Memory (see below.)
- The wake stub code can only access data loaded in RTC memory. All other RAM will be uninitialised and have random contents. The wake stub can use other RAM for temporary storage, but the contents will be overwritten when the SoC goes back to sleep or starts ESP-IDF.
- RTC memory must include any read-only data (.rodata) used by the stub.
- Data in RTC memory is initialised whenever the SoC restarts, except when waking from deep sleep. When waking from deep sleep, the values which were present before going to sleep are kept.
- Wake stub code is a part of the main esp-idf app. During normal running of esp-idf, functions can call the wake stub functions or access RTC memory. It is as if these were regular parts of the app.

#### 4.9.2 Implementing A Stub

The wake stub in esp-idf is called `esp_wake_deep_sleep()`. This function runs whenever the SoC wakes from deep sleep. There is a default version of this function provided in esp-idf, but the default function is weak-linked so if your app contains a function named `esp_wake_deep_sleep()` then this will override the default.

If supplying a custom wake stub, the first thing it does should be to call `esp_default_wake_deep_sleep()`. It is not necessary to implement `esp_wake_deep_sleep()` in your app in order to use deep sleep. It is only necessary if you want to have special behaviour immediately on wake.
If you want to swap between different deep sleep stubs at runtime, it is also possible to do this by calling the `esp_set_deep_sleep_wake_stub()` function. This is not necessary if you only use the default `esp_wake_deep_sleep()` function.

All of these functions are declared in the `esp_sleep.h` header under components/esp32.

### 4.9.3 Loading Code Into RTC Memory

Wake stub code must be resident in RTC Fast Memory. This can be done in one of two ways.

The first way is to use the `RTC_IRAM_ATTR` attribute to place a function into RTC memory:

```c
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    // Add additional functionality here
}
```

The second way is to place the function into any source file whose name starts with `rtc_wake_stub`. File names `rtc_wake_stub*` have their contents automatically put into RTC memory by the linker.

The first way is simpler for very short and simple code, or for source files where you want to mix “normal” and “RTC” code. The second way is simpler when you want to write longer pieces of code for RTC memory.

### 4.9.4 Loading Data Into RTC Memory

Data used by stub code must be resident in RTC memory.

The data can be placed in RTC Fast memory or in RTC Slow memory which is also used by the ULP.

Specifying this data can be done in one of two ways:

The first way is to use the `RTC_DATA_ATTR` and `RTC_RODATA_ATTR` to specify any data (writeable or read-only, respectively) which should be loaded into RTC memory:

```c
RTC_DATA_ATTR int wake_count;
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
    esp_default_wake_deep_sleep();
    static RTC_RODATA_ATTR const char fmt_str[] = "Wake count %d\n"
    esp_rom_printf(fmt_str, wake_count);
}
```

The RTC memory area where this data will be placed can be configured via menuconfig option named `CONFIG_ESP32_RTCDATA_IN_FAST_MEM`. This option allows to keep slow memory area for ULP programs and once it is enabled the data marked with `RTC_DATA_ATTR` and `RTC_RODATA_ATTR` are placed in the RTC fast memory segment otherwise it goes to RTC slow memory (default option). This option depends on the `CONFIG_FREERTOS_UNICORE` because RTC fast memory can be accessed only by PRO_CPU.

The attributes `RTC_FAST_ATTR` and `RTC_SLOW_ATTR` can be used to specify data that will be force placed into RTC_FAST and RTC_SLOW memory respectively. Any access to data marked with `RTC_FAST_ATTR` is allowed by PRO_CPU only and it is responsibility of user to make sure about it.

Unfortunately, any string constants used in this way must be declared as arrays and marked with `RTC_RODATA_ATTR`, as shown in the example above.

The second way is to place the data into any source file whose name starts with `rtc_wake_stub`.

For example, the equivalent example in `rtc_wake_stub_counter.c`:

```c
int wake_count;
void RTC_IRAM_ATTR esp_wake_deep_sleep(void) {
```

(continues on next page)
The second way is a better option if you need to use strings, or write other more complex code.

To reduce wake-up time use the CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP Kconfig option, see more information in Fast boot from Deep Sleep.

### 4.9.5 CRC Check For Wake Stubs

During deep sleep, all RTC Fast memory areas will be validated with CRC. When ESP32 wakes up from deep sleep, the RTC fast memory will be validated with CRC again. If the validation passes, the wake stubs code will be executed. Otherwise, the normal initialization, bootloader and esp-idf codes will be executed.

**Note:** When the CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP option is enabled, all the RTC fast memory except the wake stubs area is added to the heap.

### 4.9.6 Example

ESP-IDF provides an example to show how to implement the Deep-sleep wake stub.

- system/deep_sleep_wake_stub

### 4.10 Error Handling

#### 4.10.1 Overview

Identifying and handling run-time errors is important for developing robust applications. There can be multiple kinds of run-time errors:

- Recoverable errors:
  - Errors indicated by functions through return values (error codes)
  - C++ exceptions, thrown using throw keyword
- Unrecoverable (fatal) errors:
  - Failed assertions (using assert macro and equivalent methods, see Assertions) and abort() calls.
  - CPU exceptions: access to protected regions of memory, illegal instruction, etc.
  - System level checks: watchdog timeout, cache access error, stack overflow, stack smashing, heap corruption, etc.

This guide explains ESP-IDF error handling mechanisms related to recoverable errors, and provides some common error handling patterns.

For instructions on diagnosing unrecoverable errors, see Fatal Errors.

#### 4.10.2 Error codes

The majority of ESP-IDF-specific functions use esp_err_t type to return error codes. esp_err_t is a signed integer type. Success (no error) is indicated with ESP_OK code, which is defined as zero.
Various ESP-IDF header files define possible error codes using preprocessor defines. Usually these defines start with `ESP_ERR_` prefix. Common error codes for generic failures (out of memory, timeout, invalid argument, etc.) are defined in `esp_err.h` file. Various components in ESP-IDF may define additional error codes for specific situations.

For the complete list of error codes, see [Error Code Reference](#).

### 4.10.3 Converting error codes to error messages

For each error code defined in ESP-IDF components, `esp_err_t` value can be converted to an error code name using `esp_err_to_name()` or `esp_err_to_name_r()` functions. For example, passing `0x101` to `esp_err_to_name()` will return “ESP_ERR_NO_MEM” string. Such strings can be used in log output to make it easier to understand which error has happened.

Additionally, `esp_err_to_name_r()` function will attempt to interpret the error code as a standard POSIX error code, if no matching ESP.ERR value is found. This is done using `strerror_r` function. POSIX error codes (such as `ENOENT`, `ENOMEM`) are defined in `errno.h` and are typically obtained from `errno` variable. In ESP-IDF this variable is thread-local: multiple FreeRTOS tasks have their own copies of `errno`. Functions which set `errno` only modify its value for the task they run in.

This feature is enabled by default, but can be disabled to reduce application binary size. See `CONFIG_ESP_ERR_TO_NAME_LOOKUP`. When this feature is disabled, `esp_err_to_name()` and `esp_err_to_name_r()` are still defined and can be called. In this case, `esp_err_to_name()` will return `UNKNOWN ERROR`, and `esp_err_to_name_r()` will return `Unknown error 0xXXXX(YYYYY)`, where `0xXXXX` and `YYYYY` are the hexadecimal and decimal representations of the error code, respectively.

### 4.10.4 ESP_ERROR_CHECK macro

`ESP_ERROR_CHECK` macro serves similar purpose as `assert`, except that it checks `esp_err_t` value rather than a bool condition. If the argument of `ESP_ERROR_CHECK` is not equal `ESP_OK`, then an error message is printed on the console, and `abort()` is called.

Error message will typically look like this:

```plaintext
ESP_ERROR_CHECK failed: esp_err_t 0x107 (ESP_ERR_TIMEOUT) at 0x400d1fdf
file: "/Users/user/esp/example/main/main.c" line 20
func: app_main
expression: sdmmc_card_init(host, &card)
Backtrace: 0x40086e7c:0x3ffb4ff0 0x40087328:0x3ffb5010 0x400d1fdf:0x3fff5030...
```

**Note:** If *IDF monitor* is used, addresses in the backtrace will be converted to file names and line numbers.

- The first line mentions the error code as a hexadecimal value, and the identifier used for this error in source code. The latter depends on `CONFIG_ESP_ERR_TO_NAME_LOOKUP` option being set. Address in the program where error has occurred is printed as well.
- Subsequent lines show the location in the program where `ESP_ERROR_CHECK` macro was called, and the expression which was passed to the macro as an argument.
- Finally, backtrace is printed. This is part of panic handler output common to all fatal errors. See [Fatal Errors](#) for more information about the backtrace.

### 4.10.5 ESP_ERROR_CHECK WITHOUT_ABORT macro

`ESP_ERROR_CHECK WITHOUT_ABORT` macro serves similar purpose as `ESP_ERROR_CHECK`, except that it won’t call `abort()`.
4.10.6 ESP_RETURN_ON_ERROR macro

`ESP_RETURN_ON_ERROR` macro checks the error code, if the error code is not equal `ESP_OK`, it prints the message and returns.

4.10.7 ESP_GOTO_ON_ERROR macro

`ESP_GOTO_ON_ERROR` macro checks the error code, if the error code is not equal `ESP_OK`, it prints the message, sets the local variable `ret` to the code, and then exits by jumping to `goto_tag`.

4.10.8 ESP_RETURN_ON_FALSE macro

`ESP_RETURN_ON_FALSE` macro checks the condition, if the condition is not equal `true`, it prints the message and returns with the supplied `err_code`.

4.10.9 ESP_GOTO_ON_FALSE macro

`ESP_GOTO_ON_FALSE` macro checks the condition, if the condition is not equal `true`, it prints the message, sets the local variable `ret` to the supplied `err_code`, and then exits by jumping to `goto_tag`.

4.10.10 CHECK MACROS Examples

Some examples:

```c
static const char* TAG = "Test";

esp_err_t test_func(void)
{
    esp_err_t ret = ESP_OK;
    ESP_ERROR_CHECK(x);
    // err message, printed if `x` is not `ESP_OK`, and then `abort()`.
    ESP_ERROR_CHECK WITHOUT_ABORT(x);
    // err message, printed if `x` is not `ESP_OK`, without `abort()`.
    ESP_RETURN_ON_ERROR(x, TAG, "fail reason 1");
    // err message, printed if `x` is not `ESP_OK`, and then function returns with code `x`.
    ESP_GOTO_ON_ERROR(x, err, TAG, "fail reason 2");
    // err message, printed if `x` is not `ESP_OK`, `ret` is set to `x`, and then jumps to `err`.
    ESP_RETURN_ON_FALSE(a, err_code, TAG, "fail reason 3");
    // err message, printed if `a` is not `true`, and then function returns with code `err_code`.
    ESP_GOTO_ON_FALSE(a, err_code, err, TAG, "fail reason 4");
    // err message, printed if `a` is not `true`, `ret` is set to `err_code`, and then jumps to `err`.

    err:
    // clean up
    return ret;
}
```

**Note:** If the option `CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT` in Kconfig is enabled, the err message will be discarded, while the other action works as is.

The `ESP_RETURN_XX` and `ESP_GOTO_XX` macros can’t be called from ISR. While there are `xx_ISR` versions for each of them, e.g., `ESP_RETURN_ON_ERROR_ISR`, these macros could be used in ISR.
4.10.11 Error handling patterns

1. Attempt to recover. Depending on the situation, we may try the following methods:
   - retry the call after some time;
   - attempt to de-initialize the driver and re-initialize it again;
   - fix the error condition using an out-of-band mechanism (e.g. reset an external peripheral which is not responding).

   Example:

   ```c
   esp_err_t err;
   do {
       err = sdio_slave_send_queue(addr, len, arg, timeout);
       // keep retrying while the sending queue is full
   } while (err == ESP_ERR_TIMEOUT);
   if (err != ESP_OK) {
       // handle other errors
   }
   ```

2. Propagate the error to the caller. In some middleware components this means that a function must exit with the same error code, making sure any resource allocations are rolled back.

   Example:

   ```c
   sdmmc_card_t* card = malloc(1, sizeof(sdmmc_card_t));
   if (card == NULL) {
       return ESP_ERR_NO_MEM;
   }
   esp_err_t err = sdmmc_card_init(host, &card);
   if (err != ESP_OK) {
       // Clean up
       free(card);
       // Propagate the error to the upper layer (e.g. to notify the user).
       // Alternatively, application can define and return custom error code.
       return err;
   }
   ```

3. Convert into unrecoverable error, for example using ESP_ERROR_CHECK. See ESP_ERROR_CHECK macro section for details.

   Terminating the application in case of an error is usually undesirable behavior for middleware components, but is sometimes acceptable at application level.

   Many ESP-IDF examples use ESP_ERROR_CHECK to handle errors from various APIs. This is not the best practice for applications, and is done to make example code more concise.

   Example:

   ```c
   ESP_ERROR_CHECK(spi_bus_initialize(host, bus_config, dma_chan));
   ```

4.10.12 C++ Exceptions

See Exception handling.

4.11 ESP-BLE-MESH

Bluetooth® mesh networking enables many-to-many (m:m) device communications and is optimized for creating large-scale device networks.

Devices may relay data to other devices not in direct radio range of the originating device. In this way, mesh networks can span very large physical areas and contain large numbers of devices. It is ideally suited for building automation,
sensor networks, and other IoT solutions where tens, hundreds, or thousands of devices need to reliably and securely communicate with one another.

Bluetooth mesh is not a wireless communications technology, but a networking technology. This technology is dependent upon Bluetooth Low Energy (BLE) - a wireless communications protocol stack.

Built on top of Zephyr Bluetooth Mesh stack, the ESP-BLE-MESH implementation supports device provisioning and node control. It also supports such node features as Proxy, Relay, Low power and Friend.

Please see the ESP-BLE-MESH Architecture for information about the implementation of ESP-BLE-MESH architecture and ESP-BLE-MESH API Reference for information about respective API.

ESP-BLE-MESH is implemented and certified based on the latest Mesh Profile v1.0.1, users can refer here for the certification details of ESP-BLE-MESH.

**Note:** If you are looking for Wi-Fi based implementation of mesh for ESP32, please check another product by Espressif called ESP-WIFI-MESH. For more information and documentation see ESP-WIFI-MESH.

### 4.11.1 Getting Started with ESP-BLE-MESH

This section is intended to help you get started with ESP-BLE-MESH for the hardware based on the ESP32 chip by Espressif.

We are going to demonstrate process of setting and operation of a small ESP-BLE-MESH network of three nodes. This process will cover device provisioning and node configuration, and then sending on/off commands to Generic OnOff Server Models on specific nodes.

If you are new to ESP-IDF, please first set up development environment, compile, flash and run example application following top level ESP-IDF Get Started documentation.

**What You Need**

**Hardware:**

- Three ESP32 boards, see options.
- USB cables to connect the boards.
- Computer configured with ESP-IDF.
- Mobile phone or tablet running Android or iOS.

**Software:**

- Example application bluetooth/esp_ble_mesh/ble_mesh_node/onoff_server code to load to the ESP32 boards.
- Mobile App: nRF Mesh for Android or iOS. Optionally you can use some other Apps:
  - EspBleMesh Android App
  - Silicon Labs Android or iOS App

**Installation Step by Step**

This is a detailed roadmap to walk you through the installation process.

**Step 1. Check Hardware** Both ESP32-DevKitC and ESP-WROVER-KIT development boards are supported for ESP-BLE-MESH implementation. You can choose particular board through menuconfig: idf.py menuconfig

> Example Configuration > Board selection for ESP-BLE-MESH

**Note:** If you plan to use ESP32-DevKitC, connect a RGB LED to GPIO pins 25, 26 and 27.
Step 2. Configure Software  Enter the bluetooth/esp_ble_mesh/ble_mesh_node/onoff_server example directory, run idf.py menuconfig to select your board and then run idf.py build to compile the example.

Step 3. Upload Application to Nodes  After the bluetooth/esp_ble_mesh/ble_mesh_node/onoff_server example is compiled successfully, users can run idf.py flash to upload the same generated binary files into each of the three development boards.

Once boards are powered on, the RGB LED on each board should turn GREEN.

Step 4. Provision Nodes  In this section, we will use the nRF Mesh Android App to demonstrate how to provision an unprovisioned device. Users can also get its iOS version from the App Store.

4.1 Scanner  The Scanner is App’s functionality to search for unprovisioned devices in range. Open the App, press Scanner at the bottom and the search will start. After a short while we should see three unprovisioned devices displayed.

4.2 Identify  Users can select any unprovisioned device, then the App will try to set up a connection with the selected device. After the BLE connection is established successfully (sometimes users need to try multiple times to get connected), and proper ESP-BLE-MESH GATT Service is discovered, users can see the IDENTIFY interface button on the screen. The IDENTIFY operation can be used to tell users which device is going to be provisioned.

Note:  The IDENTIFY operation also needs some cooperation on the device side, then users can see which device is in the provisioning process. Currently when pressing the IDENTIFY interface button, no signs can be seen from the device except from the log on the serial monitor.

After the IDENTIFY interface button is pressed, users can see the PROVISION interface button.
Chapter 4. API Guides

Fig. 10: nRF Mesh - Scanner

Fig. 11: nRF Mesh - IDENTIFY - PROVISION
4.3 Provision  Then, the App will try to provision the unprovisioned device. When the device is provisioned successfully, the RGB LED on the board will turn off, and the App will implement the following procedures:

1. Disconnect with the node
2. Try to reconnect with the node
3. Connect successfully and discover ESP-BLE-MESH GATT Service
4. Get Composition Data of the node and add AppKey to it

When all the procedures are finished, the node is configured properly. And after pressing **OK**, users can see that unicast address is assigned, and Composition Data of the node is decoded successfully.

![Fig. 12: nRF Mesh - Configuration Complete](image)

Sometimes in procedure 2, the App may fail to reconnect with the node. In this case, after pressing **OK**, users can see that only unicast address of the node has been assigned, but no Composition Data has been got. Then users need to press **CONNECT** on the top right, and the previously provisioned node will be displayed on the screen, and users need to choose it and try to connect with the node.

After connecting successfully, the App will show the interface buttons which can be used to get Composition Data and add AppKey.

If the device is the second or the third one which has been provisioned by the App, and after pressing **CONNECT**, users can see two or three nodes on the screen. In this situation, users can choose any device to connect with, once succeed then go back to the main screen to choose the node which needs to be configured.

Here an example of three devices listed.

- The left picture shows that the third device is provisioned successfully, but the App failed to connect with it. When it tries to reconnect with the third node, three nodes are displayed on the App.
- The right picture shows that after connecting with any node successfully, the App displays the information of the three nodes. Users can see that the App has got the Composition Data of the first and the second nodes, but for the third one, only the unicast address has been assigned to it while the Composition Data is unknown.

4.4 Configuration  When provisioning and initial configuration are finished, users can start to configure the node, such as binding AppKey with each model with the elements, setting publication information to it, etc.

Example below shows how to bind AppKey with Generic OnOff Server Model within the Primary Element.
Chapter 4. API Guides

**Fig. 13: nRF Mesh - Initial Configuration Failed**

**Fig. 14: nRF Mesh - Reconnect - Initial Configuration**
Fig. 15: nRF Mesh - Reconnect - Three Nodes

Fig. 16: nRF Mesh - Model Bind AppKey
Chapter 4. API Guides

**Note:** No need to bind AppKey with the Configuration Server Model, since it only uses the DevKey to encrypt messages in the Upper Transport Layer.

**Step 5. Operate Network**  After all the Generic OnOff Server Models within the three elements are bound with proper AppKey, users can use the App to turn on/off the RGB LED.

In the `bluetooth/esp_ble_mesh/ble_mesh_node/onoff_server` example, the first Generic OnOff Server Model is used to control the **RED** color, the second one is used to control the **GREEN** color and the third one is used to control the **BLUE** color.

![Fig. 17: nRF Mesh - Generic OnOff Control](image)

The following screenshot shows different board with different color on.

**Note:** For **nRF Mesh** iOS App [version 1.0.4], when the node contains more than one element, the App is not behaving correctly. If users try to turn on/off the second or the third Generic OnOff Server Model, the message sent by the App is designated to the first Generic OnOff Server Model within the Primary Element.

### 4.11.2 ESP-BLE-MESH Examples

- **ESP-BLE-MESH Node OnOff Server** - shows the use of ESP-BLE-MESH as a node having a Configuration Server model and a Generic OnOff Server model. A ESP-BLE-MESH Provisioner can then provision the unprovisioned device and control a RGB LED representing on/off state, see [example code](#).
- **ESP-BLE-MESH Node OnOff Client** - shows how a Generic OnOff Client model works within a node. The node has a Configuration Server model and a Generic OnOff Client model, see [example code](#).
- **ESP-BLE-MESH Provisioner** - shows how a device can act as an ESP-BLE-MESH Provisioner to provision devices. The Provisioner has a Configuration Server model, a Configuration Client model and a Generic OnOff Client model, see [example code](#).
• ESP-BLE-MESH Fast Provisioning - Client and Server - this example is used for showing how fast provisioning can be used in order to create a mesh network. It takes no more than 60 seconds to provision 100 devices, see example client code and example server code.
• ESP-BLE-MESH and Wi-Fi Coexistence - an example that demonstrates the Wi-Fi and Bluetooth (BLE/BR/EDR) coexistence feature of ESP32. Simply put, users can use the Wi-Fi while operating Bluetooth, see example code.
• ESP-BLE-MESH Console - an example that implements BLE Mesh basic features. Within this example a node can be scanned and provisioned by Provisioner and reply to get/set message from Provisioner, see example node code.

Supported Features

Mesh Core

- **Provisioning: Node Role**
  - PB-ADV and PB-GATT
  - OOB Authentication

- **Provisioning: Provisioner Role**
  - PB-ADV and PB-GATT
  - OOB Authentication

- **Networking**
  - Relay
  - Segmentation and Reassembly
  - Key Refresh Procedure
  - IV Update Procedure
  - Friend
  - Low Power
  - Proxy Server
  - Proxy Client

- **Multiple Client Models Run Simultaneously**
  - Support multiple client models send packets to different nodes simultaneously
  - No blocking between client model and server model

- **NVS Storing**
  - Store provisioning and configuration information of ESP-BLE-MESH Node

Mesh Models

- **Foundation models**
  - Configuration Server model
  - Configuration Client model
  - Health Server model
  - Health Client model

- **Generic client models**
  - Generic OnOff Client
  - Generic Level Client
  - Generic Default Transition Time Client
  - Generic Power OnOff Client
  - Generic Power Level Client
  - Generic Battery Client
  - Generic Location Client
  - Generic Property Client

- **Sensor client models**
  - Sensor Client

- **Time and Scenes client models**
  - Time Client
  - Scene Client
  - Scheduler Client

ESP-BLE-MESH Architecture

This document introduces ESP-BLE-MESH architecture overview, ESP-BLE-MESH architecture implementation as well as ESP-BLE-MESH auxiliary routines.

• ESP-BLE-MESH Architecture Overview
  – Describes the five major parts of ESP-BLE-MESH architecture and the functionality of each part.

• ESP-BLE-MESH Architecture Implementation
  – Describes the basic functions of ESP-BLE-MESH files, the correspondence between files and ESP-BLE-MESH architecture, and the interface for calling along files.

• ESP-BLE-MESH Auxiliary Routines
  – Describe the auxiliary routines of ESP-BLE-MESH, such as Mesh network management, Mesh features, etc.

1. ESP-BLE-MESH Architecture Overview

Currently ESP-BLE-MESH has implemented most functions of Mesh Profile and all the Client Models defined in Mesh Model specification. Those missing functions/models are under development and will be provided soon. ESP-BLE-MESH architecture has been granted the official Bluetooth certification.

ESP-BLE-MESH architecture includes five key parts:

• Mesh Protocol Stack
  – Mesh Networking is responsible for processing of messages of ESP-BLE-MESH nodes.
  – Mesh Provisioning is responsible for provisioning flow of ESP-BLE-MESH devices.
  – Mesh Models is responsible for the implementation of SIG-defined models.

• Network Management
  – Implements several network management procedures, including node removal procedure, IV Index recovery procedure, etc.

• Features
  – Include several ESP-BLE-MESH features, e.g. Low Power feature, Friend feature, Relay feature, etc.

• Mesh Bearer Layer
  – Includes Advertising Bearer and GATT Bearer. The bearer layer is crucial to ESP-BLE-MESH protocol stack which is built on Bluetooth Low-Energy technology, because the protocol stack must make use of the bearer layer to transmit data via the BLE advertising channel and connection channel.

• Applications
  – Based on ESP-BLE-MESH protocol stack and Mesh Models.
  – By calling API and handling Event, Applications interact with Mesh Networking and Mesh Provisioning in ESP-BLE-MESH protocol stack, as well as a series of Models provided by Mesh Models.

1.1 Mesh Protocol Stack
Fig. 19: Figure 1.1 ESP-BLE-MESH Architecture Diagram
### 1.1.1 Mesh Networking

Mesh Networking in the protocol stack architecture implements the following functions:

- The communication between nodes in the Mesh network.
- Encryption and decryption of messages in the Mesh network.
- Management of Mesh network resources (Network Key, IV Index, etc.).
- Segmentation and reassembly of Mesh network messages.
- Model mapping of messages between different models.
- For more features, please see [ESP-BLE-MESH Feature List](#).

The implementation of Mesh Networking functions is based on hierarchy structure. Functions of each layer are shown in Table 1.1:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Layer</td>
<td>Access Layer not only defines the format of application data, but also defines and controls the encryption and decryption of the data packets conducted by Upper Transport Layer.</td>
</tr>
<tr>
<td>Upper Transport Layer</td>
<td>Upper Transport Layer encrypts, decrypts, and authenticates application data to and from the access layer; it also handles special messages called “transport control messages”, including messages related to “friendship” and heartbeat messages.</td>
</tr>
<tr>
<td>Lower Transport Layer</td>
<td>Lower Transport Layer handles segmentation and reassembly of PDU.</td>
</tr>
<tr>
<td>Network Layer</td>
<td>Network Layer defines the address type and format of the network messages, and implements the relay function of the device.</td>
</tr>
</tbody>
</table>

### 1.1.2 Mesh Provisioning

Mesh Provisioning in the protocol stack architecture implements the following functions:

- Provisioning of unprovisioned devices.
- Allocation of Mesh network resources (unicast address, IV Index, NetKey, etc.).
- Four authentication methods support during provisioning.
- For more features, please see [ESP-BLE-MESH Feature List](#).

The implementation of Mesh Provisioning functions is based on hierarchy structure. Functions of each layer are shown in Table 1.2:

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provisioning PDUs</td>
<td>Provisioning PDUs from different layers are handled using provisioning protocol.</td>
</tr>
<tr>
<td>Generic Provisioning PDU/Proxy PDU</td>
<td>The Provisioning PDUs are transmitted to an unprovisioned device using a Generic Provisioning layer or Proxy protocol layer.</td>
</tr>
<tr>
<td>PB-ADV/PB-GATT</td>
<td>These layers define how the Provisioning PDUs are transmitted as transactions that can be segmented and reassembled.</td>
</tr>
<tr>
<td>Advertising/Provisioning Service</td>
<td>The provisioning bearers define how sessions are established such that the transactions from the generic provisioning layer can be delivered to a single device.</td>
</tr>
</tbody>
</table>

### 1.1.3 Mesh Models

Mesh Models in the protocol stack architecture implements the following functions:

- Configuration Client/Server Models
- Health Client/Server Models
- Generic Client/Server Models
- Sensor Client/Server Models
- Time and Scenes Client/Server Models
- Lighting Client/Server Models

Functions of each layer are shown in Table 1.3:
Table 5: Table 1.3 Mesh Models Architecture Description

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model Layer</td>
<td>Model Layer implements models used to standardize the operation of typical user scenarios, including Generic Client/Server Models, Sensor Client/Server Models, Time and Scenes Client/Server Models, Lighting Client/Server Models and several vendor models.</td>
</tr>
<tr>
<td>Foundation Layer</td>
<td>Foundation Model Layer implements models related to ESP-BLE-MESH configuration, management, self diagnosis, etc.</td>
</tr>
</tbody>
</table>

1.2 Mesh Network Management  
Network Management implements the following functions:

- Node removal procedure is used to remove a node from the network.
- IV Index recovery procedure is used to recover a node’s IV Index.
- IV update procedure is used to update the nodes’ IV Index.
- Key refresh procedure is used to update the nodes’ NetKey, AppKey, etc.
- Network creation procedure is used to create a mesh network.
- NVS storage is used to store node’s networking information.

1.3 Mesh Features  
Features includes the following options:

- Low Power feature is used to reduce node’s power consumption.
- Friend feature is used to store messages for Low Power nodes.
- Relay feature is used to relay/forward Network PDUs received by a node over the advertising bearer.
- Proxy Server/Client are two node roles in proxy protocol, which enable nodes to send and receive Network PDUs, mesh beacons, proxy configuration messages and Provisioning PDUs over a connection-oriented bearer.

1.4 Mesh Bearer Layer  
Bearers in the protocol stack architecture are responsible for passing of data between ESP-BLE-MESH protocol stack and Bluetooth Low Energy Core.

Bearers can be taken as a carrier layer based on Bluetooth Low Energy Core, which implements the function of receiving and transmitting data for the ESP-BLE-MESH protocol stack.

Table 6: Table 1.3 Mesh Bearers Description

<table>
<thead>
<tr>
<th>Layer</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>GATT Bearer</td>
<td>The GATT Bearer uses the Proxy protocol to transmit and receive Proxy PDUs between two devices over a GATT connection.</td>
</tr>
<tr>
<td>Advertising Bearer</td>
<td>When using the Advertising Bearer, a mesh packet shall be sent in the Advertising Data of a Bluetooth Low Energy advertising PDU using the Mesh Message AD Type.</td>
</tr>
</tbody>
</table>

1.5 Mesh Applications  
The Applications in the protocol stack architecture implement the corresponding functions by calling the API provided by the ESP-BLE-MESH protocol stack and processing the Event reported by the protocol stack. There are some common applications, such as gateway, lighting and etc.

Interaction between application layer (Applications) and API / Event

- Application layer calls API
  - Call the provisioning-related API for provisioning.
  - Call the model-related API to send messages.
  - Call the device-attributes-related API to get local information about the device.
- Application layer processes Event
  The application layer is designed based on events, which take parameters to the application layer. Events are mainly divided into two categories.
  - The events completed by calling API.
    - Such as nodes sending messages.
  - The events that the protocol stack actively reports to the application layer.
    - The Event that the protocol stack actively reports.
* The Event that Model actively reports.
  * The event is reported by the callback function registered by the application layer, and the callback function also contains the corresponding processing of the event.

Interaction between API / Event and ESP-BLE-MESH protocol stack

* API used by user mainly calls functions provided by Mesh Networking, Mesh Provisioning and Mesh Models.
* The interaction between API / Event and the protocol stack does not operate across the hierarchy of the protocol stack. For example, API does not call functions related to Network Layer.

2. ESP-BLE-MESH Architecture Implementation

The design and implementation of ESP-BLE-MESH architecture is based on layers and modules. In details, Section 2.1 (Mesh Networking Implementation), Section 2.2 (Mesh Provisioning Implementation) and Section 2.3 (Mesh Bearers Implementation) are based on layers, and Section 2.4 (Mesh Models Implementation) is on modules.

* **Layer-based Approach**: With Layer-based approach, the architecture is designed according to the layers specified in the Mesh Profile Specification. Each layer has its unique files which include APIs of this layer and etc. The specific design is shown in Figure 2.1.

* **Module-based Approach**: Every file implements an independent function that can be called by other programs.

The design of ESP-BLE-MESH architecture uses layer-based approach. The sequence of layers which data packets are processed through is fixed, i.e., the processing of packets will form a message flow. Thus, we could see flows of messages from the Protocol Stack Interface Diagram in Figure 2.1.

2.1 Mesh Protocol Stack Implementation

2.1.1 Mesh Networking Implementation

The list of files and the functions implemented in each file in Mesh Networking are shown in Table 2.1:

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>access.c</td>
<td>ESP-BLE-MESH Access Layer</td>
</tr>
<tr>
<td>transport.c</td>
<td>ESP-BLE-MESH Lower/Upper Transport Layer</td>
</tr>
<tr>
<td>net.c</td>
<td>ESP-BLE-MESH Network Layer</td>
</tr>
<tr>
<td>adv.c</td>
<td>A task used to send ESP-BLE-MESH advertising packets, a callback used to handle received advertising packets and APIs used to allocate adv buffers</td>
</tr>
</tbody>
</table>

2.1.2 Mesh Provisioning Implementation

The implementation of Mesh Provisioning is divided into two chunks due to the Node/Provisioner coexistence.

Specific files that provide implementation of provisioning of Node are shown in Table 2.2:

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>prov.c</td>
<td>ESP-BLE-MESH Node provisioning (PB-ADV &amp; PB-GATT)</td>
</tr>
<tr>
<td>proxy_server.c</td>
<td>ESP-BLE-MESH Proxy Server related functionalities</td>
</tr>
<tr>
<td>beacon.c</td>
<td>APIs used to handle ESP-BLE-MESH Beacons</td>
</tr>
</tbody>
</table>

Specific files that implement functions of Provisioner are shown in Table 2.3:

<td>Receive ESP-BLE-MESH Time Scene Client messages and send proper response messages</td>
</tr>
</tbody>
</table>

## 2.2 Mesh Bearers Implementation

Portability is fully considered in the implementation of Mesh Bearers. When the ESP-BLE-MESH protocol stack is being ported to other platforms, users only need to modify mesh_bearer_adapt.c (example of NimBLE version).

### Table 11: Table 2.5 Mesh Bearers File Description

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>mesh_bearer_adapt.c</td>
<td>ESP-BLE-MESH Bearer Layer adapter, This file provides the interfaces used to receive and send ESP-BLE-MESH ADV &amp; GATT related packets.</td>
</tr>
</tbody>
</table>

**Note:** mesh_bearer_adapt.c is the implementation of Advertising Bearer and GATT Bearer in Mesh Networking framework.

## 2.3 Mesh Applications Implementation

We have provided a series of application examples for customer development, and users can develop products based on ESP-BLE-MESH Examples.

## 3. Auxiliary Routine

Auxiliary routine refers to optional functions in the ESP-BLE-MESH protocol stack. The design of the auxiliary routine generally implement the truncation of code through CONFIG_BLE_MESH.
3.1 Features

- Low Power
- Friend
- Relay
- Proxy Client/Server

3.2 Network Management

- Node Removal procedure
- IV Index Recovery procedure
- IV Update procedure
- Key Refresh procedure
- Network Creation procedure
- NVS Storage

3.3 Auxiliary Routine Implementation

When adopting the design of independent module, the two main factors should be considered:

- The module can not be implemented hierarchically, and it can be completely independent, which means it does not rely on the implementation of other modules.
- The functions in the module will be used repeatedly, so it is reasonable to design it into a module. Independent module is shown in Table 3.1:

<table>
<thead>
<tr>
<th>File</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>lpn.c</td>
<td>ESP-BLE-MESH Low Power functionality</td>
</tr>
<tr>
<td>friend.c</td>
<td>ESP-BLE-MESH Friend functionality</td>
</tr>
<tr>
<td>net.c</td>
<td>ESP-BLE-MESH Relay feature, network creation, IV Update procedure, IV Index recovery procedure, Key Refresh procedure related functionalities</td>
</tr>
<tr>
<td>proxy_server.c</td>
<td>ESP-BLE-MESH Proxy Server related functionalities</td>
</tr>
<tr>
<td>proxy_client.c</td>
<td>ESP-BLE-MESH Proxy Client related functionalities</td>
</tr>
<tr>
<td>settings.c</td>
<td>ESP-BLE-MESH NVS storage functionality</td>
</tr>
<tr>
<td>main.c</td>
<td>ESP-BLE-MESH stack initialize, stack enable, node removal related functionalities</td>
</tr>
</tbody>
</table>

ESP-BLE-MESH FAQ

This document provides a summary of frequently asked questions about developing with ESP-BLE-MESH, and is divided into seven sections:

- 1. Provisioner Development
- 2. Node Development
- 3. ESP-BLE-MESH and Wi-Fi Coexistence
- 4. Fast Provisioning
- 5. Log Help
- 6. Example Help
- 7. Others

Users could refer to the sections for quick answer to their questions. This document will be updated based on the feedback collected via various channels.

1. Provisioner Development

Generally, a Provisioner is used to provision unprovisioned devices and form a mesh network. And after provisioning, roles of the unprovisioned devices will be changed to those of a node.
1.1 What is the flow for an unprovisioned device to join ESP-BLE-MESH network?

There are two phases for a device to join ESP-BLE-MESH network via a Provisioner, namely, provisioning and configuration.

- The phase of provisioning is to assign unicast address, add NetKey and etc. to a device. By provisioning, the device joins the ESP-BLE-MESH network and its role is changed from an unprovisioned device to a node.
- The phase of configuration is to add AppKeys to the node and bind AppKeys to corresponding models. And some items are optional during configuration, including adding subscription addresses to the node, set publication information, etc. By configuration, the node can actually transmit messages to a Provisioner and receive messages from it.

1.2 If a Provisioner wants to change states of a node, what requirements should be met for a Provisioner?

- Client model that corresponds to server model of the node is required.
- NetKey and AppKey used to encrypt messages shall be owned by both the node and the Provisioner.
- The address owned by the node shall be known, which could be its unicast address or subscription address.

1.3 How can NetKey and AppKey be used?

- NetKey is used for encryption of messages in Network Layer. Nodes with the same NetKey are assumed to be in the same subnet while those with different NetKeys cannot communicate with each other.
- AppKey is used for encryption of messages in Upper Transport Layer. If client model and server model are bound to different AppKeys, the communication cannot be achieved.

1.4 How to generate a NetKey or AppKey for Provisioner? Can we use a fixed NetKey or AppKey?

- The API `esp_ble_mesh_provisioner_add_local_net_key()` can be used to add a NetKey with a fixed or random value.
- The API `esp_ble_mesh_provisioner_add_local_app_key()` can be used to add an AppKey with a fixed or random value.

1.5 Is the unicast address of Provisioner fixed?

The value of `prov_unicast_addr` in `esp_ble_mesh_prov_t` is used to set the unicast address of Provisioner, it can be set only once during initialization and can’t be changed afterwards.

1.6 Can the address of Provisioner serve as destination address of the node-reporting-status message?

The unicast address of Provisioner can be set only once during initialization and can’t be changed afterwards. In theory, it can serve as the destination address of the node-reporting-status message, provided that the unicast address of the Provisioner is known by nodes. Nodes can know the unicast address of Provisioner during configuration since Provisioner sends messages to them with its unicast address used as the source address.

Subscription address can also be used. Provisioner subscribes to a group address or virtual address, and nodes send messages to the subscription address.

1.7 Is the unicast address of the node that is firstly provisioned by Provisioner to ESP-BLE-MESH network fixed?

The value of `prov_start_address` in `esp_ble_mesh_prov_t` is used to set the starting address when the Provisioner provisions unprovisioned devices, i.e. the unicast address of the node it firstly provisioned. It can be set only once during initialization and can’t be changed afterwards.
1.8 Is the unicast address of the node that mobile App firstly provisioned fixed?

The App will decide the unicast address, and currently most of them are fixed.

1.9 How to know which unprovisioned device is the Provisioner that is provisioning currently?

The value of `prov_attention` in `esp_ble_mesh_prov_t` is used by Provisioner set to unprovisioned device during provisioning. It can be set only once during initialization and can’t be changed afterwards. When the unprovisioned device is joining the mesh network, it can display in a specific way like flashing light to notify Provisioner that it is being provisioned.

1.10 How many ways to authenticate the devices during provisioning? Which way was used in the provided examples?

There are four authentication methods, i.e. No OOB, Static OOB, Output OOB and Input OOB. In the provided examples, No OOB is used.

1.11 What information can be carried by the advertising packets of the unprovisioned device before provisioning into the network?

- Device UUID
- OOB Info
- URL Hash (optional)

1.12 Can such information be used for device identification?

For example, each unprovisioned device contains a unique Device UUID, which can be used for device identification.

1.13 How is the unicast address assigned when the node provisioned by Provisioner contains multiple elements?

- Provisioner will assign an unicast address for the primary element of the node, and unicast address of the remaining elements are incremented one by one.
- For example: If an unprovisioned device has three elements, i.e. the primary element, the second element and the third element. After provisioning, the primary element address of the node is 0x0002 while the second element address is 0x0003, and the third element address is 0x0004.

1.14 How can Provisioner get and parse the Composition Data of nodes through Configuration Client Model?

- Provisioner can get the Composition Data of nodes using the `Configuration Client Model` API `esp_ble_mesh_config_client_set_state()` with `comp_data_get` in the parameter `esp_ble_mesh_cfg_client_get_state_t` set properly.
- Users can refer to the following code to parse the Composition Data:

```c
#include <stdio.h>
#include <string.h>
#include <stdint.h>

// test date: 0C001A00001000008000300000105010000080000000000103103F002AQ0
// 0C00 1A00 0100 0800 0300 0000 05 01 0000 0800 0100 0010 0310 3F002A00

// CID is 0x000C
// PID is 0x001A
// VID is 0x0001
// CRPL is 0x0008
// Features is 0x0003 – Relay and Friend features.
// Loc is “front” – 0x0100
```

(continues on next page)
// NumS is 5
// NumV is 1
// The Bluetooth SIG Models supported are: 0x0000, 0x8000, 0x0001, 0x1000, .. 0x1003
// The Vendor Models supported are: Company Identifier 0x003F and Model Identifier 0x002A

  for(i = 1; i < head->sig_models * 2; i = i + 2) {
    data->SIG_models[i/2] = mystr[i + pos_sig_base] | (mystr[i + pos_sig_base + 1] << 8);
    printf("%d: %4.4x\n", i/2, data->SIG_models[i/2]);
  }

  pos_vnd_base = head->sig_models * 2 + pos_sig_base;

  for(i = 1; i < head->vnd_models * 2; i = i + 2) {
    data->Vendor_models[i/2].model_id = mystr[i + pos_vnd_base] | (mystr[i + pos_vnd_base + 1] << 8);
    printf("%d: %4.4x\n", i/2, data->Vendor_models[i/2].model_id);
  }
}
1.15 How can Provisioner further configure nodes through obtained Composition Data?

Provisioner do the following configuration by calling the Configuration Client Model API `esp_ble_mesh_config_client_set_state()`.

- Add AppKey to nodes with `app_key_add` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Add subscription address to the models of nodes with `model_sub_add` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Set publication information to the models of nodes with `model_pub_set` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.

1.16 Can nodes add corresponding configurations for themselves?

This method can be used in special cases like testing period.

- Here is an example to show nodes add new group addresses for their models.

```c
esp_err_t example_add_fast_prov_group_address(uint16_t model_id, uint16_t group_addr)
{
    const esp_ble_mesh_comp_t *comp = NULL;
    esp_ble_mesh_elem_t *element = NULL;
    esp_ble_mesh_model_t *model = NULL;
    int i, j;

    if (!ESP_BLE_MESH_ADDR_IS_GROUP(group_addr)) {
        return ESP_ERR_INVALID_ARG;
    }

    comp = esp_ble_mesh_get_composition_data();
    if (!comp) {
```
return ESP_FAIL;
}

for (i = 0; i < comp->element_count; i++) {
    element = &comp->elements[i];
    model = esp_ble_mesh_find_sig_model(element, model_id);
    if (!model) {
        continue;
    }
    for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
        if (model->groups[j] == group_addr) {
            break;
        }
    }
    if (j != ARRAY_SIZE(model->groups)) {
        ESP_LOGW(TAG, "%s: Group address already exists, element...
                     --index: %d", __func__, i);
        continue;
    }
    for (j = 0; j < ARRAY_SIZE(model->groups); j++) {
        if (model->groups[j] == ESP_BLE_MESH_ADDR_UNASSIGNED) {
            model->groups[j] = group_addr;
            break;
        }
    }
    if (j != ARRAY_SIZE(model->groups)) {
        ESP_LOGE(TAG, "%s: Model is full of group addresses, element...
                   --index: %d", __func__, i);
    }
}
return ESP_OK;

Note: When the NVS storage of the node is enabled, group address added and AppKey bound by this method will not be saved in the NVS when the device is powered off currently. These configuration information can only be saved if they are configured by Configuration Client Model.

1.17 How does Provisioner control nodes by grouping?

Generally there are two approaches to implement group control in ESP-BLE-MESH network, group address approach and virtual address approach. And supposing there are 10 devices, i.e., five devices with blue lights and five devices with red lights.

- Method 1: 5 blue lights can subscribe to a group address, 5 red lights subscribe to another one. By sending messages to different group addresses, Provisioner can realize group control.
- Method 2: 5 blue lights can subscribe to a virtual address, 5 red lights subscribe to another one. By sending messages to different virtual addresses, Provisioner can realize group control.

1.18 How does Provisioner add nodes to multiple subnets?

Provisioner can add multiple NetKeys to nodes during configuration, and nodes sharing the same NetKey belong to the same subnet. Provisioner can communicate with nodes on different subnets by using different NetKeys.

1.19 How does Provisioner know if a node in the mesh network is offline?
Node offline is usually defined as: the condition that the node cannot be properly communicated with other nodes in the mesh network due to power failure or some other reasons.

There is no connection between nodes and nodes in the ESP-BLE-MESH network. They communicate with each other through advertising channels.

An example is given here to show how to detect a node is offline by Provisioner.

- The node can periodically send heartbeat messages to Provisioner. And if Provisioner failed to receive heartbeat messages in a certain period, the node is considered to be offline.

**Note:** The heartbeat message should be designed into a single package (less than 11 bytes), so the transmission and reception of it can be more efficient.

### 1.20 What operations should be performed when Provisioner removes nodes from the network?

Usually when Provisioner tries to remove node from the mesh network, the procedure includes three main steps:

- Firstly, Provisioner adds the node that need to be removed to the “blacklist”.
- Secondly, Provisioner performs the **Key Refresh procedure**.
- Lastly, the node performs node reset procedure, and switches itself to an unprovisioned device.

### 1.21 In the Key Refresh procedure, how does Provisioner update the Netkey owned by nodes?

- Provisioner updates the NetKey of nodes using the **Configuration Client Model API** `esp_ble_mesh_config_client_set_state()` with `net_key_update` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.
- Provisioner updates the AppKey of nodes using the **Configuration Client Model API** `esp_ble_mesh_config_client_set_state()` with `app_key_update` in the parameter `esp_ble_mesh_cfg_client_set_state_t` set properly.

### 1.22 How does Provisioner manage nodes in the mesh network?

ESP-BLE-MESH implements several functions related to basic node management in the example, such as `esp_ble_mesh_store_node_info()`. And ESP-BLE-MESH also provides the API `esp_ble_mesh_provisioner_set_node_name()` which can be used to set the node’s local name and the API `esp_ble_mesh_provisioner_get_node_name()` which can be used to get the node’s local name.

### 1.23 What does Provisioner need when trying to control the server model of nodes?

Provisioner must include corresponding client model before controlling the server model of nodes.

Provisioner shall add its local NetKey and AppKey.

- Provisioner add NetKey by calling the API `esp_ble_mesh_provisioner_add_local_net_key()`.
- Provisioner add AppKey by calling the API `esp_ble_mesh_provisioner_add_local_app_key()`.

Provisioner shall configure its own client model.

- Provisioner bind AppKey to its own client model by calling the API `esp_ble_mesh_provisioner_bind_app_key_to_local_model()`.

### 1.24 How does Provisioner control the server model of nodes?

ESP-BLE-MESH supports all SIG-defined client models. Provisioner can use these client models to control the server models of nodes. And the client models are divided into 6 categories with each category has the corresponding functions.
Chapter 4. API Guides

**Configuration Client Model**
- The API `esp_ble_mesh_config_client_get_state()` can be used to get the `esp_ble_mesh_cfg_client_get_state_t` values of Configuration Server Model.
- The API `esp_ble_mesh_config_client_set_state()` can be used to set the `esp_ble_mesh_cfg_client_set_state_t` values of Configuration Server Model.

**Health Client Model**
- The API `esp_ble_mesh_health_client_get_state()` can be used to get the `esp_ble_mesh_health_client_get_state_t` values of Health Server Model.
- The API `esp_ble_mesh_health_client_set_state()` can be used to set the `esp_ble_mesh_health_client_set_state_t` values of Health Server Model.

**Generic Client Models**
- The API `esp_ble_mesh_generic_client_get_state()` can be used to get the `esp_ble_mesh_generic_client_get_state_t` values of Generic Server Models.
- The API `esp_ble_mesh_generic_client_set_state()` can be used to set the `esp_ble_mesh_generic_client_set_state_t` values of Generic Server Models.

**Lighting Client Models**
- The API `esp_ble_mesh_light_client_get_state()` can be used to get the `esp_ble_mesh_light_client_get_state_t` values of Lighting Server Models.
- The API `esp_ble_mesh_light_client_set_state()` can be used to set the `esp_ble_mesh_light_client_set_state_t` values of Lighting Server Models.

**Sensor Client Models**
- The API `esp_ble_mesh_sensor_client_get_state()` can be used to get the `esp_ble_mesh_sensor_client_get_state_t` values of Sensor Server Model.
- The API `esp_ble_mesh_sensor_client_set_state()` can be used to set the `esp_ble_mesh_sensor_client_set_state_t` values of Sensor Server Model.

**Time and Scenes Client Models**
- The API `esp_ble_mesh_time_scene_client_get_state()` can be used to get the `esp_ble_mesh_time_scene_client_get_state_t` values of Time and Scenes Server Models.
- The API `esp_ble_mesh_time_scene_client_set_state()` can be used to set the `esp_ble_mesh_time_scene_client_set_state_t` values of Time and Scenes Server Models.

2. Node Development

2.1 What kind of models are included by nodes?
- In ESP-BLE-MESH, nodes are all composed of a series of models with each model implements some functions of the node.
- Model has two types, client model and server model. Client model can get and set the states of server model.
- Model can also be divided into SIG model and vendor model. All behaviors of SIG models are officially defined while behaviors of vendor models are defined by users.

2.2 Is the format of messages corresponding to each model fixed?
- Messages, which consist of opcode and payload, are divided by opcode.
- The type and the format of the messages corresponding to models are both fixed, which means the messages transmitted between models are fixed.

2.3 Which functions can be used to send messages with the models of nodes?
- For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` to send messages.
- For server models, users can use the API `esp_ble_mesh_server_model_send_msg()` to send messages.
• For publication, users call the API `esp_ble_mesh_model_publish()` to publish messages.

2.4 How to achieve the transmission of messages without packet loss?

Acknowledged message is needed if users want to transmit messages without packet loss. The default time to wait for corresponding response is set in `CONFIG_BLE_MESH_CLIENT_MSG_TIMEOUT`. If the sender waits for the response until the timer expires, the corresponding timeout event would be triggered.

**Note:** Response timeout can be set in the API `esp_ble_mesh_client_model_send_msg()`. The default value (4 seconds) would be applied if the parameter `msg_timeout` is set to 0.

2.5 How to send unacknowledged messages?

For client models, users can use the API `esp_ble_mesh_client_model_send_msg()` with the parameter `need_rsp` set to `false` to send unacknowledged messages.

For server models, the messages sent by using the API `esp_ble_mesh_server_model_send_msg()` are always unacknowledged messages.

2.6 How to add subscription address to models?

Subscription address can be added through Configuration Client Model.

2.7 What is the difference between messages sent and published by models?

Messages sent by calling the API `esp_ble_mesh_client_model_send_msg()` or `esp_ble_mesh_server_model_send_msg()` will be sent in the duration determined by the Network Transmit state.

Messages published by calling the API `esp_ble_mesh_model_publish()` will be published determined by the Model Publication state. And the publication of messages is generally periodic or with a fixed number of counts. The publication period and publication count are controlled by the Model Publication state, and can be configured through Configuration Client Model.

2.8 How many bytes can be carried when sending unsegmented messages?

The total payload length (which can be set by users) of unsegmented message is 11 octets, so if the opcode of the message is 2 octets, then the message can carry 9 octets of valid information. For vendor messages, due to the 3-octets opcode, the remaining payload length is 8 octets.

2.9 When should the Relay feature of nodes be enabled?

Users can enable the Relay feature of all nodes when nodes detected in the mesh network are sparse.

For dense mesh network, users can choose to just enable the Relay feature of several nodes.

And users can enable the Relay feature by default if the mesh network size is unknown.

2.10 When should the Proxy feature of node be enabled?

If the unprovisioned device is expected to be provisioned by a phone, then it should enable the Proxy feature since almost all the phones do not support sending ESP-BLE-MESH packets through advertising bearer currently. And after the unprovisioned device is provisioned successfully and becoming a Proxy node, it will communicate with the phone using GATT bearer and using advertising bearer to communicate with other nodes in the mesh network.
2.11 How to use the Proxy filter?

The Proxy filter is used to reduce the number of Network PDUs exchanged between a Proxy Client (e.g. the phone) and a Proxy Server (e.g. the node). And with the Proxy filter, Proxy Client can explicitly request to receive only mesh messages with certain destination addresses from Proxy Server.

2.12 When a message can be relayed by a Relay node?

If a message need to be relayed, the following conditions should be met.

- The message is in the mesh network.
- The message is not sent to the unicast address of the node.
- The value of TTL in the message is greater than 1.

2.13 If a message is segmented into several segments, should the other Relay nodes just relay when one of these segments is received or wait until the message is received completely?

Relay nodes will forward segments when one of them are received rather than keeping waiting until all the segments are received.

2.14 What is the principle of reducing power consumption using Low Power feature?

- When the radio is turned on for listening, the device is consuming energy. When low power feature of the node is enabled, it will turn off its radio in the most of the time.
- And cooperation is needed between low power node and friend node, thus low power node can receive messages at an appropriate or lower frequency without the need to keep listening.
- When there are some new messages for low power node, its friend node will store the messages for it. And low power node can poll friend nodes to see if there are new messages at a fixed interval.

2.15 How to continue the communication on the network after powering-down and powering-up again?

Enable the configuration Store ESP-BLE-MESH Node configuration persistently in menuconfig.

2.16 How to send out the self-test results of nodes?

It is recommended that nodes can publish its self-test results periodically through Health Server Model.

2.17 How to transmit information between nodes?

One possible application scenario for transmitting information between nodes is that spray nodes would be triggered once smoke alarm detected high smoke concentration. There are two approaches in implementation.

- Approach 1 is that spray node subscribes to a group address. When smoke alarm detects high smoke concentration, it will publish a message whose destination address is the group address which has been subscribed by spray node.
- Approach 2 is that Provisioner can configure the unicast address of spray node to the smoke alarm. When high smoke concentration is detected, smoke alarm can use send messages to the spray node with the spray node’s unicast address as the destination address.

2.18 Is gateway a must for nodes communication?

- Situation 1: nodes only communicate within the mesh network. In this situation, no gateway is needed. ESP-BLE-MESH network is a flooded network, messages in the network have no fixed paths, and nodes can communicate with each other freely.
- Situation 2: if users want to control the nodes remotely, for example turn on some nodes before getting home, then a gateway is needed.

Espressif Systems 2336 Release v5.1.1

Submit Document Feedback
2.19 When will the IV Update procedure be performed?

IV Update procedure would be performed once sequence number of messages sent detected by the bottom layer of node reached a critical value.

2.20 How to perform IV Update procedure?

Nodes can perform IV Update procedure with Secure Network Beacon.

3. ESP-BLE-MESH and Wi-Fi Coexistence

3.1 Which modes does Wi-Fi support when it coexists with ESP-BLE-MESH?

Currently only Wi-Fi station mode supports the coexistence.

3.2 Why is the Wi-Fi throughput so low when Wi-Fi and ESP-BLE-MESH coexist?

The ESP32-DevKitC board without PSRAM can run properly but the throughput of it is low since it has no PSRAM. When Bluetooth and Wi-Fi coexist, the throughput of ESP32-DevKitC with PSRAM can be stabilized to more than 1Mbps.

Some configurations in menuconfig shall be enabled to support PSRAM:

- ESP32-specific --> Support for external, SPI-connected RAM --> Try to allocate memories of Wi-Fi and LWIP...
- Bluetooth --> Bluedroid Enable --> BT/BLE will first malloc the memory from the PSRAM
- Bluetooth --> Bluedroid Enable --> Use dynamic memory allocation in BT/BLE stack.
- Bluetooth --> Bluetooth controller --> BLE full scan feature supported.
- Wi-Fi --> Software controls Wi-Fi/Bluetooth coexistence --> Wi-Fi

4. Fast Provisioning

4.1 Why is fast provisioning needed?

Normally when they are several unprovisioned devices, users can provision them one by one. But when it comes to a large number of unprovisioned devices (e.g. 100), provisioning them one by one will take huge amount of time. With fast provisioning, users can provision 100 unprovisioned devices in about 50 seconds.

4.2 Why EspBleMesh App would wait for a long time during fast provisioning?

After the App provisioned one Proxy node, it will disconnect from the App during fast provisioning, and reconnect with the App when all the nodes are provisioned.

4.3 Why is the number of node addresses displayed in the App is more than that of existing node addresses?

Each time after a fast provisioning process, and before starting a new one, the node addresses in the App should be cleared, otherwise the number of the node address will be incorrect.

4.4 What is the usage of the count value which was input in EspBleMesh App?

The count value is provided to the Proxy node which is provisioned by the App so as to determine when to start Proxy advertising in advance.
4.5 When will Configuration Client Model of the node running fast_prov_server example start to work?

Configuration Client Model will start to work after the Temporary Provisioner functionality is enabled.

4.6 Will the Temporary Provisioner functionality be enabled all the time?

After the nodes receive messages used to turn on/off lights, all the nodes will disable its Temporary Provisioner functionality and become nodes.

5. Log Help  You can find meaning of errors or warnings when they appear at the bottom of ESP-BLE-MESH stack.

5.1 What is the meaning of warning ran out of retransmit attempts?

When the node transmits a segmented message, and due to some reasons, the receiver doesn’t receive the complete message. Then the node will retransmit the message. When the retransmission count reaches the maximum number, which is 4 currently, then this warning will appear.

5.2 What is the meaning of warning Duplicate found in Network Message Cache?

When the node receives a message, it will compare the message with the ones stored in the network cache. If the same has been found in the cache, which means it has been received before, then the message will be dropped.

5.3 What is the meaning of warning Incomplete timer expired?

When the node doesn’t receive all the segments of a segmented message during a certain period (e.g. 10 seconds), then the Incomplete timer will expire and this warning will appear.

5.4 What is the meaning of warning No matching TX context for ack?

When the node receives a segment ack and it doesn’t find any self-send segmented message related with this ack, then this warning will appear.

5.5 What is the meaning of warning No free slots for new incoming segmented messages?

When the node has no space for receiving new segmented message, this warning will appear. Users can make the space larger through the configuration CONFIG_BLE_MESH_RX_SEC_MSG_COUNT.

5.6 What is the meaning of error Model not bound to Appkey 0x0000?

When the node sends messages with a model and the model has not been bound to the AppKey with AppKey Index 0x000, then this error will appear.

5.7 What is the meaning of error Busy sending message to DST xxxx?

This error means client model of the node has transmitted a message to the target node and now is waiting for a response, users can not send messages to the same node with the same unicast address. After the corresponding response is received or timer is expired, then another message can be sent.

6. Example Help
Chapter 4  API Guides

6.1 How are the ESP-BLE-MESH callback functions classified?

- The API `esp_ble_mesh_register_prov_callback()` is used to register callback function used to handle provisioning and networking related events.
- The API `esp_ble_mesh_register_config_client_callback()` is used to register callback function used to handle Configuration Client Model related events.
- The API `esp_ble_mesh_register_config_server_callback()` is used to register callback function used to handle Configuration Server Model related events.
- The API `esp_ble_mesh_register_health_client_callback()` is used to register callback function used to handle Health Client Model related events.
- The API `esp_ble_mesh_register_health_server_callback()` is used to register callback function used to handle Health Server Model related events.
- The API `esp_ble_mesh_register_generic_client_callback()` is used to register callback function used to handle Generic Client Models related events.
- The API `esp_ble_mesh_register_light_client_callback()` is used to register callback function used to handle Lighting Client Models related events.
- The API `esp_ble_mesh_register_sensor_client_callback()` is used to register callback function used to handle Sensor Client Model related events.
- The API `esp_ble_mesh_register_time_scene_client_callback()` is used to register callback function used to handle Time and Scenes Client Models related events.
- The API `esp_ble_mesh_register_custom_model_callback()` is used to register callback function used to handle vendor model and unrealized server models related events.

7. Others

7.1 How to print the message context?

The examples use `ESP_LOG_BUFFER_HEX()` to print the message context while the ESP-BLE-MESH protocol stack uses `bt_hex()`.

7.2 Which API can be used to restart ESP32?

The API `esp_restart()`.

7.3 How to monitor the remaining space of the stack of a task?

The API `vTaskList()` can be used to print the remaining space of the task stack periodically.

7.4 How to change the level of log without changing the menuconfig output level?

The API `esp_log_level_set()` can be used to change the log output level rather than using menuconfig to change it.

ESP-BLE-MESH Terminology
<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unprovisioned Device</td>
<td>A device that is not a member of a mesh network is known as an unprovisioned device.</td>
<td>Examples: lighting devices, temperature control devices, manufacturing equipments and electric doors, etc.</td>
</tr>
<tr>
<td>Node</td>
<td>A node is a provisioned device.</td>
<td>The role of unprovisioned device will change to node after being provisioned to ESP-BLE-MESH network. Nodes (such as lighting devices, temperature control devices, manufacturing equipments, and electric doors) are devices that can send, receive, or relay messages in ESP-BLE-MESH network, and they can optionally support one or more subnets.</td>
</tr>
<tr>
<td>Relay Node</td>
<td>A node that supports the Relay feature and has the Relay feature enabled is known as a Relay node.</td>
<td>Relay nodes can receive and resend ESP-BLE-MESH messages, so the messages can be transferred further. Users can decide whether or not to enable forwarding function of nodes according to nodes’ status. Messages can be relayed for multiple times, and each relay is considered as a “hop”. Messages can hop up to 126 times, which is enough for message transmission in a wide area.</td>
</tr>
<tr>
<td>Proxy Node</td>
<td>A node that supports the Proxy feature and has the Proxy feature enabled is known as a Proxy node.</td>
<td>Proxy nodes receive messages from one bearer (it generally includes advertising bearer and GATT bearer) and resend it from another one. The purpose is to connect communication equipments that only support GATT bearer to ESP-BLE-MESH network. Generally, mobile apps need a Proxy node to access Mesh network. Without Proxy nodes, mobile apps cannot communicate with members in Mesh network.</td>
</tr>
<tr>
<td>Friend Node</td>
<td>A node that supports the Friend feature, has the Friend feature enabled, and has a friendship with a node that supports the Low Power feature is known as a Friend node.</td>
<td>Friend node, like the backup of Low Power node (LPN), can store messages that are sent to Low Power node and security updates; the stored information will be transferred to Low Power node when Low Power node needs it. Low Power node must establish “friendship” with another node that supports the Friend Feature to reduce duty cycle of its receiver, thus power consumption of Low Power node can be reduced. Low Power node needs to find a Friend node to establish a friendship with it. The process involved is called “friendship establishment”. Cooperation between Low Power node and Friend nodes enables Low Power node to schedule the use of the radio, thus Low Power node can receive messages at an appropriate or lower frequency without the need of keeping listening. Low Power node will poll Friend node to see if there is new message.</td>
</tr>
<tr>
<td>Low Power Node</td>
<td>A node that supports the Low Power feature and has a friendship with a node that supports the Friend feature is known as a Low Power node.</td>
<td>By polling, Low Power node gets information from Friend node, such as messages, security updates, and etc.</td>
</tr>
<tr>
<td>Provisioner</td>
<td>A node that is capable of adding a device to a mesh network.</td>
<td>The device that can provision unprovisioned devices is called a Provisioner. This process usually needs to be implemented through an app that is typically provided by the product manufacturer and can be used on a gateway, a smartphone, tablet or other carriers.</td>
</tr>
</tbody>
</table>
Table 14: Table 2 ESP-BLE-MESH Terminology - Composition

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>State</td>
<td>A value representing a condition of an element that is exposed by an element of a node.</td>
<td>Each node in a ESP-BLE-MESH network has an independent set of state values that indicate certain states of the device, like brightness, and color of lighting device. Change of state value will lead to change of the physical state of devices. For example, changing the on/off state of a device is actually turning on/off the device.</td>
</tr>
<tr>
<td>Model</td>
<td>A model defines the basic functionality of a node.</td>
<td>A node may contain multiple models, and each model defines basic functionalities of nodes, like the states needed by the nodes, the messages controlling the states, and actions resulted from messages handling. The function implementation of the nodes is based on models, which can be divided into SIG Model and Vendor Model, with the former defined by SIG and latter defined by users.</td>
</tr>
<tr>
<td>Element</td>
<td>An addressable entity within a device.</td>
<td>A node can contain one or more elements, with each having a unicast address and one or more models, and the models contained by the same element must not be the same.</td>
</tr>
<tr>
<td>Composition Data State</td>
<td>The Composition Data state contains information about a node, the elements it includes, and the supported models.</td>
<td>By reading the value of the Composition Data state, users can know basic information of the node, such as the number of elements, and the models in each element. Provisioner gets this message to further provision the device, such as configuring subscription address and publishing address of nodes.</td>
</tr>
</tbody>
</table>

Table 15: Table 3 ESP-BLE-MESH Terminology - Features

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low Power Feature</td>
<td>The ability to operate within a mesh network at significantly reduced receiver duty cycles only in conjunction with a node supporting the Friend feature.</td>
<td>Low Power feature reduces power consumption of nodes. When a Low Power node is searching for a Friend node, and there are multiple Friend nodes nearby, it selects the most suitable Friend node through algorithm.</td>
</tr>
<tr>
<td>Friend Feature</td>
<td>The ability to help a node supporting the Low Power feature to operate by storing messages destined for those nodes.</td>
<td>By enabling friend feature, the node can help to store information for Low Power node. The nodes enabled with friend feature may cause more power and memory consumption.</td>
</tr>
<tr>
<td>Relay Feature</td>
<td>The ability to receive and retransmit mesh messages over the advertising bearer to enable larger networks.</td>
<td>The relay feature enables ESP-BLE-MESH messages to hop among nodes for multiple times, and the transmission distance can exceed the range of direct radio transmission between two nodes, thereby covering the entire network. When a node is enabled with the relay feature to relay messages, it only relays the messages of its own subnet, and does not relay the messages of other subnets. The data integrity will not be considered when the node enabled with relay feature relays segmented messages. The node would relay every segmented message once it receives one rather than waiting for the complete message.</td>
</tr>
<tr>
<td>Proxy Feature</td>
<td>The ability to receive and retransmit mesh messages between GATT and advertising bearers.</td>
<td>The purpose of the proxy feature is to allow nodes without an advertising bearer to access the ESP-BLE-MESH network. The proxy feature is typically used in nodes that need to connect to mobile apps.</td>
</tr>
</tbody>
</table>
Table 16: Table 4 ESP-BLE-MESH Terminology - Provisioning

<table>
<thead>
<tr>
<th>Term</th>
<th>Official Definition</th>
<th>Detailed Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>PB-ADV</td>
<td>PB-ADV is a provisioning bearer used to provision a device using Generic Provisioning PDUs over the advertising channels.</td>
<td>PB-ADV transfers packets generated during the provisioning process over the advertising channels. This way can only be used for provisioning when provisioner and unprovisioned device both support PB-ADV.</td>
</tr>
<tr>
<td>PB-GATT</td>
<td>PB-GATT is a provisioning bearer used to provision a device using Proxy PDUs to encapsulate Provisioning PDUs within the Mesh Provisioning Service.</td>
<td>PB-GATT uses connection channels to transfer packets generated during the provisioning process. If an unprovisioned device wants to be provisioned through this method, it needs to implement the related Mesh Provisioning Service. Unprovisioned devices which don’t implement such service cannot be provisioned into mesh network through PB-GATT bearer.</td>
</tr>
<tr>
<td>Provisioning</td>
<td>Provisioning is a process of adding an unprovisioned device to a mesh network, managed by a Provisioner.</td>
<td>The process of provisioning turns the “unprovisioned device” into a “node”, making it a member of the ESP-BLE-MESH network.</td>
</tr>
<tr>
<td>Authentication Method</td>
<td>Authentication is a step during the provisioning of nodes.</td>
<td>There are four authentication methods for unprovisioned devices: Output OOB, Input OOB, Static OOB, and No OOB.</td>
</tr>
<tr>
<td>Input OOB</td>
<td>Input Out-of-Band</td>
<td>For example, a Provisioner generates and displays a random number, and then prompts users to take appropriate actions to input the random number into the unprovisioned device. Taking lighting switch as an example, users can press the button for several times in a certain period of time to input the random number displayed on the Provisioner. Authentication method of the Input OOB is similar to that of Output OOB, but the role of the device is reversed.</td>
</tr>
<tr>
<td>Output OOB</td>
<td>Output Out-of-Band</td>
<td>For example, an unprovisioned device will choose a random number and output the number in a way that is compatible with its functionality. If the unprovisioned device is a bulb, it can flash a specified number of times. If the unprovisioned device has an LCD screen, the random number can display as a multi-digit value. Users who start provisioning should input the observed number to authenticate the unprovisioned device.</td>
</tr>
<tr>
<td>Static OOB</td>
<td>Static Out-of-Band</td>
<td>Authentication method of Static OOB: use Static OOB information. Use 0 as Static OOB information if No OOB information is needed. Use Static OOB information to authenticate devices which are going through provisioning if OOB information is needed.</td>
</tr>
<tr>
<td>No OOB</td>
<td>No Out-of-Band</td>
<td>Authentication method of No OOB: Set the value of the Static OOB field to 0. Using this way is like not authenticating the unprovisioned devices.</td>
</tr>
</tbody>
</table>

<tbody>
<tr>
<td>Unassigned Address</td>
<td>This is a special address type, with a value of 0x0000. Its use indicates that an Element has not yet been configured or had a Unicast Address assigned to it.</td>
<td>The addresses owned by elements which has not been configured yet or no address has been allocated are unassigned addresses. These elements will not be used for messages transfer because they have no fixed address. Unassigned address is recommended to set as the value of the address before setting the address of user code.</td>
</tr>
<tr>
<td>Unicast Address</td>
<td>A unicast address is a unique address allocated to each element.</td>
<td>During provisioning, the Provisioner will assign a unicast address to each element of node within the life cycle of the nodes in the network. A unicast address may appear in the source/destination address field of a message. Messages sent to a unicast address can only be processed by the element that owns the unicast address.</td>
</tr>
<tr>
<td>Virtual Address</td>
<td>A virtual address represents a set of destination addresses. Each virtual address logically represents a Label UUID, which is a 128-bit value that does not have to be managed centrally.</td>
<td>Associated with specific UUID labels, a virtual address may serve as the publishing or subscription address of the model. A UUID label is a 128-bit value associated with elements of one or more nodes. For virtual addresses, the 15th and 14th bits are set to 1 and 0 respectively; bits from 13th to 0 are set to hash values (providing 16384 hash values). The hash is a derivation of the Label UUID. To use subscribing elements to check the full 128-bit UUID is very inefficient while hash values provide a more efficient way to determine which elements that which messages are finally sent to.</td>
</tr>
<tr>
<td>Group Address</td>
<td>A group address is an address that is programmed into zero or more elements</td>
<td>Group address is another kind of multicast address in the ESP-BLE-MESH network, which is usually used to group nodes. A message sent to the all-proxies address shall be processed by the primary element of all nodes that have the proxy functionality enabled. A message sent to the all-friends address shall be processed by the primary element of all nodes that have the friend functionality enabled. A message sent to the all-relays address shall be processed by the primary element of all nodes that have the relay functionality enabled. A message sent to the all-nodes address shall be processed by the primary element of all nodes.</td>
</tr>

<tr>
<td>Device Key (DevKey)</td>
<td>There is also a device key, which is a special application key that is unique to each node, is known only to the node and a Configuration Client, and is used to secure communications between the node and a Configuration Client.</td>
<td>The device key enables you to provision the devices, configure the nodes. The device key is used to encrypt Configuration Messages, i.e. the message transferred between the Provisioner and the node when the device is configured.</td>
</tr>
<tr>
<td>Application Key (AppKey)</td>
<td>Application keys are used to secure communications at the upper transport layer.</td>
<td>Application key is used for decryption of application data before delivering application data to application layer and encryption of them during the delivery of application layer. Some nodes in the network have a specific purpose and can restrict access to potentially sensitive data based on the needs of the application. With specific application keys, these nodes are associated with specific applications. Generally speaking, the fields using different application keys include security (access control of buildings, machine rooms and CEO offices), lighting (plant, exterior building and sidewalks) and HVAC systems. Application keys are bound to Network keys. This means application keys are only used in a context of a Network key they are bound to. An application key shall only be bound to a single Network key.</td>
</tr>
<tr>
<td>Master Security Material</td>
<td>The master security material is derived from the network key (NetKey) and can be used by other nodes in the same network. Messages encrypted with master security material can be decoded by any node in the same network.</td>
<td>The corresponding friendship messages encrypted with the friendship security material: 1. Friend Poll, 2. Friend Update, 3. Friend Subscription List, add/delete/confirm, 4. The Stored Messages sent by friend nodes to Low Power node. The corresponding friendship messages encrypted with the master security material: 1. Friend Clear, 2. Friend Clear Confirm. Based on the setup of the applications, the messages sent from the Low Power node to the friend nodes will be encrypted with the friendship security material or master security material, with the former being used by the messages transmitted between Low Power node and friend nodes and the latter being used by other network messages.</td>
</tr>

<tr>
<td>Key Refresh procedure</td>
<td>This procedure is used when the security of one or more network keys and/or one or more of the application keys has been compromised or could be compromised.</td>
<td>Key Refresh Procedure is used to update network key and application key of ESP-BLE-MESH network. Key Refresh Procedure is used when the security of one or more network keys and/or one or more application keys is threatened or potentially threatened. Keys are usually updated after some nodes in the network are removed.</td>
</tr>
<tr>
<td>IV (Initialisation Vector)</td>
<td>A node can also use an IV Update procedure to signal to peer nodes that it is updating the IV Index.</td>
<td>The IV Update procedure is used to update the value of ESP-BLE-MESH network’s IV Index. This value is related to the random number required for message encryption. To ensure that the value of the random number is not repeated, this value is periodically incremented. IV Index is a 32-bit value and a shared network resource. For example, all nodes in a mesh network share the same IV Index value. Starting from 0x00000000, the IV Index increments during the IV Update procedure and maintained by a specific process, ensuring the IV Index shared in the mesh network is the same. This can be done when the node believes that it has the risk of exhausting its sequence number, or when it determines that another node is nearly exhausting its sequence number. Note: The update time must not be less than 96 hours. It can be triggered when a secure network beacon is received, or when the node determines that its sequence number is greater than a certain value.</td>

4.12 ESP-WIFI-MESH

This guide provides information regarding the ESP-WIFI-MESH protocol. Please see the ESP-WIFI-MESH API Reference for more information about API usage.

4.12.1 Overview

ESP-WIFI-MESH is a networking protocol built atop the Wi-Fi protocol. ESP-WIFI-MESH allows numerous devices (henceforth referred to as nodes) spread over a large physical area (both indoors and outdoors) to be interconnected under a single WLAN (Wireless Local-Area Network). ESP-WIFI-MESH is self-organizing and self-healing meaning the network can be built and maintained autonomously.

The ESP-WIFI-MESH guide is split into the following sections:

1. Introduction
2. ESP-WIFI-MESH Concepts
3. Building a Network
4. Managing a Network
5. Data Transmission
6. Channel Switching
7. Performance
8. Further Notes

4.12.2 Introduction

Fig. 21: Traditional Wi-Fi Network Architecture
A traditional infrastructure Wi-Fi network is a point-to-multipoint network where a single central node known as the access point (AP) is directly connected to all other nodes known as stations. The AP is responsible for arbitrating and forwarding transmissions between the stations. Some APs also relay transmissions to/from an external IP network via a router. Traditional infrastructure Wi-Fi networks suffer the disadvantage of limited coverage area due to the requirement that every station must be in range to directly connect with the AP. Furthermore, traditional Wi-Fi networks are susceptible to overloading as the maximum number of stations permitted in the network is limited by the capacity of the AP.

ESP-WIFI-MESH differs from traditional infrastructure Wi-Fi networks in that nodes are not required to connect to a central node. Instead, nodes are permitted to connect with neighboring nodes. Nodes are mutually responsible for relaying each other's transmissions. This allows an ESP-WIFI-MESH network to have much greater coverage area as nodes can still achieve interconnectivity without needing to be in range of the central node. Likewise, ESP-WIFI-MESH is also less susceptible to overloading as the number of nodes permitted on the network is no longer limited by a single central node.

</table>

### Tree Topology

ESP-WIFI-MESH is built atop the infrastructure Wi-Fi protocol and can be thought of as a networking protocol that combines many individual Wi-Fi networks into a single WLAN. In Wi-Fi, stations are limited to a single connection with an AP (upstream connection) at any time, whilst an AP can be simultaneously connected to multiple stations (downstream connections). However ESP-WIFI-MESH allows nodes to simultaneously act as a station and an AP. Therefore a node in ESP-WIFI-MESH can have **multiple downstream connections using its softAP interface**, whilst simultaneously having a **single upstream connection using its station interface**. This naturally results in a tree network topology with a parent-child hierarchy consisting of multiple layers.

ESP-WIFI-MESH is a multiple hop (multi-hop) network meaning nodes can transmit packets to other nodes in the network through one or more wireless hops. Therefore, nodes in ESP-WIFI-MESH not only transmit their own packets, but simultaneously serve as relays for other nodes. Provided that a path exists between any two nodes on the physical layer (via one or more wireless hops), any pair of nodes within an ESP-WIFI-MESH network can communicate.

**Note:** The size (total number of nodes) in an ESP-WIFI-MESH network is dependent on the maximum number of layers permitted in the network, and the maximum number of downstream connections each node can have. Both of these variables can be configured to limit the size of the network.

### Node Types

**Root Node:** The root node is the top node in the network and serves as the only interface between the ESP-WIFI-MESH network and an external IP network. The root node is connected to a conventional Wi-Fi router and relays packets to/from the external IP network to nodes within the ESP-WIFI-MESH network. **There can only be one root node within an ESP-WIFI-MESH network** and the root node’s upstream connection may only be with the router. Referring to the diagram above, node A is the root node of the network.
Fig. 23: ESP-WIFI-MESH Tree Topology

Fig. 24: ESP-WIFI-MESH Node Types
Leaf Nodes: A leaf node is a node that is not permitted to have any child nodes (no downstream connections). Therefore a leaf node can only transmit or receive its own packets, but cannot forward the packets of other nodes. If a node is situated on the network’s maximum permitted layer, it will be assigned as a leaf node. This prevents the node from forming any downstream connections thus ensuring the network does not add an extra layer. Some nodes without a softAP interface (station only) will also be assigned as leaf nodes due to the requirement of a softAP interface for any downstream connections. Referring to the diagram above, nodes L/M/N are situated on the networks maximum permitted layer hence have been assigned as leaf nodes.

Intermediate Parent Nodes: Connected nodes that are neither the root node or a leaf node are intermediate parent nodes. An intermediate parent node must have a single upstream connection (a single parent node), but can have zero to multiple downstream connections (zero to multiple child nodes). Therefore an intermediate parent node can transmit and receive packets, but also forward packets sent from its upstream and downstream connections. Referring to the diagram above, nodes B to J are intermediate parent nodes. Intermediate parent nodes without downstream connections such as nodes E/F/G/I/J are not equivalent to leaf nodes as they are still permitted to form downstream connections in the future.

Idle Nodes: Nodes that have yet to join the network are assigned as idle nodes. Idle nodes will attempt to form an upstream connection with an intermediate parent node or attempt to become the root node under the correct circumstances (see Automatic Root Node Selection). Referring to the diagram above, nodes K and O are idle nodes.

Beacon Frames & RSSI Thresholding

Every node in ESP-WIFI-MESH that is able to form downstream connections (i.e. has a softAP interface) will periodically transmit Wi-Fi beacon frames. A node uses beacon frames to allow other nodes to detect its presence and know of its status. Idle nodes will listen for beacon frames to generate a list of potential parent nodes, one of which the idle node will form an upstream connection with. ESP-WIFI-MESH uses the Vendor Information Element to store metadata such as:

- Node Type (Root, Intermediate Parent, Leaf, Idle)
- Current layer of Node
- Maximum number of layers permitted in the network
- Current number of child nodes
- Maximum number of downstream connections to accept

The signal strength of a potential upstream connection is represented by RSSI (Received Signal Strength Indication) of the beacon frames of the potential parent node. To prevent nodes from forming a weak upstream connection, ESP-WIFI-MESH implements an RSSI threshold mechanism for beacon frames. If a node detects a beacon frame with an RSSI below a preconfigured threshold, the transmitting node will be disregarded when forming an upstream connection.

Panel A of the illustration above demonstrates how the RSSI threshold affects the number of parent node candidates an idle node has.

Panel B of the illustration above demonstrates how an RF shielding object can lower the RSSI of a potential parent node. Due to the RF shielding object, the area in which the RSSI of node X is above the threshold is significantly reduced. This causes the idle node to disregard node X even though node X is physically adjacent. The idle node will instead form an upstream connection with the physically distant node Y due to a stronger RSSI.

Note: Nodes technically still receive all beacon frames on the MAC layer. The RSSI threshold is an ESP-WIFI-MESH feature that simply filters out all received beacon frames that are below the preconfigured threshold.

Preferred Parent Node

When an idle node has multiple parent nodes candidates (potential parent nodes), the idle node will form an upstream connection with the preferred parent node. The preferred parent node is determined based on the following criteria:

- Which layer the parent node candidate is situated on
- The number of downstream connections (child nodes) the parent node candidate currently has
The selection of the preferred parent node will always prioritize the parent node candidate on the shallowest layer of the network (including the root node). This helps minimize the total number of layers in an ESP-WIFI-MESH network when upstream connections are formed. For example, given a second layer node and a third layer node, the second layer node will always be preferred.

If there are multiple parent node candidates within the same layer, the parent node candidate with the least child nodes will be preferred. This criteria has the effect of balancing the number of downstream connections amongst nodes of the same layer.

Panel A of the illustration above demonstrates an example of how the idle node G selects a preferred parent node given the five parent node candidates B/C/D/E/F. Nodes on the shallowest layer are preferred, hence nodes B/C are prioritized since they are second layer nodes whereas nodes D/E/F are on the third layer. Node C is selected as the preferred parent node due it having fewer downstream connections (fewer child nodes) compared to node B.

Panel B of the illustration above demonstrates the case where the root node is within range of the idle node G.
other words, the root node’s beacon frames are above the RSSI threshold when received by node G. The root node is always the shallowest node in an ESP-WIFI-MESH network hence is always the preferred parent node given multiple parent node candidates.

**Note:** Users may also define their own algorithm for selecting a preferred parent node, or force a node to only connect with a specific parent node (see the Mesh Manual Networking Example).

### Routing Tables

Each node within an ESP-WIFI-MESH network will maintain its individual routing table used to correctly route ESP-WIFI-MESH packets (see ESP-WIFI-MESH Packet) to the correct destination node. The routing table of a particular node will consist of the MAC addresses of all nodes within the particular node’s subnetwork (including the MAC address of the particular node itself). Each routing table is internally partitioned into multiple subtables with each subtable corresponding to the subnetwork of each child node.

![Fig. 27: ESP-WIFI-MESH Routing Tables Example](image)

Using the diagram above as an example, the routing table of node B would consist of the MAC addresses of nodes B to I (i.e. equivalent to the subnetwork of node B). Node B’s routing table is internally partitioned into two subtables containing of nodes C to F and nodes G to I (i.e. equivalent to the subnetworks of nodes C and G respectively).

**ESP-WIFI-MESH** utilizes routing tables to determine whether an ESP-WIFI-MESH packet should be forwarded upstream or downstream based on the following rules.

1. If the packet’s destination MAC address is within the current node’s routing table and is not the current node, select the subtable that contains the destination MAC address and forward the data packet downstream to the child node corresponding to the subtable.

2. If the destination MAC address is not within the current node’s routing table, forward the data packet upstream to the current node’s parent node. Doing so repeatedly will result in the packet arriving at the root node where the routing table should contain all nodes within the network.

**Note:** Users can call `esp_mesh_get_routing_table()` to obtain a node’s routing table, or `esp_mesh_get_routing_table_size()` to obtain the size of a node’s routing table. `esp_mesh_get_subnet_nodes_list()` can be used to obtain the corresponding subtable of a specific child node. Likewise `esp_mesh_get_subnet_nodes_num()` can be used to obtain the size of the
4.12.4 Building a Network

General Process

Warning: Before the ESP-WIFI-MESH network building process can begin, certain parts of the configuration must be uniform across each node in the network (see mesh_cfg_t). Each node must be configured with the same Mesh Network ID, router configuration, and softAP configuration.

An ESP-WIFI-MESH network building process involves selecting a root node, then forming downstream connections layer by layer until all nodes have joined the network. The exact layout of the network can be dependent on factors such as root node selection, parent node selection, and asynchronous power-on reset. However, the ESP-WIFI-MESH network building process can be generalized into the following steps:

1. **Root Node Selection** The root node can be designated during configuration (see section on User Designated Root Node), or dynamically elected based on the signal strength between each node and the router (see Automatic Root Node Selection). Once selected, the root node will connect with the router and begin allowing downstream connections to form. Referring to the figure above, node A is selected to be the root node hence node A forms an upstream connection with the router.

2. **Second Layer Formation** Once the root node has connected to the router, idle nodes in range of the root node will begin connecting with the root node thereby forming the second layer of the network. Once connected, these second layer nodes become intermediate parent nodes (assuming maximum permitted layers > 2) hence the next layer to form. Referring to the figure above, nodes B to D are in range of the root node. Therefore nodes B to D form upstream connections with the root node and become intermediate parent nodes.

3. **Formation of remaining layers** The remaining idle nodes will connect with intermediate parent nodes within range thereby forming a new layer in the network. Once connected, the idles nodes become intermediate parent node or leaf nodes depending on the networks maximum permitted layers. This step is repeated until there are no more idle nodes.
nodes within the network or until the maximum permitted layer of the network has been reached. Referring to the figure above, nodes E/F/G connect with nodes B/C/D respectively and become intermediate parent nodes themselves.

4. Limiting Tree Depth  To prevent the network from exceeding the maximum permitted number of layers, nodes on the maximum layer will automatically become leaf nodes once connected. This prevents any other idle node from connecting with the leaf node thereby prevent a new layer form forming. However if an idle node has no other potential parent node, it will remain idle indefinitely. Referring to the figure above, the network’s number of maximum permitted layers is set to four. Therefore when node H connects, it becomes a leaf node to prevent any downstream connections from forming.

Automatic Root Node Selection

The automatic selection of a root node involves an election process amongst all idle nodes based on their signal strengths with the router. Each idle node will transmit their MAC addresses and router RSSI values via Wi-Fi beacon frames. The MAC address is used to uniquely identify each node in the network whilst the router RSSI is used to indicate a node’s signal strength with reference to the router.

Each node will then simultaneously scan for the beacon frames from other idle nodes. If a node detects a beacon frame with a stronger router RSSI, the node will begin transmitting the contents of that beacon frame (i.e. voting for the node with the stronger router RSSI). The process of transmission and scanning will repeat for a preconfigured minimum number of iterations (10 iterations by default) and result in the beacon frame with the strongest router RSSI being propagated throughout the network.

After all iterations, each node will individually check for its vote percentage (number of votes/number of nodes participating in election) to determine if it should become the root node. If a node has a vote percentage larger than a preconfigured threshold (90% by default), the node will become a root node.

The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is automatically selected.

1. On power-on reset, each node begins transmitting beacon frames consisting of their own MAC addresses and their router RSSIs.
2. Over multiple iterations of transmission and scanning, the beacon frame with the strongest router RSSI is propagated throughout the network. Node C has the strongest router RSSI (-10 dB) hence its beacon frame is propagated.

Fig. 29: Root Node Election Example
throughout the network. All nodes participating in the election vote for node C thus giving node C a vote percentage of 100%. Therefore node C becomes a root node and connects with the router.

3. Once Node C has connected with the router, nodes A/B/D/E connect with node C as it is the preferred parent node (i.e. the shallowest node). Nodes A/B/D/E form the second layer of the network.

4. Node F and G connect with nodes D and E respectively and the network building process is complete.

**Note:** The minimum number of iterations for the election process can be configured using `esp_mesh_set_attempts()`. Users should adjust the number of iterations based on the number of nodes within the network (i.e. the larger the network the larger number of scan iterations required).

**Warning:** Vote percentage threshold can also be configured using `esp_mesh_set_vote_percentage()`. Setting a low vote percentage threshold can result in two or more nodes becoming root nodes within the same ESP-WIFI-MESH network leading to the building of multiple networks. If such is the case, ESP-WIFI-MESH has internal mechanisms to autonomously resolve the root node conflict. The networks of the multiple root nodes will be combined into a single network with a single root node. However, root node conflicts where two or more root nodes have the same router SSID but different router BSSID are not handled.

**User Designated Root Node**

The root node can also be designated by user which will entail the designated root node to directly connect with the router and forgo the election process. When a root node is designated, all other nodes within the network must also forgo the election process to prevent the occurrence of a root node conflict. The following diagram demonstrates how an ESP-WIFI-MESH network is built when the root node is designated by the user.

![Root Node Designation Example](image)

1. Node A is designated the root node by the user therefore directly connects with the router. All other nodes forgo the election process.

2. Nodes C/D connect with node A as their preferred parent node. Both nodes form the second layer of the network.
3. Likewise, nodes B/E connect with node C, and node F connects with node D. Nodes B/E/F form the third layer of the network.

4. Node G connects with node E, forming the fourth layer of the network. However the maximum permitted number of layers in this network is configured as four, therefore node G becomes a leaf node to prevent any new layers from forming.

**Note:** When designating a root node, the root node should call `esp_mesh_set_parent()` in order to directly connect with the router. Likewise, all other nodes should call `esp_mesh_fix_root()` to forgo the election process.

---

### Parent Node Selection

By default, ESP-WIFI-MESH is self-organizing meaning that each node will autonomously select which potential parent node to form an upstream connection with. The autonomously selected parent node is known as the preferred parent node. The criteria used for selecting the preferred parent node is designed to reduce the number of layers in the ESP-WIFI-MESH network and to balance the number of downstream connections between potential parent nodes (see section on **Preferred Parent Node**).

However ESP-WIFI-MESH also allows users to disable self-organizing behavior which will allow users to define their own criteria for parent node selection, or to configure nodes to have designated parent nodes (see the **Mesh Manual Networking Example**).

### Asynchronous Power-on Reset

ESP-WIFI-MESH network building can be affected by the order in which nodes power-on. If certain nodes within the network power-on asynchronously (i.e. separated by several minutes), the final structure of the network could differ from the ideal case where all nodes are powered on synchronously. Nodes that are delayed in powering on will adhere to the following rules:

**Rule 1:** If a root node already exists in the network, the delayed node will not attempt to elect a new root node, even if it has a stronger RSSI with the router. The delayed node will instead join the network like any other idle node by connecting with a preferred parent node. If the delayed node is the designated root node, all other nodes in the network will remain idle until the delayed node powers-on.

**Rule 2:** If a delayed node forms an upstream connection and becomes an intermediate parent node, it may also become the new preferred parent of other nodes (i.e. being a shallower node). This will cause the other nodes to switch their upstream connections to connect with the delayed node (see **Parent Node Switching**).

**Rule 3:** If an idle node has a designated parent node which is delayed in powering-on, the idle node will not attempt to form any upstream connections in the absence of its designated parent node. The idle node will remain idle indefinitely until its designated parent node powers-on.

The following example demonstrates the effects of asynchronous power-on with regards to network building.

1. Nodes A/C/D/F/G/H are powered-on synchronously and begin the root node election process by broadcasting their MAC addresses and router RSSIs. Node A is elected as the root node as it has the strongest RSSI.

2. Once node A becomes the root node, the remaining nodes begin forming upstream connections layer by layer with their preferred parent nodes. The result is a network with five layers.

3. Node B/E are delayed in powering-on but neither attempt to become the root node even though they have stronger router RSSIs (-20 dB and -10 dB) compared to node A. Instead both delayed nodes form upstream connections with their preferred parent nodes A and C respectively. Both nodes B/E become intermediate parent nodes after connecting.

4. Nodes D/G switch their upstream connections as node B is the new preferred parent node due to it being on a shallower layer (second layer node). Due to the switch, the resultant network has three layers instead of the original five layers.
Fig. 31: Network Building with Asynchronous Power On Example
**Synchronous Power-On:** Had all nodes powered-on synchronously, node E would have become the root node as it has the strongest router RSSI (-10 dB). This would result in a significantly different network layout compared to the network formed under the conditions of asynchronous power-on. **However the synchronous power-on network layout can still be reached if the user manually switches the root node** (see `esp_mesh_waive_root()`).

**Note:** Differences in parent node selection caused by asynchronous power-on are autonomously corrected for to some extent in ESP-WIFI-MESH (see *Parent Node Switching*).

---

**Loop-back Avoidance, Detection, and Handling**

A loop-back is the situation where a particular node forms an upstream connection with one of its descendant nodes (a node within the particular node’s subnetwork). This results in a circular connection path thereby breaking the tree topology. ESP-WIFI-MESH prevents loop-back during parent selection by excluding nodes already present in the selecting node’s routing table (see *Routing Tables*) thus prevents a particular node from attempting to connect to any node within its subnetwork.

In the event that a loop-back occurs, ESP-WIFI-MESH utilizes a path verification mechanism and energy transfer mechanism to detect the loop-back occurrence. The parent node of the upstream connection that caused the loop-back will then inform the child node of the loop-back and initiate a disconnection.

---

4.12.5 Managing a Network

ESP-WIFI-MESH is a self-healing network meaning it can detect and correct for failures in network routing. Failures occur when a parent node with one or more child nodes breaks down, or when the connection between a parent node and its child nodes becomes unstable. Child nodes in ESP-WIFI-MESH will autonomously select a new parent node and form an upstream connection with it to maintain network interconnectivity. ESP-WIFI-MESH can handle both Root Node Failures and Intermediate Parent Node Failures.

**Root Node Failure**

If the root node breaks down, the nodes connected with it (second layer nodes) will promptly detect the failure of the root node. The second layer nodes will initially attempt to reconnect with the root node. However after multiple failed attempts, the second layer nodes will initialize a new round of root node election. **The second layer node with the strongest router RSSI will be elected as the new root node** whilst the remaining second layer nodes will form an upstream connection with the new root node (or a neighboring parent node if not in range).

If the root node and multiple downstream layers simultaneously break down (e.g. root node, second layer, and third layer), the shallowest layer that is still functioning will initialize the root node election. The following example illustrates an example of self healing from a root node break down.

1. Node C is the root node of the network. Nodes A/B/D/E are second layer nodes connected to node C.

2. Node C breaks down. After multiple failed attempts to reconnect, the second layer nodes begin the election process by broadcasting their router RSSIs. Node B has the strongest router RSSI.

3. Node B is elected as the root node and begins accepting downstream connections. The remaining second layer nodes A/D/E form upstream connections with node B thus the network is healed and can continue operating normally.

**Note:** If a designated root node breaks down, the remaining nodes **will not autonomously attempt to elect a new root node** as an election process will never be attempted whilst a designated root node is used.
Intermediate Parent Node Failure

If an intermediate parent node breaks down, the disconnected child nodes will initially attempt to reconnect with the parent node. After multiple failed attempts to reconnect, each child node will begin to scan for potential parent nodes (see Beacon Frames & RSSI Thresholding).

If other potential parent nodes are available, each child node will individually select a new preferred parent node (see Preferred Parent Node) and form an upstream connection with it. If there are no other potential parent nodes for a particular child node, it will remain idle indefinitely.

The following diagram illustrates an example of self-healing from an Intermediate Parent Node break down.

Note: If a child node has a designated parent node that breaks down, the child node will make no attempt to connect with a new parent node. The child node will remain idle indefinitely.
**Root Node Switching**

ESP-WIFI-MESH does not automatically switch the root node unless the root node breaks down. Even if the root node’s router RSSI degrades to the point of disconnection, the root node will remain unchanged. Root node switching is the act of explicitly starting a new election such that a node with a stronger router RSSI will be elected as the new root node. This can be a useful method of adapting to degrading root node performance.

To trigger a root node switch, the current root node must explicitly call `esp_mesh_waive_root()` to trigger a new election. The current root node will signal all nodes within the network to begin transmitting and scanning for beacon frames (see Automatic Root Node Selection) **whilst remaining connected to the network** (i.e. not idle). If another node receives more votes than the current root node, a root node switch will be initiated. **The root node will remain unchanged otherwise.**

A newly elected root node sends a **switch request** to the current root node which in turn will respond with an acknowledgment signifying both nodes are ready to switch. Once the acknowledgment is received, the newly elected root node will disconnect from its parent and promptly form an upstream connection with the router thereby becoming the new root node of the network. The previous root node will disconnect from the router **whilst maintaining all of its downstream connections** and enter the idle state. The previous root node will then begin scanning for potential parent nodes and selecting a preferred parent.

The following diagram illustrates an example of a root node switch.

![Root Node Switch Example Diagram](image)

1. Node C is the current root node but has degraded signal strength with the router (-85db). The node C triggers a new election and all nodes begin transmitting and scanning for beacon frames **whilst still being connected**.
2. After multiple rounds of transmission and scanning, node B is elected as the new root node. Node B sends node C a **switch request** and node C responds with an acknowledgment.
3. Node B disconnects from its parent and connects with the router becoming the network’s new root node. Node C disconnects from the router, enters the idle state, and begins scanning for and selecting a new preferred parent node. **Node C maintains all its downstream connections throughout this process.**
4. Node C selects node B as its preferred parent node, forms an upstream connection, and becomes a second layer node. The network layout is similar after the switch as node C still maintains the same subnetwork. However each node in node C’s subnetwork has been placed one layer deeper as a result of the switch. **Parent Node Switching** may adjust the network layout afterwards if any nodes have a new preferred parent node as a result of the root node switch.
Chapter 4. API Guides

Note: Root node switching must require an election hence is only supported when using a self-organized ESP-WIFI-MESH network. In other words, root node switching cannot occur if a designated root node is used.

Parent Node Switching

Parent Node Switching entails a child node switching its upstream connection to another parent node of a shallower layer. **Parent Node Switching occurs autonomously** meaning that a child node will change its upstream connection automatically if a potential parent node of a shallower layer becomes available (i.e. due to an **Asynchronous Power-on Reset**).

All potential parent nodes periodically transmit beacon frames (see *Beacon Frames & RSSI Thresholding*) allowing for a child node to scan for the availability of a shallower parent node. Due to parent node switching, a self-organized ESP-WIFI-MESH network can dynamically adjust its network layout to ensure each connection has a good RSSI and that the number of layers in the network is minimized.

### 4.12.6 Data Transmission

**ESP-WIFI-MESH Packet**

ESP-WIFI-MESH network data transmissions use ESP-WIFI-MESH packets. ESP-WIFI-MESH packets are **entirely contained within the frame body of a Wi-Fi data frame**. A multi-hop data transmission in an ESP-WIFI-MESH network will involve a single ESP-WIFI-MESH packet being carried over each wireless hop by a different Wi-Fi data frame.

The following diagram shows the structure of an ESP-WIFI-MESH packet and its relation with a Wi-Fi data frame.

![Fig. 35: ESP-WIFI-MESH Packet](image)

The **header** of an ESP-WIFI-MESH packet contains the MAC addresses of the source and destination nodes. The options field contains information pertaining to the special types of ESP-WIFI-MESH packets such as a group transmission or a packet originating from the external IP network (see **MESH_OPT_SEND_GROUP** and **MESH_OPT_RECV_DS_ADDR**).

The **payload** of an ESP-WIFI-MESH packet contains the actual application data. This data can be raw binary data, or encoded under an application layer protocol such as HTTP, MQTT, and JSON (see **mesh_proto_t**).

**Note:** When sending an ESP-WIFI-MESH packet to the external IP network, the destination address field of the header will contain the IP address and port of the target server rather than the MAC address of a node (see **mesh_addr_t**). Furthermore the root node will handle the formation of the outgoing TCP/IP packet.

**Group Control & Multicasting**

Multicasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to multiple nodes within the network. Multicasting in ESP-WIFI-MESH can be achieved by either specifying a list
of target nodes, or specifying a preconfigured group of nodes. Both methods of multicasting are called via `esp_mesh_send()`.

To multicast by specifying a list of target nodes, users must first set the ESP-WIFI-MESH packet’s destination address to the **Multicast-Group Address (01:00:5E:xx:xx:xx)**. This signifies that the ESP-WIFI-MESH packet is a multicast packet with a group of addresses, and that the address should be obtained from the header options. Users must then list the MAC addresses of the target nodes as options (see `mesh_opt_t` and `MESH_OPT_SEND_GROUP`). This method of multicasting requires no prior setup but can incur a large amount of overhead data as each target node’s MAC address must be listed in the options field of the header.

Multicasting by group allows an ESP-WIFI-MESH packet to be transmitted to a preconfigured group of nodes. Each grouping is identified by a unique ID, and a node can be placed into a group via `esp_mesh_set_group_id()`. Multicasting to a group involves setting the destination address of the ESP-WIFI-MESH packet to the target group ID. Furthermore, the `MESH_DATA_GROUP` flag must set. Using groups to multicast incurs less overhead, but requires nodes to previously added into groups.

**Note:** During a multicast, all nodes within the network still receive the ESP-WIFI-MESH packet on the MAC layer. However, nodes not included in the MAC address list or the target group will simply filter out the packet.

**Broadcasting**

Broadcasting is a feature that allows a single ESP-WIFI-MESH packet to be transmitted simultaneously to all nodes within the network. Each node essentially forwards a broadcast packet to all of its upstream and downstream connections such that the packet propagates throughout the network as quickly as possible. However, ESP-WIFI-MESH utilizes the following methods to avoid wasting bandwidth during a broadcast.

1. When an intermediate parent node receives a broadcast packet from its parent, it will forward the packet to each of its child nodes whilst storing a copy of the packet for itself.
2. When an intermediate parent node is the source node of the broadcast, it will transmit the broadcast packet upstream to its parent node and downstream to each of its child nodes.
3. When an intermediate parent node receives a broadcast packet from one of its child nodes, it will forward the packet to its parent node and each of its remaining child nodes whilst storing a copy of the packet for itself.
4. When a leaf node is the source node of a broadcast, it will directly transmit the packet to its parent node.
5. When the root node is the source node of a broadcast, the root node will transmit the packet to all of its child nodes.
6. When the root node receives a broadcast packet from one of its child nodes, it will forward the packet to each of its remaining child nodes whilst storing a copy of the packet for itself.
7. When a node receives a broadcast packet with a source address matching its own MAC address, the node will discard the broadcast packet.
8. When an intermediate parent node receives a broadcast packet from its parent node which was originally transmitted from one of its child nodes, it will discard the broadcast packet.

**Upstream Flow Control**

ESP-WIFI-MESH relies on parent nodes to control the upstream data flow of their immediate child nodes. To prevent a parent node’s message buffer from overflowing due to an overload of upstream transmissions, a parent node will allocate a quota for upstream transmissions known as a **receiving window** for each of its child nodes. **Each child node must apply for a receiving window before it is permitted to transmit upstream.** The size of a receiving window can be dynamically adjusted. An upstream transmission from a child node to the parent node consists of the following steps:

1. Before each transmission, the child node sends a window request to its parent node. The window request consists of a sequence number which corresponds to the child node’s data packet that is pending transmission.
2. The parent node receives the window request and compares the sequence number with the sequence number of the previous packet sent by the child node. The comparison is used to calculate the size of the receiving window which is transmitted back to the child node.

3. The child node transmits the data packet in accordance with the window size specified by the parent node. If the child node depletes its receiving window, it must obtain another receiving windows by sending a request before it is permitted to continue transmitting.

**Note:** ESP-WIFI-MESH does not support any downstream flow control.

**Warning:** Due to Parent Node Switching, packet loss may occur during upstream transmissions.

Due to the fact that the root node acts as the sole interface to an external IP network, it is critical that downstream nodes are aware of the root node’s connection status with the external IP network. Failing to do so can lead to nodes attempting to pass data upstream to the root node whilst it is disconnected from the IP network. This results in unnecessary transmissions and packet loss. ESP-WIFI-MESH address this issue by providing a mechanism to stabilize the throughput of outgoing data based on the connection status between the root node and the external IP network. The root node can broadcast its external IP network connection status to all other nodes by calling `esp_mesh_post_toDS_state()`.

**Bi-Directional Data Stream**

The following diagram illustrates the various network layers involved in an ESP-WIFI-MESH Bidirectional Data Stream.

![Bi-Directional Data Stream Diagram](image)

**Background**

In traditional Wi-Fi networks, channels are predetermined frequency ranges. In an infrastructure basic service set (BSS), the serving AP and its connected stations must be on the same operating channels (1 to 14) in which beacons are transmitted. Physically adjacent BSS (Basic Service Sets) operating on the same channel can lead to interference and degraded performance.
In order to allow a BSS adapt to changing physical layer conditions and maintain performance, Wi-Fi contains mechanisms for **network channel switching**. A network channel switch is an attempt to move a BSS to a new operating channel whilst minimizing disruption to the BSS during this process. However it should be recognized that a channel switch may be unsuccessful in moving all stations to the new operating channel.

In an infrastructure Wi-Fi network, network channel switches are triggered by the AP with the aim of having the AP and all connected stations synchronously switch to a new channel. Network channel switching is implemented by embedding a **Channel Switch Announcement (CSA)** element within the AP’s periodically transmitted beacon frames. The CSA element is used to advertise to all connected stations regarding an upcoming network channel switch and will be included in multiple beacon frames up until the switch occurs.

A CSA element contains information regarding the **New Channel Number** and a **Channel Switch Count** which indicate the number of beacon frame intervals (TBTTs) remaining until the network channel switch occurs. Therefore, the Channel Switch Count is decremented every beacon frame and allows connected stations to synchronize their channel switch with the AP.

**ESP-WIFI-MESH Network Channel Switching**

ESP-WIFI-MESH Network Channel Switching also utilize beacon frames that contain a CSA element. However, being a multi-hop network makes the switching process in ESP-WIFI-MESH is more complex due to the fact that a beacon frame might not be able to reach all nodes within the network (i.e. in a single hop). Therefore, an ESP-WIFI-MESH network relies on nodes to forward the CSA element so that it is propagated throughout the network.

When an intermediate parent node with one or more child nodes receives a beacon frame containing a CSA, the node will forward the CSA element by including the element in its next transmitted beacon frame (i.e. with the same **New Channel Number** and **Channel Switch Count**). Given that all nodes within an ESP-WIFI-MESH network receive the same CSA, the nodes can synchronize their channel switches using the Channel Switch Count, albeit with a short delay due to CSA element forwarding.

An ESP-WIFI-MESH network channel switch can be triggered by either the router or the root node.

**Root Node Triggered**  A root node triggered channel switch can only occur when the ESP-WIFI-MESH network is not connected to a router. By calling `esp_mesh_switch_channel()`, the root node will set an initial Channel Switch Count value and begin including a CSA element in its beacon frames. Each CSA element is then received by second layer nodes, and forwarded downstream in their own beacon frames.

**Router Triggered**  When an ESP-WIFI-MESH network is connected to a router, the entire network must use the same channel as the router. Therefore, the root node will not be permitted to trigger a channel switch when it is connected to a router.

When the root node receives beacon frame containing a CSA element from the router, the root node will set Channel Switch Count value in the CSA element to a custom value before forwarding it downstream via beacon frames. It will also decrement the Channel Switch Count of subsequent CSA elements relative to the custom value. This custom value can be based on factors such as the number of network layers, the current number of nodes etc.

The setting the Channel Switch Count value to a custom value is due to the fact that the ESP-WIFI-MESH network and its router may have a different and varying beacon intervals. Therefore, the Channel Switch Count value provided by the router is irrelevant to an ESP-WIFI-MESH network. By using a custom value, nodes within the ESP-WIFI-MESH network are able to switch channels synchronously relative to the ESP-WIFI-MESH network’s beacon interval. However, this will also result in the ESP-WIFI-MESH network’s channel switch being unsynchronized with the channel switch of the router and its connected stations.

**Impact of Network Channel Switching**

- Due to the ESP-WIFI-MESH network channel switch being unsynchronized with the router’s channel switch, there will be a temporary channel discrepancy between the ESP-WIFI-MESH network and the router.
  - The ESP-WIFI-MESH network’s channel switch time is dependent on the ESP-WIFI-MESH network’s beacon interval and the root node’s custom Channel Switch Count value.
– The channel discrepancy prevents any data exchange between the root node and the router during that ESP-WIFI-MESH network’s switch.
– In the ESP-WIFI-MESH network, the root node and intermediate parent nodes will request their connected child nodes to stop transmissions until the channel switch takes place by setting the **Channel Switch Mode** field in the CSA element to 1.
– Frequent router triggered network channel switches can degrade the ESP-WIFI-MESH network’s performance. Note that this can be caused by the ESP-WIFI-MESH network itself (e.g. due to wireless medium contention with ESP-WIFI-MESH network). If this is the case, users should disable the automatic channel switching on the router and use a specified channel instead.

• **When there is a temporary channel discrepancy, the root node remains technically connected to the router.**

  – Disconnection occurs after the root node fails to receive any beacon frames or probe responses from the router over a fixed number of router beacon intervals.
  – Upon disconnection, the root node will automatically re-scan all channels for the presence of a router.

• **If the root node is unable to receive any of the router’s CSA beacon frames (e.g. due to short switch time given by the network)**

  – After the router switches channels, the root node will no longer be able to receive the router’s beacon frames and probe responses and result in a disconnection after a fixed number of beacon intervals.
  – The root node will re-scan all channels for the router after disconnection.
  – The root node will maintain downstream connections throughout this process.

**Note:** Although ESP-WIFI-MESH network channel switching aims to move all nodes within the network to a new operating channel, it should be recognized that a channel switch might not successfully move all nodes (e.g. due to reasons such as node failures).

### Channel and Router Switching Configuration

ESP-WIFI-MESH allows for autonomous channel switching to be enabled/disabled via configuration. Likewise, autonomous router switching (i.e. when a root node autonomously connects to another router) can also be enabled/disabled by configuration. Autonomous channel switching and router switching is dependent on the following configuration parameters and run-time conditions.

**Allow Channel Switch:** This parameter is set via the `allow_channel_switch` field of the `mesh_cfg_t` structure and permits an ESP-WIFI-MESH network to dynamically switch channels when set.

**Preset Channel:** An ESP-WIFI-MESH network can have a preset channel by setting the `channel` field of the `mesh_cfg_t` structure to the desired channel number. If this field is unset, the `allow_channel_switch` parameter is overridden such that channel switches are always permitted.

**Allow Router Switch:** This parameter is set via the `allow_router_switch` field of the `mesh_router_t` and permits an ESP-WIFI-MESH to dynamically switch to a different router when set.

**Preset Router BSSID:** An ESP-WIFI-MESH network can have a preset router by setting the `bssid` field of the `mesh_router_t` structure to the BSSID of the desired router. If this field is unset, the `allow_router_switch` parameter is overridden such that router switches are always permitted.

**Root Node Present:** The presence of a root node will also affect whether or a channel or router switch is permitted.

The following table illustrates how the different combinations of parameters/conditions affect whether channel switching and/or router switching is permitted. Note that `X` represents a “don’t care” for the parameter.
### 4.12.8 Performance

The performance of an ESP-WIFI-MESH network can be evaluated based on multiple metrics such as the following:

**Network Building Time:** The amount of time taken to build an ESP-WIFI-MESH network from scratch.

**Healing Time:** The amount of time taken for the network to detect a node break down and carry out appropriate actions to heal the network (such as generating a new root node or forming new connections).

**Per-hop latency:** The latency of data transmission over one wireless hop. In other words, the time taken to transmit a data packet from a parent node to a child node or vice versa.

**Network Node Capacity:** The total number of nodes the ESP-WIFI-MESH network can simultaneously support. This number is determined by the maximum number of downstream connections a node can accept and the maximum number of layers permissible in the network.

The following table lists the common performance figures of an ESP-WIFI-MESH network:

<table>
<thead>
<tr>
<th>Preset Channel Switch</th>
<th>Allow Channel Switch</th>
<th>Preset Router BSSID</th>
<th>Allow Router Switch</th>
<th>Root Present</th>
<th>Node Permitted Switches?</th>
</tr>
</thead>

</tbody>
</table>

**Note:** The following test conditions were used to generate the performance figures above.

- Number of test devices: **100**
- Maximum Downstream Connections to Accept: **6**
- Maximum Permissible Layers: **6**

**Note:** Throughput depends on packet error rate and hop count.

**Note:** The throughput of root node’s access to the external IP network is directly affected by the number of nodes in the ESP-WIFI-MESH network and the bandwidth of the router.
Chapter 4. API Guides

Note: The performance figures can vary greatly between installations based on network configuration and operating environment.

4.12.9 Further Notes

- Data transmission uses Wi-Fi WPA2-PSK encryption
- Mesh networking IE uses AES encryption

4.13 Support for External RAM

4.13.1 Introduction

ESP32 has a few hundred kilobytes of internal RAM, residing on the same die as the rest of the chip components. It can be insufficient for some purposes, so ESP32 has the ability to also use up to 4 MB of external SPI RAM memory. The external memory is incorporated in the memory map and, with certain restrictions, is usable in the same way as internal data RAM.

4.13.2 Hardware

ESP32 supports SPI PSRAM (Pseudostatic RAM) connected in parallel with the SPI flash chip. While ESP32 is capable of supporting several types of RAM chips, ESP-IDF currently only supports Espressif branded PSRAM chips (e.g., ESP-PSRAM32, ESP-PSRAM64, etc.).

Note: Some PSRAM chips are 1.8 V devices and some are 3.3 V. The working voltage of the PSRAM chip must match the working voltage of the flash component. Consult the datasheet for your PSRAM chip and ESP32 device to find out the working voltages. For a 1.8 V PSRAM chip, make sure to either set the MTDI pin to a high signal level on bootup, or program ESP32 eFuses to always use the VDD_SIO level of 1.8 V. Not doing this can damage the PSRAM and/or flash chip.

Note: Espressif produces both modules and system-in-package chips that integrate compatible PSRAM and flash and are ready to mount on a product PCB. Consult the Espressif website for more information.

For specific details about connecting the SoC or module pins to an external PSRAM chip, consult the SoC or module datasheet.

4.13.3 Configuring External RAM

ESP-IDF fully supports the use of external RAM in applications. Once the external RAM is initialized at startup, ESP-IDF can be configured to integrate the external RAM in several ways:

- Integrate RAM into the ESP32 Memory Map
- Add External RAM to the Capability Allocator
- Provide External RAM via malloc() (default)
- Allow .bss Segment to Be Placed in External Memory
• *Allow .noinit Segment to Be Placed in External Memory*

**Integrate RAM into the ESP32 Memory Map**

Select this option by choosing “Integrate RAM into memory map” from `CONFIG_SPIRAM_USE`.

This is the most basic option for external SPI RAM integration. Most likely, you will need another, more advanced option.

During the ESP-IDF startup, external RAM is mapped into the data address space, starting at address 0x3F800000 (byte-accessible). The length of this region is the same as the SPI RAM size (up to the limit of 4 MB).

Applications can manually place data in external memory by creating pointers to this region. So if an application uses external memory, it is responsible for all management of the external SPI RAM: coordinating buffer usage, preventing corruption, etc.

**Add External RAM to the Capability Allocator**

Select this option by choosing “Make RAM allocatable using `heap_caps_malloc(..., MALLOC_CAP_SPIRAM)`” from `CONFIG_SPIRAM_USE`.

When enabled, memory is mapped to address 0x3F800000 and also added to the capabilities-based heap memory allocator using `MALLOC_CAP_SPIRAM`.

To allocate memory from external RAM, a program should call `heap_caps_malloc(size, MALLOC_CAP_SPIRAM)`. After use, this memory can be freed by calling the normal `free()` function.

**Provide External RAM via malloc()**

Select this option by choosing “Make RAM allocatable using malloc() as well” from `CONFIG_SPIRAM_USE`. This is the default option.

In this case, memory is added to the capability allocator as described for the previous option. However, it is also added to the pool of RAM that can be returned by the standard `malloc()` function.

This allows any application to use the external RAM without having to rewrite the code to use `heap_caps_malloc(..., MALLOC_CAP_SPIRAM)`.

An additional configuration item, `CONFIG_SPIRAM_MALLOC_ALWAYSINTERNAL`, can be used to set the size threshold when a single allocation should prefer external memory:

- When allocating a size less than the threshold, the allocator will try internal memory first.
- When allocating a size equal to or larger than the threshold, the allocator will try external memory first.

If a suitable block of preferred internal/external memory is not available, the allocator will try the other type of memory.

Because some buffers can only be allocated in internal memory, a second configuration item `CONFIG_SPIRAM_MALLOC_RESERVE_INTERNAL` defines a pool of internal memory which is reserved for only explicitly internal allocations (such as memory for DMA use). Regular `malloc()` will not allocate from this pool. The `MALLOC_CAP_DMA` and `MALLOC_CAP_INTERNAL` flags can be used to allocate memory from this pool.

**Allow .bss Segment to Be Placed in External Memory**

Enable this option by checking `CONFIG_SPIRAM_ALLOW_BSS_SEG_EXTERNAL_MEMORY`.

If enabled, a region of the address space starting from 0x3F800000 will be used to store zero-initialized data (BSS segment) from the lwIP, net80211, libpp, and bluedroid ESP-IDF libraries.

Additional data can be moved from the internal BSS segment to external RAM by applying the macro `EXT_RAM_BSS_ATTR` to any static declaration (which is not initialized to a non-zero value).
It is also possible to place the BSS section of a component or a library to external RAM using linker fragment scheme `extram_bss`.

This option reduces the internal static memory used by the BSS segment.

Remaining external RAM can also be added to the capability heap allocator using the method shown above.

**Allow .noinit Segment to Be Placed in External Memory**

Enable this option by checking `CONFIG_SPIRAM_ALLOW_NOINIT_SEG_EXTERNAL_MEMORY`. If enabled, a region of the address space provided in external RAM will be used to store non-initialized data. The values placed in this segment will not be initialized or modified even during startup or restart.

By applying the macro `EXT_RAM_NOINIT_ATTR`, data could be moved from the internal NOINIT segment to external RAM. Remaining external RAM can still be added to the capability heap allocator using the method shown above, *Add External RAM to the Capability Allocator*.

### 4.13.4 Restrictions

External RAM use has the following restrictions:

- When flash cache is disabled (for example, if the flash is being written to), the external RAM also becomes inaccessible. Any read operations from or write operations to it will lead to an illegal cache access exception. This is also the reason why ESP-IDF does not by default allocate any task stacks in external RAM (see below).

- External RAM uses the same cache region as the external flash. This means that frequently accessed variables in external RAM can be read and modified almost as quickly as in internal RAM. However, when accessing large chunks of data (>32 KB), the cache can be insufficient, and speeds will fall back to the access speed of the external RAM. Moreover, accessing large chunks of data can “push out” cached flash, possibly making the execution of code slower afterwards.

- In general, external RAM will not be used as task stack memory. `xTaskCreate()` and similar functions will always allocate internal memory for stack and task TCBs.

The option `CONFIG_SPIRAM_ALLOW_STACK_EXTERNAL_MEMORY` can be used to allow placing task stacks into external memory. In these cases `xTaskCreateStatic()` must be used to specify a task stack buffer allocated from external memory, otherwise task stacks will still be allocated from internal memory.

### 4.13.5 Failure to Initialize

By default, failure to initialize external RAM will cause the ESP-IDF startup to abort. This can be disabled by enabling the config item `CONFIG_SPIRAM_IGNORE_NOTFOUND`.

If `CONFIG_SPIRAM_ALLOW_BSS_SEG_EXTERNAL_MEMORY` is enabled, the option to ignore failure is not available as the linker will have assigned symbols to external memory addresses at link time.

- Regarding stacks in PSRAM: For tasks that do not call ROM code in any way (directly or indirectly), the `CONFIG_SPIRAM_ALLOW_STACK_EXTERNAL_MEMORY` option will eliminate the check in `xTaskCreateStatic()`, allowing a task’s stack to be in external RAM. However, using this is not advised.

- When used at 80 MHz clock speed, external RAM must also occupy either the HSPI or VSPI bus. Select which SPI host will be used by `CONFIG_SPIRAM_OCCUPY_SPI_HOST`.

### 4.13.6 Chip Revisions

There are some issues with certain revisions of ESP32 that have repercussions for use with external RAM. The issues are documented in the ESP32 Series SoC Errata document. In particular, ESP-IDF handles the bugs mentioned in the following ways:
ESP32 Rev v0.0

ESP-IDF has no workaround for the bugs in this revision of silicon, and it cannot be used to map external PSRAM into ESP32’s main memory map.

ESP32 Rev v1.0

The bugs in this revision of silicon cause issues if certain sequences of machine instructions operate on external memory. (ESP32 Series SoC Errata 3.2). As a workaround, the `-mfix-esp32-psram-cache-issue` flag has been added to the ESP32 GCC compiler such that these sequences are filtered out. As a result, the compiler only outputs code that can safely be executed. The `CONFIG_SPIRAM_CACHE_WORKAROUND` option can be used to enable this workaround.

Aside from linking to a recompiled version of Newlib with the additional flag, ESP-IDF also does the following:

- Avoids using some ROM functions
- Allocates static memory for the Wi-Fi stack

ESP32 Rev v3.0

ESP32 rev v3.0 fixes the PSRAM cache issue found in rev v1.0. When `CONFIG_ESP32_REV_MIN` option is set to rev v3.0, compiler workarounds related to PSRAM will be disabled. For more information about ESP32 v3.0, see ESP32 Chip Revision v3.0 User Guide.

4.14 Fatal Errors

4.14.1 Overview

In certain situations, execution of the program cannot be continued in a well defined way. In ESP-IDF, these situations include:

- CPU Exceptions: Illegal Instruction, Load/Store Alignment Error, Load/Store Prohibited error, Double Exception.
- System level checks and safeguards:
  - `Interrupt watchdog` timeout
  - `Task watchdog` timeout (only fatal if `CONFIG_ESP_TASK_WDT_PANIC` is set)
  - Cache access error
  - Brownout detection event
  - Stack overflow
  - Stack smashing protection check
  - Heap integrity check
  - Undefined behavior sanitizer (UBSAN) checks
- Failed assertions, via `assert`, `configASSERT` and similar macros.

This guide explains the procedure used in ESP-IDF for handling these errors, and provides suggestions on troubleshooting the errors.

4.14.2 Panic Handler

Every error cause listed in the `Overview` will be handled by the `panic handler`.

The panic handler will start by printing the cause of the error to the console. For CPU exceptions, the message will be similar to
Guru Meditation Error: Core 0 panic'ed (IllegalInstruction). Exception was unhandled.

For some of the system level checks (interrupt watchdog, cache access error), the message will be similar to
Guru Meditation Error: Core 0 panic'ed (Cache disabled but cached memory region accessed). Exception was unhandled.

In all cases, the error cause will be printed in parentheses. See Guru Meditation Errors for a list of possible error causes.

Subsequent behavior of the panic handler can be set using CONFIG_ESP_SYSTEM_PANIC configuration choice. The available options are:

- **Print registers and reboot** (CONFIG_ESP_SYSTEM_PANIC_PRINT_REBOOT) — default option. This will print register values at the point of the exception, print the backtrace, and restart the chip.
- **Print registers and halt** (CONFIG_ESP_SYSTEM_PANIC_PRINT_HALT) Similar to the above option, but halt instead of rebooting. External reset is required to restart the program.
- **Silent reboot** (CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT) Don’t print registers or backtrace, restart the chip immediately.
- **Invoke GDB Stub** (CONFIG_ESP_SYSTEM_PANIC_GDBSTUB) Start GDB server which can communicate with GDB over console UART port. This option will only provide read-only debugging or post-mortem debugging. See GDB Stub for more details.
- **Invoke dynamic GDB Stub** (ESP_SYSTEM_GDBSTUB_RUNTIME) Start GDB server which can communicate with GDB over console UART port. This option allows the user to debug a program at run time and set breakpoints, alter the execution, etc. See GDB Stub for more details.

The behavior of the panic handler is affected by three other configuration options.

- If **CONFIG_ESP_DEBUG_OCDWARE** is enabled (which is the default), the panic handler will detect whether a JTAG debugger is connected. If it is, execution will be halted and control will be passed to the debugger. In this case, registers and backtrace are not dumped to the console, and GDBStub / Core Dump functions are not used.
- If the **Core Dump** feature is enabled, then the system state (task stacks and registers) will be dumped to either Flash or UART, for later analysis.
- If **CONFIG_ESP_PANIC_HANDLER_IRAM** is disabled (disabled by default), the panic handler code is placed in flash memory, not IRAM. This means that if ESP-IDF crashes while flash cache is disabled, the panic handler will automatically re-enable flash cache before running GDB Stub or Core Dump. This adds some minor risk, if the flash cache status is also corrupted during the crash.
- If this option is enabled, the panic handler code (including required UART functions) is placed in IRAM, and hence will decrease the usable memory space in SRAM. But this may be necessary to debug some complex issues with crashes while flash cache is disabled (for example, when writing to SPI flash) or when flash cache is corrupted when an exception is triggered.
- If **CONFIG_ESP_SYSTEM_PANIC_REBOOT_DELAY_SECONDS** is enabled (enabled by default) and set to a number higher than 0, the panic handler will delay the reboot for that amount of time in seconds. This can help if the tool used to monitor serial output does not provide a possibility to stop and examine the serial output. In that case, delaying the reboot will allow users to examine and debug the panic handler output (backtrace, etc.) for the duration of the delay. After the delay, the device will reboot. The reset reason is preserved.

The following diagram illustrates the panic handler behavior:

### 4.14.3 Register Dump and Backtrace

Unless the **CONFIG_ESP_SYSTEM_PANIC_SILENT_REBOOT** option is enabled, the panic handler prints some of the CPU registers, and the backtrace, to the console

<table>
<thead>
<tr>
<th>Core 0 register dump:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC : 0x400e14ed  PS : 0x00060030  A0 : 0x800d0805  A1 : ...</td>
</tr>
<tr>
<td>← 0x3ffe5030</td>
</tr>
<tr>
<td>A2 : 0x00000000  A3 : 0x00000001  A4 : 0x00000001  A5 : ...</td>
</tr>
<tr>
<td>← 0x3ffe50dc</td>
</tr>
</tbody>
</table>

(continues on next page)
Fig. 37: Panic Handler Flowchart (click to enlarge)
The register values printed are the register values in the exception frame, i.e., values at the moment when the CPU exception or another fatal error has occurred.

A Register dump is not printed if the panic handler has been executed as a result of an abort() call.

In some cases, such as interrupt watchdog timeout, the panic handler may print additional CPU registers (EPC1-EPC4) and the registers/backtrace of the code running on the other CPU.

The backtrace line contains PC:SP pairs, where PC is the Program Counter and SP is Stack Pointer, for each stack frame of the current task. If a fatal error happens inside an ISR, the backtrace may include PC:SP pairs both from the task which was interrupted, and from the ISR.

If IDF Monitor is used, Program Counter values will be converted to code locations (function name, file name, and line number), and the output will be annotated with additional lines:

To find the location where a fatal error has happened, look at the lines which follow the “Backtrace” line. Fatal error location is the top line, and subsequent lines show the call stack.

4.14.4 GDB Stub

If the CONFIG_ESP_SYSTEM_PANIC_GDBSTUB option is enabled, the panic handler will not reset the chip when a fatal error happens. Instead, it will start a GDB remote protocol server, commonly referred to as GDB Stub. When this happens, a GDB instance running on the host computer can be instructed to connect to the ESP32 UART port.

If IDF Monitor is used, GDB is started automatically when a GDB Stub prompt is detected on the UART. The output looks like this:
Chapter 4. API Guides

Entering gdb stub now.
$T0b#e6GNU gdb (crosstool-NG crosstool-ng-1.22.0-80-gff1f415) 7.10

and "show warranty" for details.
This GDB was configured as "--host=x86_64-build_apple-darwin16.3.0 --target=xtensa-
esp32-elf".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
Find the GDB manual and other documentation resources online at:
For help, type "help".
Type "apropos word" to search for commands related to "word"...
Reading symbols from /Users/user/esp/example/build/example.elf...done.
Remote debugging using /dev/cu.usbserial-31301
0x400e1b41 in app_main ()
at /Users/user/esp/example/build/example.elf...done.
0x400e1b41 in app_main ()
   at /Users/user/esp/example/main/main.cpp:36
36   *((int*) 0) = 0;
(gdb)
The GDB prompt can be used to inspect CPU registers, local and static variables, and arbitrary locations in memory. It
is not possible to set breakpoints, change the PC, or continue execution. To reset the program, exit GDB and perform
an external reset: Ctrl-T Ctrl-R in IDF Monitor, or using the external reset button on the development board.

4.14.5 RTC Watchdog Timeout

The RTC watchdog is used in the startup code to keep track of execution time and it also helps to prevent a lock-up
caused by an unstable power source. It is enabled by default (see CONFIG_BOOTLOADER_WDT_ENABLE). If the
execution time is exceeded, the RTC watchdog will restart the system. In this case, the ROM bootloader will print a
message with the RTC Watchdog Timeout reason for the reboot.

rst:0x10 (RTCWDT_RTC_RESET)

The RTC watchdog covers the execution time from the first stage bootloader (ROM bootloader) to application
startup. It is initially set in the ROM bootloader, then configured in the bootloader with the CONFIG_BOOTLOADER_WDT_TIME_MS option (9000 ms by default). During the application initialization stage,
it is reconfigured because the source of the slow clock may have changed, and finally disabled right before the
app_main() call. There is an option CONFIG_BOOTLOADER_WDT_DISABLE_IN_USER_CODE which prevents
the RTC watchdog from being disabled before app_main. Instead, the RTC watchdog remains active and
must be fed periodically in your application’s code.

4.14.6 Guru Meditation Errors

This section explains the meaning of different error causes, printed in parens after the Guru Meditation Er-
ror: Core panic'ed message.

Note: See the Guru Meditation Wikipedia article for historical origins of “Guru Meditation”.

IllegalInstruction

This CPU exception indicates that the instruction which was executed was not a valid instruction. Most common
reasons for this error include:
• FreeRTOS task function has returned. In FreeRTOS, if a task function needs to terminate, it should call `vTaskDelete()` and delete itself, instead of returning.
• Failure to read next instruction from SPI flash. This usually happens if:
  – Application has reconfigured the SPI flash pins as some other function (GPIO, UART, etc.). Consult the Hardware Design Guidelines and the datasheet for the chip or module for details about the SPI flash pins.
  – Some external device has accidentally been connected to the SPI flash pins, and has interfered with communication between ESP32 and SPI flash.
• In C++ code, exiting from a non-void function without returning a value is considered to be an undefined behavior. When optimizations are enabled, the compiler will often omit the epilogue in such functions. This most often results in an IllegalInstruction exception. By default, ESP-IDF build system enables `-Werror=return-type` which means that missing return statements are treated as compile time errors. However if the application project disables compiler warnings, this issue might go undetected and the IllegalInstruction exception will occur at run time.

**InstrFetchProhibited**

This CPU exception indicates that the CPU could not read an instruction because the address of the instruction does not belong to a valid region in instruction RAM or ROM.

Usually, this means an attempt to call a function pointer, which does not point to valid code. PC (Program Counter) register can be used as an indicator: it will be zero or will contain a garbage value (not 0x4xxxxxxxx).

**LoadProhibited, StoreProhibited**

These CPU exceptions happen when an application attempts to read from or write to an invalid memory location. The address which has been written/read is found in the EXCVADDR register in the register dump. If this address is zero, it usually means that the application has attempted to dereference a NULL pointer. If this address is close to zero, it usually means that the application has attempted to access a member of a structure, but the pointer to the structure is NULL. If this address is something else (garbage value, not in 0x3fxxxxxxx-0x6xxxxxxx range), it likely means that the pointer used to access the data is either not initialized or has been corrupted.

**IntegerDivideByZero**

Application has attempted to do an integer division by zero.

**LoadStoreAlignment**

Application has attempted to read or write a memory location, and the address alignment does not match the load/store size. For example, a 32-bit read can only be done from a 4-byte aligned address, and a 16-bit write can only be done to a 2-byte aligned address.

**LoadStoreError**

This exception may happen in the following cases:

• If the application has attempted to do an 8- or 16-bit read to, or write from, a memory region which only supports 32-bit reads/writes. For example, dereferencing a `char*` pointer to instruction memory (IRAM, IROM) will result in such an error.
• If the application has attempted to write to a read-only memory region, such as IROM or DROM.

**Unhandled debug exception**

This will usually be followed by a message like:
Debug exception reason: Stack canary watchpoint triggered (task_name)

This error indicates that the application has written past the end of the stack of the task with name task_name. Note that not every stack overflow is guaranteed to trigger this error. It is possible that the task writes to memory beyond the stack canary location, in which case the watchpoint will not be triggered.

**Interrupt Watchdog Timeout on CPU0/CPU1**

Indicates that an interrupt watchdog timeout has occurred. See *Watchdogs* for more information.

**Cache disabled but cached memory region accessed**

In some situations, ESP-IDF will temporarily disable access to external SPI Flash and SPI RAM via caches. For example, this happens when spi_flash APIs are used to read/write/erase/mmap regions of SPI Flash. In these situations, tasks are suspended, and interrupt handlers not registered with ESP_INTR_FLAG_IRAM are disabled. Make sure that any interrupt handlers registered with this flag have all the code and data in IRAM/DRAM. Refer to the *SPI flash API documentation* for more details.

### 4.14.7 Other Fatal Errors

**Brownout**

ESP32 has a built-in brownout detector, which is enabled by default. The brownout detector can trigger a system reset if the supply voltage goes below a safe level. The brownout detector can be configured using `CONFIG_ESP_BROWNOUT_DET` and `CONFIG_ESP_BROWNOUT_DET_LVL_SEL` options.

When the brownout detector triggers, the following message is printed:

```
Brownout detector was triggered
```

The chip is reset after the message is printed.

Note that if the supply voltage is dropping at a fast rate, only part of the message may be seen on the console.

**Corrupt Heap**

ESP-IDF’s heap implementation contains a number of run-time checks of the heap structure. Additional checks ( “Heap Poisoning” ) can be enabled in menuconfig. If one of the checks fails, a message similar to the following will be printed:

```
CORRUPT HEAP: Bad tail at 0x3ffe270a. Expected 0xbbad5678 got 0xbbac5678
assertion "head != NULL" failed: file "/Users/user/esp/esp-idf/components/heap/multi_heap_poisoning.c", line 201, function: multi_heap_free
abort() was called at PC 0x400dca43 on core 0
```

Consult *Heap Memory Debugging* documentation for further information.

**Stack Smashing**

Stack smashing protection (based on GCC `-fstack-protector*` flags) can be enabled in ESP-IDF using `CONFIG_COMPILER_STACK_CHECK_MODE` option. If stack smashing is detected, message similar to the following will be printed:

```
Espressif Systems
Chapter 4. API Guides

Stack smashing protect failure!
abort() was called at PC 0x400d2138 on core 0

Backtrace: 0x4008e6c0:0x3ffc1780 0x4008e8b7:0x3ffc17a0 0x400d2138:0x3ffc17c0...
    0x400e79d5:0x3ffc17e0 0x400e79a7:0x3ffc1840 0x400e79df:0x3ffc18a0...
    0x400e2235:0x3ffc18c0 0x400e1916:0x3ffc18f0 0x400e19cd:0x3ffc1910...
    0x400e1a11:0x3ffc1930 0x400e1bb2:0x3ffc1950 0x400d2c44:0x3ffc1a80

The backtrace should point to the function where stack smashing has occurred. Check the function code for unbounded access to local arrays.

Undefined Behavior Sanitizer (UBSAN) Checks

Undefined behavior sanitizer (UBSAN) is a compiler feature which adds run-time checks for potentially incorrect operations, such as:

- overflows (multiplication overflow, signed integer overflow)
- shift base or exponent errors (e.g. shift by more than 32 bits)
- integer conversion errors

See GCC documentation of `-fsanitize=undefined` option for the complete list of supported checks.

Enabling UBSAN

UBSAN is disabled by default. It can be enabled at file, component, or project level by adding the `-fsanitize=undefined` compiler option in the build system.

When enabling UBSAN for code which uses the SOC hardware register header files (`soc/xxx_reg.h`), it is recommended to disable shift-base sanitizer using `-fno-sanitize=shift-base` option. This is due to the fact that ESP-IDF register header files currently contain patterns which cause false positives for this specific sanitizer option.

To enable UBSAN at project level, add the following code at the end of the project’s `CMakeLists.txt` file:

```
idf_build_set_property(COMPILE_OPTIONS "-fsanitize=undefined" "-fno-sanitize=shift-base" APPEND)
```

Alternatively, pass these options through the `EXTRA_CFLAGS` and `EXTRA_CXXFLAGS` environment variables.

Enabling UBSAN results in significant increase of code and data size. Most applications, except for the trivial ones, will not fit into the available RAM of the microcontroller when UBSAN is enabled for the whole application. Therefore it is recommended that UBSAN is instead enabled for specific components under test.

To enable UBSAN for a specific component (`component_name`) from the project’s `CMakeLists.txt` file, add the following code at the end of the file:

```
idf_component_get_property(lib component_name COMPONENT_LIB)
target_compile_options({$lib} PRIVATE "-fsanitize=undefined" "-fno-sanitize=shift-base")
```

**Note:** See the build system documentation for more information about build properties and component properties.

To enable UBSAN for a specific component (`component_name`) from `CMakeLists.txt` of the same component, add the following at the end of the file:

```
target_compile_options({$COMPONENT_LIB} PRIVATE "-fsanitize=undefined" "-fno-sanitize=shift-base")
```
UBSAN Output  When UBSAN detects an error, a message and the backtrace are printed, for example:

```
Undefined behavior of type out_of_bounds
Backtrace:
0x4008b383: panic_abort at /path/to/esp-idf/components/esp_system/panic.c:367
0x4008c791: esp_system_abort at /path/to/esp-idf/components/esp_system/system_api.c:106
0x4008c587: __ubsan_default_handler at /path/to/esp-idf/components/esp_system/ubsan.c:152
0x4008c6be: __ubsan_handle_out_of_bounds at /path/to/esp-idf/components/esp_system/ubsan.c:223
0x400db74f: test_ub at main.c:128
0x400db99c: app_main at main.c:56 (discriminator 1)
```

When using IDF Monitor, the backtrace will be decoded to function names and source code locations, pointing to the location where the issue has happened (here it is main.c:128):

```
0x4008b383: panic_abort at /path/to/esp-idf/components/esp_system/panic.c:367
0x4008c791: esp_system_abort at /path/to/esp-idf/components/esp_system/system_api.c:106
0x4008c587: __ubsan_default_handler at /path/to/esp-idf/components/esp_system/ubsan.c:152
0x4008c6be: __ubsan_handle_out_of_bounds at /path/to/esp-idf/components/esp_system/ubsan.c:223
0x400db74f: test_ub at main.c:128
0x400db99c: app_main at main.c:56 (discriminator 1)
```

The types of errors reported by UBSAN can be as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>type_mismatch, type_mismatch_v1</td>
<td>Incorrect pointer value: null, unaligned, not compatible with the given type.</td>
</tr>

<td>Unreachable code executed.</td>
</tr>
<tr>
<td>missing_return</td>
<td>Non-void function has reached its end without returning a value (C++ only).</td>
</tr>
<tr>
<td>vla_bound_not_positive</td>
<td>Size of variable length array is not positive.</td>
</tr>
<tr>
<td>load_invalid_value</td>
<td>Value of bool or enum (C++ only) variable is invalid (out of bounds).</td>
</tr>
<tr>
<td>nonnull_arg</td>
<td>Null argument passed to a function which is declared with a non-null attribute.</td>
</tr>
<tr>
<td>nonnull_return</td>
<td>Null value returned from a function which is declared with returns_nonnull attribute.</td>
</tr>
<tr>
<td>builtin_unreachable</td>
<td>__builtin_unreachable function called.</td>
</tr>
<tr>
<td>pointer_overflow</td>
<td>Overflow in pointer arithmetic.</td>
</tr>
</tbody>
</table>

### 4.15 Flash Encryption

This is a quick start guide to ESP32’s flash encryption feature. Using application code as an example, it demonstrates how to test and verify flash encryption operations during development and production.
4.15.1 Introduction

Flash encryption is intended for encrypting the contents of the ESP32’s off-chip flash memory. Once this feature is enabled, firmware is flashed as plaintext, and then the data is encrypted in place on the first boot. As a result, physical readout of flash will not be sufficient to recover most flash contents.

With flash encryption enabled, the following types of data are encrypted by default:

- Firmware bootloader
- Partition Table
- All “app” type partitions

Other types of data can be encrypted conditionally:

- Any partition marked with the encrypted flag in the partition table. For details, see Encrypted Partition Flag.
- Secure Boot bootloader digest if Secure Boot is enabled (see below).

Secure Boot is a separate feature which can be used together with flash encryption to create an even more secure environment.

**Important:** For production use, flash encryption should be enabled in the “Release” mode only.

**Important:** Enabling flash encryption limits the options for further updates of ESP32. Before using this feature, read the document and make sure to understand the implications.

4.15.2 Relevant eFuses

The flash encryption operation is controlled by various eFuses available on ESP32. The list of eFuses and their descriptions is given in the table below. The names in eFuse column are also used by espfuse.py tool. For usage in the eFuse API, modify the name by adding ESP_EFUSE_, for example: esp_efuse_read_field_bit(ESP_EFUSE_DISABLE_DL_ENCRYPT).

<table>
<thead>
<tr>
<th>eFuse</th>
<th>Description</th>
<th>Bit Depth</th>
</tr>
</thead>
<tbody>
<tr>
<td>CODING_SCHEME</td>
<td>Controls actual number of block1 bits used to derive final 256-bit AES key. Possible values: 0 for 256 bits, 1 for 192 bits, 2 for 128 bits. Final AES key is derived based on the FLASH_CRYPT_CONFIG value.</td>
<td>2</td>
</tr>
<tr>
<td>flash_encryption (block1)</td>
<td>AES key storage.</td>
<td>256 bit key block</td>
</tr>
<tr>
<td>FLASH_CRYPT_CONFIG</td>
<td>Controls the AES encryption process.</td>
<td>4</td>
</tr>
<tr>
<td>DISABLE_DL_ENCRYPT</td>
<td>If set, disables flash encryption operation while running in Firmware Download mode.</td>
<td>1</td>
</tr>
<tr>
<td>DISABLE_DL_DECRYPT</td>
<td>If set, disables flash decryption while running in UART Firmware Download mode.</td>
<td>1</td>
</tr>
<tr>
<td>FLASH_CRYPT_CNT</td>
<td>Enables/disables encryption at boot time. If even number of bits set (0, 2, 4, 6) - encrypt flash at boot time. If odd number of bits set (1, 3, 5, 7) - do not encrypt flash at boot time.</td>
<td>7</td>
</tr>
</tbody>
</table>

**Note:**
- R/W access control is available for all the eFuse bits listed in the table above.
- The default value of these bits is 0 after manufacturing.
Read and write access to eFuse bits is controlled by appropriate fields in the registers WR_DIS and RD_DIS. For more information on ESP32 eFuses, see eFuse manager. To change protection bits of eFuse field using esperfuse.py, use these two commands: read_protect_efuse and write_protect_efuse. Example esperfuse.py write_protect_efuse DISABLE_DL_ENCRYPT.

4.15.3 Flash Encryption Process

Assuming that the eFuse values are in their default states and the firmware bootloader is compiled to support flash encryption, the flash encryption process executes as shown below:

1. On the first power-on reset, all data in flash is un-encrypted (plaintext). The ROM bootloader loads the firmware bootloader.
2. Firmware bootloader reads the FLASH_CRYPT_CNT eFuse value (0b0000000). Since the value is 0 (even number of bits set), it configures and enables the flash encryption block. It also sets the FLASH_CRYPT_CONFIG eFuse to 0xF. For more information on the flash encryption block, see ESP32 Technical Reference Manual > eFuse Controller (eFuse) > Flash Encryption Block [PDF].
3. Firmware bootloader uses RNG (random) module to generate an AES-256 bit key and then writes it into the flash_encryption eFuse. The key cannot be accessed via software as the write and read protection bits for the flash_encryption eFuse are set. The flash encryption operations happen entirely by hardware, and the key cannot be accessed via software.
4. Flash encryption block encrypts the flash contents - the firmware bootloader, applications and partitions marked as encrypted. Encrypting in-place can take time, up to a minute for large partitions.
5. Firmware bootloader sets the first available bit in FLASH_CRYPT_CNT (0b0000001) to mark the flash contents as encrypted. Odd number of bits is set.
6. For Development Mode, the firmware bootloader sets only the eFuse bits DISABLE_DL_DECRYPT and DISABLE_DL_CACHE to allow the UART bootloader to re-flash encrypted binaries. Also, the FLASH_CRYPT_CNT eFuse bits are NOT write-protected.
7. For Release Mode, the firmware bootloader sets the eFuse bits DISABLE_DL_ENCRYPT, DISABLE_DL_DECRYPT, and DISABLE_DL_CACHE to 1 to prevent the UART bootloader from decrypting the flash contents. It also write-protecs the FLASH_CRYPT_CNT eFuse bits. To modify this behavior, see Enabling UART Bootloader Encryption/Decryption.
8. The device is then rebooted to start executing the encrypted image. The firmware bootloader calls the flash decryption block to decrypt the flash contents and then loads the decrypted contents into IRAM.

During the development stage, there is a frequent need to program different plaintext flash images and test the flash encryption process. This requires that Firmware Download mode is able to load new plaintext images as many times as it might be needed. However, during manufacturing or production stages, Firmware Download mode should not be allowed to access flash contents for security reasons.

Hence, two different flash encryption configurations were created: for development and for production. For details on these configurations, see Section Flash Encryption Configuration.

4.15.4 Flash Encryption Configuration

The following flash encryption modes are available:

- Development Mode - recommended for use only during development. In this mode, it is still possible to flash new plaintext firmware to the device, and the bootloader will transparently encrypt this firmware using the key stored in hardware. This allows, indirectly, to read out the plaintext of the firmware in flash.
- Release Mode - recommended for manufacturing and production. In this mode, flashing plaintext firmware to the device without knowing the encryption key is no longer possible.

This section provides information on the mentioned flash encryption modes and step by step instructions on how to use them.
**Development Mode**

During development, you can encrypt flash using either an ESP32 generated key or external host-generated key.

**Using ESP32 Generated Key**  Development mode allows you to download multiple plaintext images using Firmware Download mode.

To test flash encryption process, take the following steps:

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in Relevant eFuses. See how to check ESP32 Flash Encryption Status.

2. In Project Configuration Menu, do the following:
   - **Enable flash encryption on boot.**
   - **Select encryption mode** (Development mode by default).
   - **Select UART ROM download mode** (enabled by default). Note that for the ESP32 target, the choice is only available when CONFIG_ESP32_REV_MIN level is set to 3 (ESP32 V3).
   - **Select the appropriate bootloader log verbosity.**
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See Bootloader Size.

3. Run the command given below to build and flash the complete images.

   ```
   idf.py flash monitor
   ```

   **Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

A sample output of the first ESP32 boot after enabling flash encryption is given below:

```

Sample program to check Flash Encryption
This is ESP32 chip with 2 CPU cores, WiFi/BT/BLE, silicon revision 1, 4MB external...

Flash encryption feature is enabled
Flash encryption mode is DEVELOPMENT
Flash in encrypted mode with flash_crypt_cnt = 1
Halting...

At this stage, if you need to update and re-flash binaries, see Re-flashing Updated Partitions.

Using Host Generated Key  It is possible to pre-generate a flash encryption key on the host computer and burn it into the eFuse. This allows you to pre-encrypt data on the host and flash already encrypted data without needing a plaintext flash update. This feature can be used in both Development Mode and Release Mode. Without a pre-generated key, data is flashed in plaintext and then ESP32 encrypts the data in-place.

Note:  This option is not recommended for production, unless a separate key is generated for each individual device.

To use a host generated key, take the following steps:

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in Relevant eFuses. See how to check ESP32 Flash Encryption Status.

2. Generate a random key by running:

   ```
   espsecure.py generate_flash_encryption_key my_flash_encryption_key.bin
   ```

3. Before the first encrypted boot, burn the key into your device’s eFuse using the command below. This action can be done only once.

   ```
   espefuse.py --port PORT burn_key flash_encryption my_flash_encryption_key.bin
   ```

   If the key is not burned and the device is started after enabling flash encryption, the ESP32 will generate a random key that software cannot access or modify.

4. In Project Configuration Menu, do the following:

   - Enable flash encryption on boot
   - Select encryption mode (Development mode by default)
   - Select the appropriate bootloader log verbosity
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See Bootloader Size.

5. Run the command given below to build and flash the complete images.
**Note:** This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

If using Development Mode, then the easiest way to update and re-flash binaries is **Re-flashing Updated Partitions**.

If using Release Mode, then it is possible to pre-encrypt the binaries on the host and then flash them as ciphertext. See **Manually Encrypting Files**.

**Re-flashing Updated Partitions**  If you update your application code (done in plaintext) and want to re-flash it, you will need to encrypt it before flashing. To encrypt the application and flash it in one step, run:

```
idf.py encrypted-app-flash monitor
```

If all partitions needs to be updated in encrypted format, run:

```
idf.py encrypted-flash monitor
```

**Release Mode**

In Release mode, UART bootloader cannot perform flash encryption operations. New plaintext images can ONLY be downloaded using the over-the-air (OTA) scheme which will encrypt the plaintext image before writing to flash.

To use this mode, take the following steps:

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in **Relevant eFuses**. See how to check **ESP32 Flash Encryption Status**.
2. In **Project Configuration Menu**, do the following:
   - **Enable flash encryption on boot**
   - **Select Release mode** (Note that once Release mode is selected, the DISABLE_DL_ENCRYPT and DISABLE_DL_DECRYPT eFuse bits will be burned to disable flash encryption hardware in ROM Download Mode.)
   - **Select UART ROM download mode (Permanently disabled (recommended))** (Note that this option is only available when CONFIG_ESP32_REV_MIN is set to 3 (ESP32 V3)). The default choice is to keep UART ROM download mode enabled, however it’s recommended to permanently disable this mode to reduce the options available to an attacker.
   - **Select the appropriate bootloader log verbosity**
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See **Bootloader Size**.

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```
Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as encrypted then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

Once the flash encryption is enabled in Release mode, the bootloader will write-protect the FLASH_CRYPT_CNT eFuse.

For subsequent plaintext field updates, use OTA scheme.

Note: If you have pre-generated the flash encryption key and stored a copy, and the UART download mode is not permanently disabled via CONFIG_SECURE_UART_ROM_DL_MODE (ESP32 V3 only), then it is possible to update the flash locally by pre-encrypting the files and then flashing the ciphertext. See Manually Encrypting Files.

Best Practices

When using Flash Encryption in production:

- Do not reuse the same flash encryption key between multiple devices. This means that an attacker who copies encrypted data from one device cannot transfer it to a second device.
- When using ESP32 V3, if the UART ROM Download Mode is not needed for a production device then it should be disabled to provide an extra level of protection. Do this by calling esp_efuse_disable_rom_download_mode() during application startup. Alternatively, configure the project CONFIG_ESP32_REV_MIN level to 3 (targeting ESP32 V3 only) and select the CONFIG_SECURE_UART_ROM_DL_MODE to “Permanently disable ROM Download Mode (recommended)” . The ability to disable ROM Download Mode is not available on earlier ESP32 versions.
- Enable Secure Boot as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

4.15.5 Possible Failures

Once flash encryption is enabled, the FLASH_CRYPT_CNT eFuse value will have an odd number of bits set. It means that all the partitions marked with the encryption flag are expected to contain encrypted ciphertext. Below are the three typical failure cases if the ESP32 is erroneously loaded with plaintext data:

1. If the bootloader partition is re-flashed with a plaintext firmware bootloader image, the ROM bootloader will fail to load the firmware bootloader resulting in the following failure:

```plaintext
rst:0x3 (SW_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
flash read err, 1000
ets_main.c 371
ets Jun 8 2016 00:22:57

rst:0x7 (TG0WDT_SYS_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
flash read err, 1000
ets_main.c 371
ets Jun 8 2016 00:22:57

rst:0x7 (TG0WDT_SYS_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
```

(continues on next page)
Note: This error also appears if the flash contents are erased or corrupted.

2. If the firmware bootloader is encrypted, but the partition table is re-flashed with a plaintext partition table image, the bootloader will fail to read the partition table resulting in the following failure:

```
rst:0x7 (TG0WDT_SYS_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
flash read err, 1000
ets_main.c 371
ets Jun 8 2016 00:22:57
```

```
flash read err, 1000
ets_main.c 371
ets Jun 8 2016 00:22:57
```

```
flash read err, 1000
ets_main.c 371
ets Jun 8 2016 00:22:57
```

```
Note: This error also appears if the flash contents are erased or corrupted.

2. If the firmware bootloader is encrypted, but the partition table is re-flashed with a plaintext partition table image, the bootloader will fail to read the partition table resulting in the following failure:

```
rst:0x3 (SW_RESET), boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00

```

(continues on next page)
### 4.15.6 ESP32 Flash Encryption Status

1. Ensure that you have an ESP32 device with default flash encryption eFuse settings as shown in Relevant eFuses.

To check if flash encryption on your ESP32 device is enabled, do one of the following:

- flash the application example security/flash_encryption onto your device. This application prints the `FLASH_CRYPT_CNT` eFuse value and if flash encryption is enabled or disabled.
- Find the serial port name under which your ESP32 device is connected, replace PORT with your port name in the following command, and run it:

```
espconfuse.py -p PORT summary
```

### 4.15.7 Reading and Writing Data in Encrypted Flash

ESP32 application code can check if flash encryption is currently enabled by calling `esp_flash_encryption_enabled()`. Also, a device can identify the flash encryption mode by calling `esp_get_flash_encryption_mode()`.

Once flash encryption is enabled, be more careful with accessing flash contents from code.

**Scope of Flash Encryption**

Whenever the `FLASH_CRYPT_CNT` eFuse is set to a value with an odd number of bits, all flash content accessed via the MMU’s flash cache is transparently decrypted. It includes:

- Executable application code in flash (IROM).
- All read-only data stored in flash (DROM).
- Any data accessed via `spi_flash_mmap()`.
- The firmware bootloader image when it is read by the ROM bootloader.

**Important:** The MMU flash cache unconditionally decrypts all existing data. Data which is stored unencrypted in flash memory will also be “transparently decrypted” via the flash cache and will appear to software as random garbage.

**Reading from Encrypted Flash**

To read data without using a flash cache MMU mapping, you can use the partition read function `esp_partition_read()`. This function will only decrypt data when it is read from an encrypted partition. Data read from unencrypted partitions will not be decrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also use the following SPI flash API functions:

- `esp_flash_read()` to read raw (encrypted) data which will not be decrypted
Chapter 4. API Guides

- `esp_flash_read_encrypted()` to read and decrypt data

Data stored using the Non-Volatile Storage (NVS) API is always stored and read decrypted from the perspective of flash encryption. It is up to the library to provide encryption feature if required. Refer to NVS Encryption for more details.

**Writing to Encrypted Flash**

It is recommended to use the partition write function `esp_partition_write()`. This function will only encrypt data when it is written to an encrypted partition. Data written to unencrypted partitions will not be encrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also pre-encrypt and write data using the function `esp_flash_write_encrypted()`.

Also, the following ROM function exist but not supported in esp-idf applications:

- `esp_rom_spiflash_write_encrypted` pre-encrypts and writes data to flash
- `SPIWrite` writes unencrypted data to flash

Since data is encrypted in blocks, the minimum write size for encrypted data is 16 bytes and the alignment is also 16 bytes.

### 4.15.8 Updating Encrypted Flash

**OTA Updates**

OTA updates to encrypted partitions will automatically write encrypted data if the function `esp_partition_write()` is used.

Before building the application image for OTA updating of an already encrypted device, enable the option **Enable flash encryption on boot** in project configuration menu.

For general information about ESP-IDF OTA updates, please refer to OTA

**Updating Encrypted Flash via Serial**

Flashing an encrypted device via serial bootloader requires that the serial bootloader download interface has not been permanently disabled via eFuse.

In Development Mode, the recommended method is **Re-flashing Updated Partitions**.

In Release Mode, if a copy of the same key stored in eFuse is available on the host then it’s possible to pre-encrypt files on the host and then flash them. See **Manually Encrypting Files**.

### 4.15.9 Disabling Flash Encryption

If flash encryption was enabled accidentally, flashing of plaintext data will soft-brick the ESP32. The device will reboot continuously, printing the error `flash read err, 1000 or invalid header: 0xXXXXXX`

For flash encryption in Development mode, encryption can be disabled by burning the `FLASH_CRYPT_CNT` eFuse. It can only be done three times per chip by taking the following steps:

1. In Project Configuration Menu, disable **Enable flash encryption on boot**, then save and exit.
2. Open project configuration menu again and double-check that you have disabled this option! If this option is left enabled, the bootloader will immediately re-enable encryption when it boots.
3. With flash encryption disabled, build and flash the new bootloader and application by running `idf.py flash`.
4. Use `esefuse.py` (in components/esptool_py/esptool) to disable the `FLASH_CRYPT_CNT` by running:
Reset the ESP32. Flash encryption will be disabled, and the bootloader will boot as usual.

4.15.10  Key Points About Flash Encryption

- Flash memory contents is encrypted using AES-256. The flash encryption key is stored in the flash_encryption eFuse internal to the chip and, by default, is protected from software access.
- The flash encryption algorithm is AES-256, where the key is “tweaked” with the offset address of each 32 byte block of flash. This means that every 32-byte block (two consecutive 16 byte AES blocks) is encrypted with a unique key derived from the flash encryption key.
- Flash access is transparent via the flash cache mapping feature of ESP32 - any flash regions which are mapped to the address space will be transparently decrypted when read.
- Some data partitions might need to remain unencrypted for ease of access or might require the use of flash-friendly update algorithms which are ineffective if the data is encrypted. NVS partitions for non-volatile storage cannot be encrypted since the NVS library is not directly compatible with flash encryption. For details, refer to NVS Encryption.
- If flash encryption might be used in future, the programmer must keep it in mind and take certain precautions when writing code that uses encrypted flash.
- If secure boot is enabled, re-flashing the bootloader of an encrypted device requires a “Re-flashable” secure boot digest (see Flash Encryption and Secure Boot).

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See Bootloader Size.

**Important:** Do not interrupt power to the ESP32 while the first boot encryption pass is running. If power is interrupted, the flash contents will be corrupted and will require flashing with unencrypted data again. In this case, re-flashing will not count towards the flashing limit.

4.15.11  Limitations of Flash Encryption

Flash encryption protects firmware against unauthorised readout and modification. It is important to understand the limitations of the flash encryption feature:

- Flash encryption is only as strong as the key. For this reason, we recommend keys are generated on the device during first boot (default behaviour). If generating keys off-device, ensure proper procedure is followed and don’t share the same key between all production devices.
- Not all data is stored encrypted. If storing data on flash, check if the method you are using (library, API, etc.) supports flash encryption.
- Flash encryption does not prevent an attacker from understanding the high-level layout of the flash. This is because the same AES key is used for every pair of adjacent 16 byte AES blocks. When these adjacent 16 byte blocks contain identical content (such as empty or padding areas), these blocks will encrypt to produce matching pairs of encrypted blocks. This may allow an attacker to make high-level comparisons between encrypted devices (i.e. to tell if two devices are probably running the same firmware version).
- For the same reason, an attacker can always tell when a pair of adjacent 16 byte blocks (32 byte aligned) contain two identical 16 byte sequences. Keep this in mind if storing sensitive data on the flash, design your flash storage so this doesn’t happen (using a counter byte or some other non-identical value every 16 bytes is sufficient). NVS Encryption deals with this and is suitable for many uses.
- Flash encryption alone may not prevent an attacker from modifying the firmware of the device. To prevent unauthorised firmware from running on the device, use flash encryption in combination with Secure Boot.
4.15.12 Flash Encryption and Secure Boot

It is recommended to use flash encryption in combination with Secure Boot. However, if Secure Boot is enabled, additional restrictions apply to device re-flashing:

- **OTA Updates** are not restricted, provided that the new app is signed correctly with the Secure Boot signing key.
- **Plaintext serial flash updates** are only possible if the Re-flashable Secure Boot mode is selected and a Secure Boot key was pre-generated and burned to the ESP32 (refer to Secure Boot). In such configuration, `idf.py bootloader` will produce a pre-digested bootloader and secure boot digest file for flashing at offset 0x0. When following the plaintext serial re-flashing steps it is necessary to re-flash this file before flashing other plaintext data.
- **Re-flashing via Pregenerated Flash Encryption Key** is still possible, provided the bootloader is not re-flashed. Re-flashing the bootloader requires the same Re-flashable option to be enabled in the Secure Boot config.

4.15.13 Advanced Features

The following section covers advanced features of flash encryption.

### Encrypted Partition Flag

Some partitions are encrypted by default. Other partitions can be marked in the partition table description as requiring encryption by adding the flag `encrypted` to the partitions’ flag field. As a result, data in these marked partitions will be treated as encrypted in the same manner as an app partition.

<table>
<thead>
<tr>
<th># Name, Type, SubType, Offset, Size, Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvs, data, nvs, 0x9000, 0x6000</td>
</tr>
<tr>
<td>phy_init, data, phy, 0xf000, 0x1000</td>
</tr>
<tr>
<td>factory, app, factory, 0x100000, 1M</td>
</tr>
<tr>
<td>secret_data, 0x40, 0x01, 0x20000, 256K, encrypted</td>
</tr>
</tbody>
</table>

For details on partition table description, see *partition table*.

Further information about encryption of partitions:

- Default partition tables do not include any encrypted data partitions.
- With flash encryption enabled, the app partition is always treated as encrypted and does not require marking.
- If flash encryption is not enabled, the flag “encrypted” has no effect.
- You can also consider protecting phy_init data from physical access, readout, or modification, by marking the optional phy partition with the flag `encrypted`.
- The nvs partition cannot be encrypted, because the NVS library is not directly compatible with flash encryption.

### Enabling UART Bootloader Encryption/Decryption

On the first boot, the flash encryption process burns by default the following eFuses:

- **DISABLE_DL_ENCRYPT** which disables flash encryption operation when running in UART bootloader boot mode.
- **DISABLE_DL_DECRYPT** which disables transparent flash decryption when running in UART bootloader mode, even if the eFuse FLASH_CRYPT_CNT is set to enable it in normal operation.
- **DISABLE_DL_CACHE** which disables the entire MMU flash cache when running in UART bootloader mode.

However, before the first boot you can choose to keep any of these features enabled by burning only selected eFuses and write-protect the rest of eFuses with unset value 0. For example:

```
esefuse.py --port PORT burn_efuse DISABLE_DL_DECRYPT
esefuse.py --port PORT write_protect_efuse DISABLE_DL_ENCRYPT
```
Important: Leaving DISABLE_DL_DECRYPT unset (0) makes flash encryption useless.

An attacker with physical access to the chip can use UART bootloader mode with custom stub code to read out the flash contents.

Setting FLASH_CRYPT_CONFIG

The eFuse FLASH_CRYPT_CONFIG determines the number of bits in the flash encryption key which are “tweaked” with the block offset. For details, see Flash Encryption Algorithm.

On the first boot of the firmware bootloader, this value is set to the maximum 0xF.

It is possible to burn this eFuse manually and write protect it before the first boot in order to select different tweak values. However, this is not recommended.

It is strongly recommended to never write-protect FLASH_CRYPT_CONFIG when it is unset. Otherwise, its value will remain zero permanently, and no bits in the flash encryption key will be tweaked. As a result, the flash encryption algorithm will be equivalent to AES ECB mode.

JTAG Debugging

By default, when Flash Encryption is enabled (in either Development or Release mode) then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables flash encryption.

See JTAG with Flash Encryption or Secure Boot for more information about using JTAG Debugging with Flash Encryption.

Manually Encrypting Files

Manually encrypting or decrypting files requires the flash encryption key to be pre-burned in eFuse (see Using Host Generated Key) and a copy to be kept on the host. If the flash encryption is configured in Development Mode then it’s not necessary to keep a copy of the key or follow these steps, the simpler Re-flashing Updated Partitions steps can be used.

The key file should be a single raw binary file (example: key.bin).

For example, these are the steps to encrypt the file build/my-app.bin to flash at offset 0x10000. Run espsecure.py as follows:

```
espsecure.py encrypt_flash_data --keyfile /path/to/key.bin --address 0x10000 --output my-app-ciphertext.bin build/my-app.bin
```

The file my-app-ciphertext.bin can then be flashed to offset 0x10000 using esptool.py. To see all of the command line options recommended for esptool.py, see the output printed when idf.py build succeeds.

Note: If the flashed ciphertext file is not recognized by the ESP32 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset.

If your ESP32 uses non-default FLASH_CRYPT_CONFIG value in eFuse then you will need to pass the --flash_crypt_conf argument to espsecure.py to set the matching value. This will not happen if the device configured flash encryption by itself, but may happen if burning eFuses manually to enable flash encryption.

The command espsecure.py decrypt_flash_data can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.
4.15.14 Technical Details

The following sections provide some reference information about the operation of flash encryption.

Flash Encryption Algorithm

- AES-256 operates on 16-byte blocks of data. The flash encryption engine encrypts and decrypts data in 32-byte blocks - two AES blocks in series.
- The main flash encryption key is stored in the flash_encryption eFuse and, by default, is protected from further writes or software readout.
- AES-256 key size is 256 bits (32 bytes) read from the flash_encryption eFuse. The hardware AES engine uses the key in reversed byte order as compared to the storage order in flash_encryption.
  - If the CODING_SCHEME eFuse is set to 0 (default, “None” Coding Scheme) then the eFuse key block is 256 bits and the key is stored as-is (in reversed byte order).
  - If the CODING_SCHEME eFuse is set to 1 (3/4 Encoding) then the eFuse key block is 192 bits (in reversed byte order), so overall entropy is reduced. The hardware flash encryption still operates on a 256-bit key, after being read (and un-reversed), the key is extended as \( \text{key} = \text{key}[0:255] + \text{key}[64:127] \).
- AES algorithm is used inverted in flash encryption, so the flash encryption “encrypt” operation is AES decrypt and the “decrypt” operation is AES encrypt. This is for performance reasons and does not alter the efficiency of the algorithm.
- Each 32-byte block (two adjacent 16-byte AES blocks) is encrypted with a unique key. The key is derived from the main flash encryption key in flash_encryption, XORed with the offset of this block in the flash (a “key tweak”).
- The specific tweak depends on the FLASH_CRYPT_CONFIG eFuse setting. This is a 4-bit eFuse where each bit enables XORing of a particular range of the key bits:
  - Bit 1, bits 0-66 of the key are XORed.
  - Bit 2, bits 67-131 of the key are XORed.
  - Bit 3, bits 132-194 of the key are XORed.
  - Bit 4, bits 195-256 of the key are XORed.
- It is recommended that FLASH_CRYPT_CONFIG is always left at the default value 0xF, so that all key bits are XORed with the block offset. For details, see Setting FLASH_CRYPT_CONFIG.
- The high 19 bits of the block offset (bit 5 to bit 23) are XORed with the main flash encryption key. This range is chosen for two reasons: the maximum flash size is 16MB (24 bits), and each block is 32 bytes so the least significant 5 bits are always zero.
- There is a particular mapping from each of the 19 block offset bits to the 256 bits of the flash encryption key to determine which bit is XORed with which. See the variable _FLASH_ENCRYPTION_TWEAK_PATTERN in the espsecure.py source code for complete mapping.
- To see the full flash encryption algorithm implemented in Python, refer to the _flash_encryption_operation() function in the espsecure.py source code.

4.16 Hardware Abstraction

Hardware abstraction in ESP-IDF are a group of API that allow users to control peripherals at differing levels of abstraction, as opposed to interfacing with hardware using only the ESP-IDF drivers. ESP-IDF Hardware abstraction will likely be useful for users writing high performance bare-metal drivers, or for those attempting to port an ESP chip to another platform.

This guide is split into the following sections:

1. Architecture
2. LL (Low Level) Layer
3. HAL (Hardware Abstraction Layer)
**Warning:** Hardware abstraction API (excluding the driver and xxx_types.h) should be considered an experimental feature, thus cannot be considered public API. Hardware abstraction API do not adhere to the API name changing restrictions of ESP-IDF’s versioning scheme. In other words, it is possible that Hardware Abstraction API may change in between non-major release versions.

**Note:** Although this document mainly focuses on hardware abstraction of peripherals (e.g., UART, SPI, I2C), certain layers of hardware abstraction extend to other aspects of hardware as well (e.g., some of the CPU’s features are partially abstracted).

### 4.16.1 Architecture

Hardware abstraction in ESP-IDF is comprised of the following layers, ordered from low level (closer to hardware) to high level (further away from hardware) of abstraction.

- Low Level (LL) Layer
- Hardware Abstraction Layer (HAL)
- Driver Layers

The LL Layer, and HAL are entirely contained within the **hal** component. Each layer is dependent on the layer below it (i.e, driver depends on HAL, HAL depends on LL, LL depends on the register header files).

For a particular peripheral xxx, its hardware abstraction will generally consist of the header files described in the table below. Files that are **Target Specific** will have a separate implementation for each target (i.e., a separate copy for each chip). However, the **#include** directive will still be target-independent (i.e., will be the same for different targets) as the build system will automatically include the correct version of the header and source files.
Table 23: Hardware Abstraction Header Files

<table>
<thead>
<tr>
<th>Include Directive</th>
<th>Target Specific</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#include 'soc/xxx_caps.h&quot;</td>
<td>Y</td>
<td>This header contains a list of C macros specifying the various capabilities of the ESP32’s peripheralxxx. Hardware capabilities of a peripheral include things such as the number of channels, DMA support, hardware FIFO/buffer lengths, etc.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_struct.h&quot; #include &quot;soc/xxx_reg.h&quot;</td>
<td>Y</td>
<td>The two headers contain a representation of a peripheral’s registers in C structure and C macro format respectively. Users can operate a peripheral at the register level via either of these two header files.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_pins.h&quot;</td>
<td>Y</td>
<td>If certain signals of a peripheral are mapped to a particular pin of the ESP32, their mappings are defined in this header as C macros.</td>
</tr>
<tr>
<td>#include &quot;soc/xxx_periph.h&quot;</td>
<td>N</td>
<td>This header is mainly used as a convenience header file to automatically include xxx_caps.h, xxx_struct.h, and xxx_reg.h.</td>
</tr>
</tbody>
</table>
| #include "hal/xxx_types.h" | N | This header contains type definitions and macros that are shared among the LL, HAL, and driver layers. Moreover, it is considered public API thus can be included by the application level. The shared types and definitions usually related to non-implementation specific concepts such as the following:  
  • Protocol related types/macros such as a frames, modes, common bus speeds, etc.  
  • Features/characteristics of an xxx peripheral that are likely to be present on any implementation (implementation-independent) such as channels, operating modes, signal amplification or attenuation intensities, etc. |
| #include "hal/xxx_ll.h" | Y | This header contains the Low Level (LL) Layer of hardware abstraction. LL Layer API are primarily used to abstract away register operations into readable functions. |
| #include "hal/xxx_hal.h" | Y | The Hardware Abstraction Layer (HAL) is used to abstract away peripheral operation steps into functions (e.g., reading a buffer, starting a transmission, handling an event, etc). The HAL is built on top of the LL Layer. |
| #include "driver/xxx.h" | N | The driver layer is the highest level of ESP-IDF’s hardware abstraction. Driver layer API are meant to be called from ESP-IDF applications, and internally utilize OS primitives. Thus, driver layer API are event-driven, and can used in a multi-threaded environment. |

4.16.2 LL (Low Level) Layer

The primary purpose of the LL Layer is to abstract away register field access into more easily understandable functions. LL functions essentially translate various in/out arguments into the register fields of a peripheral in the form of get/set functions. All the necessary bit shifting, masking, offsetting, and endianness of the register fields should be handled by the LL functions.

```c
//Inside xxx_ll.h
static inline void xxx_ll_set_baud_rate(xxx_dev_t *hw,
    xxx_ll_clk_src_t clock_source,
    uint32_t baud_rate) {
    uint32_t src_clk_freq = (source_clk == XXX_SCLK_APB) ? APB_CLK_FREQ : REF_CLK_FREQ;
    uint32_t clock_divider = src_clk_freq / baud;
    // Set clock select field
    hw->clk_div_reg.divider = clock_divider >> 4;
    // Set clock divider field
```
The code snippet above illustrates typical LL functions for a peripheral xxx. LL functions typically have the following characteristics:

- All LL functions are defined as **static inline** so that there is minimal overhead when calling these functions due to compiler optimization. These functions are not guaranteed to be inlined by the compiler, so any LL function that will be called when the cache is disabled (e.g. from an IRAM ISR context) should be marked with **__attribute__((always_inline))**.
- The first argument should be a pointer to a `xxx_dev_t` type. The `xxx_dev_t` type is a structure representing the peripheral’s registers, thus the first argument is always a pointer to the starting address of the peripheral’s registers. Note that in some cases where the peripheral has multiple channels with identical register layouts, `xxx_dev_t *hw` may point to the registers of a particular channel instead.
- LL functions should be short and in most cases are deterministic. In other words, the worst case runtime of the LL function can be determined at compile time. Thus, any loops in LL functions should be finite bounded; however, there are currently a few exceptions to this rule.
- LL functions are not thread safe, it is the responsibility of the upper layers (driver layer) to ensure that registers or register fields are not accessed concurrently.

### 4.16.3 HAL (Hardware Abstraction Layer)

The HAL layer models the operational process of a peripheral as a set of general steps, where each step has an associated function. For each step, the details of a peripheral’s register implementation (i.e., which registers need to be set/read) are hidden (abstracted away) by the HAL. By modeling peripheral operation as a set of functional steps, any minor hardware implementation differences of the peripheral between different targets or chip versions can be abstracted away by the HAL (i.e., handled transparently). In other words, the HAL API for a particular peripheral will remain mostly the same across multiple targets/chip versions.

The following HAL function examples are selected from the Watchdog Timer HAL as each function maps to one of the steps in a WDT’s operation life cycle, thus illustrating how a HAL abstracts a peripheral’s operation into functional steps.

```c
// Initialize one of the WDTs
void wdt_hal_init(wdt_hal_context_t *hal, wdt_inst_t wdt_inst, uint32_t prescaler, _Bool enable_intr);

// Configure a particular timeout stage of the WDT
void wdt_hal_config_stage(wdt_hal_context_t *hal, wdt_stage_t stage, uint32_t timeout, wdt_stage_action_t behavior);

// Start the WDT
void wdt_hal_enable(wdt_hal_context_t *hal);

// Feed (i.e., reset) the WDT
void wdt_hal_feed(wdt_hal_context_t *hal);

// Handle a WDT timeout
void wdt_hal_handle_intr(wdt_hal_context_t *hal);

// Stop the WDT
void wdt_hal_disable(wdt_hal_context_t *hal);

// De-initialize the WDT
void wdt_hal_deinit(wdt_hal_context_t *hal);
```
HAL functions will generally have the following characteristics:

- The first argument to a HAL function has the `xxx_hal_context_t` * type. The HAL context type is used to store information about a particular instance of the peripheral (i.e. the context instance). A HAL context is initialized by the `xxx_hal_init()` function and can store information such as the following:
  - The channel number of this instance
  - Pointer to the peripheral’s (or channel’s) registers (i.e., a `xxx_dev_t` * type)
  - Information about an ongoing transaction (e.g., pointer to DMA descriptor list in use)
  - Some configuration values for the instance (e.g., channel configurations)
  - Variables to maintain state information regarding the instance (e.g., a flag to indicate if the instance is waiting for transaction to complete)
- HAL functions should not contain any OS primitives such as queues, semaphores, mutexes, etc. All synchronization/concurrency should be handled at higher layers (e.g., the driver).
- Some peripherals may have steps that cannot be further abstracted by the HAL, thus will end up being a direct wrapper (or macro) for an LL function.
- Some HAL functions may be placed in IRAM thus may carry an IRAM_ATTR or be placed in a separate `xxx_hal_iram.c` source file.

### 4.17 High-Level Interrupts

The Xtensa architecture has support for 32 interrupts, divided over 7 levels (levels 1 to 7, with 7 being an NMI), plus an assortment of exceptions. On the ESP32, the interrupt mux allows most interrupt sources to be routed to these interrupts using the interrupt allocator. Normally, interrupts will be written in C, but ESP-IDF allows high-level interrupts to be written in assembly as well, resulting in very low interrupt latencies.

#### 4.17.1 Interrupt Levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Symbol</th>
<th>Remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>N/A</td>
<td>Exception and level 0 interrupts. Handled by ESP-IDF</td>
</tr>
<tr>
<td>2-3</td>
<td>N/A</td>
<td>Medium level interrupts. Handled by ESP-IDF</td>
</tr>
<tr>
<td>4</td>
<td>xt_highint4</td>
<td>Free to use (See 1)</td>
</tr>
<tr>
<td>5</td>
<td>xt_highint5</td>
<td>Normally used by ESP-IDF debug logic (See 1)</td>
</tr>
<tr>
<td></td>
<td>NMI</td>
<td>Free to use</td>
</tr>
<tr>
<td></td>
<td>dbg</td>
<td>Debug exception. Called on e.g. a BREAK instruction. (See 2)</td>
</tr>
</tbody>
</table>

The following notes give more information about the items in the tables above.

1. ESP-IDF debug logic can be configured to run on `xt_highint4` or `xt_highint5` in `CONFIG_ESP_SYSTEM_CHECK_INT_LEVEL`. Bluetooth’s interrupt can be configured to run on level 4 by enabling `CONFIG_BTDM_CTRL_HLI`. If `CONFIG_BTDM_CTRL_HLI` is enabled, ESP-IDF debug logic must be running on level 5 interrupt.

2. If `CONFIG_BTDM_CTRL_HLI` is enabled, `xt_debugexception` is used to fix live lock issue in ESP32 ECO3.

Using these symbols is done by creating an assembly file (suffix .S) and defining the named symbols, like this:

```assembly
.section .iram1,"ax"
.global xt_highint5
.type xt_highint5,@function
.align 4
xt_highint5:
... your code here
rsr a0, EXCSAVE_5
rfi 5
```

For a real-life example, see the `esp_system/port/soc/esp32/highint_hdl.S` file; the panic handler interrupt is implemented there.
4.17.2 Notes

• Do not call C code from a high-level interrupt; as these interrupts are run from a critical section, this can cause the target to crash. Note that although the panic handler interrupt does call normal C code, this exception is allowed due to the fact that this handler never returns (i.e., the application will not continue to run after the panic handler). So breaking C code execution flow is not a problem.

When `CONFIG_BTDM_CTRL_HLI` is enabled, C code is also called from a high-level interrupt, this is possible thanks to some additional protection added to it.

• Make sure your assembly code gets linked in. Indeed, as the free-to-use symbols are declared as weak, the linker may discard the file containing the symbol. This will happen if the only symbol defined, or used, from the user file is the `xt_*` free-to-use symbol. To avoid this, in the assembly file containing the `xt_*` symbol, define another symbol, like:

```assembly
.global ld_include_my_isr_file
ld_include_my_isr_file:

Here it is called `ld_include_my_isr_file` but can have any name, as long as it is not defined anywhere else in the project.

Then, in the component `CMakeLists.txt`, add this name as an unresolved symbol to the ld command line arguments:

```
target_link_libraries(${COMPONENT_TARGET} "-u ld_include_my_isr_file")
```

This should cause the linker to always include the file defining `ld_include_my_isr_file`, causing the ISR to always be linked in.

• High-level interrupts can be routed and handled using `esp_intr_alloc()` and associated functions. The handler and handler arguments to `esp_intr_alloc()` must be NULL, however.

• In theory, medium priority interrupts could also be handled in this way. ESP-IDF does not support this yet.

• To check Xtensa instruction set architecture (ISA), please refer to the Xtensa ISA Summary.

4.18 JTAG Debugging

This document provides a guide to installing OpenOCD for ESP32 and debugging using GDB. The document is structured as follows:

Introduction Introduction to the purpose of this guide.

How it Works? Description how ESP32, JTAG interface, OpenOCD and GDB are interconnected and working together to enable debugging of ESP32.

Selecting JTAG Adapter What are the criteria and options to select JTAG adapter hardware.

Setup of OpenOCD Procedure to install OpenOCD and verify that it is installed.

Configuring ESP32 Target Configuration of OpenOCD software and setting up of JTAG adapter hardware, which together make up the debugging target.

Launching Debugger Steps to start up a debug session with GDB from Eclipse and from Command Line.

Debugging Examples If you are not familiar with GDB, check this section for debugging examples provided from Eclipse as well as from Command Line.

Building OpenOCD from Sources Procedure to build OpenOCD from sources for Windows, Linux and macOS operating systems.

Tips and Quirks This section provides collection of tips and quirks related to JTAG debugging of ESP32 with OpenOCD and GDB.

4.18.1 Introduction

The ESP32 has two powerful Xtensa cores, allowing for a great deal of variety of program architectures. The FreeRTOS OS that comes with ESP-IDF is capable of multi-core preemptive scheduling, allowing for an intuitive way of
writing software.

The downside of the ease of programming is that debugging without the right tools is harder: figuring out a bug that is caused by two threads, running even simultaneously on two different CPU cores, can take a long time when all you have are `printf()` statements. A better (and in many cases quicker) way to debug such problems is by using a debugger, connected to the processors over a debug port.

Espressif has ported OpenOCD to support the ESP32 processor and the multi-core FreeRTOS (which is the foundation of most ESP32 apps). Additionally, some extra tools have been written to provide extra features that OpenOCD does not support natively.

This document provides a guide to installing OpenOCD for ESP32 and debugging using GDB under Linux, Windows and macOS. Except for OS specific installation procedures, the s/w user interface and use procedures are the same across all supported operating systems.

**Note:** Screenshots presented in this document have been made for Eclipse Neon 3 running on Ubuntu 16.04 LTS. There may be some small differences in what a particular user interface looks like, depending on whether you are using Windows, macOS or Linux and / or a different release of Eclipse.

### 4.18.2 How it Works?

The key software and hardware components that perform debugging of ESP32 with OpenOCD over JTAG (Joint Test Action Group) interface is presented in the diagram below under the “Debugging With JTAG” label. These components include xtensa-esp32-elf-gdb debugger, OpenOCD on chip debugger, and the JTAG adapter connected to ESP32 target.

Likewise, the “Application Loading and Monitoring” label indicates the key software and hardware components that allow an application to be compiled, built, and flashed to ESP32, as well as to provide means to monitor diagnostic messages from ESP32.

“Debugging With JTAG” and “Application Loading and Monitoring” is integrated under the Eclipse IDE in order to provide a quick and easy transition between writing/compiling/loading/debugging code. The Eclipse IDE (and the integrated debugging software) is available for Windows, Linux and macOS platforms. Depending on user preferences, both the debugger and `idf.py build` can also be used directly from terminal/command line, instead of Eclipse.
If the *ESP-WROVER-KIT* is used, then connection from PC to ESP32 is done effectively with a single USB cable. This is made possible by the FT2232H chip, which provides two USB channels, one for JTAG and the other for UART connection.

### 4.18.3 Selecting JTAG Adapter

The quickest and most convenient way to start with JTAG debugging is by using *ESP-WROVER-KIT*. Each version of this development board has JTAG interface already built in. No need for an external JTAG adapter and extra wiring / cable to connect JTAG to ESP32. ESP-WROVER-KIT is using FT2232H JTAG interface operating at 20 MHz clock speed, which is difficult to achieve with an external adapter.

If you decide to use separate JTAG adapter, look for one that is compatible with both the voltage levels on the ESP32 as well as with the OpenOCD software. The JTAG port on the ESP32 is an industry-standard JTAG port which lacks (and does not need) the TRST pin. The JTAG I/O pins all are powered from the VDD_3P3_RTC pin (which normally would be powered by a 3.3 V rail) so the JTAG adapter needs to be able to work with JTAG pins in that voltage range.

On the software side, OpenOCD supports a fair amount of JTAG adapters. See [https://openocd.org/doc/html/Debug-Adapter-Hardware.html](https://openocd.org/doc/html/Debug-Adapter-Hardware.html) for an (unfortunately slightly incomplete) list of the adapters OpenOCD works with. This page lists SWD-compatible adapters as well; take note that the ESP32 does not support SWD. JTAG adapters that are hardcoded to a specific product line, e.g. ST-LINK debugging adapters for STM32 families, will not work.

The minimal signalling to get a working JTAG connection are TDI, TDO, TCK, TMS and GND. Some JTAG debuggers also need a connection from the ESP32 power line to a line called e.g. Vtar to set the working voltage. SRST can optionally be connected to the CH_PD of the ESP32, although for now, support in OpenOCD for that line is pretty minimal.

*ESP-Prog* is an example for using an external board for debugging by connecting it to the JTAG pins of ESP32.

### 4.18.4 Setup of OpenOCD

If you have already set up ESP-IDF with CMake build system according to the *Getting Started Guide*, then OpenOCD is already installed. After setting up the environment in your terminal, you should be able to run OpenOCD. Check this by executing the following command:

```
openocd --version
```

The output should be as follows (although the version may be more recent than listed here):

```
Open On-Chip Debugger v0.10.0-esp32-20190708 (2019-07-08-11:04)
Licensed under GNU GPL v2
For bug reports, read
https://openocd.org/doc/doxygen/bugs.html
```

You may also verify that OpenOCD knows where its configuration scripts are located by printing the value of *OPENOCD_SCRIPTS* environment variable, by typing `echo $OPENOCD_SCRIPTS` (for Linux and macOS) or `echo %OPENOCD_SCRIPTS%` (for Windows). If a valid path is printed, then OpenOCD is set up correctly.

If any of these steps do not work, please go back to the *setting up the tools* section of the Getting Started Guide.

---

**Note:** It is also possible to build OpenOCD from source. Please refer to *Building OpenOCD from Sources* section for details.

### 4.18.5 Configuring ESP32 Target

Once OpenOCD is installed, you can proceed to configuring the ESP32 target (i.e ESP32 board with JTAG interface). Configuring the target is split into the following three steps:
Chapter 4. API Guides

- Configure and connect JTAG interface
- Run OpenOCD
- Upload application for debugging

Configure and connect JTAG interface

This step depends on the JTAG and ESP32 board you are using (see the two cases described below).

Configure ESP-WROVER-KIT JTAG Interface

All versions of ESP-WROVER-KIT boards have built-in JTAG functionality. Putting it to work requires setting jumpers or DIP switches to enable JTAG functionality, and configuring USB drivers. Please refer to step by step instructions below.

Configure Hardware

- Enable on-board JTAG functionality by setting JP8 according to ESP-WROVER-KIT V4.1 Getting Started Guide, Section Setup Options.
- Verify if ESP32 pins used for JTAG communication are not connected to some other h/w that may disturb JTAG operation:

<table>
<thead>
<tr>
<th>ESP32 Pin</th>
<th>JTAG Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDO / GPIO15</td>
<td>TDO</td>
</tr>
<tr>
<td>MTDI / GPIO12</td>
<td>TDI</td>
</tr>
<tr>
<td>MTCK / GPIO13</td>
<td>TCK</td>
</tr>
<tr>
<td>MTMS / GPIO14</td>
<td>TMS</td>
</tr>
</tbody>
</table>

Configure USB Drivers

Install and configure USB drivers, so OpenOCD is able to communicate with JTAG interface on ESP-WROVER-KIT board as well as with UART interface used to upload application for flash. Follow steps below specific to your operating system.

**Note:** ESP-WROVER-KIT uses an FT2232 adapter. The following instructions can also be used for other FT2232 based JTAG adapters.

**Windows**

2. Wait until USB ports of ESP-WROVER-KIT are recognized by Windows and drives are installed. If they do not install automatically, then download them from https://ftdichip.com/drivers/d2xx-drivers/ and install manually.
3. Download Zadig tool (Zadig_X.X.exe) from https://zadig.akeo.ie/ and run it.
4. In Zadig tool go to “Options” and check “List All Devices”.
5. Check the list of devices that should contain two ESP-WROVER-KIT specific USB entries: “Dual RS232-HS (Interface 0)” and “Dual RS232-HS (Interface 1)”. The driver name would be “FTDIBUS (vxxxx)” and USB ID: 0403 6010.
6. The first device (Dual RS232-HS (Interface 0)) is connected to the JTAG port of the ESP32. Original “FTDIBUS (vxxxx)” driver of this device should be replaced with “WinUSB (v6xxxxx)”. To do so, select “Dual RS232-HS (Interface 0) and reinstall attached driver to the “WinUSB (v6xxxxx)” , see picture above.

**Note:** Do not change the second device “Dual RS232-HS (Interface 1)”. It is routed to ESP32’s serial port (UART) used for upload of application to ESP32’s flash.
Now ESP-WROVER-KIT’s JTAG interface should be available to the OpenOCD. To carry on with debugging environment setup, proceed to section Run OpenOCD.

**Linux**

2. Open a terminal, enter `ls -l /dev/ttyUSB*` command and check, if board’s USB ports are recognized by the OS. You are looking for similar result:

   ```
   user-name@computer-name:~/esp$ ls -l /dev/ttyUSB*
   crw-rw---- 1 root dialout 188, 0 Jul 10 19:04 /dev/ttyUSB0
   crw-rw---- 1 root dialout 188, 1 Jul 10 19:04 /dev/ttyUSB1
   ```

3. To set up access permissions to USB devices supported by OpenOCD, copy the `udev` rules file into the `/etc/udev/rules.d` directory.

4. Log off and login, then cycle the power to the board to make the changes effective. In terminal enter again `ls -l /dev/ttyUSB*` command to verify, if group-owner has changed from `dialout` to `plugdev`:

   ```
   user-name@computer-name:~/esp$ ls -l /dev/ttyUSB*
   crw-rw-r-- 1 root plugdev 188, 0 Jul 10 19:07 /dev/ttyUSB0
   crw-rw-r-- 1 root plugdev 188, 1 Jul 10 19:07 /dev/ttyUSB1
   ```

   If you see similar result and you are a member of `plugdev` group, then the set up is complete.

The `/dev/ttyUSBn` interface with lower number is used for JTAG communication. The other interface is routed to ESP32’s serial port (UART) used for upload of application to ESP32’s flash.

Now ESP-WROVER-KIT’s JTAG interface should be available to the OpenOCD. To carry on with debugging environment setup, proceed to section Run OpenOCD.

**MacOS** On macOS, using FT2232 for JTAG and serial port at the same time needs some additional steps. When the OS loads FTDI serial port driver, it does so for both channels of FT2232 chip. However only one of these channels is used as a serial port, while the other is used as JTAG. If the OS has loaded FTDI serial port driver for the channel used for JTAG, OpenOCD will not be able to connect to the chip. There are two ways around this:

1. Manually unload the FTDI serial port driver before starting OpenOCD, start OpenOCD, then load the serial port driver.

2. Modify FTDI driver configuration so that it doesn’t load itself for channel A of FT2232 chip, which is the channel used for JTAG on ESP-WROVER-KIT.
Manually unloading the driver

1. Install FTDI driver from https://ftdichip.com/drivers/vcp-drivers/
2. Connect USB cable to the ESP-WROVER-KIT.
3. Unload the serial port driver:

   ```
   sudo kextunload -b com.FTDI.driver.FTDIUSBSerialDriver
   ```

   In some cases you may need to unload Apple’s FTDI driver as well:
   - macOS < 10.15:
     ```
     sudo kextunload -b com.apple.driver.AppleUSBFTDI
     ```
   - macOS 10.15:
     ```
     sudo kextunload -b com.apple.DriverKit-AppleUSBFTDI
     ```

   **Warning:** Attempting to use serial over the wrong channel with the FTDI driver will cause a kernel panic. The ESP-WROVER-KIT uses channel A for JTAG and channel B for serial.

4. Run OpenOCD:

   ```
   openocd -f board/esp32-wrover-kit-3.3v.cfg
   ```

5. In another terminal window, load FTDI serial port driver again:

   ```
   sudo kextload -b com.FTDI.driver.FTDIUSBSerialDriver
   ```

   **Note:** If you need to restart OpenOCD, there is no need to unload FTDI driver again — just stop OpenOCD and start it again. The driver only needs to be unloaded if ESP-WROVER-KIT was reconnected or power was toggled.

   This procedure can be wrapped into a shell script, if desired.

Modifying FTDI driver

In a nutshell, this approach requires modification to FTDI driver configuration file, which prevents the driver from being loaded for channel B of FT2232H.

**Note:** Other boards may use channel A for JTAG, so use this option with caution.

**Warning:** This approach also needs signature verification of drivers to be disabled, so may not be acceptable for all users.

1. Open FTDI driver configuration file using a text editor (note `sudo`):

   ```
   sudo nano /Library/Extensions/FTDIUSBSerialDriver.kext/Contents/Info.plist
   ```

2. Find and delete the following lines:

   ```xml
   <key>FT2232H_B</key>
   <dict>
     <key>CFBundleIdentifier</key>
     <string>com.FTDI.driver.FTDIUSBSerialDriver</string>
     <key>IOClass</key>
     <string>FTDIUSBSerialDriver</string>
     <key>IOProviderClass</key>
     <string>IOUSBInterface</string>
     <key>bConfigurationValue</key>
     <integer>1</integer>
   </dict>
   ```

   (continues on next page)
3. Save and close the file
4. Disable driver signature verification:
   1. Open Apple logo menu, choose “Restart…”
   2. When you hear the chime after reboot, press CMD+R immediately
   3. Once Recovery mode starts up, open Terminal
   4. Run the command:
      ```
      csrutil enable --without kext
      ```
   5. Restart again

After these steps, serial port and JTAG can be used at the same time.

To carry on with debugging environment setup, proceed to section Run OpenOCD.

**Configure Other JTAG Interfaces**

For guidance about which JTAG interface to select when using OpenOCD with ESP32, refer to the section Selecting JTAG Adapter. Then follow the configuration steps below to get it working.

**Configure Hardware**

1. Identify all pins/signals on JTAG interface and ESP32 board that should be connected to establish communication.

<table>
<thead>
<tr>
<th>ESP32 Pin</th>
<th>JTAG Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDO / GPIO15</td>
<td>TDO</td>
</tr>
<tr>
<td>MTDI / GPIO12</td>
<td>TDI</td>
</tr>
<tr>
<td>MTCK / GPIO13</td>
<td>TCK</td>
</tr>
<tr>
<td>MTMS / GPIO14</td>
<td>TMS</td>
</tr>
</tbody>
</table>

2. Verify if ESP32 pins used for JTAG communication are not connected to some other hardware that may disturb JTAG operation.
3. Connect identified pin/signals of ESP32 and JTAG interface.

**Configure Drivers** You may need to install driver software to make JTAG work with computer. Refer to documentation of your JTAG adapter for related details.

On Linux, adding OpenOCD udev rules is required and is done by copying the udev rules file into the `/etc/udev/rules.d` directory.

**Connect** Connect JTAG interface to the computer. Power on ESP32 and JTAG interface boards. Check if the JTAG interface is visible on the computer.

To carry on with debugging environment setup, proceed to section Run OpenOCD.
Run OpenOCD

Once target is configured and connected to computer, you are ready to launch OpenOCD.

Open a terminal and set it up for using the ESP-IDF as described in the setting up the environment section of the Getting Started Guide. Then run OpenOCD (this command works on Windows, Linux, and macOS):

```
openocd -f board/esp32-wrover-kit-3.3v.cfg
```

**Note:** The files provided after `-f` above are specific for ESP-WROVER-KIT with ESP32-WROOM-32 module. You may need to provide different files depending on the hardware that is used. For guidance see Configuration of OpenOCD for Specific Target.

You should now see similar output (this log is for ESP-WROVER-KIT with ESP32-WROOM-32 module):

```
user-name@computer-name:~/esp/esp-idf$ openocd -f board/esp32-wrover-kit-3.3v.cfg
Open On-Chip Debugger v0.10.0-esp32-20190708 (2019-07-08-11:04)
Licensed under GNU GPL v2
For bug reports, read https://openocd.org/doc/doxygen/bugs.html
none separate
adapter speed: 20000 kHz
force hard breakpoints
Info : ftdi: if you experience problems at higher adapter clocks, try the command →"ftdi_tdo_sample_edge falling"
Info : clock speed 20000 kHz
Info : JTAG tap: esp32.cpu0 tap/device found: 0x120034e5 (mfg: 0x272 (Tensilica), →part: 0x2003, ver: 0x1)
Info : JTAG tap: esp32.cpu1 tap/device found: 0x120034e5 (mfg: 0x272 (Tensilica), →part: 0x2003, ver: 0x1)
Info : esp32: Debug controller was reset (pwrstat=0x5F, after clear 0x0F).
Info : esp32: Core was reset (pwrstat=0x5F, after clear 0x0F).
```

- If there is an error indicating permission problems, please see section on “Permissions delegation” in the OpenOCD README file located in the ~/esp/openocd-esp32 directory.
- In case there is an error in finding the configuration files, e.g. Can't find board/esp32-wrover-kit-3.3v.cfg, check if the OPENOCD_SCRIPTS environment variable is set correctly. This variable is used by OpenOCD to look for the files specified after the `-f` option. See Setup of OpenOCD section for details. Also check if the file is indeed under the provided path.
- If you see JTAG errors (e.g.,...all ones or...all zeroes), please check your JTAG connections, whether other signals are connected to JTAG besides ESP32’s pins, and see if everything is powered on correctly.

Upload application for debugging

Build and upload your application to ESP32 as usual, see Step 5. First Steps on ESP-IDF.

Another option is to write application image to flash using OpenOCD via JTAG with commands like this:

```
openocd -f board/esp32-wrover-kit-3.3v.cfg -c "program_esp filename.bin 0x10000... →verify exit"
```

OpenOCD flashing command `program_esp` has the following format:

```
program_esp <image_file> <offset> [verify] [reset] [exit] [compress] [encrypt]
```

- `image_file` - Path to program image file.
- `offset` - Offset in flash bank to write image.
- `verify` - Optional. Verify flash contents after writing.
• reset - Optional. Reset target after programing.
• exit - Optional. Finally exit OpenOCD.
• compress - Optional. Compress image file before programming.
• encrypt - Optional. Encrypt binary before writing to flash. Same functionality with idf.py encrypted-flash

You are now ready to start application debugging. Follow the steps described in the section below.

4.18.6 Launching Debugger

The toolchain for ESP32 features GNU Debugger, in short GDB. It is available with other toolchain programs under filename: xtensa-esp32-elf-gdb. GDB can be called and operated directly from command line in a terminal. Another option is to call it from within IDE (like Eclipse, Visual Studio Code, etc.) and operate indirectly with help of GUI instead of typing commands in a terminal.

The options of using debugger are discussed under links below.

• Eclipse
• Command Line
• Configuration for Visual Studio Code Debug

It is recommended to first check if debugger works from Command Line and then move to using Eclipse.

4.18.7 Debugging Examples

This section is intended for users not familiar with GDB. It presents example debugging session from Eclipse using simple application available under get-started/blink and covers the following debugging actions:

1. Navigating through the code, call stack and threads
2. Setting and clearing breakpoints
3. Halting the target manually
4. Stepping through the code
5. Checking and setting memory
6. Watching and setting program variables
7. Setting conditional breakpoints

Similar debugging actions are provided using GDB from Command Line.

Note: Debugging FreeRTOS Objects is currently only available for command line debugging.

Before proceeding to examples, set up your ESP32 target and load it with get-started/blink.

4.18.8 Building OpenOCD from Sources

Please refer to separate documents listed below, that describe build process.

Building OpenOCD from Sources for Windows

Note: This document outlines how to build a binary of OpenOCD from its source files instead of downloading the pre-built binary. For a quick setup, users can download a pre-built binary of OpenOCD from Espressif GitHub instead of compiling it themselves (see Setup of OpenOCD for more details).
Note: All code snippets in this document are assumed to be running in an MSYS2 shell with the MINGW32 subsystem.

Install Dependencies

Install packages that are required to compile OpenOCD:

```
pacman --S --noconfirm --needed autoconf automake git make \
mingw-w64-i686-gcc \
mingw-w64-i686-toolchain \
mingw-w64-i686-libtool \
mingw-w64-i686-pkg-config \
mingw-w64-cross-winthreads-git \
p7zip
```

Download Sources of OpenOCD

The sources for the ESP32-enabled variant of OpenOCD are available from Espressif’s GitHub under https://github.com/espressif/openocd-esp32. These source files can be pulled via Git using the following commands:

```
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in ~/esp/openocd-esp32 directory.

Downloading libusb

The libusb library is also required when building OpenOCD. The following commands will download a particular release of libusb and uncompress it to the current directory.

```
wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z
```

We now need to export the following variables such that the libusb library gets linked into the OpenOCD build.

```
export CPPFLAGS="$CPPFLAGS -I$(PWD)/libusb/include/libusb-1.0"
export LDFLAGS="$LDFLAGS -L$(PWD)/libusb/MinGW32/.libs/dll"
```

Build OpenOCD

The following commands will configure OpenOCD then build it.

```
cd ~/openocd-esp32
export CPPFLAGS="$CPPFLAGS -D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS=""./bootstrap
./configure --disable-doxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --
build=i686-w64-mingw32 --host=i686-w64-mingw32
make
cp ../libusb/MinGW32/dll/libusb-1.0.dll ./src
```

Once the build is completed, the OpenOCD binary will be placed in ~/openocd-esp32/src/.

You can then optionally call `make install`. This will copy the OpenOCD binary to a user specified location.

- This location can be specified when OpenOCD is configured, or by setting `export DESTDIR="/custom/install/dir"` before calling `make install`.
- If you have an existing OpenOCD (from e.g. another development platform), you may want to skip this call as your existing OpenOCD may get overwritten.

Note:
Chapter 4. API Guides

- Should an error occur, resolve it and try again until the command `make` works.
- If there is a submodule problem from OpenOCD, please `cd` to the `openocd-esp32` directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
- If the information of your device is not shown in the log, use `./configure` to enable it as described in `./openocd-esp32/doc/INSTALL.txt`.
- For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.Windows`.
- Don’t forget to copy `libusb-1.0.dll` and `libwinpthread-1.dll` into `OOCD_INSTALLDIR/bin` from `~/esp/openocd-esp32/src`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in `~/esp/openocd-esp32/src` directory.

**Full Listing**  For greater convenience, all of commands called throughout the OpenOCD build process have been listed in the code snippet below. Users can copy this code snippet into a shell script then execute it:

```
pacman -S --noconfirm --needed autoconf automake git make mingw-w64-i686-gcc mingw-w64-i686-toolchain mingw-w64-i686-libtool mingw-w64-i686-pkg-config mingw-w64-i686-cross-wintpthreads-git p7zip

cd ~/esp

git clone --recursive https://github.com/espressif/openocd-esp32.git

wget https://github.com/libusb/libusb/releases/download/v1.0.22/libusb-1.0.22.7z
7z x -olibusb ./libusb-1.0.22.7z

export CPPFLAGS="$CPPFLAGS -I$(PWD)/libusb/include/libusb-1.0"; export LDFLAGS="-
$LDFLAGS -L$(PWD)/libusb/MinGW32/.libs/dll"

export CPPFLAGS="$CPPFLAGS -D__USE_MINGW_ANSI_STDIO=1 -Wno-error"; export CFLAGS="-
$CFLAGS -Wno-error"

cd ~/esp/openocd-esp32

./bootstrap

./configure --disable-doxygen-pdf --enable-ftdi --enable-jlink --enable-ulink --
build=1686-w64-mingw32 --host=1686-w64-mingw32

make

cp ./libusb/MinGW32/dll/libusb-1.0.dll ./src

cp /opt/i686-w64-mingw32/bin/libwinpthread-1.dll ./src

# # optional
# export DESTDIR="SPWD"
# make install
# cp ./src/libusb-1.0.dll $DESTDIR/mingw32/bin
# cp ./src/libwinpthread-1.dll $DESTDIR/mingw32/bin
```

**Next Steps**  To carry on with debugging environment setup, proceed to section Configuring ESP32 Target.

**Building OpenOCD from Sources for Linux**

The following instructions are alternative to downloading binary OpenOCD from Espressif GitHub. To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section Setup of OpenOCD.

**Download Sources of OpenOCD**  The sources for the ESP32-enabled variant of OpenOCD are available from Espressif GitHub under https://github.com/espressif/openocd-esp32. To download the sources, use the following commands:
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git

The clone of sources should be now saved in ~/esp/openocd-esp32 directory.

Install Dependencies   Install packages that are required to compile OpenOCD.

Note:   Install the following packages one by one, check if installation was successful and then proceed to the next package. Resolve reported problems before moving to the next step.

```
sudo apt-get install make
sudo apt-get install libtool
sudo apt-get install pkg-config
sudo apt-get install autoconf
sudo apt-get install automake
sudo apt-get install texinfo
sudo apt-get install libusb-1.0
```

Note:
• Version of pkg-config should be 0.2.3 or above.
• Version of autoconf should be 2.6.4 or above.
• Version of automake should be 1.9 or above.
• When using USB-Blaster, ASIX Presto, OpenJTAG and FT2232 as adapters, drivers libFTDI and FTD2XX need to be downloaded and installed.
• When using CMSIS-DAP, HIDAPI is needed.

Build OpenOCD   Proceed with configuring and building OpenOCD:

```
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g. another development platform), as it may get overwritten.

Note:
• Should an error occur, resolve it and try again until the command `make` works.
• If there is a submodule problem from OpenOCD, please cd to the openocd-esp32 directory and input `git submodule update --init`.
• If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
• If the information of your device is not shown in the log, use `./configure` to enable it as described in `../openocd-esp32/doc/INSTALL.txt`.
• For details concerning compiling OpenOCD, please refer to openocd-esp32/README.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in ~/openocd-esp32/bin directory.

Next Steps   To carry on with debugging environment setup, proceed to section Configuring ESP32 Target.
Building OpenOCD from Sources for MacOS

The following instructions are alternative to downloading binary OpenOCD from Espressif GitHub. To quickly setup the binary OpenOCD, instead of compiling it yourself, backup and proceed to section Setup of OpenOCD.

**Download Sources of OpenOCD**  The sources for the ESP32-enabled variant of OpenOCD are available from Espressif GitHub under https://github.com/espressif/openocd-esp32. To download the sources, use the following commands:

```bash
cd ~/esp
git clone --recursive https://github.com/espressif/openocd-esp32.git
```

The clone of sources should be now saved in ~/esp/openocd-esp32 directory.

**Install Dependencies**  Install packages that are required to compile OpenOCD using Homebrew:

```bash
brew install automake libtool libusb wget gcc@4.9 pkg-config
```

**Build OpenOCD**  Proceed with configuring and building OpenOCD:

```bash
cd ~/esp/openocd-esp32
./bootstrap
./configure
make
```

Optionally you can add `sudo make install` step at the end. Skip it, if you have an existing OpenOCD (from e.g. another development platform), as it may get overwritten.

**Note:**

- Should an error occur, resolve it and try again until the command `make` works.
- Error `Unknown command 'raggedright'` may indicate that the required version of texinfo was not installed on your computer or installed but was not linked to your PATH. To resolve this issue make sure texinfo is installed and PATH is adjusted prior to the `./bootstrap` by running:

```bash
brew install texinfo
export PATH=/usr/local/opt/texinfo/bin:$PATH
```

- If there is a submodule problem from OpenOCD, please `cd` to the openocd-esp32 directory and input `git submodule update --init`.
- If the `./configure` is successfully run, information of enabled JTAG will be printed under OpenOCD configuration summary.
- If the information of your device is not shown in the log, use `./configure` to enable it as described in `./openocd-esp32/doc/INSTALL.txt`.
- For details concerning compiling OpenOCD, please refer to `openocd-esp32/README.OSX`.

Once `make` process is successfully completed, the executable of OpenOCD will be saved in ~/esp/openocd-esp32/src/openocd directory.

**Next Steps**  To carry on with debugging environment setup, proceed to section Configuring ESP32 Target.

The examples of invoking OpenOCD in this document assume using pre-built binary distribution described in section Setup of OpenOCD.
To use binaries build locally from sources, change the path to OpenOCD executable to `src/openocd` and set the `OPENOCD_SCRIPTS` environment variable so that OpenOCD can find the configuration files. For Linux and macOS:

```
cd ~/esp/openocd-esp32
export OPENOCD_SCRIPTS=$PWD/tcl
```

For Windows:

```
cd %USERPROFILE%\esp\openocd-esp32
set "OPENOCD_SCRIPTS=%CD%\tcl"
```

Example of invoking OpenOCD build locally from sources, for Linux and macOS:

```
src/openocd -f board/esp32-wrover-kit-3.3v.cfg
```

and Windows:

```
src\openocd -f board\esp32-wrover-kit-3.3v.cfg
```

### 4.18.9 Tips and Quirks

This section provides collection of links to all tips and quirks referred to from various parts of this guide.

**Tips and Quirks**

This section provides collection of all tips and quirks referred to from various parts of this guide.

**Breakpoints and Watchpoints Available**

ESP32 debugger supports 2 hardware implemented breakpoints and 64 software ones. Hardware breakpoints are implemented by ESP32 chip’s logic and can be set anywhere in the code: either in flash or IRAM program’s regions. Additionally there are 2 types of software breakpoints implemented by OpenOCD: flash (up to 32) and IRAM (up to 32) breakpoints. Currently GDB can not set software breakpoints in flash. So until this limitation is removed those breakpoints have to be emulated by OpenOCD as hardware ones (see below for details). ESP32 also supports 2 watchpoints, so 2 variables can be watched for change or read by the GDB command `watch myVariable`. Note that menuconfig option `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` uses the last watchpoint and will not provide expected results, if you also try to use it within OpenOCD/GDB. See menuconfig’s help for detailed description.

**What Else Should I Know About Breakpoints?**

Emulating part of hardware breakpoints using software flash ones means that the GDB command `hb myFunction` which is invoked for function in flash will use pure hardware breakpoint if it is available otherwise one of the 32 software flash breakpoints is used. The same rule applies to `b myFunction-like` commands. In this case GDB will decide what type of breakpoint to set itself. If `myFunction` is resided in writable region (IRAM) software IRAM breakpoint will be used otherwise hardware or software flash breakpoint is used as it is done for `hb` command.

**Flash Mappings vs SW Flash Breakpoints**

In order to set/clear software breakpoints in flash, OpenOCD needs to know their flash addresses. To accomplish conversion from the ESP32 address space to the flash one, OpenOCD uses mappings of program’s code regions resided in flash. Those mappings are kept in the image header which is prepended to program binary data (code and data segments) and is specific to every application image written to the flash. So to support software flash breakpoints OpenOCD should know where application image under debugging is resided in the flash. By default OpenOCD reads partition table at 0x8000 and uses mappings from the first found application image, but there can be the cases when it will not work, e.g. partition table is not at standard flash location or even there can be multiple images: one factory and two OTA and you may want to debug any of them. To cover
all possible debugging scenarios OpenOCD supports special command which can be used to set arbitrary location of application image to debug. The command has the following format:

```plaintext
esp appimage_offset <offset>
```

Offset should be in hex format. To reset to the default behaviour you can specify -1 as offset.

**Note:** Since GDB requests memory map from OpenOCD only once when connecting to it, this command should be specified in one of the TCL configuration files, or passed to OpenOCD via its command line. In the latter case command line should look like below:

```
openocd -f board/esp32-wrover-kit-3.3v.cfg -c "init; halt; esp appimage_offset... 0x210000"
```

Another option is to execute that command via OpenOCD telnet session and then connect GDB, but it seems to be less handy.

**Why Stepping with “next” Does Not Bypass Subroutine Calls?** When stepping through the code with `next` command, GDB is internally setting a breakpoint (one out of two available) ahead in the code to bypass the subroutine calls. This functionality will not work, if the two available breakpoints are already set elsewhere in the code. If this is the case, delete breakpoints to have one “spare”. With both breakpoints already used, stepping through the code with `next` command will work as like with `step` command and debugger will step inside subroutine calls.

**Support Options for OpenOCD at Compile Time** ESP-IDF has some support options for OpenOCD debugging which can be set at compile time:

- `CONFIG_ESP_DEBUG_OCD_AWARE` is enabled by default. If a panic or unhandled exception is thrown and a JTAG debugger is connected (ie OpenOCD is running), ESP-IDF will break into the debugger.
- `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` (disabled by default) sets watchpoint index 1 (the second of two) at the end of any task stack. This is the most accurate way to debug task stack overflows. Click the link for more details.

Please see the [project configuration menu](#) menu for more details on setting compile-time options.

**FreeRTOS Support** OpenOCD has explicit support for the ESP-IDF FreeRTOS. GDB can see FreeRTOS tasks as threads. Viewing them all can be done using the GDB `i threads` command, changing to a certain task is done with `thread n`, with n being the number of the thread. FreeRTOS detection can be disabled in target’s configuration. For more details see [Configuration of OpenOCD for Specific Target](#).

GDB has a Python extension for FreeRTOS support. ESP-IDF automatically loads this module into GDB with the `idf.py gdb` command when the system requirements are met. See more details in [Debugging FreeRTOS Objects](#).

**Why to Set SPI Flash Voltage in OpenOCD Configuration?** The MTDI pin of ESP32, being among four pins used for JTAG communication, is also one of ESP32’s bootstrapping pins. On power up ESP32 is sampling binary level on MTDI to set its internal voltage regulator used to supply power to external SPI flash chip. If binary level on MTDI pin on power up is low, the voltage regulator is set to deliver 3.3 V, if it is high, then the voltage is set to 1.8 V. The MTDI pin should have a pull-up or may rely on internal weak pull down resistor (see [ESP32 Series Datasheet](#) for details), depending on the type of SPI chip used. Once JTAG is connected, it overrides the pull-up or pull-down resistor that is supposed to do the bootstrapping.

To handle this issue ESP32’s board configuration file (e.g. `board\esp32-wrover-kit-3.3v.cfg` for ESP-WROVER-KIT board) provides `ESP32_FLASH_VOLTAGE` parameter to set the idle state of the TDO line to a specified binary level, therefore reducing the chance of a bad bootup of application due to incorrect flash voltage.

Check specification of ESP32 module connected to JTAG, what is the power supply voltage of SPI flash chip. Then set `ESP32_FLASH_VOLTAGE` accordingly. Most WROOM modules use 3.3 V flash. WROVER earlier than ESP32-WROVER-B use 1.8 V flash, while ESP32-WROVER-B and -E modules use 3.3 V flash.
Optimize JTAG Speed  
In order to achieve higher data rates and minimize number of dropped packets it is recommended to optimize setting of JTAG clock frequency, so it is at maximum and still provides stable operation of JTAG. To do so use the following tips.

1. The upper limit of JTAG clock frequency is 20 MHz if CPU runs at 80 MHz, or 26 MHz if CPU runs at 160 MHz or 240 MHz.
2. Depending on particular JTAG adapter and the length of connecting cables, you may need to reduce JTAG frequency below 20 MHz or 26 MHz.
3. In particular reduce frequency, if you get DSR/DIR errors (and they do not relate to OpenOCD trying to read from a memory range without physical memory being present there).
4. ESP-WROVER-KIT operates stable at 20 MHz or 26 MHz.

What is the Meaning of Debugger’s Startup Commands?  
On startup, debugger is issuing sequence of commands to reset the chip and halt it at specific line of code. This sequence (shown below) is user defined to pick up at most convenient/appropriate line and start debugging.

• set remote hardware-watchpoint-limit 2 —Restrict GDB to using two hardware watchpoints supported by the chip, 2 for ESP32. For more information see https://sourceware.org/gdb/onlinedocs/gdb/Remote-Configuration.html.
• mon reset halt —reset the chip and keep the CPUs halted
• flushregs —monitor (mon) command can not inform GDB that the target state has changed. GDB will assume that whatever stack the target had before mon reset halt will still be valid. In fact, after reset the target state will change, and executing flushregs is a way to force GDB to get new state from the target.
• thb app_main —insert a temporary hardware breakpoint at app_main, put here another function name if required
• c —resume the program. It will then stop at breakpoint inserted at app_main.

Configuration of OpenOCD for Specific Target  
There are several kinds of OpenOCD configuration files (*.cfg). All configuration files are located in subdirectories of share/openocd/scripts directory of OpenOCD distribution (or tcl/scripts directory of the source repository). For the purposes of this guide, the most important ones are board, interface and target.

• interface configuration files describe the JTAG adapter. Examples of JTAG adapters are ESP-Prog and J-Link.
• target configuration files describe specific chips, or in some cases, modules.
• board configuration files are provided for development boards with a built-in JTAG adapter. Such files include an interface configuration file to choose the adapter, and target configuration file to choose the chip/module.

The following configuration files are available for ESP32:
Table 26: OpenOCD configuration files for ESP32

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>board/esp32-wrover-kit-3v.cfg</td>
<td>Board configuration file for ESP-WROVER-KIT with a 3.3 V ESP32-WROOM-32 module or ESP32-WROVER-B / ESP32-WROVER-E module.</td>
</tr>
<tr>
<td>board/esp32-wrover-kit-18v.cfg</td>
<td>Board configuration file for ESP-WROVER-KIT with an 1.8 V ESP32-WROVER module.</td>
</tr>
<tr>
<td>board/esp32-ethernet-kit3v.cfg</td>
<td>Board configuration file for ESP-Ethernet-KIT with a 3.3 V ESP32-WROVER-B / ESP32-WROVER-E module.</td>
</tr>
<tr>
<td>target/esp32.cfg</td>
<td>ESP32 target configuration file. Can be used together with one of the interface/configuration files.</td>
</tr>
<tr>
<td>target/esp32-solo-1.cfg</td>
<td>Target configuration file for ESP32-SOLO-1 module. Different from esp32.cfg in that it only configures one CPU.</td>
</tr>
<tr>
<td>interface/ftdi/esp32_devkitj_v1.cfg</td>
<td>JTAG adapter configuration file for ESP-WROVER-KIT and ESP-Prog boards.</td>
</tr>
</tbody>
</table>

If you are using one of the boards which have a pre-defined configuration file, you only need to pass one -f argument to OpenOCD, specifying that file.

If you are using a board not listed here, you need to specify both the interface configuration file and target configuration file.

**Custom Configuration Files**  OpenOCD configuration files are written in TCL, and include a variety of choices for customization and scripting. This can be useful for non-standard debugging situations. Please refer to OpenOCD Manual for the TCL scripting reference.

**OpenOCD Configuration Variables**  The following variables can be optionally set before including the ESP-specific target configuration file. This can be done either in a custom configuration file, or from the command line.

The syntax for setting a variable in TCL is:

```
set VARIABLE_NAME value
```

To set a variable from the command line (replace the name of .cfg file with the correct file for your board):

```
openocd -c 'set VARIABLE_NAME value' -f board/esp-xxxxx-kit.cfg
```

It is important to set the variable before including the ESP-specific configuration file, otherwise the variable will not have effect. You can set multiple variables by repeating the -c option.

Table 27: Common ESP-related OpenOCD variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESPRTOS</td>
<td>Set to none to disable RTOS support. In this case, thread list will not be available in GDB. Can be useful when debugging FreeRTOS itself, and stepping through the scheduler code.</td>
</tr>
<tr>
<td>ESP_FLASH_SIZE</td>
<td>Set to 0 to disable Flash breakpoints support.</td>
</tr>
<tr>
<td>ESP_SEMIHOST_BASEDIR</td>
<td>Set to the path (on the host) which will be the default directory for semihosting functions.</td>
</tr>
</tbody>
</table>
Table 28: ESP32-specific OpenOCD variables

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESP32_FLASH_VOLTAGE</td>
<td>When using 1.8 V flash ESP32 based modules, set this variable to 1.8. Refer to <em>Why to Set SPI Flash Voltage in OpenOCD Configuration?</em>.</td>
</tr>
<tr>
<td>ESP32_ONLYCPU</td>
<td>For multi-core targets, can be set to 1 to only enable single core debugging.</td>
</tr>
</tbody>
</table>

**How Debugger Resets ESP32?** The board can be reset by entering `mon reset` or `mon reset halt` into GDB.

**Can JTAG Pins be Used for Other Purposes?** Operation of JTAG may be disturbed, if some other hardware is connected to JTAG pins besides ESP32 module and JTAG adapter. ESP32 JTAG is using the following pins:

<table>
<thead>
<tr>
<th>ESP32 Pin</th>
<th>JTAG Signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDO / GPIO15</td>
<td>TDO</td>
</tr>
<tr>
<td>MTDI / GPIO12</td>
<td>TDI</td>
</tr>
<tr>
<td>MTCK / GPIO13</td>
<td>TCK</td>
</tr>
<tr>
<td>MTMS / GPIO14</td>
<td>TMS</td>
</tr>
</tbody>
</table>

JTAG communication will likely fail, if configuration of JTAG pins is changed by a user application. If OpenOCD initializes correctly (detects all the CPU cores in the SOC), but loses sync and spews out a lot of DTR/DIR errors when the program is running, it is likely that the application reconfigures the JTAG pins to something else, or the user forgot to connect Vtar to a JTAG adapter that requires it.

Below is an excerpt from series of errors on the dual-core ESP32 reported by GDB after the application stepped into the code that reconfigured MTDO pin to be an input:

```
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates target still busy!
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
  → an exception!
cpu0: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
  → an overrun!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates target still busy!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
  → an exception!
cpu1: xtensa_resume (line 431): DSR (FFFFFFFF) indicates DIR instruction generated...
  → an overrun!
```

**JTAG with Flash Encryption or Secure Boot** By default, enabling Flash Encryption and/or Secure Boot will disable JTAG debugging. On first boot, the bootloader will burn an eFuse bit to permanently disable JTAG at the same time it enables the other features.

The project configuration option `CONFIG_SECURE_BOOT_ALLOW_JTAG` will keep JTAG enabled at this time, removing all physical security but allowing debugging. (Although the name suggests Secure Boot, this option can be applied even when only Flash Encryption is enabled).

However, OpenOCD may attempt to automatically read and write the flash in order to set *software breakpoints*. This has two problems:

- Software breakpoints are incompatible with Flash Encryption, OpenOCD currently has no support for encrypting or decrypting flash contents.
- If Secure Boot is enabled, setting a software breakpoint will change the digest of a signed app and make the signature invalid. This means if a software breakpoint is set and then a reset occurs, the signature verification will fail on boot.

To disable software breakpoints while using JTAG, add an extra argument `-c 'set ESP_FLASH_SIZE 0'` to the start of the OpenOCD command line, see *OpenOCD Configuration Variables*. 
**Note:** For the same reason, the ESP-IDF app may fail bootloader verification of app signatures, when this option is enabled and a software breakpoint is set.

**JTAG and ESP32-WROOM-32 AT Firmware Compatibility Issue** The ESP32-WROOM series of modules come pre-flashed with AT firmware. This firmware configures the pins GPIO12 to GPIO15 as SPI slave interface, which makes using JTAG impossible.

To make JTAG available, build new firmware that is not using pins GPIO12 to GPIO15 dedicated to JTAG communication. After that, flash the firmware onto your module. See also *Can JTAG Pins be Used for Other Purposes?*.

**Reporting Issues with OpenOCD/GDB** In case you encounter a problem with OpenOCD or GDB programs itself and do not find a solution searching available resources on the web, open an issue in the OpenOCD issue tracker under https://github.com/espressif/openocd-esp32/issues.

1. In issue report provide details of your configuration:
   a. JTAG adapter type, and the chip/module being debugged.
   b. Release of ESP-IDF used to compile and load application that is being debugged.
   c. Details of OS used for debugging.
   d. Is OS running natively on a PC or on a virtual machine?
2. Create a simple example that is representative to observed issue. Describe steps how to reproduce it. In such an example debugging should not be affected by non-deterministic behaviour introduced by the Wi-Fi stack, so problems will likely be easier to reproduce, if encountered once.
3. Prepare logs from debugging session by adding additional parameters to start up commands.
   **OpenOCD:**
   ```
   openocd -l openocd_log.txt -d3 -f board/esp32-wrover-kit-3.3v.cfg
   ```
   Logging to a file this way will prevent information displayed on the terminal. This may be a good thing taken amount of information provided, when increased debug level -d3 is set. If you still like to see the log on the screen, then use another command instead:
   ```
   openocd -d3 -f board/esp32-wrover-kit-3.3v.cfg 2>&1 | tee openocd.log
   ```
   **Debugger:**
   ```
   xtensa-esp32-elf-gdb -ex "set remotelogfile gdb_log.txt" [all other options]
   ```
   Optionally add command remotelogfile gdb_log.txt to the gdbinit file.
4. Attach both openocd_log.txt and gdb_log.txt files to your issue report.

**Using Debugger**

This section covers configuration and running debugger using several methods:

- from Eclipse
- from Command Line
- using idf.py debug targets

See also a separate document *Configuration for Visual Studio Code Debug* describing how to run a debugger from VS Code.
Eclipse

Note: It is recommended to first check if debugger works using `idf.py debug targets` or from `Command Line` and then move to using Eclipse.

Debugging functionality is provided out of box in standard Eclipse installation. Another option is to use plugins like “GDB Hardware Debugging” plugin. We have found this plugin quite convenient and decided to use throughout this guide.

To begin with, install “GDB Hardware Debugging” plugin by opening Eclipse and going to Help > Install New Software.

Once installation is complete, configure debugging session following steps below. Please note that some of configuration parameters are generic and some are project specific. This will be shown below by configuring debugging for “blink” example project. If not done already, add this project to Eclipse workspace following guidance in Eclipse Plugin. The source of get-started/blink application is available in examples directory of ESP-IDF repository.

1. In Eclipse go to Run > Debug Configuration. A new window will open. In the window’s left pane double click “GDB Hardware Debugging” (or select “GDB Hardware Debugging” and press the “New” button) to create a new configuration.
2. In a form that will show up on the right, enter the “Name:” of this configuration, e.g. “Blink checking”.
3. On the “Main” tab below, under “Project:”, press “Browse” button and select the “blink” project.
4. In next line “C/C++ Application:” press “Browse” button and select “blink.elf” file. If “blink.elf” is not there, then likely this project has not been build yet. See Eclipse Plugin how to do it.
5. Finally, under “Build (if required) before launching” click “Disable auto build”.

A sample window with settings entered in points 1 - 5 is shown below.

7. Change default configuration of “Remote host” by entering 3333 under the “Port number”.

Configuration entered in points 6 and 7 is shown on the following picture.
Fig. 41: Configuration of GDB Hardware Debugging - Debugger tab
8. The last tab to that requires changing of default configuration is “Startup”. Under “Initialization Commands” uncheck “Reset and Delay (seconds)” and “Halt”. Then, in entry field below, enter the following lines:

```plaintext
mon reset halt
flushregs
set remote hardware-watchpoint-limit 2
```

**Note:** If you want to update image in the flash automatically before starting new debug session add the following lines of commands at the beginning of “Initialization Commands” textbox:

```plaintext
mon reset halt
mon program_esp ${workspace_loc:blink/build/blink.bin} 0x10000 verify
```

For description of `program_esp` command see *Upload application for debugging.*

10. Further down on the same tab, establish an initial breakpoint to halt CPUs after they are reset by debugger. The plugin will set this breakpoint at the beginning of the function entered under “Set break point at:”. Checkout this option and enter `app_main` in provided field.

11. Checkout “Resume” option. This will make the program to resume after `mon reset halt` is invoked per point 8. The program will then stop at breakpoint inserted at `app_main`. Configuration described in points 8 - 11 is shown below.

![Fig. 42: Configuration of GDB Hardware Debugging - Startup tab](image)

If the “Startup” sequence looks convoluted and respective “Initialization Commands” are not clear to you, check *What is the Meaning of Debugger’s Startup Commands?* for additional explanation.
12. If you previously completed Configuring ESP32 Target steps described above, so the target is running and ready to talk to debugger, go right to debugging by pressing “Debug” button. Otherwise press “Apply” to save changes, go back to Configuring ESP32 Target and return here to start debugging.

Once all 1 - 12 configuration steps are satisfied, the new Eclipse perspective called “Debug” will open as shown on example picture below.

![Fig. 43: Debug Perspective in Eclipse]

If you are not quite sure how to use GDB, check Eclipse example debugging session in section Debugging Examples.

**Command Line**

1. Begin with completing steps described under Configuring ESP32 Target. This is prerequisite to start a debugging session.

2. Open a new terminal session and go to directory that contains project for debugging, e.g.

   ```
   cd ~/esp/blink
   ```

3. When launching a debugger, you will need to provide couple of configuration parameters and commands. Instead of entering them one by one in command line, create a configuration file and name it `gdbinit`:

   ```
   target remote :3333
   set remote hardware-watchpoint-limit 2
   mon reset halt
   flushregs
   thb app_main
   c
   ```

   Save this file in current directory.

   For more details what’s inside `gdbinit` file, see What is the Meaning of Debugger’s Startup Commands?
4. Now you are ready to launch GDB. Type the following in the terminal:

```
xxtensa-esp32-elf-gdb -x gdbinit build/blink.elf
```

5. If previous steps have been done correctly, you will see a similar log concluded with `(gdb)` prompt:

```
user-name@computer-name:/esp/blink$ xxtensa-esp32-elf-gdb -x gdbinit build/
--blink.elf

```

Note the third line from bottom that shows debugger halting at breakpoint established in `gdbinit` file at function `app_main()`. Since the processor is halted, the LED should not be blinking. If this is what you see as well, you are ready to start debugging.

If you are not quite sure how to use GDB, check Command Line example debugging session in section Debugging Examples.
**idf.py debug targets**  It is also possible to execute the described debugging tools conveniently from idf.py. These commands are supported:

1. **idf.py openocd**
   
   Runs OpenOCD in a console with configuration defined in the environment or via command line. It uses default script directory defined as `OPENOCD_SCRIPTS` environmental variable, which is automatically added from an Export script (export.sh or export.bat). It is possible to override the script location using command line argument `--openocd-scripts`. As for the JTAG configuration of the current board, please use the environmental variable `OPENOCD_COMMANDS` or `--openocd-commands` command line argument. If none of the above is defined, OpenOCD is started with `-f board/esp32-wrover-kit-3.3v.cfg` board definition.

2. **idf.py gdb**
   
   Starts the gdb the same way as the **Command Line**, but generates the initial gdb scripts referring to the current project elf file.

3. **idf.py gdbtui**
   
   The same as 2, but starts the gdb with `tui` argument allowing very simple source code view.

4. **idf.py gdbgui**
   
   Starts `gdbgui` debugger frontend enabling out-of-the-box debugging in a browser window. Please run the install script with the `-enable-gdbgui` argument in order to make this option supported, e.g. `install.sh --enable-gdbgui`.

   It is possible to combine these debugging actions on a single command line allowing convenient setup of blocking and non-blocking actions in one step. `idf.py` implements a simple logic to move the background actions (such as `openocd`) to the beginning and the interactive ones (such as gdb, monitor) to the end of the action list. An example of a very useful combination is:

   ```bash
   idf.py openocd gdbgui monitor
   ```

   The above command runs OpenOCD in the background, starts `gdbgui` to open a browser window with active debugger frontend and opens a serial monitor in the active console.

**Debugging Examples**

This section describes debugging with GDB from **Eclipse** as well as from **Command Line**.

**Eclipse** Verify if your target is ready and loaded with `get-started/blink` example. Configure and start debugger following steps in section **Eclipse**. Pick up where target was left by debugger, i.e. having the application halted at breakpoint established at `app_main()`.

**Examples in this section**

1. **Navigating through the code, call stack and threads**
2. **Setting and clearing breakpoints**
3. **Halting the target manually**
4. **Stepping through the code**
5. **Checking and setting memory**
6. **Watching and setting program variables**
7. **Setting conditional breakpoints**

**Navigating through the code, call stack and threads**  When the target is halted, debugger shows the list of threads in “Debug” window. The line of code where program halted is highlighted in another window below, as shown on the following picture. The LED stops blinking.

Specific thread where the program halted is expanded showing the call stack. It represents function calls that lead up to the highlighted line of code, where the target halted. The first line of call stack under Thread #1 contains the last called function `app_main()`, that in turn was called from function `main_task()` shown in a line below. Each
Fig. 44: Debug Perspective in Eclipse
Fig. 45: Target halted during debugging
Chapter 4. API Guides

line of the stack also contains the file name and line number where the function was called. By clicking / highlighting
the stack entries, in window below, you will see contents of this file.

By expanding threads you can navigate throughout the application. Expand Thread #5 that contains much longer call
stack. You will see there, besides function calls, numbers like 0x4000000c. They represent addresses of binary
code not provided in source form.

![Function call stack](image)

**Fig. 46: Navigate through the call stack**

In another window on right, you can see the disassembled machine code no matter if your project provides it in source
or only the binary form.

Go back to the `app_main()` in Thread #1 to familiar code of blink.c file that will be examined in more details
in the following examples. Debugger makes it easy to navigate through the code of entire application. This comes
handy when stepping through the code and working with breakpoints and will be discussed below.

**Setting and clearing breakpoints** When debugging, we would like to be able to stop the application at critical
lines of code and then examine the state of specific variables, memory and registers / peripherals. To do so we are
using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let’s establish two breakpoints when the state of LED changes. Basing on code listing above, this happens at lines
33 and 36. To do so, hold the “Control” on the keyboard and double clik on number 33 in file blink.c file. A
dialog will open where you can confirm your selection by pressing “OK” button. If you do not like to see the dialog
just double click the line number. Set another breakpoint in line 36.

Information how many breakpoints are set and where is shown in window “Breakpoints” on top right. Click “Show
Breakpoints Supported by Selected Target” to refresh this list. Besides the two just set breakpoints the list may contain
temporary breakpoint at function `app_main()` established at debugger start. As maximum two breakpoints are
allowed (see Breakpoints and Watchpoints Available), you need to delete it, or debugging will fail.
Fig. 47: Setting a breakpoint

1. Hold the Control key and double click on a line number
2. A dialog with breakpoint at selected line will open
Fig. 48: Three breakpoints are set / maximum two are allowed
If you now click “Resume” (click blink_task() under “Tread #8”), if “Resume” button is grayed out, the processor will run and halt at a breakpoint. Clicking “Resume” another time will make it run again, halt on second breakpoint, and so on.

You will be also able to see that LED is changing the state after each click to “Resume” program execution.

Read more about breakpoints under Breakpoints and Watchpoints Available and What Else Should I Know About Breakpoints?

**Halting the target manually** When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any break points defined. In such case, to go back to debugging mode, you can break program execution manually by pressing “Suspend” button.

To check it, delete all breakpoints and click “Resume”. Then click “Suspend”. Application will be halted at some random point and LED will stop blinking. Debugger will expand tread and highlight the line of code where application halted.

In particular case above, the application has been halted in line 52 of code in file freertos_hooks.c Now you can resume it again by pressing “Resume” button or do some debugging as discussed below.

**Stepping through the code** It is also possible to step through the code using “Step Into (F5)” and “Step Over (F6)” commands. The difference is that “Step Into (F5)” is entering inside subroutines calls, while “Step Over (F6)” steps over the call, treating it as a single source line.

Before being able to demonstrate this functionality, using information discussed in previous paragraph, make sure that you have only one breakpoint defined at line 36 of blink.c.

Resume program by entering pressing F8 and let it halt. Now press “Step Over (F6)” one by one couple of times, to see how debugger is stepping one program line at a time.
Fig. 50: Stepping through the code with "Step Over (F6)"
If you press “Step Into (F5)” instead, then debugger will step inside subroutine calls.

![Step Into (F5)](image)

Fig. 51: Stepping through the code with “Step Into (F5)”

In this particular case debugger stepped inside `gpio_set_level(BLINK_GPIO, 0)` and effectively moved to `gpio.c` driver code. See Why Stepping with “next” Does Not Bypass Subroutine Calls? for potential limitation of using next command.

**Checking and setting memory** To display or set contents of memory use “Memory” tab at the bottom of “Debug” perspective.

With the “Memory” tab, we will read from and write to the memory location 0x3FF44004 labeled as GPIO.OUT_REG used to set and clear individual GPIO’s.

For more information, see ESP32 Technical Reference Manual > IO_MUX and GPIO Matrix (GPIO, IO_MUX) [PDF].

Being in the same blink.c project as before, set two breakpoints right after `gpio_set_level` instruction. Click “Memory” tab and then “Add Memory Monitor” button. Enter 0x3FF44004 in provided dialog.

Now resume program by pressing F8 and observe “Monitor” tab.

You should see one bit being flipped over at memory location 0x3FF44004 (and LED changing the state) each time F8 is pressed.

To set memory use the same “Monitor” tab and the same memory location. Type in alternate bit pattern as previously observed. Immediately after pressing enter you will see LED changing the state.

**Watching and setting program variables** A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file blink.c by adding a declaration of a global variable `int i` above definition of function `blink_task`. Then add `i++` inside while(1) of this function to get `i` incremented on each blink.
Fig. 52: Observing memory location 0x3FF44004 changing one bit to “ON”

Fig. 53: Observing memory location 0x3FF44004 changing one bit to “OFF”
Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter a breakpoint in the line where you put `i++`.

In next step, in the window with “Breakpoints”, click the “Expressions” tab. If this tab is not visible, then add it by going to the top menu Window > Show View > Expressions. Then click “Add new expression” and enter `i`.

Resume program execution by pressing F8. Each time the program is halted you will see `i` value being incremented.

To modify `i` enter a new number in “Value” column. After pressing “Resume (F8)” the program will keep incrementing `i` starting from the new entered number.

**Setting conditional breakpoints** Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Right click on the breakpoint to open a context menu and select “Breakpoint Properties”. Change the selection under “Type:” to “Hardware” and enter a “Condition:” like `i == 2`.

If current value of `i` is less than 2 (change it if required) and program is resumed, it will blink LED in a loop until condition `i == 2` gets true and then finally halt.

**Command Line** Verify if your target is ready and loaded with `get-started/blink` example. Configure and start debugger following steps in section **Command Line**. Pick up where target was left by debugger, i.e. having the application halted at breakpoint established at `app_main()`:

```
Temporary breakpoint 1, app_main () at /home/user-name/esp/blink/main/./blink.c:43
43  xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5, NULL);
```

![Watching program variable “i”](Image)

Fig. 54: Watching program variable “i”
Fig. 55: Setting a conditional breakpoint
Examples in this section

1. Navigating through the code, call stack and threads
2. Setting and clearing breakpoints
3. Halting and resuming the application
4. Stepping through the code
5. Checking and setting memory
6. Watching and setting program variables
7. Setting conditional breakpoints
8. Debugging FreeRTOS Objects

Navigating through the code, call stack and threads

When you see the (gdb) prompt, the application is halted. LED should not be blinking.

To find out where exactly the code is halted, enter `l` or `list`, and debugger will show couple of lines of code around the halt point (line 43 of code in file `blink.c`)

```c
38 }
39 }
40 void app_main()
41 {
42     xTaskCreate(&blink_task, "blink_task", configMINIMAL_STACK_SIZE, NULL, 5,
            NULL);
43 }
```

Check how code listing works by entering, e.g. `l 30, 40` to see particular range of lines of code.

You can use `bt` or `backtrace` to see what function calls lead up to this code:

```c
(gdb) bt
#0 app_main () at /home/user-name/esp/blink/main/.blink.c:43
#1 0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/---esp32/.cpu_start.c:339
(gdb)
```

Line #0 of output provides the last function call before the application halted, i.e. `app_main ()` we have listed previously. The `app_main ()` was in turn called by function `main_task` from line 339 of code located in file `cpu_start.c`.

To get to the context of `main_task` in file `cpu_start.c`, enter `frame N`, where N = 1, because the `main_task` is listed under #1:

```c
(gdb) frame 1
#1 0x400d057e in main_task (args=0x0) at /home/user-name/esp/esp-idf/components/---esp32/.cpu_start.c:339
339     app_main();
```

Enter `l` and this will reveal the piece of code that called `app_main()` (in line 339):

```c
334     ;
335 }
336 #endif
337 //Enable allocation in region where the startup stacks were located.
338 heap_caps_enable_nonos_stack_heaps();
339 app_main();
340 vTaskDelete(NULL);
341 }
```

(continues on next page)
By listing some lines before, you will see the function name main_task we have been looking for:

```c
(gdb) l 326, 341
326 static void main_task(void* args)
327 {
328   // Now that the application is about to start, disable boot watchdogs
329   REG_CLR_BIT(TIMG_WDTCONFIG0_REG(0), TIMG_WDT_FLASHBOOT_MOD_EN_S);
330   REG_CLR_BIT(RTC_CNTL_WDTCONFIG0_REG, RTC_CNTL_WDT_FLASHBOOT_MOD_EN);
331   #if !CONFIG_FREERTOS_UNICORE
332     // Wait for FreeRTOS initialization to finish on APP CPU, before replacing its startup stack
333     while (port_xSchedulerRunning[1] == 0) {
334       ;
335   }
336   #endif
337   // Enable allocation in region where the startup stacks were located.
338   heap_caps_enable_nonos_stack_heaps();
339   app_main();
340   vTaskDelete(NULL);
341 }
```

To see the other code, enter `i threads`. This will show the list of threads running on target:

```
(gdb) i threads
   Id Target Id    Frame
    8 Thread 1073411336 (dport) 0x400d0848 in dport_access_init_core (arg=
      —<optimized out>)
      at /home/user-name/esp/esp-idf/components/esp32/./dport_access.c:170
    7 Thread 1073408744 (ipc0) xQueueGenericReceive (xQueue=0x3ffae694, pvBuffer=0x0, xTicksToWait=1644638200, xJustPeeking=0) at /home/user-name/esp/esp-idf/components/freertos/./queue.c:1452
    6 Thread 1073431096 (Tmr Svc) prvTimerTask (pvParameters=0x0) at /home/user-name/esp/esp-idf/components/freertos/./timers.c:445
    5 Thread 1073410208 (ipc1 : Running) 0x4000bfea in ?? ()
    4 Thread 1073432224 (dport) dport_access_init_core (arg=0x0)
      at /home/user-name/esp/esp-idf/components/esp32/./dport_access.c:150
    3 Thread 1073413512 (IDLE) prvIdleTask (pvParameters=0x0)
      at /home/user-name/esp/esp-idf/components/freertos/./tasks.c:3282
    2 Thread 1073411772 (main : Running) app_main () at /home/user-name/esp/blink/.main/.../blink.c:43
```

The thread list shows the last function calls per each thread together with the name of C source file if available.

You can navigate to specific thread by entering `thread N`, where N is the thread Id. To see how it works go to thread 5:

```
(gdb) thread 5
[Switching to thread 5 (Thread 1073410208)]
#0 0x4000bfea in ?? ()
```

Then check the backtrace:
As you see, the backtrace may contain several entries. This will let you check what exact sequence of function calls lead to the code where the target halted. Question marks ?? instead of a function name indicate that application is available only in binary format, without any source file in C language. The value like 0x4000bfea is the memory address of the function call.

Using `bt`, `i threads`, `thread N` and `list` commands we are now able to navigate through the code of entire application. This comes handy when stepping through the code and working with breakpoints and will be discussed below.

### Setting and clearing breakpoints

When debugging, we would like to be able to stop the application at critical lines of code and then examine the state of specific variables, memory and registers / peripherals. To do so we are using breakpoints. They provide a convenient way to quickly get to and halt the application at specific line.

Let’s establish two breakpoints when the state of LED changes. Basing on code listing above this happens at lines 33 and 36. Breakpoints may be established using command `break M` where M is the code line number:

```plaintext
(gdb) break 33
Breakpoint 2 at 0x400db6f6: file /home/user-name/esp/blink/main/./blink.c, line 33.
(gdb) break 36
Breakpoint 3 at 0x400db704: file /home/user-name/esp/blink/main/./blink.c, line 36.
```

If you new enter `c`, the processor will run and halt at a breakpoint. Entering `c` another time will make it run again, halt on second breakpoint, and so on:

```plaintext
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F6 (active)   APP_CPU: PC=0x400D10D8
Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
  blink.c:33
 33     gpio_set_level(BLINK_GPIO, 0);
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB6F8 (active)   APP_CPU: PC=0x400D10D8
Target halted. PRO_CPU: PC=0x400DB704 (active)   APP_CPU: PC=0x400D10D8
Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
  blink.c:36
 36     gpio_set_level(BLINK_GPIO, 1);
(gdb)
```

You will be also able to see that LED is changing the state only if you resume program execution by entering `c`.

To examine how many breakpoints are set and where, use command `info break`: 
Chapter 4. API Guides

(gdb) info break
Num Type Disp Enb Address What
2 breakpoint keep y 0x400db6f6 in blink_task at /home/user-name/esp/
→ blink/main./blink.c:33
  breakpoint already hit 1 time
3 breakpoint keep y 0x400db704 in blink_task at /home/user-name/esp/
→ blink/main./blink.c:36
  breakpoint already hit 1 time
(gdb)

Please note that breakpoint numbers (listed under **Num**) start with 2. This is because first breakpoint has been already established at function **app_main()** by running command `thb app_main` on debugger launch. As it was a temporary breakpoint, it has been automatically deleted and now is not listed anymore.

To remove breakpoints enter delete **N** command (in short `d **N**`), where **N** is the breakpoint number:

(gdb) delete 1
No breakpoint number 1.
(gdb) delete 2
(gdb)

Read more about breakpoints under **Breakpoints and Watchpoints Available** and **What Else Should I Know About Breakpoints?**

**Halting and resuming the application** When debugging, you may resume application and enter code waiting for some event or staying in infinite loop without any breakpoints defined. In such case, to go back to debugging mode, you can break program execution manually by entering Ctrl+C.

To check it delete all breakpoints and enter **c** to resume application. Then enter Ctrl+C. Application will be halted at some random point and LED will stop blinking. Debugger will print the following:

(gdb) c
Continuing.
^CTarget halted. PRO_CPU: PC=0x400D0C00 APP_CPU: PC=0x400D0C00 (active)
[New Thread 1073433532]
Program received signal SIGINT, Interrupt.
[Switching to Thread 1073413512]
0x400d0c00 in esp_vApplicationIdleHook () at /home/user-name/esp/esp-idf/
→ components/esp32./freertos_hooks.c:52
  52 asm("waiti 0");
(gdb)

In particular case above, the application has been halted in line 52 of code in file `freertos_hooks.c`. Now you can resume it again by enter **c** or do some debugging as discussed below.

**Stepping through the code** It is also possible to step through the code using **step** and **next** commands (in short **s** and **n**). The difference is that **step** is entering inside subroutines calls, while **next** steps over the call, treating it as a single source line.

To demonstrate this functionality, using command break and delete discussed in previous paragraph, make sure that you have only one breakpoint defined at line 36 of `blink.c`:

(gdb) info break
Num Type Disp Enb Address What
3 breakpoint keep y 0x400db704 in blink_task at /home/user-name/esp/
→ blink/main./blink.c:36
  breakpoint already hit 1 time
(gdb)

Resume program by entering **c** and let it halt:
Chapter 4. API Guides

(gdb) c  
Continuing.  
Target halted. PRO_CPU: PC=0x400DB754 (active)  APP_CPU: PC=0x400D1128  

Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./  
→ blink.c:36  
36  
gpio_set_level(BLINK_GPIO, 1);  
(gdb)  

Then enter n couple of times to see how debugger is stepping one program line at a time: 

(gdb) n  
Target halted. PRO_CPU: PC=0x400DB756 (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DB758 (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DC04C (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DB75B (active)  APP_CPU: PC=0x400D1128  
37  
vTaskDelay(1000 / portTICK_PERIOD_MS);  
(gdb) n  
Target halted. PRO_CPU: PC=0x400DB75E (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DB75F (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400846FC (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DC04C (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DC04F (active)  APP_CPU: PC=0x400D1128  
33  
gpio_set_level(BLINK_GPIO, 0);  
(gdb)  

If you enter s instead, then debugger will step inside subroutine calls: 

(gdb) s  
Target halted. PRO_CPU: PC=0x400DB748 (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DB74B (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DC04C (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DC04F (active)  APP_CPU: PC=0x400D1128  
gpio_set_level (gpio_num=GPIO_NUM_4, level=0) at /home/user-name/esp/esp-idf/  
→ components/driver/gpio/gpio.c:183  
183  
GPIO_CHECK(GPIO_IS_VALID_OUTPUT_GPIO(gpio_num), "GPIO output gpio_num error  
→ ", ESP_ERR_INVALID_ARG);  
(gdb)  

In this particular case debugger stepped inside gpio_set_level(BLINK_GPIO, 0) and effectively moved to  
gpio.c  driver code.  

See Why Stepping with “next” Does Not Bypass Subroutine Calls? for potential limitation of using next command.  

Checking and setting memory  
Displaying the contents of memory is done with command x. With additional parameters you may vary the format and count of memory locations displayed. Run help x to see more details.  
Companion command to x is set that let you write values to the memory.  
We will demonstrate how x and set work by reading from and writing to the memory location 0x3FF44004  
labeled as GPIO_OUT_REG used to set and clear individual GPIO’s.  
For more information, see ESP32 Technical Reference Manual > IO MUX and GPIO Matrix (GPIO, IO_MUX) [PDF].  

Being in the same blink.c project as before, set two breakpoints right after gpio_set_level instruction. Enter two times c to get to the break point followed by x /1wx 0x3FF44004 to display contents of GPIO_OUT_REG memory location:  

(gdb) c  
Continuing.  
Target halted. PRO_CPU: PC=0x400DB75E (active)  APP_CPU: PC=0x400D1128  
Target halted. PRO_CPU: PC=0x400DB74E (active)  APP_CPU: PC=0x400D1128  

Breakpoint 2, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./  
→ blink.c:34  
(continues on next page)
34 \texttt{vTaskDelay(1000 / portTICK\_PERIOD\_MS);}
\texttt{(gdb) x /1wx 0x3FF44004}
\texttt{0x3ff44004: 0x00000000}
\texttt{(gdb) c}
Continuing.
Target halted. PRO\_CPU: PC=0x400DB751 (active) APP\_CPU: PC=0x400D1128
Target halted. PRO\_CPU: PC=0x400DB75B (active) APP\_CPU: PC=0x400D1128
Breakpoint 3, blink\_task (pvParameter=0x0) at /home/user-name/esp/blink/main/.
→ blink.c:37
37 \texttt{vTaskDelay(1000 / portTICK\_PERIOD\_MS);}
\texttt{(gdb) x /1wx 0x3FF44004}
\texttt{0x3ff44004: 0x00000010}
\texttt{(gdb)}

If your are blinking LED connected to GPIO4, then you should see fourth bit being flipped each time the LED changes the state:

\begin{verbatim}
0x3ff44004: 0x00000000
...
0x3ff44004: 0x00000010
\end{verbatim}

Now, when the LED is off, that corresponds to \texttt{0x3ff44004: 0x00000000} being displayed, try using \texttt{set} command to set this bit by writing \texttt{0x00000010} to the same memory location:

\begin{verbatim}
(gdb) x /1wx 0x3FF44004
0x3ff44004: 0x00000000
(gdb) set {unsigned int}0x3FF44004=0x000010
\end{verbatim}

You should see the LED to turn on immediately after entering \texttt{set \{unsigned int\}0x3FF44004=0x000010} command.

\textbf{Watching and setting program variables} A common debugging tasks is checking the value of a program variable as the program runs. To be able to demonstrate this functionality, update file \texttt{blink.c} by adding a declaration of a global variable \texttt{int i} above definition of function \texttt{blink\_task}. Then add \texttt{i++} inside \texttt{while(1)} of this function to get \texttt{i} incremented on each blink.

Exit debugger, so it is not confused with new code, build and flash the code to the ESP and restart debugger. There is no need to restart OpenOCD.

Once application is halted, enter the command \texttt{watch i}:

\begin{verbatim}
(gdb) watch i
Hardware watchpoint 2: i
(gdb)
\end{verbatim}

This will insert so called “watchpoint” in each place of code where variable \texttt{i} is being modified. Now enter \texttt{continue} to resume the application and observe it being halted:

\begin{verbatim}
(gdb) c
Continuing.
Target halted. PRO\_CPU: PC=0x400DB751 (active) APP\_CPU: PC=0x400D0811
[New Thread 1073432196]
Program received signal SIGTRAP, Trace/breakpoint trap.
[Switching to Thread 1073432196]
0x400db751 in blink\_task (pvParameter=0x0) at /home/user-name/esp/blink/main/.
→ blink.c:33
33 \texttt{i++;
(gdb)}
\end{verbatim}
Resume application couple more times so i gets incremented. Now you can enter `print i` (in short `p i`) to check the current value of `i`:

```
(gdb) p i
$1 = 3
(gdb)
```

To modify the value of `i` use `set` command as below (you can then print it out to check if it has been indeed changed):

```
(gdb) set var i = 0
(gdb) p i
$3 = 0
(gdb)
```

You may have up to two watchpoints, see Breakpoints and Watchpoints Available.

**Setting conditional breakpoints**  Here comes more interesting part. You may set a breakpoint to halt the program execution, if certain condition is satisfied. Delete existing breakpoints and try this:

```
(gdb) break blink.c:34 if (i == 2)
Breakpoint 3 at 0x400db753: file /home/user-name/esp/blink/main/./blink.c, line 34.
(gdb)
```

Above command sets conditional breakpoint to halt program execution in line 34 of `blink.c` if `i == 2`.

If current value of `i` is less than 2 and program is resumed, it will blink LED in a loop until condition `i == 2` gets true and then finally halt:

```
(gdb) set var i = 0
(gdb) c
Continuing.
Target halted. PRO_CPU: PC=0x400DB755 (active) APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB753 (active) APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB755 (active) APP_CPU: PC=0x400D112C
Target halted. PRO_CPU: PC=0x400DB753 (active) APP_CPU: PC=0x400D112C
Breakpoint 3, blink_task (pvParameter=0x0) at /home/user-name/esp/blink/main/./
   --blink.c:34
34   gpio_set_level(BLINK_GPIO, 0);
(gdb)
```

**Debugging FreeRTOS Objects**  This part might be interesting when you are debugging FreeRTOS task interactions. Users that need to use the FreeRTOS task interactions can use the GDB `freertos` command. The `freertos` command is not native to GDB and comes from the `freertos-gdb` Python extension module. The `freertos` command contains a series of sub-commands as demonstrated in the code snippet:

```
(gdb) freertos
"freertos" must be followed by the name of a subcommand.
List of freertos subcommands:

freertos queue   -- Generate a print out of the current queues info.
freertos semaphore  -- Generate a print out of the current semaphores info.
freertos task    -- Generate a print out of the current tasks and their states.
freertos timer   -- Generate a print out of the current timers info.
```

For a more detailed description of this extension, please refer to [https://pypi.org/project/freertos-gdb](https://pypi.org/project/freertos-gdb).

**Note:**  The freertos-gdb Python module is included as a Python package requirement by ESP-IDF, thus should be automatically installed (see Step 3. Set up the tools for more details).
The FreeRTOS extension automatically loads in case GDB is executed with command via `idf.py gdb`. Otherwise, the module could be enabled via the `python import freertos_gdb` command inside GDB. Users only need to have Python 3.6 (or above) that contains a Python shared library.

**Obtaining help on commands**  Commands presented so far should provide a very basic and intended to let you quickly get started with JTAG debugging. Check help what are the other commands at your disposal. To obtain help on syntax and functionality of particular command, being at `(gdb)` prompt type `help` and command name:

```
(gdb) help next
Step program, proceeding through subroutine calls.
Usage: next [N]
Unlike "step", if the current source line calls a subroutine, this command does not enter the subroutine, but instead steps over the call, in effect treating it as a single source line.
```

By typing just `help`, you will get top level list of command classes, to aid you drilling down to more details. Optionally refer to available GDB cheat sheets, for instance [https://darkdust.net/files/GDB%20Cheat%20Sheet.pdf](https://darkdust.net/files/GDB%20Cheat%20Sheet.pdf). Good to have as a reference (even if not all commands are applicable in an embedded environment).

**Ending debugger session**  To quit debugger enter `q`:

```
(gdb) q
A debugging session is active.

Inferior 1 [Remote target] will be detached.

Quit anyway? (y or n) y
Detaching from program: /home/user-name/esp/blink/build/blink.elf, Remote target
Ending remote debugging.
user-name@computer-name:~/esp/blink$
```

### 4.19 Linker Script Generation

#### 4.19.1 Overview

There are several *memory regions* where code and data can be placed. Code and read-only data are placed by default in flash, writable data in RAM, etc. However, it is sometimes necessary to change these default placements.

For example, it may be necessary to place:

- critical code in RAM for performance reasons.
- executable code in IRAM so that it can be ran while cache is disabled.
- code in RTC memory for use in a wake stub.
- code in RTC memory for use by the ULP coprocessor.
With the linker script generation mechanism, it is possible to specify these placements at the component level within ESP-IDF. The component presents information on how it would like to place its symbols, objects or the entire archive. During build, the information presented by the components are collected, parsed and processed; and the placement rules generated is used to link the app.

### 4.19.2 Quick Start

This section presents a guide for quickly placing code/data to RAM and RTC memory - placements ESP-IDF provides out-of-the-box.

For this guide, suppose we have the following:

- a component named `my_component` that is archived as library `libmy_component.a` during build
- three source files archived under the library, `my_src1.c`, `my_src2.c` and `my_src3.c` which are compiled as `my_src1.o`, `my_src2.o` and `my_src3.o`, respectively
- under `my_src1.o`, the function `my_function1` is defined; under `my_src2.o`, the function `my_function2` is defined
- there is bool-type config `PERFORMANCE_MODE` (y/n) and int type config `PERFORMANCE_LEVEL` (with range 0-3) in `my_component`’s Kconfig

#### Creating and Specifying a Linker Fragment File

Before anything else, a linker fragment file needs to be created. A linker fragment file is simply a text file with a `.lf` extension upon which the desired placements will be written. After creating the file, it is then necessary to present it to the build system. The instructions for the build systems supported by ESP-IDF are as follows:

In the component’s `CMakeLists.txt` file, specify argument `LDFRAGMENTS` in the `idf_component_register` call. The value of `LDFRAGMENTS` can either be an absolute path or a relative path from the component directory to the created linker fragment file.

```plaintext
# file paths relative to CMakeLists.txt
idf_component_register(
    ...,
    LDFRAGMENTS "path/to/linker_fragment_file.lf" "path/to/another_linker_fragment_file.lf"
    ...
)
```

#### Specifying placements

It is possible to specify placements at the following levels of granularity:

- object file (.obj or .o files)
- symbol (function/variable)
- archive (.a files)
Placing object files  Suppose the entirety of my_src1.o is performance-critical, so it is desirable to place it in RAM. On the other hand, the entirety of my_src2.o contains symbols needed coming out of deep sleep, so it needs to be put under RTC memory.

In the linker fragment file, we can write:

```
[mapping:my_component]
archive: libmy_component.a
entries:
  my_src1 (noflash)  # places all my_src1 code/read-only data under IRAM/DRAM
  my_src2 (rtc)     # places all my_src2 code/ data and read-only data under...
                  # RTC fast memory/RTC slow memory
```

What happens to my_src3.o? Since it is not specified, default placements are used for my_src3.o. More on default placements here.

Placing symbols  Continuing our example, suppose that among functions defined under object1.o, only my_function1 is performance-critical; and under object2.o, only my_function2 needs to execute after the chip comes out of deep sleep. This could be accomplished by writing:

```
[mapping:my_component]
archive: libmy_component.a
entries:
  my_src1:my_function1 (noflash)
  my_src2:my_function2 (rtc)
```

The default placements are used for the rest of the functions in my_src1.o and my_src2.o and the entire object3.o. Something similar can be achieved for placing data by writing the variable name instead of the function name, like so:

```
my_src1:my_variable (noflash)
```

Warning: There are limitations in placing code/data at symbol granularity. In order to ensure proper placements, an alternative would be to group relevant code and data into source files, and use object-granularity placements.

Placing entire archive  In this example, suppose that the entire component archive needs to be placed in RAM. This can be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
  * (noflash)
```

Similarly, this places the entire component in RTC memory:

```
[mapping:my_component]
archive: libmy_component.a
entries:
  * (rtc)
```

Configuration-dependent placements  Suppose that the entire component library should only have special placement when a certain condition is true; for example, when CONFIG_PERFORMANCE_MODE == y. This could be written as:

```
[mapping:my_component]
archive: libmy_component.a
```
entries:
  if PERFORMANCE_MODE = y:
    * (noflash)
  else:
    * (default)

For a more complex config-dependent placement, suppose the following requirements: when CONFIG_PERFORMANCE_LEVEL == 1, only object1.o is put in RAM; when CONFIG_PERFORMANCE_LEVEL == 2, object1.o and object2.o; and when CONFIG_PERFORMANCE_LEVEL == 3 all object files under the archive are to be put into RAM. When these three are false however, put entire library in RTC memory. This scenario is a bit contrived, but, it can be written as:

```
[mapping:my_component]
archive: libmy_component.a
entries:
  if PERFORMANCE_LEVEL = 1:
    my_src1 (noflash)
  elif PERFORMANCE_LEVEL = 2:
    my_src1 (noflash)
    my_src2 (noflash)
  elif PERFORMANCE_LEVEL = 3:
    my_src1 (noflash)
    my_src2 (noflash)
    my_src3 (noflash)
  else:
    * (rtc)
```

Nesting condition-checking is also possible. The following is equivalent to the snippet above:

```
[mapping:my_component]
archive: libmy_component.a
entries:
  if PERFORMANCE_LEVEL <= 3 && PERFORMANCE_LEVEL > 0:
    if PERFORMANCE_LEVEL >= 1:
      object1 (noflash)
    if PERFORMANCE_LEVEL >= 2:
      object2 (noflash)
    if PERFORMANCE_LEVEL >= 3:
      object2 (noflash)
  else:
    * (rtc)
```

The ‘default’ placements

Up until this point, the term ‘default placements’ has been mentioned as fallback placements when the placement rules rtc and noflash are not specified. It is important to note that the tokens noflash or rtc are not merely keywords, but are actually entities called fragments, specifically schemes.

In the same manner as rtc and noflash are schemes, there exists a `default` scheme which defines what the default placement rules should be. As the name suggests, it is where code and data are usually placed, i.e. code/constants is placed in flash, variables placed in RAM, etc. More on the default scheme here.

Note: For an example of an ESP-IDF component using the linker script generation mechanism, see `freertos/CMakeLists.txt`. freertos uses this to place its object files to the instruction RAM for performance reasons.

This marks the end of the quick start guide. The following text discusses the internals of the mechanism in a little bit more detail. The following sections should be helpful in creating custom placements or modifying default behavior.
4.19.3 Linker Script Generation Internals

Linking is the last step in the process of turning C/C++ source files into an executable. It is performed by the toolchain’s linker, and accepts linker scripts which specify code/data placements, among other things. With the linker script generation mechanism, this process is no different, except that the linker script passed to the linker is dynamically generated from: (1) the collected linker fragment files and (2) linker script template.

**Note:** The tool that implements the linker script generation mechanism lives under tools/ldgen.

Linker Fragment Files

As mentioned in the quick start guide, fragment files are simple text files with the .lf extension containing the desired placements. This is a simplified description of what fragment files actually contain are ‘fragments’. Fragments are entities which contain pieces of information which, when put together, form placement rules that tell where to place sections of object files in the output binary. There are three types of fragments: sections, scheme and mapping.

**Grammar** The three fragment types share a common grammar:

```
[type:name]
key: value
key:
 value
value
value
...
```

- **type:** Corresponds to the fragment type, can either be sections, scheme or mapping.
- **name:** The name of the fragment, should be unique for the specified fragment type.
- **key, value:** Contents of the fragment; each fragment type may support different keys and different grammars for the key values.
  - For sections and scheme, the only supported key is entries
  - For mappings, both archive and entries are supported.

**Note:** In cases where multiple fragments of the same type and name are encountered, an exception is thrown.

**Note:** The only valid characters for fragment names and keys are alphanumeric characters and underscore.

Condition Checking

Condition checking enable the linker script generation to be configuration-aware. Depending on whether expressions involving configuration values are true or not, a particular set of values for a key can be used. The evaluation uses eval_string from kconfiglib package and adheres to its required syntax and limitations. Supported operators are as follows:

- **comparison**
  - LessThan <
  - LessThanOrEqualTo <=
  - MoreThan >
  - MoreThanOrEqualTo >=
  - Equal =
  - NotEqual !=

- **logical**
  - Or ||
• **grouping**
  - Parenthesis ()

Condition checking behaves as you would expect an `if...elseif/elif...else` block in other languages. Condition-checking is possible for both key values and entire fragments. The two sample fragments below are equivalent:

```plaintext
# Value for keys is dependent on config
[type:name]
key_1:
if CONDITION = y:
    value_1
else:
    value_2
key_2:
if CONDITION = y:
    value_a
else:
    value_b

# Entire fragment definition is dependent on config
if CONDITION = y:
    [type:name]
    key_1:
    value_1
    key_2:
    value_a
else:
    [type:name]
    key_1:
    value_2
    key_2:
    value_b
```

**Comments**

Comment in linker fragment files begin with `#`. Like in other languages, comment are used to provide helpful descriptions and documentation and are ignored during processing.

**Types Sections**

Sections fragments defines a list of object file sections that the GCC compiler emits. It may be a default section (e.g. `.text`, `.data`) or it may be user defined section through the `__attribute__` keyword.

The use of an optional `+` indicates the inclusion of the section in the list, as well as sections that start with it. This is the preferred method over listing both explicitly.

```plaintext
[sections:name]
entries:
  .section+
  .section
...
```

**Example:**

```plaintext
# Non-preferred
[sections:text]
entries:
  .text
  .text.*
```

(continues on next page)
# Preferred, equivalent to the one above

```markdown
[sections:text]

entries:

- .text+ # means .text and .text.*
- .literal+ # means .literal and .literal.*
```

## Scheme

Scheme fragments define what target a sections fragment is assigned to.

```markdown
[scheme:name]

entries:

- sections -> target
- sections -> target
...
```

### Example:

```markdown
[scheme:noflash]

entries:

- text -> iram0_text # the entries under the sections fragment named...
  - text will go to iram0_text
- rodata -> dram0_data # the entries under the sections fragment named...
  - rodata will go to dram0_data
```

The default scheme

There exists a special scheme with the name default. This scheme is special because catch-all placement rules are generated from its entries. This means that, if one of its entries is `text -> flash_text`, the placement rule will be generated for the target `flash_text`.

```
* (.literal .literal.* .text .text.*)
```

These catch-all rules then effectively serve as fallback rules for those whose mappings were not specified.

The default scheme is defined in `esp_system/app.lf`. The noflash and rtc scheme fragments which are built-in schemes referenced in the quick start guide are also defined in this file.

## Mapping

Mapping fragments define what scheme fragment to use for mappable entities, i.e. object files, function names, variable names, archives.

```markdown
[mapping:name]

archive: archive # output archive file name, as built (i.e. libxxx.
  - a)

entries:

- object:symbol {scheme} # symbol granularity
- object {scheme} # object granularity
  * {scheme} # archive granularity
```

There are three levels of placement granularity:

- **symbol**: The object file name and symbol name are specified. The symbol name can be a function name or a variable name.
- **object**: Only the object file name is specified.
- **archive**: * is specified, which is a short-hand for all the object files under the archive.

To know what an entry means, let us expand a sample object-granularity placement:
object (scheme)

Then expanding the scheme fragment from its entries definitions, we have:

object (sections -> target,  
sections -> target,  
...
)

Expanding the sections fragment with its entries definition:

object (.section,  
    # given this object file
    .section,  
        # put its sections listed here at this
        ... -> target,  
          # target
    .section,
    .section,  
        # same should be done for these sections
        ... -> target,
    ...
    )  

# and so on

Example:

[mapping:map]
archive: libfreertos.a
entries:
    * (noflash)

Aside from the entity and scheme, flags can also be specified in an entry. The following flags are supported (note: <> = argument name, [] = optional):

1. **ALIGN(<alignment>[, pre, post])**
   
   Align the placement by the amount specified in alignment. Generates

2. **SORT([<sort_by_first>,<sort_by_second>])**
   
   Emits **SORT_BY_NAME**, **SORT_BY_ALIGNMENT**, **SORT_BY_INIT_PRIORITY** or **SORT** in the input section description.
   
   Possible values for sort_by_first and sort_by_second are: name, alignment, init_priority.
   
   If both sort_by_first and sort_by_second are not specified, the input sections are sorted by name. If both are specified, then the nested sorting follows the same rules discussed in [https://sourceware.org/binutils/docs/ld/Input-Section-Wildcards.html](https://sourceware.org/binutils/docs/ld/Input-Section-Wildcards.html).

3. **KEEP()**
   
   Prevent the linker from discarding the placement by surrounding the input section description with KEEP command. See [https://sourceware.org/binutils/docs/ld/Input-Section-Keep.html](https://sourceware.org/binutils/docs/ld/Input-Section-Keep.html) for more details.

4. **SURROUND(<name>)**
   
   Generate symbols before and after the placement. The generated symbols follow the naming _<name>_start and _<name>_end. For example, if name == sym1,

When adding flags, the specific section -> target in the scheme needs to be specified. For multiple section -> target, use a comma as a separator. For example,
Putting it all together, the following mapping fragment, for example,

```plaintext
[mapping:name]
archive: lib1.a
entries:
    obj1 (noflash);
    rodata -> dram0_data KEEP() SORT() ALIGN(8) SURROUND(my_sym)
```

generates an output on the linker script:

```plaintext
._ = ALIGN(8)
_my_sym_start = ABSOLUTE(.)
KEEP(lib1.a:obj1.*{ SORT(.rodata) SORT(.rodata.*) })
_my_sym_end = ABSOLUTE(.)
```

Note that ALIGN and SURROUND, as mentioned in the flag descriptions, are order sensitive. Therefore, if for the same mapping fragment these two are switched, the following is generated instead:

```plaintext
_my_sym_start = ABSOLUTE(.)
._ = ALIGN(8)
KEEP(lib1.a:obj1.*{ SORT(.rodata) SORT(.rodata.*) })
_my_sym_end = ABSOLUTE(.)
```

**On Symbol-Granularity Placements** Symbol granularity placements is possible due to compiler flags `-ffunction-sections` and `-ffdata-sections`. ESP-IDF compiles with these flags by default. If the user opts to remove these flags, then the symbol-granularity placements will not work. Furthermore, even with the presence of these flags, there are still other limitations to keep in mind due to the dependence on the compiler’s emitted output sections.

For example, with `-ffunction-sections`, separate sections are emitted for each function; with section names predictably constructed i.e. `.text.{func_name}` and `.literal.{func_name}`. This is not the case for string literals within the function, as they go to pooled or generated section names.

With `-fdata-sections`, for global scope data the compiler predictably emits either `.data.{var_name}`, `.rodata.{var_name}` or `.bss.{var_name}; and so Type I mapping entry works for these. However, this is not the case for static data declared in function scope, as the generated section name is a result of mangling the variable name with some other information.

**Linker Script Template**

The linker script template is the skeleton in which the generated placement rules are put into. It is an otherwise ordinary linker script, with a specific marker syntax that indicates where the generated placement rules are placed.

To reference the placement rules collected under a target token, the following syntax is used:

```plaintext
mapping[target]
```

Example:

The example below is an excerpt from a possible linker script template. It defines an output section `.iram0.text`, and inside is a marker referencing the target `iram0_text`.

```plaintext
.iram0.text :
{
    /* Code marked as running out of IRAM */
    _iram_text_start = ABSOLUTE(.);

    /* Marker referencing iram0_text */
    mapping[iram0_text]

    (continues on next page)
```
Suppose the generator collected the fragment definitions below:

```plaintext
[sections:text]
    .text+
    .literal+
[sections:iram]
    .iram1+
[scheme:default]
    entries:
        text -> flash_text
        iram -> iram0_text
[scheme:noflash]
    entries:
        text -> iram0_text
[mapping:freertos]
    archive: libfreertos.a
    entries:
        * (noflash)
```

Then the corresponding excerpt from the generated linker script will be as follows:

```plaintext
.iram0.text :
{
    /* Code marked as running out of IRAM */
    _iram_text_start = ABSOLUTE(.);

    /* Placement rules generated from the processed fragments, placed where the-
    _marker was in the template */
    "libfreertos.a:(.literal .text .literal.* .text.*)"
    "*.iram1 .iram1.*"
    "*.iram0.text"

    _iram_text_end = ABSOLUTE(.);
} > iram0_0_seg

*libfreertos.a:(.literal .text .literal.* .text.*)

    Rule generated from the entry * (noflash) of the freertos mapping fragment. All text sections
    of all object files under the archive libfreertos.a will be collected under the target iram0_text
    (as per the noflash scheme) and placed wherever in the template iram0_text is referenced by a
    marker.

*(.iram1 .iram1.*)

    Rule generated from the default scheme entry iram -> iram0_text. Since the default scheme
    specifies an iram -> iram0_text entry, it too is placed wherever iram0_text is referenced
    by a marker. Since it is a rule generated from the default scheme, it comes first among all other rules
    collected under the same target name.

The linker script template currently used is esp_system/ld/esp32/sections.ld.in; the generated output
script sections.ld is put under its build directory.

Submit Document Feedback
Migrate to ESP-IDF v5.0 Linker Script Fragment Files Grammar

The old grammar supported in ESP-IDF v3.x would be dropped in ESP-IDF v5.0. Here are a few notes on how to migrate properly:

1. Now indentation is enforced and improperly indented fragment files would generate a runtime parse exception. This was not enforced in the old version but previous documentation and examples demonstrate properly indented grammar.
2. Migrate the old condition entry to the `if...elif...else` structure for conditionals. You can refer to the earlier chapter for detailed grammar.
3. Mapping fragments now requires a name like other fragment types.

4.20 lwIP

ESP-IDF uses the open source lwIP lightweight TCP/IP stack. The ESP-IDF version of lwIP (esp-lwip) has some modifications and additions compared to the upstream project.

4.20.1 Supported APIs

ESP-IDF supports the following lwIP TCP/IP stack functions:

- BSD Sockets API
- Netconn API is enabled but not officially supported for ESP-IDF applications

Adapted APIs

**Warning:** When using any lwIP API (other than BSD Sockets API), please make sure that it is thread safe. To check if a given API call is safe, enable `CONFIG_LWIP_CHECK_THREAD_SAFETY` and run the application. This way lwIP asserts the TCP/IP core functionality to be correctly accessed; the execution aborts if it is not locked properly or accessed from the correct task (lwIP FreeRTOS Task). The general recommendation is to use ESP-NETIF component to interact with lwIP.

Some common lwIP “app” APIs are supported indirectly by ESP-IDF:

- DHCP Server & Client are supported indirectly via the ESP-NETIF functionality
- Simple Network Time Protocol (SNTP) is also supported via the ESP-NETIF, or directly via the `lwp/include/apps/esp_snntp.h` functions that provide thread-safe API to lwip/lwip/src/include/lwip/apps/snntp.h functions (see also SNTP Time Synchronization)
- ICMP Ping is supported using a variation on the lwIP ping API. See ICMP Echo.
- NetBIOS lookup is available using the standard lwIP API, `protocols/http_server/restful_server` has an option to demonstrate using NetBIOS to look up a host on the LAN.
- mDNS uses a different implementation to the lwIP default mDNS (see mDNS Service), but lwIP can look up mDNS hosts using standard APIs such as `gethostbyname()` and the convention `hostname.local`, provided the `CONFIG_LWIP_DNS_SUPPORT_MDNS_QUERIES` setting is enabled.
- The PPP implementation in lwIP can be used to create PPoS (PPP over serial) interface in ESP-IDF. Please refer to the documentation of ESP-NETIF component to create and configure a PPP network interface, by means of the `ESP_NETIF_DEFAULT_PPP()` macro defined in `esp_netif/include/esp_netif_defaults.h`. Additional runtime settings are provided via the `esp_netif/include/esp_netif_ppp.h`. PPoS interfaces are typically used to interact with NBIoT/GSM/LTE modems; more application level friendly API is supported by esp_modem library, which uses this PPP lwIP module behind the scenes.
4.20.2 BSD Sockets API

The BSD Sockets API is a common cross-platform TCP/IP sockets API that originated in the Berkeley Standard Distribution of UNIX but is now standardized in a section of the POSIX specification. BSD Sockets are sometimes called POSIX Sockets or Berkeley Sockets.

As implemented in ESP-IDF, lwIP supports all of the common usages of the BSD Sockets API.

References

A wide range of BSD Sockets reference material is available, including:
- Single UNIX Specification BSD Sockets page
- Berkeley Sockets Wikipedia page

Examples

A number of ESP-IDF examples show how to use the BSD Sockets APIs:
- protocols/sockets/tcp_server
- protocols/sockets/tcp_client
- protocols/sockets/udp_server
- protocols/sockets/udp_client
- protocols/sockets/udp_multicast
- protocols/http_request (Note: this is a simplified example of using a TCP socket to send an HTTP request. The ESP HTTP Client is a much better option for sending HTTP requests.)

Supported functions

The following BSD socket API functions are supported. For full details see lwip/lwip/src/include/lwip/sockets.h.

- socket()
- bind()
- accept()
- shutdown()
- getpeername()
- getssockopt() & setsockopt() (see Socket Options)
- close() (via Virtual filesystem component)
- read(), readv(), write(), writev() (via Virtual filesystem component)
- recv(), recvmsg(), recvfrom()
- send(), sendmsg(), sendto()
- select() (via Virtual filesystem component)
- poll() (Note: on ESP-IDF, poll() is implemented by calling select internally, so using select() directly is recommended if a choice of methods is available.)
- fcntl() (see fcntl)

Non-standard functions:

- ioctl() (see ioctl)

Note: Some lwIP application sample code uses prefixed versions of BSD APIs, for example lwip_socket() instead of the standard socket(). Both forms can be used with ESP-IDF, but using standard names is recommended.
Socket Error Handling

BSD Socket error handling code is very important for robust socket applications. Normally the socket error handling involves the following aspects:

- Detecting the error.
- Getting the error reason code.
- Handle the error according to the reason code.

In lwIP, we have two different scenarios of handling socket errors:

- Socket API returns an error. For more information, see Socket API Errors.
- `select(int maxfdp1, fd_set *readset, fd_set *writeset, fd_set *exceptset, struct timeval *timeout)` has exception descriptor indicating that the socket has an error. For more information, see `select()` Errors.

Socket API Errors

The error detection

- We can know that the socket API fails according to its return value.

Get the error reason code

- When socket API fails, the return value doesn’t contain the failure reason and the application can get the error reason code by accessing errno. Different values indicate different meanings. For more information, see <Socket Error Reason Code>.

Example:

```c
int err;
int sockfd;
if (sockfd = socket(AF_INET, SOCK_STREAM, 0) < 0) {
    // the error code is obtained from errno
    err = errno;
    return err;
}
```

select() Errors

The error detection

- Socket error when `select()` has exception descriptor

Get the error reason code

- If the `select` indicates that the socket fails, we can’t get the error reason code by accessing errno, instead we should call `getsockopt()` to get the failure reason code. Because `select()` has exception descriptor, the error code will not be given to errno.

Note: `getsockopt` function prototype `int getsockopt(int s, int level, int optname, void *optval, socklen_t *optlen)`. Its function is to get the current value of the option of any type, any state socket, and store the result in optval. For example, when you get the error code on a socket, you can get it by `getsockopt(sockfd, SOL_SOCKET, SO_ERROR, &err, &optlen).

Example:

```c
int err;
if (select(sockfd + 1, NULL, NULL, &exfds, &tval) <= 0) {
    err = errno;
    return err;
} else {
    if (FD_ISSET(sockfd, &exfds)) {

</tbody>
</table>

Socket Options

The getsockopt() and setsockopt() functions allow getting/setting per-socket options.

Not all standard socket options are supported by lwIP in ESP-IDF. The following socket options are supported:

Common options Used with level argument SOL_SOCKET.

- SO_REUSEADDR (available if CONFIG_LWIP_SO_REUSE is set, behavior can be customized by setting CONFIG_LWIP_SO_REUSE_RXTOALL)
- SO_KEEPALIVE
- SO_BROADCAST
- SO_ACCEPTCONN
- SO_RCVBUF (available if CONFIG_LWIP_SO_RCVBUF is set)
- SO_SNDTIMEO / SO_RCVTIMEO
- SO_ERROR (this option is only used with select(), see Socket Error Handling)
- SO_TYPE
- SO_NO_CHECK (for UDP sockets only)

IP options Used with level argument IPPROTO_IP.

- IP_TOS
- IP_TTL
- IP_PKTINFO (available if CONFIG_LWIP_NETBUF_RECVINFO is set)

For multicast UDP sockets:

- IP_MULTICAST_IF
- IP_MULTICAST_LOOP
- IP_MULTICAST_TTL
- IP_ADD_MEMBERSHIP
- IP_DROP_MEMBERSHIP
**TCP options**  
TCP sockets only. Used with level argument `IPPROTO_TCP`.

- TCP_NODELAY

Options relating to TCP keepalive probes:

- TCP_KEEPALIVE (int value, TCP keepalive period in milliseconds)
- TCP_KEEPIDLE (same as TCP_KEEPALIVE, but the value is in seconds)
- TCP_KEEPINTVL (int value, interval between keepalive probes in seconds)
- TCP_KEEPCNT (int value, number of keepalive probes before timing out)

**IPv6 options**  
IPv6 sockets only. Used with level argument `IPPROTO_IPV6`.

- IPV6_CHECKSUM
- IPV6_V6ONLY

For multicast IPv6 UDP sockets:

- IPV6_JOIN_GROUP / IPV6_ADD_MEMBERSHIP
- IPV6_LEAVE_GROUP / IPV6_DROP_MEMBERSHIP
- IPV6_MULTICAST_IF
- IPV6_MULTICAST_HOPS
- IPV6_MULTICAST_LOOP

**fcntl**

The `fcntl()` function is a standard API for manipulating options related to a file descriptor. In ESP-IDF, the *Virtual filesystem component* layer is used to implement this function.

When the file descriptor is a socket, only the following `fcntl()` values are supported:

- O_NONBLOCK to set/clear non-blocking I/O mode. Also supports O_NDELAY, which is identical to O_NONBLOCK.
- O_RDONLY, O_WRONLY, O_RDWR flags for different read/write modes. These can read via F_GETFL, only, they cannot be set using F_SETFL. A TCP socket will return a different mode depending on whether the connection has been closed at either end or is still open at both ends. UDP sockets always return O_RDWR.

**ioctl**

The `ioctl()` function provides a semi-standard way to access some internal features of the TCP/IP stack. In ESP-IDF, the *Virtual filesystem component* layer is used to implement this function.

When the file descriptor is a socket, only the following `ioctl()` values are supported:

- FIONREAD returns the number of bytes of pending data already received in the socket’s network buffer.
- FIONBIO is an alternative way to set/clear non-blocking I/O status for a socket, equivalent to `fcntl(fd, F_SETFL, O_NONBLOCK, ...)`.  

**4.20.3 Netconn API**

lwIP supports two lower level APIs as well as the BSD Sockets API: the Netconn API and the Raw API.

The lwIP Raw API is designed for single threaded devices and is not supported in ESP-IDF.

The Netconn API is used to implement the BSD Sockets API inside lwIP, and it can also be called directly from ESP-IDF apps. This API has lower resource usage than the BSD Sockets API, in particular it can send and receive data without needing to first copy it into internal lwIP buffers.

---

**Important:** Espressif does not test the Netconn API in ESP-IDF. As such, this functionality is *enabled but not supported*. Some functionality may only work correctly when used from the BSD Sockets API.
For more information about the Netconn API, consult lwip/lwip/src/include/lwip/api.h and this wiki page which is part of the unofficial lwIP Application Developers Manual.

4.20.4 lwIP FreeRTOS Task

lwIP creates a dedicated TCP/IP FreeRTOS task to handle socket API requests from other tasks.

A number of configuration items are available to modify the task and the queues ("mailboxes") used to send data to/from the TCP/IP task:

- `CONFIG_LWIP_TCPIP_RECVMBOX_SIZE`
- `CONFIG_LWIP_TCPIP_TASK_STACK_SIZE`
- `CONFIG_LWIP_TCPIP_TASK_AFFINITY`

4.20.5 IPv6 Support

Both IPv4 and IPv6 are supported as a dual stack and are enabled by default. Both IPv6 and IPv4 may be disabled separately if they are not needed (see Minimum RAM usage). IPv6 support is limited to Stateless Autoconfiguration only. Stateful configuration is not supported in ESP-IDF (not in upstream lwip). IPv6 Address configuration is defined by means of these protocols or services:

- SLAAC IPv6 Stateless Address Autoconfiguration (RFC-2462)
- DHCPv6 Dynamic Host Configuration Protocol for IPv6 (RFC-8415)

None of these two types of address configuration is enabled by default, so the device uses only Link Local addresses or statically defined addresses.

Stateless Autoconfiguration Process

To enable address autoconfiguration using Router Advertisement protocol please enable:

- `CONFIG_LWIP_IPV6_AUTOCONFIG`

This configuration option enables IPv6 autoconfiguration for all network interfaces (in contrast to the upstream lwIP, where the autoconfiguration needs to be explicitly enabled for each netif with netif->ip6_autoconfig_enabled=1

DHCPv6

DHCPv6 in lwIP is very simple and support only Stateless configuration. It could be enabled using:

- `CONFIG_LWIP_IPV6_DHCP6`

Since the DHCPv6 works only in its stateless configuration, the Stateless Autoconfiguration Process has to be enabled, too, by means of `CONFIG_LWIP_IPV6_AUTOCONFIG`. Moreover, the DHCPv6 needs to be explicitly enabled form the application code using

```
dhcp6_enable_stateless(netif);
```

DNS servers in IPv6 autoconfiguration

In order to autoconfigure DNS server(s), especially in IPv6 only networks, we have these two options

- Recursive domain name system – this belongs to the Neighbor Discovery Protocol (NDP), uses Stateless Autoconfiguration Process. Number of servers must be set `CONFIG_LWIP_IPV6_RDNSS_MAX_DNS_SERVERS`, this is option is disabled (set to 0) by default.
- DHCPv6 stateless configuration – uses DHCPv6 to configure DNS servers. Note that the this configuration assumes IPv6 Router Advertisement Flags (RFC-5175) to be set to
  - Managed Address Configuration Flag $= 0$
Other Configuration Flag = 1

4.20.6 esp-lwip custom modifications

Additions

The following code is added which is not present in the upstream lwIP release:

**Thread-safe sockets** It is possible to close() a socket from a different thread to the one that created it. The close() call will block until any function calls currently using that socket from other tasks have returned.

It is, however, not possible to delete a task while it is actively waiting on select() or poll() APIs. It is always necessary that these APIs exit before destroying the task, as this might corrupt internal structures and cause subsequent crashes of the lwIP. (These APIs allocate globally referenced callback pointers on stack, so that when the task gets destroyed before unrolling the stack, the lwIP would still hold pointers to the deleted stack)

**On demand timers** lwIP IGMP and MLD6 features both initialize a timer in order to trigger timeout events at certain times.

The default lwIP implementation is to have these timers enabled all the time, even if no timeout events are active. This increases CPU usage and power consumption when using automatic light sleep mode. esp-lwip default behaviour is to set each timer “on demand” so it is only enabled when an event is pending.

To return to the default lwIP behaviour (always-on timers), disable `CONFIG_LWIP_TIMERS_ONDEMAND`.

**Lwip timers API** When users are not using WiFi, these APIs provide users with the ability to turn off lwIP timer to reduce power consumption.

The following API functions are supported. For full details see `lwip/lwip/src/include/lwip/timeouts.h`.

- `sys_timeouts_init()`
- `sys_timeouts_deinit()`

**Additional Socket Options**

- Some standard IPv4 and IPv6 multicast socket options are implemented (see `Socket Options`).
- Possible to set IPv6-only UDP and TCP sockets with `IPV6_V6ONLY` socket option (normal lwIP is TCP only).

**IP layer features**

- IPv4 source based routing implementation is different.
- IPv4 mapped IPv6 addresses are supported.

**Customized lwIP hooks** The original lwIP supports implementing custom compile-time modifications via `LWIP_HOOK_FILENAME`. This file is already used by the IDF port layer, but IDF users could still include and implement any custom additions via a header file defined by the macro `ESP_IDF_LWIP_HOOK_FILENAME`. Here is an example of adding a custom hook file to the build process (the hook is called `my_hook.h` and located in the project’s main folder):

```c
idf_component_get_property(lwip, lwip COMPONENT_LIB)
target_compile_options(${lwip} PRIVATE "-I${PROJECT_DIR}/main")
target_compile_definitions(${lwip} PRIVATE "-DESP_IDF_LWIP_HOOK_FILENAME="my_hook.h""")
```
Limitations

Calling `send()` or `sendto()` repeatedly on a UDP socket may eventually fail with `errno` equal to `ENOMEM`. This is a limitation of buffer sizes in the lower layer network interface drivers. If all driver transmit buffers are full then UDP transmission will fail. Applications sending a high volume of UDP datagrams who don’t wish for any to be dropped by the sender should check for this error code and re-send the datagram after a short delay.

Increasing the number of TX buffers in the Wi-Fi or Ethernet project configuration (as applicable) may also help.

4.20.7 Performance Optimization

TCP/IP performance is a complex subject, and performance can be optimized towards multiple goals. The default settings of ESP-IDF are tuned for a compromise between throughput, latency, and moderate memory usage.

Maximum throughput

Espressif tests ESP-IDF TCP/IP throughput using the `wifi/iperf` example in an RF sealed enclosure. The `wifi/iperf/sdkconfig.defaults` file for the iperf example contains settings known to maximize TCP/IP throughput, usually at the expense of higher RAM usage. To get maximum TCP/IP throughput in an application at the expense of other factors then suggest applying settings from this file into the project `sdkconfig`.

**Important:** Suggest applying changes a few at a time and checking the performance each time with a particular application workload.

- If a lot of tasks are competing for CPU time on the system, consider that the lwIP task has configurable CPU affinity (`CONFIG_LWIP_TCPIP_TASK_AFFINITY`) and runs at fixed priority `ESP_TASK_TCPIP_PRIO` (18). Configure competing tasks to be pinned to a different core, or to run at a lower priority. See also [Built-In Task Priorities](#).
- If using `select()` function with socket arguments only, disabling `CONFIG_VFS_SUPPORT_SELECT` will make `select()` calls faster.
- If there is enough free IRAM, select `CONFIG_LWIP_IRAM_OPTIMIZATION` to improve TX/RX throughput.

If using a Wi-Fi network interface, please also refer to [Wi-Fi Buffer Usage](#).

Minimum latency

Except for increasing buffer sizes, most changes which increase throughput will also decrease latency by reducing the amount of CPU time spent in lwIP functions.

- For TCP sockets, lwIP supports setting the standard `TCP_NODELAY` flag to disable Nagle’s algorithm.

Minimum RAM usage

Most lwIP RAM usage is on-demand, as RAM is allocated from the heap as needed. Therefore, changing lwIP settings to reduce RAM usage may not change RAM usage at idle but can change it at peak.

- Reducing `CONFIG_LWIP_MAX_SOCKETS` reduces the maximum number of sockets in the system. This will also cause TCP sockets in the `WAIT_CLOSE` state to be closed and recycled more rapidly (if needed to open a new socket), further reducing peak RAM usage.
- Reducing `CONFIG_LWIP_TCPIP_RECVMBBOX_SIZE`, `CONFIG_LWIP_TCP_RECVMBBOX_SIZE` and `CONFIG_LWIP_UDP_RECVMBBOX_SIZE` reduce memory usage at the expense of throughput, depending on usage.
- Reducing `CONFIG_LWIP_TCP_MSL`, `CONFIG_LWIP_TCP_FIN_WAIT_TIMEOUT` reduces the maximum segment lifetime in the system. This will also cause TCP sockets in the `TIME_WAIT`, `FIN_WAIT_2` state to be closed and recycled more rapidly.
Disabling `CONFIG_LWIP_IPV6` can save about 39 KB for firmware size and 2KB RAM when the system is powered up and 7KB RAM when the TCP/IP stack is running. If there is no requirement for supporting IPV6 then it can be disabled to save flash and RAM footprint.

Disabling `CONFIG_LWIP_IPV4` can save about 26 KB of firmware size and 600B RAM on power up and 6 KB RAM when the TCP/IP stack is running. If the local network supports IPv6-only configuration then IPv4 can be disabled to save flash and RAM footprint.

If using Wi-Fi, please also refer to Wi-Fi Buffer Usage.

**Peak Buffer Usage**  The peak heap memory that lwIP consumes is the theoretically-maximum memory that the lwIP driver consumes. Generally, the peak heap memory that lwIP consumes depends on:

- the memory required to create a UDP connection: `lwip_udp_conn`
- the memory required to create a TCP connection: `lwip_tcp_conn`
- the number of UDP connections that the application has: `lwip_udp_con_num`
- the number of TCP connections that the application has: `lwip_tcp_con_num`
- the TCP TX window size: `lwip_tcp_tx_win_size`
- the TCP RX window size: `lwip_tcp_rx_win_size`

So, the peak heap memory that the LwIP consumes can be calculated with the following formula:

\[
\text{lwip_dynamic_peek_memory} = (\text{lwip_udp_con_num} \times \text{lwip_udp_conn}) + (\text{lwip_tcp_con_num} \times (\text{lwip_tcp_tx_win_size} + \text{lwip_tcp_rx_win_size} + \text{lwip_tcp_conn}))
\]

Some TCP-based applications need only one TCP connection. However, they may choose to close this TCP connection and create a new one when an error (such as a sending failure) occurs. This may result in multiple TCP connections existing in the system simultaneously, because it may take a long time for a TCP connection to close, according to the TCP state machine (refer to RFC793).

### 4.21 Memory Types

ESP32 chip has multiple memory types and flexible memory mapping features. This section describes how ESP-IDF uses these features by default.

ESP-IDF distinguishes between instruction memory bus (IRAM, IROM, RTC FAST memory) and data memory bus (DRAM, DROM). Instruction memory is executable, and can only be read or written via 4-byte aligned words.

Data memory is not executable and can be accessed via individual byte operations. For more information about the different memory buses consult the ESP32 Technical Reference Manual > System and Memory [PDF].

#### 4.21.1 DRAM (Data RAM)

Non-constant static data (.data) and zero-initialized data (.bss) is placed by the linker into Internal SRAM as data memory. The remaining space in this region is used for the runtime heap.

By applying the `EXT_RAM_BSS_ATTR` macro, zero-initialized data can also be placed into external RAM. To use this macro, the `CONFIG_SPIRAM_ALLOW_BSS_SEG_EXTERNAL_MEMORY` needs to be enabled. See Allow .bss Segment to Be Placed in External Memory.

The available size of the internal DRAM region is reduced by 64 KB (by shifting start address to 0x3FFC0000) if Bluetooth stack is used. Length of this region is also reduced by 16 KB or 32 KB if trace memory is used. Due to some memory fragmentation issues caused by ROM, it is also not possible to use all available DRAM for static allocations - however the remaining DRAM is still available as heap at runtime.

**Note:** There is 520 KB of available SRAM (320 KB of DRAM and 200 KB of IRAM) on the ESP32. However, due to a technical limitation, the maximum statically allocated DRAM usage is 160 KB. The remaining 160 KB (for a total of 320 KB of DRAM) can only be allocated at runtime as heap.
Constant data may also be placed into DRAM, for example if it is used in a non-flash-safe ISR (see explanation under *How to Place Code in IRAM*).

**“noinit” DRAM**

The macro __NOINIT_ATTR can be used as attribute to place data into .noinit section. The values placed into this section will not be initialized at startup and should keep its value after software restart.

By applying the EXT_RAM_NOINIT_ATTR macro, non-initialized value could also be placed in external RAM. To do this, the CONFIG_SPIRAM_ALLOW_NOINIT_SEG_EXTERNAL_MEMORY needs to be enabled. See *Allow .noinit Segment to Be Placed in External Memory*. If the CONFIG_SPIRAM_ALLOW_NOINIT_SEG_EXTERNAL_MEMORY is not enabled, EXT_RAM_NOINIT_ATTR will behave just as __NOINIT_ATTR, it will make data to be placed into .noinit segment in internal RAM.

Example:

```c
__NOINIT_ATTR uint32_t noinit_data;
```

### 4.21.2 IRAM (Instruction RAM)

ESP-IDF allocates part of the Internal SRAM0 region for instruction RAM. The region is defined in *ESP32 Technical Reference Manual > System and Memory > Embedded Memory* [PDF]. Except for the first 64 KB block which is used for PRO and APP MMU caches, the rest of this memory range (i.e. from 0x40080000 to 0x400A0000) is used to store parts of the application which need to run from RAM.

**When to Place Code in IRAM**

Cases when parts of the application should be placed into IRAM:

- Interrupt handlers must be placed into IRAM if ESP_INTR_FLAG_IRAM is used when registering the interrupt handler. For more information, see *IRAM-Safe Interrupt Handlers*.
- Some timing critical code may be placed into IRAM to reduce the penalty associated with loading the code from flash. ESP32 reads code and data from flash via the MMU cache. In some cases, placing a function into IRAM may reduce delays caused by a cache miss and significantly improve that function’s performance.

**How to Place Code in IRAM**

Some code is automatically placed into the IRAM region using the linker script.

If some specific application code needs to be placed into IRAM, it can be done by using the Linker Script Generation feature and adding a linker script fragment file to your component that targets at the entire source files or functions with the noflash placement. See the *Linker Script Generation* docs for more information.

Alternatively, it’s possible to specify IRAM placement in the source code using the IRAM_ATTR macro:

```c
#include "esp_attr.h"

void IRAM_ATTR gpio_isr_handler(void* arg)
{
    // ...
}
```

There are some possible issues with placement in IRAM, that may cause problems with IRAM-safe interrupt handlers:

- Strings or constants inside an IRAM_ATTR function may not be placed in RAM automatically. It’s possible to use DRAM_ATTR attributes to mark these, or using the linker script method will cause these to be automatically placed correctly.
Chapter 4. API Guides

```c
void IRAM_ATTR gpio_isr_handler(void* arg) {
    const static DRAM_ATTR uint8_t INDEX_DATA[] = { 45, 33, 12, 0 };  
    const static char *MSG = DRAM_STR("I am a string stored in RAM");
}
```

Note that knowing which data should be marked with DRAM_ATTR can be hard, the compiler will sometimes recognize that a variable or expression is constant (even if it is not marked const) and optimize it into flash, unless it is marked with DRAM_ATTR.

- GCC optimizations that automatically generate jump tables or switch/case lookup tables place these tables in flash. IDF by default builds all files with -fno-jump-tables -fno-tree-switch-conversion flags to avoid this.

Jump table optimizations can be re-enabled for individual source files that don’t need to be placed in IRAM.

For instructions on how to add the -fno-jump-tables -fno-tree-switch-conversion options when compiling individual source files, see Controlling Component Compilation.

### 4.21.3 IROM (code executed from flash)

If a function is not explicitly placed into IRAM (Instruction RAM) or RTC memory, it is placed into flash. As IRAM is limited, most of an application’s binary code must be placed into IROM instead.

The mechanism by which Flash MMU is used to allow code execution from flash is described in ESP32 Technical Reference Manual > Memory Management and Protection Units (MMU, MPU) [PDF].

During Application Startup Flow, the bootloader (which runs from IRAM) configures the MMU flash cache to map the app’s instruction code region to the instruction space. Flash accessed via the MMU is cached using some internal SRAM and accessing cached flash data is as fast as accessing other types of internal memory.

### 4.21.4 DROM (data stored in flash)

By default, constant data is placed by the linker into a region mapped to the MMU flash cache. This is the same as the IROM (code executed from flash) section, but is for read-only data not executable code.

The only constant data not placed into this memory type by default are literal constants which are embedded by the compiler into application code. These are placed as the surrounding function’s executable instructions.

The DRAM_ATTR attribute can be used to force constants from DROM into the DRAM (Data RAM) section (see above).

### 4.21.5 RTC Slow memory

Global and static variables used by code which runs from RTC memory must be placed into RTC Slow memory. For example deep sleep variables can be placed here instead of RTC FAST memory, or code and variables accessed by the ULP Coprocessor programming.

The attribute macro named RTC_NOINIT_ATTR can be used to place data into this type of memory. The values placed into this section keep their value after waking from deep sleep.

Example:

```c
RTC_NOINIT_ATTR uint32_t rtc_noinit_data;
```
4.21.6 RTC FAST memory

The same region of RTC FAST memory can be accessed as both instruction and data memory. Code which has to run after wake-up from deep sleep mode has to be placed into RTC memory. Please check detailed description in deep sleep documentation.

RTC FAST memory can only be accessed by the PRO CPU.

In single core mode, remaining RTC FAST memory is added to the heap unless the option CONFIG_ESP_SYSTEM_ALLOW_RTC_FAST_MEM_AS_HEAP is disabled. This memory can be used interchangeably with DRAM (Data RAM), but is slightly slower to access and not DMA capable.

4.21.7 DMA Capable Requirement

Most peripheral DMA controllers (e.g. SPI, sdmmc, etc.) have requirements that sending/receiving buffers should be placed in DRAM and word-aligned. We suggest to place DMA buffers in static variables rather than in the stack. Use macro DMA_ATTR to declare global/local static variables like:

```c
DMA_ATTR uint8_t buffer[] = "I want to send something";

void app_main()
{
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

Or:

```c
void app_main()
{
    DMA_ATTR static uint8_t buffer[] = "I want to send something";
    // initialization code...
    spi_transaction_t temp = {
        .tx_buffer = buffer,
        .length = 8 * sizeof(buffer),
    };
    spi_device_transmit(spi, &temp);
    // other stuff
}
```

It is also possible to allocate DMA-capable memory buffers dynamically by using the MALLOC_CAP_DMA capabilities flag.

4.21.8 DMA Buffer in the Stack

Placing DMA buffers in the stack is possible but discouraged. If doing so, pay attention to the following:

- Placing DRAM buffers on the stack is not recommended if the stack may be in PSRAM. If the stack of a task is placed in the PSRAM, several steps have to be taken as described in Support for External RAM.
- Use macro WORD_ALIGNED_ATTR in functions before variables to place them in proper positions like:
4.22 OpenThread

OpenThread is an IP stack running on the 802.15.4 MAC layer which features mesh network and low power consumption.

4.22.1 Mode of the OpenThread stack

OpenThread can run under the following modes on Espressif chips:

Standalone node

The full OpenThread stack and the application layer runs on the same chip. This mode is available on chips with 15.4 radio such as ESP32-H2, ESP32-C6.

Radio Co-Processor (RCP)

The chip will be connected to another host running the OpenThread IP stack. It will send and received 15.4 packets on behalf of the host. This mode is available on chips with 15.4 radio such as ESP32-H2, ESP32-C6. The underlying transport between the chip and the host can be SPI or UART. For sake of latency, we recommend to use SPI as the underlying transport.

OpenThread host

For chips without 15.4 radio, it can be connected to an RCP and run OpenThread under host mode. This mode enables OpenThread on Wi-Fi chips such as ESP32, ESP32-S2, ESP32-S3 and ESP32-C3. The following diagram shows how devices work under different modes:

4.22.2 How To Write an OpenThread Application

The OpenThread openthread/ot_cli example will be a good place to start at. It demonstrates basic OpenThread initialization and simple socket-based server and client.

Before OpenThread initialization

- s1.1 The main task calls esp_vfs_eventfd_register() to initialize the eventfd virtual filesystem. The eventfd file system is used for task notification in the OpenThread driver.
- s1.2 The main task calls nvs_flash_init() to initialize the NVS where the Thread network data is stored.
Chapter 4. API Guides

Fig. 56: OpenThread device modes

- s1.3 Optional. The main task calls `esp_netif_init()` only when it wants to create the network interface for Thread.
- s1.4: The main task calls `esp_event_loop_create()` to create the system Event task and initialize an application event’s callback function.

OpenThread stack initialization

- s2.1: Call `esp_openthread_init()` to initialize the OpenThread stack.

OpenThread network interface initialization

The whole stage is optional and only required if the application wants to create the network interface for Thread.
- s3.1: Call `esp_netif_new()` with `ESP_NETIF_DEFAULT_OPENTHREAD` to create the interface. - s3.2: Call `esp_openthread_netif_glue_init()` to create the OpenThread interface handlers. - s3.3: Call `esp_netif_attach()` to attach the handlers to the interface.

The OpenThread main loop

- s4.3: Call `esp_openthread_launch_mainloop()` to launch the OpenThread main loop. Note that this is a busy loop and will not return until the OpenThread stack is terminated.

Calling OpenThread APIs

The OpenThread APIs are not thread-safe. When calling OpenThread APIs from other tasks, make sure to hold the lock with `esp_openthread_lock_acquire()` and release the lock with `esp_openthread_lock_release()` afterwards.

Deinitialization

The following steps are required to deinitialize the OpenThread stack: - Call `esp_netif_destroy()` and `esp_openthread_netif_glue_deinit()` to deinitialize the OpenThread network interface if you have created one. - Call `esp_openthread_deinit()` to deinitialize the OpenThread stack.
4.22.3 The OpenThread border router

The OpenThread border router connects the Thread network with other IP networks. It will provide IPv6 connectivity, service registration and commission functionality. To launch an OpenThread border router on an ESP chip, you need to connect an RCP to a Wi-Fi capable chip such as ESP32. Call `esp_openthread_border_router_init()` during the initialization will launch all the border routing functionalities.

You may refer to the openthread/ot_br example and the README for further border router details.

4.23 Partition Tables

4.23.1 Overview

A single ESP32’s flash can contain multiple apps, as well as many different kinds of data (calibration data, filesystems, parameter storage, etc). For this reason a partition table is flashed to (default offset) 0x800 in the flash.

The partition table length is 0xC00 bytes, as we allow a maximum of 95 entries. An MD5 checksum, used for checking the integrity of the partition table at runtime, is appended after the table data. Thus, the partition table occupies an entire flash sector, which size is 0x1000 (4 KB). As a result, any partition following it must be at least located at (default offset) + 0x1000.

Each entry in the partition table has a name (label), type (app, data, or something else), subtype and the offset in flash where the partition is loaded.

The simplest way to use the partition table is to open the project configuration menu (`idf.py menuconfig`) and choose one of the simple predefined partition tables under `CONFIG_PARTITION_TABLE_TYPE`:

- “Single factory app, no OTA”
- “Factory app, two OTA definitions”

In both cases the factory app is flashed at offset 0x10000. If you execute `idf.py partition-table` then it will print a summary of the partition table.

4.23.2 Built-in Partition Tables

Here is the summary printed for the “Single factory app, no OTA” configuration:

```plaintext
# ESP-IDF Partition Table
# Name, Type, SubType, Offset, Size, Flags
nvs, data, nvs, 0x9000, 0x6000,
phy_init, data, phy, 0xf000, 0x1000,
factory, app, factory, 0x10000, 1M,
```

- At a 0x10000 (64 KB) offset in the flash is the app labelled “factory”. The bootloader will run this app by default.
- There are also two data regions defined in the partition table for storing NVS library partition and PHY init data.

Here is the summary printed for the “Factory app, two OTA definitions” configuration:

```plaintext
# ESP-IDF Partition Table
# Name, Type, SubType, Offset, Size, Flags
nvs, data, nvs, 0x9000, 0x4000,
otadata, data, ota, 0xd000, 0x2000,
phy_init, data, phy, 0xf000, 0x1000,
factory, app, factory, 0x10000, 1M,
```

(continues on next page)
• There are now three app partition definitions. The type of the factory app (at 0x10000) and the next two “OTA” apps are all set to “app”, but their subtypes are different.

• There is also a new “otadata” slot, which holds the data for OTA updates. The bootloader consults this data in order to know which app to execute. If “otadata” is empty, it will execute the factory app.

4.23.3 Creating Custom Tables

If you choose “Custom partition table CSV” in menuconfig then you can also enter the name of a CSV file (in the project directory) to use for your partition table. The CSV file can describe any number of definitions for the table you need.

The CSV format is the same format as printed in the summaries shown above. However, not all fields are required in the CSV. For example, here is the “input” CSV for the OTA partition table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>SubType</th>
<th>Offset</th>
<th>Size</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvs</td>
<td>data</td>
<td>nvs</td>
<td>0x9000</td>
<td>0x4000</td>
<td></td>
</tr>
<tr>
<td>otadata</td>
<td>data</td>
<td>otata</td>
<td>0xd000</td>
<td>0x2000</td>
<td></td>
</tr>
<tr>
<td>phy_init</td>
<td>data</td>
<td>phy</td>
<td>0xf000</td>
<td>0x1000</td>
<td></td>
</tr>
<tr>
<td>factory</td>
<td>app</td>
<td>factory</td>
<td>0x1000</td>
<td></td>
<td>1M</td>
</tr>
<tr>
<td>ota_0</td>
<td>app</td>
<td>ota_0</td>
<td></td>
<td></td>
<td>1M</td>
</tr>
<tr>
<td>ota_1</td>
<td>app</td>
<td>ota_1</td>
<td></td>
<td></td>
<td>1M</td>
</tr>
<tr>
<td>nvs_key</td>
<td>data</td>
<td>nvs_keys</td>
<td></td>
<td></td>
<td>0x1000</td>
</tr>
</tbody>
</table>

• Whitespace between fields is ignored, and so is any line starting with # (comments).

• Each non-comment line in the CSV file is a partition definition.

• The “Offset” field for each partition is empty. The gen_esp32part.py tool fills in each blank offset, starting after the partition table and making sure each partition is aligned correctly.

Name Field

Name field can be any meaningful name. It is not significant to the ESP32. The maximum length of names is 16 bytes, including one null terminator. Names longer than the maximum length will be truncated.

Type Field

Partition type field can be specified as app (0x00) or data (0x01). Or it can be a number 0-254 (or as hex 0x00-0xFE). Types 0x00-0x3F are reserved for ESP-IDF core functions.

If your app needs to store data in a format not already supported by ESP-IDF, then please add a custom partition type value in the range 0x40-0xFE.

See esp_partition_type_t for the enum definitions for app and data partitions.

If writing in C++ then specifying a application-defined partition type requires casting an integer to esp_partition_type_t in order to use it with the partition API. For example:

```c
static const esp_partition_type_t APP_PARTITION_TYPE_A = (esp_partition_type_t)0x40;
```

The ESP-IDF bootloader ignores any partition types other than app (0x00) and data (0x01).
SubType

The 8-bit SubType field is specific to a given partition type. ESP-IDF currently only specifies the meaning of the subtype field for app and data partition types.

See enum `esp_partition_subtype_t` for the full list of subtypes defined by ESP-IDF, including the following:

- When type is `app`, the SubType field can be specified as `factory` (0x00), `ota_0` (0x10) ··· `ota_15` (0x1F) or `test` (0x20).
  - `factory` (0x00) is the default app partition. The bootloader will execute the factory app unless there it sees a partition of type data/ota, in which case it reads this partition to determine which OTA image to boot.
  - OTA never updates the factory partition.
  - If you want to conserve flash usage in an OTA project, you can remove the factory partition and use `ota_0` instead.
  - `ota_0` (0x10) ··· `ota_15` (0x1F) are the OTA app slots. When OTA is in use, the OTA data partition configures which app slot the bootloader should boot. When using OTA, an application should have at least two OTA application slots (ota_0 & ota_1). Refer to the OTA documentation for more details.
  - `test` (0x20) is a reserved subtype for factory test procedures. It will be used as the fallback boot partition if no other valid app partition is found. It is also possible to configure the bootloader to read a GPIO input during each boot, and boot this partition if the GPIO is held low, see `Boot from Test Firmware`.

- When type is `data`, the subtype field can be specified as `ota` (0x00), `phy` (0x01), `nvs` (0x02), `nvs_keys` (0x04), or a range of other component-specific subtypes (see `subtype enum`).
  - `ota` (0) is the OTA data partition which stores information about the currently selected OTA app slot. This partition should be 0x2000 bytes in size. Refer to the OTA documentation for more details.
  - `phy` (1) is for storing PHY initialisation data. This allows PHY to be configured per-device, instead of in firmware.
    - In the default configuration, the phy partition is not used and PHY initialisation data is compiled into the app itself. As such, this partition can be removed from the partition table to save space.
    - To load PHY data from this partition, open the project configuration menu (idf.py menuconfig) and enable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION` option. You will also need to flash your devices with phy init data as the esp-idf build system does not do this automatically.
  - `nvs` (2) is for the Non-Volatile Storage (NVS) API.
    - NVS is used to store per-device PHY calibration data (different to initialisation data).
    - NVS is used to store WiFi data if the `esp_wifi_set_storage(WIFI_STORAGE_FLASH)` initialisation function is used.
    - The NVS API can also be used for other application data.
    - It is strongly recommended that you include an NVS partition of at least 0x3000 bytes in your project.
    - If using NVS API to store a lot of data, increase the NVS partition size from the default 0x6000 bytes.
  - `nvs_keys` (4) is for the NVS key partition. See Non-Volatile Storage (NVS) API for more details.
    - It is used to store NVS encryption keys when NVS Encryption feature is enabled.
    - The size of this partition should be 4096 bytes (minimum partition size).
  - There are other predefined data subtypes for data storage supported by ESP-IDF. These include FAT filesystem (`ESP_PARTITION_SUBTYPE_DATA_FAT`), SPIFFS (`ESP_PARTITION_SUBTYPE_DATA_SPIFFS`), etc.

Other subtypes of data type are reserved for future ESP-IDF uses.

- If the partition type is any application-defined value (range 0x40-0xFE), then subtype field can be any value chosen by the application (range 0x00-0xFE).

Note that when writing in C++, an application-defined subtype value requires casting to type `esp_partition_subtype_t` in order to use it with the partition API.

Extra Partition SubTypes

A component can define a new partition subtype by setting the `EXTRA_PARTITION_SUBTYPES` property. This property is a CMake list, each entry of which is a comma separated string with `<type>, <subtype>, <value>` format. The build system uses this property to add extra subtypes and creates fields named `ESP_PARTITION_SUBTYPE_<type>._<subtype>` in `esp_partition_subtype_t`. The
project can use this subtype to define partitions in the partitions table CSV file and use the new fields in `esp_partition_subtype_t`.

**Offset & Size**

The offset represents the partition address in the SPI flash, which sector size is 0x1000 (4 KB). Thus, the offset must be a multiple of 4 KB.

Partitions with blank offsets in the CSV file will start after the previous partition, or after the partition table in the case of the first partition.

Partitions of type `app` have to be placed at offsets aligned to 0x10000 (64 K). If you leave the offset field blank, `gen_esp32part.py` will automatically align the partition. If you specify an unaligned offset for an app partition, the tool will return an error.

Sizes and offsets can be specified as decimal numbers, hex numbers with the prefix 0x, or size multipliers K or M (1024 and 1024*1024 bytes).

If you want the partitions in the partition table to work relative to any placement (``CONFIG_PARTITION_TABLE_OFFSET``) of the table itself, leave the offset field (in CSV file) for all partitions blank. Similarly, if changing the partition table offset then be aware that all blank partition offsets may change to match, and that any fixed offsets may now collide with the partition table (causing an error).

**Flags**

Only one flag is currently supported, `encrypted`. If this field is set to `encrypted`, this partition will be encrypted if `Flash Encryption` is enabled.

**Note:** `app` type partitions will always be encrypted, regardless of whether this flag is set or not.

### 4.23.4 Generating Binary Partition Table

The partition table which is flashed to the ESP32 is in a binary format, not CSV. The tool `partition_table/gen_esp32part.py` is used to convert between CSV and binary formats.

If you configure the partition table CSV name in the project configuration (`idf.py menuconfig`) and then build the project or run `idf.py partition-table`, this conversion is done as part of the build process.

To convert CSV to Binary manually:

```
python gen_esp32part.py input_partitions.csv binary_partitions.bin
```

To convert binary format back to CSV manually:

```
python gen_esp32part.py binary_partitions.bin input_partitions.csv
```

To display the contents of a binary partition table on stdout (this is how the summaries displayed when running `idf.py partition-table` are generated:

```
python gen_esp32part.py binary_partitions.bin
```

### 4.23.5 Partition Size Checks

The ESP-IDF build system will automatically check if generated binaries fit in the available partition space, and will fail with an error if a binary is too large.

Currently these checks are performed for the following binaries:
• Bootloader binary must fit in space before partition table (see Bootloader Size).
• App binary should fit in at least one partition of type “app”. If the app binary doesn’t fit in any app partition, the build will fail. If it only fits in some of the app partitions, a warning is printed about this.

**Note:** Although the build process will fail if the size check returns an error, the binary files are still generated and can be flashed (although they may not work if they are too large for the available space.)

### MD5 Checksum

The binary format of the partition table contains an MD5 checksum computed based on the partition table. This checksum is used for checking the integrity of the partition table during the boot.

The MD5 checksum generation can be disabled by the `--disable-md5sum` option of `gen_esp32part.py` or by the `CONFIG_PARTITION_TABLE_MD5` option. This is useful for example when one uses a bootloader from ESP-IDF before v3.1 which cannot process MD5 checksums and the boot fails with the error message `invalid magic number 0xebeb`.

### 4.23.6 Flashing the Partition Table

• *idf.py partition-table-flash:* will flash the partition table with `esptool.py`.
• *idf.py flash:* Will flash everything including the partition table.

A manual flashing command is also printed as part of `idf.py partition-table` output.

**Note:** Note that updating the partition table doesn’t erase data that may have been stored according to the old partition table. You can use `idf.py erase-flash` (or `esptool.py erase_flash`) to erase the entire flash contents.

### 4.23.7 Partition Tool (parttool.py)

The component `partition_table` provides a tool `parttool.py` for performing partition-related operations on a target device. The following operations can be performed using the tool:

• reading a partition and saving the contents to a file (`read_partition`)
• writing the contents of a file to a partition (`write_partition`)
• erasing a partition (`erase_partition`)
• retrieving info such as name, offset, size and flag ( “encrypted”) of a given partition (`get_partition_info`)

The tool can either be imported and used from another Python script or invoked from shell script for users wanting to perform operation programmatically. This is facilitated by the tool’s Python API and command-line interface, respectively.

#### Python API

Before anything else, make sure that the `parttool` module is imported.

```python
import sys
import os

idf_path = os.environ["IDF_PATH"] # get value of IDF_PATH from environment
parttool_dir = os.path.join(idf_path, "components", "partition_table") # parttool.py lives in $IDF_PATH/components/partition_table
```

(continues on next page)
sys.path.append(parttool_dir)  # this enables Python to find parttool module
from parttool import *  # import all names inside parttool module

The starting point for using the tool’s Python API to do is create a ParttoolTarget object:

```python
# Create a partool.py target device connected on serial port /dev/ttyUSB1
target = ParttoolTarget("/dev/ttyUSB1")
```

The created object can now be used to perform operations on the target device:

```python
# Erase partition with name 'storage'
target.erase_partition(PartitionName("storage"))

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin'
target.read_partition(PartitionType("data", "spiffs"), "spiffs.bin")

# Write to partition 'factory' the contents of a file named 'factory.bin'
target.write_partition(PartitionName("factory"), "factory.bin")

# Print the size of default boot partition
storage = target.get_partition_info(PARTITION_BOOT_DEFAULT)
print(storage.size)
```

The partition to operate on is specified using PartitionName or PartitionType or PARTITION_BOOT_DEFAULT. As the name implies, these can be used to refer to partitions of a particular name, type-subtype combination, or the default boot partition.

More information on the Python API is available in the docstrings for the tool.

**Command-line Interface**

The command-line interface of parttool.py has the following structure:

```bash
parttool.py [command-args] [subcommand] [subcommand-args]

- command-args - These are arguments that are needed for executing the main...
- subcommand - This is the operation to be performed
- subcommand-args - These are arguments that are specific to the chosen operation
```

```bash
# Erase partition with name 'storage'
parttool.py --port "/dev/ttyUSB1" erase_partition --partition-name=storage

# Read partition with type 'data' and subtype 'spiffs' and save to file 'spiffs.bin'
parttool.py --port "/dev/ttyUSB1" read_partition --partition-type-data --partition-type-spiffs --output "spiffs.bin"

# Write to partition 'factory' the contents of a file named 'factory.bin'
parttool.py --port "/dev/ttyUSB1" write_partition --partition-name-factory --input "factory.bin"

# Print the size of default boot partition
parttool.py --port "/dev/ttyUSB1" get_partition_info --partition-boot-default --info size
```

More information can be obtained by specifying `--help` as argument:
4.24 Performance

ESP-IDF ships with default settings that are designed for a trade-off between performance, resource usage, and available functionality.

These guides describe how to optimize a firmware application for a particular aspect of performance. Usually this involves some trade-off in terms of limiting available functions, or swapping one aspect of performance (such as execution speed) for another (such as RAM usage).

4.24.1 How to Optimize Performance

1. Decide what the performance-critical aspects of your application are (for example: a particular response time to a certain network operation, a particular startup time limit, particular peripheral data throughput, etc.).
2. Find a way to measure this performance (some methods are outlined in the guides below).
3. Modify the code and project configuration and compare the new measurement to the old measurement.
4. Repeat step 3 until the performance meets the requirements set out in step 1.

4.24.2 Guides

Maximizing Execution Speed

Overview Optimizing execution speed is a key element of software performance. Code that executes faster can also have other positive effects, like reducing overall power consumption. However, improving execution speed may have trade-offs with other aspects of performance such as Minimizing Binary Size.

Choose What To Optimize If a function in the application firmware is executed once per week in the background, it may not matter if that function takes 10 ms or 100 ms to execute. If a function is executed constantly at 10 Hz, it matters greatly if it takes 10 ms or 100 ms to execute.

Most application firmwares will only have a small set of functions which require optimal performance. Perhaps those functions are executed very often, or have to meet some application requirements for latency or throughput. Optimization efforts should be targeted at these particular functions.

Measuring Performance The first step to improving something is to measure it.

Basic Performance Measurements If measuring performance relative to an external interaction with the world, you may be able to measure this directly (for example see the examples wifi/iperf and ethernet/iperf for measuring general network performance, or you can use an oscilloscope or logic analyzer to measure timing of an interaction with a device peripheral.)

Otherwise, one way to measure performance is to augment the code to take timing measurements:

```c
#include "esp_timer.h"

void measure_important_function(void) {
  const unsigned MEASUREMENTS = 5000;
  uint64_t start = esp_timer_get_time();
  // Code to be measured...
  const uint64_t end = esp_timer_get_time();
  // Calculate performance...
}
```

(continues on next page)
for (int retries = 0; retries < MEASUREMENTS; retries++) {
    important_function(); // This is the thing you need to measure
}

uint64_t end = esp_timer_get_time();

printf("%u iterations took %llu milliseconds (%llu microseconds per ...
... invocation)\n", MEASUREMENTS, (end - start)/1000, (end - start)/MEASUREMENTS);
}

Executing the target multiple times can help average out factors like RTOS context switches, overhead of measurements, etc.

- Using esp_timer_get_time() generates “wall clock” timestamps with microsecond precision, but has moderate overhead each time the timing functions are called.
- It’s also possible to use the standard Unix gettimeofday() and utime() functions, although the overhead is slightly higher.
- Otherwise, including hal/cpu_hal.h and calling the HAL function cpu_hal_get_cycle_count() will return the number of CPU cycles executed. This function has lower overhead than the others. It is good for measuring very short execution times with high precision. The CPU cycles are counted per-core, so only use this method from an interrupt handler, or a task that is pinned to a single core.
- While performing “microbenchmarks” (i.e. benchmarking only a very small routine of code that runs in less than 1-2 milliseconds), the flash cache performance can sometimes cause big variations in timing measurements depending on the binary. This happens because binary layout can cause different patterns of cache misses in a particular sequence of execution. If the test code is larger then this effect usually averages out. Executing a small function multiple times when benchmarking can help reduce the impact of flash cache misses. Alternatively, move this code to IRAM (see Targeted Optimizations).

External Tracing   The Application Level Tracing library allows measuring code execution with minimal impact on the code itself.

Tasks     If the option CONFIG_FREERTOS_GENERATE_RUN_TIME_STATS is enabled then the FreeRTOS API vTaskGetRunTimeStats() can be used to retrieve runtime information about the processor time used by each FreeRTOS task.

SEgger SystemView is an excellent tool for visualizing task execution and looking for performance issues or improvements in the system as a whole.

Improving Overall Speed   The following optimizations will improve the execution of nearly all code - including boot times, throughput, latency, etc:

- Set CONFIG_ESPTOOLPY_FLASHFREQ to 80 MHz. This is double the 40 MHz default value and will double the speed at which code is loaded or executed from flash. You should verify that the board or module that connects the ESP32 to the flash chip is rated for 80 MHz operation at the relevant temperature ranges, before changing this setting. The hardware datasheet(s) will have this information.
- Set CONFIG_ESPTOOLPY_FLASHMODE to QIO or QOUT mode (Quad I/O). Both will almost double the speed at which code is loaded or executed from flash compared to the default DIO mode. QIO is slightly faster than QOUT if both are supported. Note that both the flash chip model and the electrical connections between the ESP32 and the flash chip must support quad I/O modes or the SoC will not work correctly.
- Set CONFIG_COMPILER_OPTIMIZATION to “Optimize for performance (-O2)”. This may slightly increase binary size compared to the default setting, but will almost certainly increase performance of some code. Note that if your code contains C or C++ Undefined Behaviour then increasing the compiler optimization level may expose bugs that otherwise are not seen.
Chapter 4. API Guides

- If the application uses PSRAM and is based on ESP32 rev. 3 (ECO3), setting `CONFIG_ESP32_REV_MIN` to 3 will disable PSRAM bug workarounds, reducing the code size and improving overall performance.
- Avoid using floating point arithmetic (`float`). Even though ESP32 has a single precision hardware floating point unit, floating point calculations are always slower than integer calculations. If possible then use fixed point representations, a different method of integer representation, or convert part of the calculation to be integer only before switching to floating point.
- Avoid using double precision floating point arithmetic (`double`). These calculations are emulated in software and are very slow. If possible then use an integer-based representation, or single-precision floating point.

**Reduce Logging Overhead**  Although standard output is buffered, it’s possible for an application to be limited by the rate at which it can print data to log output once buffers are full. This is particularly relevant for startup time if a lot of output is logged, but can happen at other times as well. There are multiple ways to solve this problem:

- Reduce the volume of log output by lowering the app `CONFIG_LOG_DEFAULT_LEVEL` (the equivalent bootloader setting is `CONFIG_BOOTLOADER_LOG_LEVEL`). This also reduces the binary size, and saves some CPU time spent on string formatting.
- Increase the speed of logging output by increasing the `CONFIG_ESP_CONSOLE_UART_BAUDRATE`.

**Not Recommended**  The following options will also increase execution speed, but are not recommended as they also reduce the debuggability of the firmware application and may increase the severity of any bugs.

- Set `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL` to disabled. This also reduces firmware binary size by a small amount. However, it may increase the severity of bugs in the firmware including security-related bugs. If necessary to do this to optimize a particular function, consider adding `#define NDEBUG` in the top of that single source file instead.

**Targeted Optimizations**  The following changes will increase the speed of a chosen part of the firmware application:

- Move frequently executed code to IRAM. By default, all code in the app is executed from flash cache. This means that it’s possible for the CPU to have to wait on a “cache miss” while the next instructions are loaded from flash. Functions which are copied into IRAM are loaded once at boot time, and then will always execute at full speed. IRAM is a limited resource, and using more IRAM may reduce available DRAM, so a strategic approach is needed when moving code to IRAM. See `IRAM (Instruction RAM)` for more information.
- Jump table optimizations can be re-enabled for individual source files that don’t need to be placed in IRAM. For hot paths in large switch cases this will improve performance. For instructions on how to add the `-fjump-tables -ftree-switch-conversion` options when compiling individual source files, see `Controlling Component Compilation`.

**Improving Startup Time**  In addition to the overall performance improvements shown above, the following options can be tweaked to specifically reduce startup time:

- Minimizing the `CONFIG_LOG_DEFAULT_LEVEL` and `CONFIG_BOOTLOADER_LOG_LEVEL` has a large impact on startup time. To enable more logging after the app starts up, set the `CONFIG_LOG_MAXIMUM_LEVEL` as well and then call `esp_log_level_set()` to restore higher level logs. The `system/startup_time` main function shows how to do this.
- If using deep sleep, setting `CONFIG_BOOTLOADER_SKIP_VALIDATE_IN_DEEP_SLEEP` allows a faster wake from sleep. Note that if using Secure Boot this represents a security compromise, as Secure Boot validation will not be performed on wake.
• Setting `CONFIG_BOOTLOADER_SKIP_VALIDATE_ON_POWER_ON` will skip verifying the binary on every boot from power-on reset. How much time this saves depends on the binary size and the flash settings. Note that this setting carries some risk if the flash becomes corrupt unexpectedly. Read the help text of the `config item` for an explanation and recommendations if using this option.

• It’s possible to save a small amount of time during boot by disabling RTC slow clock calibration. To do so, set `CONFIG_RTC_CLK_CAL_CYCLES` to 0. Any part of the firmware that uses RTC slow clock as a timing source will be less accurate as a result.

The example project `system/startup_time` is pre-configured to optimize startup time. The file `system/startup_time/sdkconfig.defaults` contain all of these settings. You can append these to the end of your project’s own `sdkconfig` file to merge the settings, but please read the documentation for each setting first.

**Task Priorities** As ESP-IDF FreeRTOS is a real-time operating system, it’s necessary to ensure that high throughput or low latency tasks are granted a high priority in order to run immediately. Priority is set when calling `xTaskCreate()` or `xTaskCreatePinnedToCore()` and can be changed at runtime by calling `vTaskPrioritySet()`.

It’s also necessary to ensure that tasks yield CPU (by calling `vTaskDelay()`, `sleep()`, or by blocking on semaphores, queues, task notifications, etc) in order to not starve lower priority tasks and cause problems for the overall system. The Task Watchdog Timer (TWDT) provides a mechanism to automatically detect if task starvation happens, however note that a Task WDT timeout does not always indicate a problem (sometimes the correct operation of the firmware requires some long-running computation). In these cases tweaking the Task WDT timeout or even disabling the Task WDT may be necessary.

**Built-In Task Priorities** ESP-IDF starts a number of system tasks at fixed priority levels. Some are automatically started during the boot process, some are started only if the application firmware initializes a particular feature. To optimize performance, structure application task priorities so that they are not delayed by system tasks, while also not starving system tasks and impacting other functions of the system.

This may require splitting up a particular task. For example, perform a time-critical operation in a high priority task or an interrupt handler and do the non-time-critical part in a lower priority task.

Header `components/esp_system/include/esp_task.h` contains macros for the priority levels used for built-in ESP-IDF tasks system. See **Background Tasks** for more details about the system tasks.

Common priorities are:

- **Main task that executes app_main function** has minimum priority (1). This task is pinned to Core 0 by default (configurable).
- **High Resolution Timer (ESP Timer)** system task to manage high precision timer events and execute callbacks has high priority (22, `ESP_TASK_TIMER_PRIO`). This task is pinned to Core 0.
- FreeRTOS Timer Task to handle FreeRTOS timer callbacks is created when the scheduler initializes and has minimum task priority (1, configurable). This task is pinned to Core 0.
- **Event Loop Library** system task to manage the default system event loop and execute callbacks has high priority (20, `ESP_TASK_EVENT_PRIO`) and pinned to Core 0. This configuration is only used if the application calls `esp_event_loop_create_default()`, it’s possible to call `esp_event_loop_create()` with a custom task configuration instead.
- **lwIP TCP/IP task** has high priority (18, `ESP_TASK_TCPIP_PRIO`) and is not pinned to any core (configurable).
- **Wi-Fi Driver** task has high priority (23) and is pinned to Core 0 by default (configurable).
- Wi-Fi `wpa_supplicant` component may create dedicated tasks while the Wi-Fi Protected Setup (WPS), WPA2 EAP-TLS, Device Provisioning Protocol (DPP) or BSS Transition Management (BTM) features are in use. These tasks all have low priority (2) and are not pinned to any core.
- **Bluetooth Controller** task has high priority (23, `ESP_TASK_BT_CONTROLLER_PRIO`) and is pinned to Core 0 by default (configurable). The Bluetooth Controller needs to respond to requests with low latency, so it should always be close to the highest priority task assigned to a single CPU.
- **NimBLE Bluetooth Host** host task has high priority (21) and is pinned to Core 0 by default (configurable).
- **Bluedroid Bluetooth Host** creates multiple tasks when used:
Chapter 4. API Guides

- Stack event callback task ("BTC") has high priority (19).
- Stack BTU layer task has high priority (20).
- Host HCI host task has high priority (22).

All Bluedroid Tasks are pinned to the same core, which is Core 0 by default (configurable).

- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config ETH_MAC_DEFAULT_CONFIG then the priority is medium-high (15) and the task is not pinned to any core. These settings can be changed by passing a custom eth_mac_config_t struct when initializing the Ethernet MAC.
- If using the MQTT component, it creates a task with default priority 5 (configurable, depends on CONFIG_MQTT_USE_CUSTOM_CONFIG) and not pinned to any core (configurable).
- To see what is the task priority for mDNS service, please check Performance Optimization.

Choosing application task priorities

With a few exceptions (most importantly the lwIP TCP/IP task), in the default configuration most built-in tasks are pinned to Core 0. This makes it quite easy for the application to place high priority tasks on Core 1. Using priority 19 or higher will guarantee an application task can run on Core 1 without being preempted by any built-in task. To further isolate the tasks running on each CPU, configure the lwIP task to only run on Core 0 instead of either core (this may reduce total TCP/IP throughput depending on what other tasks are running).

In general, it’s not recommended to set task priorities on Core 0 higher than the built-in Wi-Fi/BT operations as starving them of CPU may make the system unstable. Choosing priority 19 and Core 0 will allow lower layer Wi-Fi/BT functionality to run without delays, but still pre-empts the lwIP TCP/IP stack and other less time-critical internal functionality - this is an option for time-critical tasks that don’t perform network operations. Any task that does TCP/IP network operations should run at lower priority than the lwIP TCP/IP task (18) to avoid priority inversion issues.

Note: Setting a task to always run in preference to built-in ESP-IDF tasks does not require pinning to Core 1. The task can be left unpinned - at priority 17 or lower - to optionally run on Core 0 as well, if no higher priority built-in task is running there. Using unpinned tasks can improve the overall CPU utilization, however it makes reasoning about task scheduling more complex.

Note: Task execution is always completely suspended when writing to the built-in SPI flash chip. Only IRAM-Safe Interrupt Handlers will continue executing.

Improving Interrupt Performance

ESP-IDF supports dynamic Interrupt allocation with interrupt preemption. Each interrupt in the system has a priority, and higher priority interrupts will preempt lower priority ones.

Interrupt handlers will execute in preference to any task (provided the task is not inside a critical section). For this reason, it’s important to minimize the amount of time spent executing in an interrupt handler.

To obtain the best performance for a particular interrupt handler:

- Assign more important interrupts a higher priority using a flag such as ESP_INTR_FLAG_LEVEL2 or ESP_INTR_FLAG_LEVEL3 when calling esp_intr_alloc().
- Assign the interrupt on a CPU where built-in Wi-Fi/BT tasks are not configured to run (this means assigning on Core 1 by default, see Built-In Task Priorities). Interrupts are assigned on the same CPU where the esp_intr_alloc() function call is made.
- If you’re sure the entire interrupt handler can run from IRAM (see IRAM-Safe Interrupt Handlers) then set the ESP_INTR_FLAG_IRAM flag when calling esp_intr_alloc() to assign the interrupt. This prevents it being temporarily disabled if the application firmware writes to the internal SPI flash.
- Even if the interrupt handler is not IRAM safe, if it is going to be executed frequently then consider moving the handler function to IRAM anyhow. This minimizes the chance of a flash cache miss when the interrupt code is executed (see Targeted Optimizations). It’s possible to do this without adding the ESP_INTR_FLAG_IRAM flag to mark the interrupt as IRAM-safe, if only part of the handler is guaranteed to be in IRAM.
Improving Network Speed

• For Wi-Fi, see *How to Improve Wi-Fi Performance* and *Wi-Fi Buffer Usage*
• For lwIP TCP/IP (Wi-Fi and Ethernet), see *Performance Optimization*
• The `wifi/iperf` example contains a configuration that is heavily optimized for Wi-Fi TCP/IP throughput. Append the contents of the files `wifi/iperf/sdkconfig.defaults`, `wifi/iperf/sdkconfig.defaults.esp32` and `wifi/iperf/sdkconfig.ci.99` to your project `sdkconfig` file in order to add all of these options. Note that some of these options may have trade-offs in terms of reduced debuggability, increased firmware size, increased memory usage, or reduced performance of other features. To get the best result, read the documentation pages linked above and use this information to determine exactly which options are best suited for your app.

Improving I/O performance Using standard C library functions like `fread` and `fwrite` instead of platform specific unbuffered syscalls such as `read` and `write` can be slow. These functions are designed to be portable, so they are not necessarily optimized for speed, have a certain overhead and are buffered.

*FatFS* specific information and tips:

• Maximum size of the R/W request == FatFS cluster size (allocation unit size)
• Use `read` and `write` instead of `fread` and `fwrite`
• To increase speed of buffered reading functions like `fread` and `fgets`, you can increase a size of the file buffer (Newlib’s default is 128 bytes) to a higher number like 4096, 8192 or 16384. This can be done locally via `setvbuf` function used on a certain file pointer or globally applied to all files via modifying `CONFIG_FATFS_VFS_FSTAT_BLKSIZE`.

**Note:** Setting a bigger buffer size will also increase the heap memory usage.

Minimizing Binary Size

The ESP-IDF build system compiles all source files in the project and ESP-IDF, but only functions and variables that are actually referenced by the program are linked into the final binary. In some cases, it is necessary to reduce the total size of the firmware binary (for example, in order to fit it into the available flash partition size).

The first step to reducing the total firmware binary size is measuring what is causing the size to increase.

Measuring Static Sizes To optimize both firmware binary size and memory usage it’s necessary to measure statically allocated RAM (“data”, “bss”), code (“text”) and read-only data ("rodata") in your project.

Using the `idf.py` sub-commands `size`, `size-components` and `size-files` provides a summary of memory used by the project:

**Note:** It is possible to add `-DOUTPUT_FORMAT=csv` or `-DOUTPUT_FORMAT=json` to get the output in CSV or JSON format.

**Size Summary (idf.py size)**

```
$ idf.py size
[...]
Total sizes:
  DRAM .data size:  14956 bytes
  DRAM .bss  size:  15808 bytes
Used static DRAM:  30764 bytes ( 149972 available, 17.0% used)
Used static IRAM:  83918 bytes ( 47154 available, 64.0% used)
  Flash code:  559943 bytes
  Flash rodata:  176736 bytes
Total image size:~  835553 bytes (.bin may be padded larger)
```
This output breaks down the size of all static memory regions in the firmware binary:

- **DRAM .data size** is statically allocated RAM that is assigned to non-zero values at startup. This uses RAM (DRAM) at runtime and also uses space in the binary file.
- **DRAM .bss size** is statically allocated RAM that is assigned zero at startup. This uses RAM (DRAM) at runtime but doesn’t use any space in the binary file.
- **Used static DRAM** is the total DRAM used by .data + .bss. The available size is the estimated amount of DRAM which will be available as heap memory at runtime (due to metadata overhead and implementation constraints, and heap allocations done by ESP-IDF during startup, the actual free heap at startup will be lower than this).
- **Used static IRAM** is the total size of executable code executed from IRAM. This uses space in the binary file and also reduces IRAM and/or DRAM (depending on sizes) available as heap memory at runtime. See Optimizing IRAM Usage.
- **Flash code** is the total size of executable code executed from flash cache (IROM). This uses space in the binary file.
- **Flash rodata** is the total size of read-only data loaded from flash cache (DROM). This uses space in the binary file.
- **Total image size** is the estimated total binary file size, which is the total of all the used memory types except for .bss.

**Component Usage Summary (idf.py size-components)** The summary output provided by idf.py size does not give enough detail to find the main contributor to excessive binary size. To analyze in more detail, use idf.py size-components

```
$ idf.py size-components
[...]
Total sizes:
  DRAM .data size: 14956 bytes
  DRAM .bss size: 15808 bytes
  Used static DRAM: 30764 bytes (149972 available, 17.0% used)
  Used static IRAM: 83918 bytes (47154 available, 64.0% used)
  Flash code: 559943 bytes
  Flash rodata: 176736 bytes
Total image size: ~835553 bytes (.bin may be padded larger)
```

Per-archive contributions to ELF file:

```
--rodata
  Total
  libnet80211.a 1267 6044 0 5490 0 107445
   18484 138730
   liblwip.a 21 3838 0 0 0 97465
   16116 117440
   libmbedtls.a 60 524 0 0 0 27655
   69907 98146
   libmbedcrypto.a 64 81 0 30 0 76645
   11661 88481

    4228 24150
   libnvs_flash.a 0 24 0 0 0 14347
    2924 17295
   libspi_flash.a 1562 294 0 8851 0 1840
    1913 14460
(continues on next page)
```
The first lines of output from `idf.py size-components` are the same as `idf.py size`. After this a table is printed of “per-archive contributions to ELF file”. This means how much each static library archive has contributed to the final binary size.

Generally, one static library archive is built per component, although some are binary libraries included by a particular component (for example, `libnet80211.a` is included by `esp_wifi` component). There are also toolchain libraries such as `libc.a` and `libgcc.a` listed here, these provide Standard C/C++ Library and toolchain built-in functionality.

If your project is simple and only has a “main” component, then all of the project’s code will be shown under `libmain.a`. If your project includes its own components (see `Build System`), then they will each be shown on a separate line.

The table is sorted in descending order of the total contribution to the binary size.

The columns are as follows:

- **DRAM .data & .bss & other**: .data and .bss are the same as for the totals shown above (static variables, these both reduce total available RAM at runtime but .bss doesn’t contribute to the binary file size). “other” is a column for any custom section types that also contribute to RAM size (usually this value is 0).
- **IRAM**: is the same as for the totals shown above (code linked to execute from IRAM, uses space in the binary file and also reduces IRAM that can be dynamically allocated at runtime using `HEAP_CAP_32BIT`.
- **D/IRAM**: Shows IRAM space which, due to occupying D/IRAM space, is also reducing available DRAM available as heap at runtime.
- **Flash code & rodata**: these are the same as the totals above, IROM and DROM space accessed from flash cache that contribute to the binary size.

**Source File Usage Summary (idf.py size-files)** For even more detail, run `idf.py size-files` to get a summary of the contribution each object file has made to the final binary size. Each object file corresponds to a single source file.

```
$ idf.py size-files
[...]  
 Total sizes:
 DRAM .data size:  14956 bytes
 DRAM .bss size:  15808 bytes
 Used static DRAM: 30764 bytes ( 149972 available, 17.0% used)
 Used static IRAM:  83918 bytes ( 47154 available, 64.0% used)
 Flash code:  559943 bytes
 Flash rodata:  176736 bytes
 Total image size:~  835553 bytes (.bin may be padded larger)
```

(continues on next page)
## Per-file contributions to ELF file:

Object File | DRAM .data & .bss & other | IRAM | D/IRAM | Flash code &...
--- | --- | --- | --- | ---

| File            | Total | .text | .data & .bss | .rodata | .data | .bss | .bss(.bss) | .text(.text) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) | .bss(.bss) | .bss(.bss) | .data(.data) |
After the summary of total sizes, a table of “Per-file contributions to ELF file” is printed.

The columns are the same as shown above for idy.py size-components, but this time the granularity is the contribution of each individual object file to the binary size.

For example, we can see that the file `x509.crt.bundle.S.o` contributed 64212 bytes to the total firmware size, all as .rodata in flash. Therefore we can guess that this application is using the ESP x509 Certificate Bundle feature and not using this feature would save at last this many bytes from the firmware size.

Some of the object files are linked from binary libraries and therefore you won’t find a corresponding source file. To locate which component a source file belongs to, it’s generally possible to search in the ESP-IDF source tree or look in the Linker Map File for the full path.

### Comparing Two Binaries

If making some changes that affect binary size, it’s possible to use an ESP-IDF tool to break down the exact differences in size.

This operation isn’t part of idf.py, it’s necessary to run the `esp_idf_size` Python tool directly.

To do so, first locate the linker map file in the build directory. It will have the name `PROJECTNAME.map`. The `esp_idf_size` tool performs its analysis based on the output of the linker map file.

To compare with another binary, you will also need its corresponding .map file saved from the build directory.

For example, to compare two builds: one with the default `CONFIG_COMPILER_OPTIMIZATION` setting “Debug (-Og)” configuration and one with “Optimize for size (-Os)”:

```bash
$ python -m esp_idf_size --diff build_Og/https_request.map build_Os/https_request.map
```

We can see from the “Difference” column that changing this one setting caused the whole binary to be over 60 KB smaller and over 5 KB more RAM is available.

It’s also possible to use the “diff” mode to output a table of component-level (static library archive) differences:

**Note:** To get the output in JSON or CSV format using `esp_idf_size` it is possible to use the `--format` option.
Also at the individual source file level:

```
python -m esp_idf_size --files --diff build_Og/https_request.map build_Oshttps_request.map
```

Other options (like writing the output to a file) are available, pass --help to see the full list.

**Showing Size When Linker Fails**  If too much static memory is used, then the linker will fail with an error such as DRAM segment data does not fit, region `iram0_0_seg' overflowed by 44 bytes, or similar.

In these cases idf.py size will not succeed either. However it is possible to run esp_idf_size manually in order to view the partial static memory usage (the memory usage will miss the variables which could not be linked, so there still appears to be some free space.)

The map file argument is `<projectname>.map` in the build directory

```
python -m esp_idf_size build/project_name.map
```

It is also possible to view the equivalent of size-components or size-files output:

```
python -m esp_idf_size --archives build/project_name.map
python -m esp_idf_size --files build/project_name.map
```

**Linker Map File**  This is an advanced analysis method, but it can be very useful. Feel free to skip ahead to :ref:`reducing-overall-size` and possibly come back to this later.

The idf.py size analysis tools all work by parsing the GNU binutils “linker map file” , which is a summary of everything the linker did when it created ( “linked” ) the final firmware binary file.

Linker map files themselves are plain text files, so it’s possible to read them and find out exactly what the linker did. However, they are also very complex and long - often 100,000 or more lines!

The map file itself is broken into parts and each part has a heading. The parts are:

- **Archive member included to satisfy reference by file (symbol).** This shows you: for each object file included in the link, what symbol (function or variable) was the linker searching for when it included that object file. If you’re wondering why some object file in particular was included in the binary, this part may give a clue. This part can be used in conjunction with the Cross Reference Table at the end of the file. Note that not every object file shown in this list ends up included in the final binary, some end up in the Discarded input sections list instead.

- **Allocating common symbols** - This is a list of (some) global variables along with their sizes. Common symbols have a particular meaning in ELF binary files, but ESP-IDF doesn’t make much use of them.

- **Discarded input sections** - These sections were read by the linker as part of an object file to be linked into the final binary, but then nothing else referred to them so they were discarded from the final binary. For ESP-IDF this can be very long, as we compile each function and static variable to a unique section in order to minimize the final binary size (specifically ESP-IDF uses compiler options `-ffunction-sections -fdata-sections and linker option --gc-sections). Items mentioned in this list do not contribute to the final binary.

- **Memory Configuration, Linker script and memory map** These two parts go together. Some of the output comes directly from the linker command line and the Linker Script, both provided by the Build System. The linker script is partially generated from the ESP-IDF project using the Linker Script Generation feature.

As the output of the Linker script and memory map part of the map unfolds, you can see each symbol (function or static variable) linked into the final binary along with its address (as a 16 digit hex number), its length (also in hex), and the library and object file it was linked from (which can be used to determine the component and the source file).
Following all of the output sections that take up space in the final .bin file, the memory map also includes some sections in the ELF file that are only used for debugging (ELF sections .debug_*), etc.). These don’t contribute to the final binary size. You’ll notice the address of these symbols is a very low number (starting from 0x0000000000000000 and counting up).

- **Cross Reference Table.** This table shows for each symbol (function or static variable), the list of object file(s) that referred to it. If you’re wondering why a particular thing is included in the binary, this will help determine what included it.

**Note:** Unfortunately, the Cross Reference Table doesn’t only include symbols that made it into the final binary. It also includes symbols in discarded sections. Therefore, just because something is shown here doesn’t mean that it was included in the final binary - this needs to be checked separately.

**Note:** Linker map files are generated by the GNU binutils linker “ld”, not ESP-IDF. You can find additional information online about the linker map file format. This quick summary is written from the perspective of ESP-IDF build system in particular.

### Reducing Overall Size

The following configuration options will reduce the final binary size of almost any ESP-IDF project:

- Set `CONFIG_COMPILER_OPTIMIZATION` to “Optimize for size (-Os)” . In some cases, “Optimize for performance (-O2)” will also reduce the binary size compared to the default. Note that if your code contains C or C++ Undefined Behaviour then increasing the compiler optimization level may expose bugs that otherwise don’t happen.
- Reduce the compiled-in log output by lowering the app `CONFIG_LOG_DEFAULT_LEVEL`. If the `CONFIG_LOG_MAXIMUM_LEVEL` is changed from the default then this setting controls the binary size instead. Reducing compiled-in logging reduces the number of strings in the binary, and also the code size of the calls to logging functions.
- Set the `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL` to “Silent”. This avoids compiling in a dedicated assertion string and source file name for each assert that may fail. It’s still possible to find the failed assert in the code by looking at the memory address where the assertion failed.
- Besides the `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL`, you can disable or silent the assertion for HAL component separately by setting `CONFIG_HAL_DEFAULTASSERTIONLEVEL`. It is to notice that ESP-IDF lowers HAL assertion level in bootloader to be silent even if `CONFIG_HAL_DEFAULTASSERTIONLEVEL` is set to full-assertion level. This is to reduce the bootloader size.
- Set `CONFIG_COMPILER_OPTIMIZATION_CHECKS_SILENT`. This removes specific error messages for particular internal ESP-IDF error check macros. This may make it harder to debug some error conditions by reading the log output.
- If the binary needs to run on only certain revision(s) of ESP32, increasing `CONFIG_ESP32_REV_MIN` to match can result in a reduced binary size. This will make a large difference if setting ESP32 minimum revision 3, and PSRAM is enabled.
- Don’t enable `CONFIG_COMPILER_CXX_EXCEPTIONS`, `CONFIG_COMPILER_CXX_RTTI`, or set the `CONFIG_COMPILER_STACKCHECKMODE` to Overall. All of these options are already disabled by default, but they have a large impact on binary size.
- Disabling `CONFIG_ESP_ERR_TO_NAME_LOOKUP` will remove the lookup table to translate user-friendly names for error values (see Error Handling) in error logs, etc. This saves some binary size, but error values will be printed as integers only.
- Setting `CONFIG_ESP_SYSTEM_PANIC` to “Silent reboot” will save a small amount of binary size, however this is only recommended if no one will use UART output to debug the device.
- If the application binary uses only one of the security versions of the protocomm component, then the support for others can be disabled to save some code size. The support can be disabled through `CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_0`, `CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_1`, or `CONFIG_ESP_PROTOCOMM_SUPPORT_SECURITY_VERSION_2` respectively.
**Note:** In addition to the many configuration items shown here, there are a number of configuration options where changing the option from the default will increase binary size. These are not noted here. Where the increase is significant, this is usually noted in the configuration item help text.

**Targeted Optimizations**  The following binary size optimizations apply to a particular component or a function:

**Wi-Fi**
- Disabling `CONFIG_ESP_WIFI_ENABLE_WPA3_SAE` will save some Wi-Fi binary size if WPA3 support is not needed. (Note that WPA3 is mandatory for new Wi-Fi device certifications.)
- Disabling `CONFIG_ESP_WIFI_SOFTAP_SUPPORT` will save some Wi-Fi binary size if soft-AP support is not needed.

**ADC**
- Disabling ADC calibration features `CONFIG_ADC_CAL_EFUSE_TP_ENABLE`, `CONFIG_ADC_CAL_EFUSE_VREF_ENABLE`, `CONFIG_ADC_CAL_LUT_ENABLE` will save a small amount of binary size if ADC driver is used, at expense of accuracy.

**Bluetooth NimBLE**  If using NimBLE Bluetooth Host then the following modifications can reduce binary size:

- Set `CONFIG_BTDM_CTRL_BLE_MAX_CONN` to 1 if only one BLE connection is needed.
- `CONFIG_BT_NIMBLE_MAX_CONNECTIONS` to 1 if only one BLE connection is needed.
- Disable either `CONFIG_BT_NIMBLE_ROLE_CENTRAL` or `CONFIG_BT_NIMBLE_ROLE_OBSERVER` if these roles are not needed.
- Reducing `CONFIG_BT_NIMBLE_LOG_LEVEL` can reduce binary size. Note that if the overall log level has been reduced as described above in **Reducing Overall Size** then this also reduces the NimBLE log level.

**lwIP IPv6**
- Setting `CONFIG_LWIP_IPV6` to false will reduce the size of the lwIP TCP/IP stack, at the cost of only supporting IPv4.

**Note:** IPv6 is required by some components such as *coap* and *ASIO port*, These components will not be available if IPv6 is disabled.

**lwIP IPv4**
- If IPv4 connectivity is not required, setting `CONFIG_LWIP_IPV4` to false will reduce the size of the lwIP, supporting IPv6 only TCP/IP stack.

**Note:** Before disabling IPv4 support, please note that IPv6 only network environments are not ubiquitous and must be supported in the local network, e.g. by your internet service provider or using constrained local network settings.

**Newlib nano formatting**  By default, ESP-IDF uses newlib “full” formatting for I/O (printf, scanf, etc.)

Enabling the config option `CONFIG_NEWLIB_NANO_FORMAT` will switch newlib to the “nano” formatting mode. This both smaller in code size and a large part of the implementation is compiled into the ESP32 ROM, so it doesn’t need to be included in the binary at all.
The exact difference in binary size depends on which features the firmware uses, but 25 KB ~ 50 KB is typical. Enabling Nano formatting reduces the stack usage of each function that calls printf() or another string formatting function, see Reducing Stack Sizes.

“Nano” formatting doesn’t support 64-bit integers, or C99 formatting features. For a full list of restrictions, search for --enable-newlib-nano-formatted-io in the Newlib README file.

**mbedTLS features** Under Component Config -> mbedTLS there are multiple mbedTLS features which are enabled by default but can be disabled if not needed to save code size.

These include:

- `CONFIG_MBEDTLS_HAVE_TIME`
- `CONFIG_MBEDTLS_ECDSA_DETERMINISTIC`
- `CONFIG_MBEDTLS_SHA512_C`
- `CONFIG_MBEDTLS_CLIENT_SSL_SESSION_TICKETS`
- `CONFIG_MBEDTLS_SERVER_SSL_SESSION_TICKETS`
- `CONFIG_MBEDTLS_SSL_CONTEXT_SERIALIZATION`
- `CONFIG_MBEDTLS_SSL_ALPN`
- `CONFIG_MBEDTLS_SSL_RENEGOTIATION`
- `CONFIG_MBEDTLS_CCM_C`
- `CONFIG_MBEDTLS_GCM_C`
- `CONFIG_MBEDTLS_ECP_C` (Alternatively: Leave this option enabled but disable some of the elliptic curves listed in the sub-menu.)
- Change `CONFIG_MBEDTLS_TLS_MODE` if both server & client functionalities are not needed
- Consider disabling some ciphersuites listed in the “TLS Key Exchange Methods” sub-menu (i.e. `CONFIG_MBEDTLS_KEY_EXCHANGE_RSA`)

The help text for each option has some more information.

**Important:** It is **strongly not recommended to disable all these mbedTLS options.** Only disable options where you understand the functionality and are certain that it is not needed in the application. In particular:

- Ensure that any TLS server(s) the device connects to can still be used. If the server is controlled by a third party or a cloud service, recommend ensuring that the firmware supports at least two of the supported cipher suites in case one is disabled in a future update.
- Ensure that any TLS client(s) that connect to the device can still connect with supported/recommended cipher suites. Note that future versions of client operating systems may remove support for some features, so it is recommended to enable multiple supported cipher suites or algorithms for redundancy.

If depending on third party clients or servers, always pay attention to announcements about future changes to supported TLS features. If not, the ESP32 device may become inaccessible if support changes.

**Note:** Not every combination of mbedTLS compile-time config is tested in ESP-IDF. If you find a combination that fails to compile or function as expected, please report the details on GitHub.

**VFS** Virtual filesystem feature in ESP-IDF allows multiple filesystem drivers and file-like peripheral drivers to be accessed using standard I/O functions (open, read, write, etc.) and C library functions (fopen, fread, fwrite, etc.). When filesystem or file-like peripheral driver functionality is not used in the application this feature can be fully or partially disabled. VFS component provides the following configuration options:

- `CONFIG_VFS_SUPPORT_TERMIOS` — can be disabled if the application doesn’t use termios family of functions. Currently, these functions are implemented only for UART VFS driver. Most applications can disable this option. Disabling this option reduces the code size by about 1.8 kB.
- `CONFIG_VFS_SUPPORT_SELECT` — can be disabled if the application doesn’t use select function with file descriptors. Currently, only the UART and eventfd VFS drivers implement select support. Note that
when this option is disabled, `select` can still be used for socket file descriptors. Disabling this option reduces the code size by about 2.7 kB.

- `CONFIG_VFS_SUPPORT_DIR` — can be disabled if the application doesn’t use directory related functions, such as `readdir` (see the description of this option for the complete list). Applications which only open, read and write specific files and don’t need to enumerate or create directories can disable this option, reducing the code size by 0.5 kB or more, depending on the filesystem drivers in use.
- `CONFIG_VFS_SUPPORT_IOCTL` — can be disabled if the application doesn’t use filesystems or file-like peripheral drivers. This disables all VFS functionality, including the three options mentioned above. When this option is disabled, `console` can’t be used. Note that the application can still use standard I/O functions with socket file descriptors when this option is disabled. Compared to the default configuration, disabling this option reduces code size by about 9.4 kB.

**Bootloader Size**

This document deals with the size of an ESP-IDF app binary only, and not the ESP-IDF Second stage bootloader.

For a discussion of ESP-IDF bootloader binary size, see **Bootloader Size**.

**IRAM Binary Size**

If the IRAM section of a binary is too large, this issue can be resolved by reducing IRAM memory usage. See **Optimizing IRAM Usage**.

**Minimizing RAM Usage**

In some cases, a firmware application’s available RAM may run low or run out entirely. In these cases, it’s necessary to tune the memory usage of the firmware application.

In general, firmware should aim to leave some “headroom” of free internal RAM in order to deal with extraordinary situations or changes in RAM usage in future updates.

**Background**

Before optimizing ESP-IDF RAM usage, it’s necessary to understand the basics of ESP32 memory types, the difference between static and dynamic memory usage in C, and the way ESP-IDF uses stack and heap. This information can all be found in **Heap Memory Allocation**.

**Measuring Static Memory Usage**

The `idf.py` tool can be used to generate reports about the static memory usage of an application. Refer to the Binary Size chapter for more information.

**Measuring Dynamic Memory Usage**

ESP-IDF contains a range of heap APIs for measuring free heap at runtime. See **Heap Memory Debugging**.

**Note:**

In embedded systems, heap fragmentation can be a significant issue alongside total RAM usage. The heap measurement APIs provide ways to measure the “largest free block”. Monitoring this value along with the total number of free bytes can give a quick indication of whether heap fragmentation is becoming an issue.

**Reducing Static Memory Usage**

- Reducing the static memory usage of the application increases the amount of RAM available for heap at runtime, and vice versa.
- Generally speaking, minimizing static memory usage requires monitoring the `.data` and `.bss` sizes. For tools to do this, see **Measuring Static Sizes**.
- Internal ESP-IDF functions do not make heavy use of static RAM allocation in C. In many instances (including: Wi-Fi library, Bluetooth controller) “static” buffers are still allocated from heap, but the allocation is done once when the feature is initialized and will be freed if the feature is deinitialized. This is done in order to maximize the amount of free memory at different points in the application life-cycle.
To minimize static memory use:

- Declare structures, buffers, or other variables `const` whenever possible. Constant data can be stored in flash not RAM. This may require changing functions in the firmware to take `const *` arguments instead of mutable pointer arguments. These changes can also reduce the stack usage of some functions.
- If using Bluedroid, setting the option `CONFIG_BT_BLE_DYNAMIC_ENV_MEMORY` will cause Bluedroid to allocate memory on initialization and free it on deinitialization. This doesn’t necessarily reduce the peak memory usage, but changes it from static memory usage to runtime memory usage.
- If `Coredump` component is enabled, `ESP_COREDUMP_LOG` macros will use ~5KB internal memory to place strings into DRAM. By disabling `CONFIG_ESP_COREDUMP_LOGS` option, these logs are disabled and the memory is reclaimed.

### Reducing Stack Sizes

In FreeRTOS, task stacks are usually allocated from the heap. The stack size for each task is fixed (passed as an argument to `xTaskCreate()`). Each task can use up to its allocated stack size, but using more than this will cause an otherwise valid program to crash with a stack overflow or heap corruption.

Therefore, determining the optimum sizes of each task stack can substantially reduce RAM usage.

To determine optimum task stack sizes:

- Combine tasks. The best task stack size is 0 bytes, achieved by combining a task with another existing task. Anywhere that the firmware can be structured to perform multiple functions sequentially in a single task will increase free memory. In some cases, using a “worker task” pattern where jobs are serialized into a FreeRTOS queue (or similar) and then processed by generic worker tasks may help.
- Consolidate task functions. String formatting functions (like `printf`) are particularly heavy users of stack, so any task which doesn’t ever call these can usually have its stack size reduced.
- Enabling `Newlib nano formatting` will reduce the stack usage of any task that calls `printf()` or other C string formatting functions.
- Avoid allocating large variables on the stack. In C, any large struct or array allocated as an “automatic” variable (i.e. default scope of a C declaration) will use space on the stack. Minimize the sizes of these, allocate them statically and/or see if you can save memory by allocating them from the heap only when they are needed.
- Avoid deep recursive function calls. Individual recursive function calls don’t always add a lot of stack usage each time they are called, but if each function includes large stack-based variables then the overhead can get quite high.
- At runtime, call the function `uxTaskGetStackHighWaterMark()` with the handle of any task where you think there is unused stack memory. This function returns the minimum lifetime free stack memory in bytes. The easiest time to call this is from the task itself: call `uxTaskGetStackHighWaterMark(NULL)` to get the current task’s high water mark after the time that the task has achieved its peak stack usage (i.e. if there is a main loop, execute the main loop a number of times with all possible states and then call `uxTaskGetStackHighWaterMark()`). Often, it’s possible to subtract almost the entire value returned here from the total stack size of a task, but allow some safety margin to account for unexpected small increases in stack usage at runtime.
- Call `uxTaskGetSystemState()` at runtime to get a summary of all tasks in the system. This includes their individual stack “high watermark” values.
- When debugger watchpoints are not being used, set the `CONFIG_FREERTOS_WATCHPOINT_END_OF_STACK` option to trigger an immediate panic if a task writes the word at the end of its assigned stack. This is slightly more reliable than the default `CONFIG_FREERTOS_CHECK_STACKOVERFLOW` option of “Check using canary bytes”, because the panic happens immediately, not on the next RTOS context switch. Neither option is perfect, it’s possible in some cases for stack pointer to skip the watchpoint or canary bytes and corrupt another region of RAM, instead.

### Internal Stack Sizes

ESP-IDF allocates a number of internal tasks for housekeeping purposes or operating system functions. Some are created during the startup process, and some are created at runtime when particular features are initialized.

The default stack sizes for these tasks are usually set conservatively high, to allow all common usage patterns. Many of the stack sizes are configurable, and it may be possible to reduce them to match the real runtime stack usage of the task.
**Important:** If internal task stack sizes are set too small, ESP-IDF will crash unpredictably. Even if the root cause is task stack overflow, this is not always clear when debugging. It is recommended that internal stack sizes are only reduced carefully (if at all), with close attention to “high water mark” free space under load. If reporting an issue that occurs when internal task stack sizes have been reduced, please always include this information and the specific configuration that is being used.

- **Main task that executes app_main function** has stack size `CONFIG_ESP_MAIN_TASK_STACK_SIZE`.
- **High Resolution Timer (ESP Timer) system task** which executes callbacks has stack size `CONFIG_ESP_TIMER_TASK_STACK_SIZE`.
- FreeRTOS Timer Task to handle FreeRTOS timer callbacks has stack size `CONFIG_FREERTOS_TIMER_TASK_STACK_DEPTH`.
- **Event Loop Library** system task to execute callbacks for the default system event loop has stack size `CONFIG_ESP_SYSTEM_EVENT_TASK_STACK_SIZE`.
- **lwIP** TCP/IP task has stack size `CONFIG_LWIP_TCPIP_TASK_STACK_SIZE`.
- **Bluedroid Bluetooth Host** have task stack sizes `CONFIG_BT_BTC_TASK_STACK_SIZE`, `CONFIG_BT_BTU_TASK_STACK_SIZE`.
- **NimBLE Bluetooth Host** has task stack size `CONFIG_BT_NIMBLE_HOST_TASK_STACK_SIZE`.
- The Ethernet driver creates a task for the MAC to receive Ethernet frames. If using the default config `ETH_MAC_DEFAULT_CONFIG` then the task stack size is 4 KB. This setting can be changed by passing a custom `eth_mac_config_t` struct when initializing the Ethernet MAC.
- FreeRTOS idle task stack size is configured by `CONFIG_FREERTOS_IDLE_TASK_STACKSIZE`.
- If using the MQTT component, it creates a task with stack size configured by `CONFIG_MQTT_TASK_STACK_SIZE`. MQTT stack size can also be configured using `task_stack` field of `esp_mqtt_client_config_t`.
- To see how to optimize RAM usage when using mDNS, please check Performance Optimization.

**Note:** Aside from built-in system features such as esp-timer, if an ESP-IDF feature is not initialized by the firmware then no associated task is created. In those cases, the stack usage is zero and the stack size configuration for the task is not relevant.

**Reducing Heap Usage** For functions that assist in analyzing heap usage at runtime, see Heap Memory Debugging.

Normally, optimizing heap usage consists of analyzing the usage and removing calls to `malloc()` that aren’t being used, reducing the corresponding sizes, or freeing previously allocated buffers earlier.

There are some ESP-IDF configuration options that can reduce heap usage at runtime:

- lwIP documentation has a section to configure Minimum RAM usage.
- **Wi-Fi Buffer Usage** describes options to either reduce numbers of “static” buffers or reduce the maximum number of “dynamic” buffers in use, in order to minimize memory usage at possible cost of performance. Note that “static” Wi-Fi buffers are still allocated from heap when Wi-Fi is initialized and will be freed if Wi-Fi is deinitialized.
- The Ethernet driver allocates DMA buffers for the internal Ethernet MAC when it is initialized - configuration options are `CONFIG_ETH_DMA_BUFFER_SIZE`, `CONFIG_ETH_DMA_RX_BUFFER_NUM`, `CONFIG_ETH_DMA_TX_BUFFER_NUM`.
- Several Mbed TLS configuration options can be used to reduce heap memory usage. See the Mbed TLS docs for details.
- In single core mode only, it’s possible to use IRAM as byte accessible memory (added to the regular heap) by enabling `CONFIG_ESP32_IRAM_AS_8BIT_ACCESSIBLE_MEMORY`. Note that this option carries a performance penalty and the risk of security issues caused by executable data. If this option is enabled then it’s possible to set other options to prefer certain buffers be allocated from this memory: `mbedtls`, `NimBLE`.
- Reduce `CONFIG_BTDM_CTRL_BLE_MAX_CONN` if using BLE.
- Reduce `CONFIG_BTDM_CTRL_BR_EDR_MAX_ACL_CONN` if using Bluetooth Classic.
Optimizing IRAM Usage  If the app allocates more static IRAM than is available then the app will fail to build and linker errors such as section `.iram0.text' will not fit in region `iram0_0_seg', IRAM0 segment data does not fit and region `iram0_0_seg' overflowed by 84 bytes will be seen. If this happens, it is necessary to find ways to reduce static IRAM usage in order to link the application.

To analyze the IRAM usage in the firmware binary, use Measuring Static Sizes. If the firmware failed to link, steps to analyze are shown at Showing Size When Linker Fails.

The following options will reduce IRAM usage of some ESP-IDF features:

- Enable CONFIG_FREERTOS_PLACE_FUNCTIONS_INTO_FLASH. Provided these functions are not (incorrectly) used from ISRs, this option is safe to enable in all configurations.
- Enable CONFIG_FREERTOS_PLACE_SNAPSHOT_FUNS_INTO_FLASH. Enabling this option will place snapshot-related functions, such as vTaskGetSnapshot or uxTaskGetSnapshotAll, in flash.
- Enable CONFIG_RINGBUF_PLACE_FUNCTIONS_INTO_FLASH. Provided these functions are not (incorrectly) used from ISRs, this option is safe to enable in all configurations.
- Enable CONFIG_RINGBUF_PLACE_ISR_FUNCTIONS_INTO_FLASH. This option is not safe to use if the ISR ringbuf functions are used from an IRAM interrupt context, e.g. if CONFIG_UART_ISR_IN_IRAM is enabled. For the IDF drivers where this is the case you will get an error at run-time when installing the driver in question.
- Disable Wi-Fi options CONFIG_ESP_WIFI_IRAM_OPT and/or CONFIG_ESP_WIFI_RX_IRAM_OPT. Disabling these options will free available IRAM at the cost of Wi-Fi performance.
- CONFIG_SPI_FLASH_ROM_DRIVER_PATCH disabling this option will free some IRAM but is only available in some flash configurations (see the configuration item help text).
- If the application uses PSRAM and is based on ESP32 rev. 3 (ECO3), setting CONFIG_ESP32_REV_MIN to 3 will disable PSRAM bug workarounds, saving ~10kB or more of IRAM.
- Disabling CONFIG_ESP_EVENT_POST_FROM_IRAM_ISR prevents posting esp_event events from IRAM-Safe Interrupt Handlers but will save some IRAM.
- Disabling CONFIG_SPI_MASTER_ISR_IN_IRAM prevents spi_master interrupts from being serviced while writing to flash, and may otherwise reduce spi_master performance, but will save some IRAM.
- Disabling CONFIG_SPI_SLAVE_ISR_IN_IRAM prevents spi_slave interrupts from being serviced while writing to flash, will save some IRAM.
- Setting CONFIG_HAL_DEFAULT_ASSERTION_LEVEL to disable assertion for HAL component will save some IRAM especially for HAL code who calls HALASSERT a lot and resides in IRAM.
- Refer to sdkconfig menu Auto-detect flash chips and you can disable flash drivers which you don't need to save some IRAM.
- Enable CONFIG_HEAP_PLACE_FUNCTION_INTO_FLASH. Provided that CONFIG_SPI_MASTER_ISR_IN_IRAM is not enabled and the heap functions are not (incorrectly) used from ISRs, this option is safe to enable in all configuration.

Using SRAM1 for IRAM  The SRAM1 memory area is normally used for DRAM, but it is possible to use parts of it for IRAM with CONFIG_ESP_SYSTEM_ESP32_SRAM1_REGION_AS_IRAM. This memory would previously be reserved for DRAM data usage (e.g. bss) by the software bootloader and later added to the heap. After this option was introduced, the bootloader DRAM size was reduced to a value closer to what it normally actually needs.

This option depends on IDF being able to recognize that the new SRAM1 area is also a valid load address for an image segment. If the software bootloader was compiled before this option existed, then the bootloader will not be able to load an app which has code placed in this new extended IRAM area. This would typically happen if you are doing an OTA update, where only the app would be updated.

If the IRAM section were to be placed in an invalid area then this would be detected during the bootup process and result in a failed boot:
Chapter 4. API Guides

Warning: Apps compiled with `CONFIG_ESP_SYSTEM_ESP32 SRAM1_REGION_AS_IRAM`, may fail to boot if used together with a software bootloader compiled before this config option was introduced. If you are using an older bootloader and updating over OTA, please test carefully before pushing any update.

Any memory which ends up not being used for static IRAM will be added to the heap.

Putting C Library in Flash When compiling for ESP32 revisions older than ECO3 (`CONFIG_ESP32 REV_MIN`), PSRAM cache bug workaround (`CONFIG_SPIRAM_CACHE_WORKAROUND`) option is enabled, and the C library functions normally located in ROM are recompiled with the workaround and placed into IRAM instead. For most applications, it is safe to move many of the C library functions into Flash, reclaiming some IRAM. Corresponding options include:

- `CONFIG_SPIRAM_CACHE_LIBMATH_IN_IRAM`: affects the functions `abs`, `div`, `labs`, `ldiv`, `quorem`, `fpcclassify` and `nan`.
- `CONFIG_SPIRAM_CACHE_LIBNUMPARSER_IN_IRAM`: affects the functions `utoa`, `itoa`, `atoi`, `atol`, `strtol`, and `strtoul`.
- `CONFIG_SPIRAM_CACHE_LIBIO_IN_IRAM`: affects the functions `wctomb`, `fwrite`, `wbuf`, `wsetup`, `fputwc`, `wctomb_r`, `ungetc`, `makebuf`, `fflush`, `refill`, and `sccl`.
- `CONFIG_SPIRAM_CACHE_LIBTIME_IN_IRAM`: affects the functions `asctime`, `asctime_r`, `ctime`, `ctime_r`, `lcltime`, `lcltime_r`, `gmtime`, `gmtime_r`, `strftime`, `mktime`, `strftime`, `time`, `getzinfo`, `systimes`, `month_lengths`, `timelocal`, `tzvars`, `tzlock`, `tz_calc_limits`, and `strptime`.
- `CONFIG_SPIRAM_CACHE_LIBCHAR_IN_IRAM`: affects the functions `isalpha`, `isalnum`, `isblank`, `islower`, `ispunct`, `isprint`, `isascii`, `isupper`, `isgraph`, `islower`, `isprint`, `ispunct`, `isspace`, and `isupper`.
- `CONFIG_SPIRAM_CACHE_LIBJMP_IN_IRAM`: affects the functions `longjmp` and `setjump`.
- `CONFIG_SPIRAM_CACHE_LIBSTR_IN_IRAM`: affects the functions `strlen`, `strcmp`, `strchr`, `strcoll`, `strncpy`, `strndup`, `strndup_r`, `strchr`, `strlcat`, `strlcpy`, `strlchr`, `strlcpy`, `strlstr`, `strlstr`, `strcoll`, `strncpy`, `strndup`, `strndup_r`, `strchr`, `strsep`, `strspn`, `strstr`, `strtok`, and `strtof`.
- `CONFIG_SPIRAM_CACHE_LIBRAND_IN_IRAM`: affects the functions `srand`, `rand`, and `rand_r`.
- `CONFIG_SPIRAM_CACHE_LIBENV_IN_IRAM`: affects the functions `environ`, `envlock`, and `getenv_r`.
- `CONFIG_SPIRAM_CACHE_LIBFILE_IN_IRAM`: affects the functions `lock`, `isatty`, `fclose`, `open`, `close`, `creat`, `read`, `rshift`, `sbbrk`, `stdio`, `sysbrk`, `sysclose`, `sysopen`, `creat`, `sysread`, `syswrite`, `impure`, `fwalk`, and `findfp`.
- `CONFIG_SPIRAM_CACHE_LIBMISC_IN_IRAM`: affects the functions `raise` and `system`.

The exact amount of IRAM saved will depend on how much C library code is actually used by the application. In addition to these, the following options may be used to move more of the C library code into Flash, however note that this may result in reduced performance. Also take care to not use corresponding C library functions from interrupts which may be called while cache is disabled (allocated with `ESP_INTR_FLAG_IRAM` flag), refer to `IRAM-Safe Interrupt Handlers` for more details. For these reasons, the functions `itoa`, `memcmp`, `memcpy`, `memset`, `strcat`, `strchr`, and `strlen` are always put in IRAM.

Note: Moving frequently-called functions from IRAM to flash may increase their execution time.

Note: Other configuration options exist that will increase IRAM usage by moving some functionality into IRAM, usually for performance, but the default option is not to do this. These are not listed here. The IRAM size impact of
enabling these options is usually noted in the configuration item help text.

4.25 Reproducible Builds

4.25.1 Introduction

ESP-IDF build system has support for reproducible builds.

When reproducible builds are enabled, the application built with ESP-IDF doesn’t depend on the build environment. Both the .elf file and .bin files of the application remains exactly the same, even if the following variables change:

- Directory where the project is located
- Directory where ESP-IDF is located (IDF_PATH)
- Build time

4.25.2 Reasons for non-reproducible builds

There are several reasons why an application may depend on the build environment, even when the same source code and tools versions are used.

- In C code, __FILE__ preprocessor macro is expanded to the full path of the source file.
- __DATE__ and __TIME__ preprocessor macros are expanded to compilation date and time.
- When the compiler generates object files, it adds sections with debug information. These sections help debuggers, like GDB, to locate the source code which corresponds to a particular location in the machine code. These sections typically contain paths of relevant source files. These paths may be absolute, and will include the path to ESP-IDF or to the project.

There are also other possible reasons, such as unstable order of inputs and non-determinism in the build system.

4.25.3 Enabling reproducible builds in ESP-IDF

Reproducible builds can be enabled in ESP-IDF using CONFIG_APP_REPRODUCIBLE_BUILD option.

This option is disabled by default. It can be enabled in menuconfig.

The option may also be added into sdkconfig.defaults. If adding the option into sdkconfig.defaults, delete the sdkconfig file and run the build again. See Custom Sdkconfig Defaults for more information.

4.25.4 How reproducible builds are achieved

ESP-IDF achieves reproducible builds using the following measures:

- In ESP-IDF source code, __DATE__ and __TIME__ macros are not used when reproducible builds are enabled. Note, if the application source code uses these macros, the build will not be reproducible.
- ESP-IDF build system passes a set of -fmacro-prefix-map and -fdebug-prefix-map flags to replace base paths with placeholders:
  - Path to ESP-IDF is replaced with /IDF
  - Path to the project is replaced with /IDF_PROJECT
  - Path to the build directory is replaced with /IDF_BUILD
  - Paths to components are replaced with /COMPONENT_NAME_DIR (where NAME is the name of the component)
- Build date and time are not included into the application metadata structure if CONFIG_APP_REPRODUCIBLE_BUILD is enabled.
- ESP-IDF build system ensures that source file lists, component lists and other sequences are sorted before passing them to CMake. Various other parts of the build system, such as the linker script generator also perform sorting to ensure that same output is produced regardless of the environment.
4.25.5 Reproducible builds and debugging

When reproducible builds are enabled, file names included in debug information sections are altered as shown in the previous section. Due to this fact, the debugger (GDB) is not able to locate the source files for the given code location.

This issue can be solved using GDB set substitute-path command. For example, by adding the following command to GDB init script, the altered paths can be reverted to the original ones:

```
set substitute-path /COMPONENT_FREERTOS_DIR /home/user/esp/esp-idf/components/
```

ESP-IDF build system generates a file with the list of such set substitute-path commands automatically during the build process. The file is called prefix_map_gdbinit and is located in the project build directory.

When `idf.py gdb` is used to start debugging, this additional gdbinit file is automatically passed to GDB. When launching GDB manually or from an IDE, please pass this additional gdbinit script to GDB using `-x build/prefix_map_gdbinit argument`.

4.25.6 Factors which still affect reproducible builds

Note that the built application still depends on:

- ESP-IDF version
- Versions of the build tools (CMake, Ninja) and the cross-compiler

*IDF Docker Image* can be used to ensure that these factors do not affect the build.

4.26 RF calibration

ESP32 supports three RF calibration methods during RF initialization:

1. Partial calibration
2. Full calibration
3. No calibration

4.26.1 Partial calibration

During RF initialization, the partial calibration method is used by default for RF calibration. It is done based on the full calibration data which is stored in the NVS. To use this method, please go to *menuconfig* and enable `CONFIG_ESP_PHY_CALIBRATION_AND_DATA_STORAGE`.

4.26.2 Full calibration

Full calibration is triggered in the following conditions:

1. NVS does not exist.
2. The NVS partition to store calibration data is erased.
3. Hardware MAC address is changed.
4. PHY library version is changed.
5. The RF calibration data loaded from the NVS partition is broken.

It takes about 100ms more than partial calibration. If boot duration is not critical, it is suggested to use the full calibration method. To switch to the full calibration method, go to *menuconfig* and disable `CONFIG_ESP_PHY_CALIBRATION_AND_DATA_STORAGE`. If you use the default method of RF calibration, there are two ways to add the function of triggering full calibration as a last-resort remedy:

1. Erase the NVS partition if you don’t mind all of the data stored in the NVS partition is erased. That is indeed the easiest way.
2. Call API `esp_phy_erase_cal_data_in_nvs()` before initializing WiFi and BT/BLE based on some conditions (e.g., an option provided in some diagnostic mode). In this case, only phy namespace of the NVS partition is erased.

### 4.26.3 No calibration

No calibration method is only used when the device wakes up from deep sleep.

### 4.26.4 PHY initialization data

The PHY initialization data is used for RF calibration. There are two ways to get the PHY initialization data.

One is the default initialization data which is located in the header file `components/esp_phy/esp32/include/phy_init_data.h`. It is embedded into the application binary after compiling and then stored into read-only memory (DROM). To use the default initialization data, please go to menuconfig and disable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION`.

Another is the initialization data which is stored in a partition. When using a custom partition table, make sure that PHY data partition is included (type: `data`, subtype: `phy`). With default partition table, this is done automatically. If initialization data is stored in a partition, it has to be flashed there, otherwise runtime error will occur. To switch to the initialization data stored in a partition, go to menuconfig and enable `CONFIG_ESP_PHY_INIT_DATA_IN_PARTITION`.

### 4.26.5 API Reference

#### Header File

- `components/esp_phy/include/esp_phy_init.h`

#### Functions

```c
const esp_phy_init_data_t *esp_phy_get_init_data (void)

Get PHY init data.

If “Use a partition to store PHY init data” option is set in menuconfig, this function will load PHY init data from a partition. Otherwise, PHY init data will be compiled into the application itself, and this function will return a pointer to PHY init data located in read-only memory (DROM).

If “Use a partition to store PHY init data” option is enabled, this function may return NULL if the data loaded from flash is not valid.

**Note:** Call `esp_phy_release_init_data` to release the pointer obtained using this function after the call to `esp_wifi_init`.

**Returns** pointer to PHY init data structure

```c
void esp_phy_release_init_data (const esp_phy_init_data_t *data)

Release PHY init data.

**Parameters** `data` – pointer to PHY init data structure obtained from `esp_phy_get_init_data` function
```
esp_err_t esp_phy_load_cal_data_from_nvs(esp_phy_calibration_data_t *out_cal_data)

Function called by esp_phy_load_cal_and_init to load PHY calibration data.

This is a convenience function which can be used to load PHY calibration data from NVS. Data can be stored to NVS using esp_phy_store_cal_data_to_nvs function.

If calibration data is not present in the NVS, or data is not valid (was obtained for a chip with a different MAC address, or obtained for a different version of software), this function will return an error.

Parameters  
out_cal_data – pointer to calibration data structure to be filled with loaded data.

Returns  ESP_OK on success

esp_err_t esp_phy_store_cal_data_to_nvs(const esp_phy_calibration_data_t *cal_data)

Function called by esp_phy_load_cal_and_init to store PHY calibration data.

This is a convenience function which can be used to store PHY calibration data to the NVS. Calibration data is returned by esp_phy_load_cal_and_init function. Data saved using this function to the NVS can later be loaded using esp_phy_store_cal_data_to_nvs function.

Parameters  
cal_data – pointer to calibration data which has to be saved.

Returns  ESP_OK on success

esp_err_t esp_phy_erase_cal_data_in_nvs(void)

Erase PHY calibration data which is stored in the NVS.

This is a function which can be used to trigger full calibration as a last-resort remedy if partial calibration is used. It can be called in the application based on some conditions (e.g. an option provided in some diagnostic mode).

Returns  ESP_OK on success

void esp_phy_enable(void)

Enable PHY and RF module.

PHY and RF module should be enabled in order to use WiFi or BT. Now PHY and RF enabling job is done automatically when start WiFi or BT. Users should not call this API in their application.

void esp_phy_disable(void)

Disable PHY and RF module.

PHY module should be disabled in order to shutdown WiFi or BT. Now PHY and RF disabling job is done automatically when stop WiFi or BT. Users should not call this API in their application.

void esp_btbb_enable(void)

Enable BTBB module.

BTBB module should be enabled in order to use IEEE802154 or BT. Now BTBB enabling job is done automatically when start IEEE802154 or BT. Users should not call this API in their application.

void esp_btbb_disable(void)

Disable BTBB module.

Disable BTBB module, used by IEEE802154 or Bluetooth. Users should not call this API in their application.

void esp_phy_load_cal_and_init(void)

Load calibration data from NVS and initialize PHY and RF module.

void esp_phy_modem_init(void)

Initialize backup memory for Phy power up/down.

void esp_phy_modem_deinit(void)

Deinitialize backup memory for Phy power up/down Set phy_init_flag if all modems deinit on ESP32C3.

void esp_phy_common_clock_enable(void)

Enable WiFi/BT common clock.
void esp_phy_common_clock_disable (void)
Disable WiFi/BT common clock.

int64_t esp_phy_rf_get_on_ts (void)
Get the time stamp when PHY/RF was switched on.

    Returns return 0 if PHY/RF is never switched on. Otherwise return time in microsecond since boot when phy/rf was last switched on

esp_err_t esp_phy_update_country_info (const char *country)
Update the corresponding PHY init type according to the country code of Wi-Fi.

    Parameters country - country code
    Returns ESP_OK on success.
    Returns esp_err_t code describing the error on fail

cchar *get_phy_version_str (void)
Get PHY lib version.

    Returns PHY lib version.

void phy_track_pll_init (void)
Enable phy track pll.

void phy_track_pll_deinit (void)
Disable phy track pll.

**Structures**

struct esp_phy_init_data_t
Structure holding PHY init parameters.

    Public Members

    uint8_t params[128]
    opaque PHY initialization parameters

struct esp_phy_calibration_data_t
Opaque PHY calibration data.

    Public Members

    uint8_t version[4]
    PHY version

    uint8_t mac[6]
    The MAC address of the station

    uint8_t opaque[1894]
    calibration data
Enumerations

enum esp_phy_calibration_mode_t
PHY calibration mode.

Values:

enumerator PHY_RF_CAL_PARTIAL
Do part of RF calibration. This should be used after power-on reset.

denumerator PHY_RF_CAL_NONE
Don’t do any RF calibration. This mode is only suggested to be used after deep sleep reset.

denumerator PHY_RF_CAL_FULL
Do full RF calibration. Produces best results, but also consumes a lot of time and current. Suggested to be used once.

Header File

- components/esp_phy/include/esp_phy_cert_test.h

Functions

void esp_wifi_power_domain_on (void)
Wifi power domain power on.

void esp_wifi_power_domain_off (void)
Wifi power domain power off.

void esp_phy_rftest_config (uint8_t conf)
Environment variable configuration.

Parameters conf – Set to 1 to enter RF test mode.

void esp_phy_rftest_init (void)
RF initialization configuration.

void esp_phy_tx_contin_en (bool contin_en)
TX Continuous mode.

Parameters contin_en – Set to true for continuous packet sending, which can be used for certification testing; Set to false to cancel continuous mode, which is the default mode and can be used for WLAN tester.

void esp_phy_cbw40m_en (bool en)
HT40/HT20 mode selection.

Parameters en – Set to false to enter 11n HT20 mode; Set to true to enter 11n HT40 mode;

void esp_phy_wifi_tx (uint32_t chan, esp_phy_wifi_rate_t rate, int8_t backoff, uint32_t length_byte, uint32_t packet_delay, uint32_t packet_num)
Wi-Fi TX command.

Parameters

- chan – channel setting, 1~14;
- rate – rate setting;
- backoff – Transmit power attenuation, unit is 0.25dB. For example, 4 means that the power is attenuated by 1dB;
Chapter 4. API Guides

- **length_byte** - TX packet length configuration, indicating PSDU Length, unit is byte;
- **packet_delay** - TX packet interval configuration, unit is us;
- **packet_num** - The number of packets sent, 0 means sending packets continuously, other values represent the number of packets to send.

```c
void esp_phy_test_start_stop (uint8_t value)
Test start/stop command, used to stop transmitting or receiving state.

Parameters
value - Value should be set to 3 before TX/RX. Set value to 0 to end TX/RX state.
```

```c
void esp_phy_wifi_rx (uint32_t chan, esp_phy_wifi_rate_t rate)
Wi-Fi RX command.

Parameters
- **chan** - channel setting, 1~14;
- **rate** - rate setting;
```

```c
void esp_phy_wifi_tx_tone (uint32_t start, uint32_t chan, uint32_t backoff)
Wi-Fi Carrier Wave(CW) TX command.

Parameters
- **start** - enable CW, 1 means transmit, 0 means stop transmitting;
- **chan** - CW channel setting, 1-14;
- **backoff** - CW power attenuation parameter, unit is 0.25dB. 4 indicates the power is attenuated by 1dB.
```

```c
void esp_phy_ble_tx (uint32_t txpwr, uint32_t chan, uint32_t len, esp_phy_ble_type_t data_type, uint32_t syncw, esp_phy_ble_rate_t rate, uint32_t tx_num_in)
BLE TX command.

Parameters
- **txpwr** - Transmit power level. Tx power is about (level-8)*3 dBm, step is 3dB. Level 8 is around 0 dBm;
- **chan** - channel setting, range is 0-39, corresponding frequency freq=2402+chan*2;
- **len** - Payload length setting, range is 0-255, unit is byte, 37 bytes is employed generally;
- **data_type** - Data type setting;
- **syncw** - Packet identification (need to be provided by the packet generator or instrument manufacturer), 0x71764129 is employed generally;
- **rate** - rate setting;
- **tx_num_in** - The number of packets sent, 0 means sending packets continuously, other values represent the number of packets to send.
```

```c
void esp_phy_ble_rx (uint32_t chan, uint32_t syncw, esp_phy_ble_rate_t rate)
BLE RX command.

Parameters
- **chan** - channel selection, range is 0-39; Channels 0, 1, 2~10 correspond to 2404MHz, 2406MHz, 2408MHz~2424MHz respectively; Channels 11, 12, 13~36 correspond to 2428MHz, 2430MHz, 2432MHz~2478MHz respectively; Channel 37: 2402MHz, Channel 38: 2426MHz, Channel 39: 2480MHz;
- **syncw** - Packet identification (need to be provided by the packet generator or instrument manufacturer), 0x71764129 is employed generally;
- **rate** - rate setting;
```

```c
void esp_phy_bt_tx_tone (uint32_t start, uint32_t chan, uint32_t power)
BLE Carrier Wave(CW) TX command.

Parameters
- **start** - enable CW, 1 means transmit, 0 means stop transmitting;
- **chan** - Single carrier transmission channel selection, range is 0~39, corresponding frequency freq = 2402+chan*2;
- **power** - CW power attenuation parameter, unit is 0.25dB. 4 indicates the power is attenuated by 1dB.
void esp_phy_get_rx_result (esp_phy_rx_result_t *rx_result)

Get some RX information.

Parameters rx_result – This struct for storing RX information;

Structures

struct espphy_rx_result_t
Structure holding PHY RX result.

Public Members

uint32_t phy_rx_correct_count
The number of desired packets received

int phy_rx_rssi
Average RSSI of desired packets

uint32_t phy_rx_total_count
The number of total packets received

uint32_t phy_rx_result_flag
0 means no RX info; 1 means the lastest Wi-Fi RX info; 2 means the lastest BLE RX info.

Enumerations

enum esp_phy_wifi_rate_t

Values:

enumerator PHY_RATE_1M
enumerator PHY_RATE_2M
enumerator PHY_RATE_5M5
enumerator PHY_RATE_11M
enumerator PHY_RATE_6M
enumerator PHY_RATE_9M
enumerator PHY_RATE_12M
enumerator PHY_RATE_18M
enumerator PHY_RATE_24M
enumerator PHY_RATE_36M
enumerator PHY_RATE_48M

enumerator **PHY_BLE_TYPE_00111100**

enumerator **PHY_BLE_TYPE_MAX**

### 4.27 Security

This guide provides an overview of the overall security features available in Espressif solutions. It is highly recommended to consider this guide while designing the products with Espressif platform and ESP-IDF software stack from the **security** perspective.

#### 4.27.1 Goals

High level security goals are as follows:

1. Preventing untrusted code execution
2. Protecting the identity and integrity of the code stored in the off-chip flash memory
3. Securing device identity
4. Secure storage for confidential data
5. Authenticated and encrypted communication from the device

#### 4.27.2 Platform Security

**Secure Boot**

Secure Boot feature ensures that only authenticated software can execute on the device. Secure boot process forms a chain of trust by verifying all mutable software entities involved in the ESP-IDF boot process. Signature verification happens during both boot-up as well as OTA updates.

Please refer to the **Secure Boot (v2) Guide** for detailed documentation about this feature.

For ESP32 before ECO3, please refer to **Secure Boot (v1) Guide**.

---

**Important:** It is highly recommended that a secure boot feature be enabled on all production devices.

**Secure Boot Best Practices**

- Generate the signing key on a system with a quality source of entropy.
- Always keep the signing key private. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
- Ensure that all security eFuses have been correctly programmed, includes disabling of the debug interfaces, non-required boot mediums (e.g., UART DL mode) etc.

**Flash Encryption**

Flash Encryption feature helps to encrypt the contents on the off-chip flash memory and thus provides the **confidentiality** aspect to the software or data stored in the flash memory.

Please refer to the **Flash Encryption Guide** for detailed documentation about this feature.
Flash Encryption Best Practices

- It is recommended to use Flash Encryption release mode for the production use-cases.
- It is recommended to have a unique flash encryption key per device.
- Enable Secure Boot as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

Debug Interfaces

JTAG

- JTAG interfaces stays disabled if any of the security features are enabled, please refer to JTAG with Flash Encryption or Secure Boot for more information.
- JTAG interface can also be disabled in the absence of any other security features using eFuse API.

UART DL Mode For ESP32 ECO3 case, UART Download mode stays disabled if any of the security features are enabled in their release configuration. Alternatively, it can also be disabled by calling esp_efuse_disable_rom_download_mode() at runtime.

| Important: | If UART Download mode is disabled then esptool can not work on the device. |

4.27.3 Network Security

Wi-Fi

In addition to the traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), Wi-Fi driver in ESP-IDF also supports additional state-of-the-art security protocols. Please refer to the Wi-Fi Security for detailed documentation.

TLS (Transport Layer Security)

It is recommended to use TLS (Transport Layer Security) in all external communications, e.g., cloud communication, OTA updates etc. from the ESP device. ESP-IDF supports mbedTLS as the official TLS stack.

TLS is default integrated in ESP HTTP Client, ESP HTTPS Server and several other components that ship with ESP-IDF.

| Note: | It is recommended to use ESP-IDF protocol components in their default configuration which has been ensured to be secure. Disabling HTTPS and similar security critical configurations should be avoided. |

ESP-TLS Abstraction ESP-IDF provides an abstraction layer for most used TLS functionalities and hence it is recommended that an application makes use of the API exposed by ESP-TLS.

| TLS Server verification section highlights diverse ways in which the identity of server could be established on the device side. |

ESP Certificate Bundle The ESP x509 Certificate Bundle API provides an easy way to include a bundle of custom x509 root certificates for TLS server verification. The certificate bundle is the easiest way to verify the identity of almost all standard TLS servers.

| Important: | It is highly recommended to verify the identity of the server (based on X.509 certificates) to avoid establishing communication with the fake server. |
4.27.4 Product Security

Secure Provisioning

Secure Provisioning refers to a process of secure on-boarding of the ESP device on to the Wi-Fi network. This mechanism also allows provision of additional custom configuration data during the initial provisioning phase from the provisioning entity (e.g., Smartphone).

ESP-IDF provides various security schemes to establish a secure session between ESP and the provisioning entity, they are highlighted at Security Schemes.

Please refer to the Wi-Fi Provisioning documentation for details and example code for this feature.

Note: Espressif provides Android and iOS Phone Apps along with their sources so that it could be easy to further customize them as per the product requirement.

Secure OTA (Over-the-air) Updates

- OTA Updates must happen over secure transport, e.g., HTTPS.
- ESP-IDF provides a simplified abstraction layer ESP HTTPS OTA for this.
- If Secure Boot is enabled then server should host the signed application image.
- If Flash Encryption is enabled then no additional steps are required on the server side, encryption shall be taken care on the device itself during flash write.
- OTA update Rollback Process can help to switch the application as active only after its functionality has been verified.

Anti-Rollback Protection Anti-rollback protection feature ensures that device only executes application that meets the security version criteria as stored in its eFuse. So even though the application is trusted and signed by legitimate key it may contain some revoked security feature or credential and hence device must reject any such application.

ESP-IDF allows this feature for the application only and it’s managed through 2nd stage bootloader. The security version is stored in the device eFuse and it’s compared against the application image header during both bootup and over-the-air updates.

Please see more information to enable this feature in the Anti-rollback guide.

Encrypted Firmware Distribution Encrypted firmware distribution during over-the-air updates ensure that the application stays encrypted in transit from server to the device. This can act as an additional layer of protection on top of the TLS communication during OTA updates and protect the identity of the application.

Please see working example for this documented in OTA Upgrades with Pre-Encrypted Firmware section.

Secure Storage

Secure storage refers to the application specific data that can be stored in a secure manner on the device (off-chip flash memory). This is typically read-write flash partition and holds device specific configuration data e.g., Wi-Fi credentials.

ESP-IDF provides “NVS (Non-volatile Storage)” management component which allows encrypted data partitions. This feature is tied with the platform Flash Encryption feature described earlier.

Please refer to the NVS Encryption for detailed documentation on the working and instructions to enable this feature.

Important: By default, ESP-IDF components writes the device specific data into the default NVS partition (includes Wi-Fi credentials too) and it is recommended to protect this data using “NVS Encryption” feature.
Secure Device Control

ESP-IDF provides capability to control an ESP device over Wi-Fi + HTTP or BLE in a secure manner using ESP Local Control component.

Please refer to the ESP Local Control for detailed documentation about this feature.

4.27.5 Security Policy

ESP-IDF GitHub repository has attached Security Policy Brief.

Advisories

- Espressif publishes critical Security Advisories on the website, this includes both hardware and software related.
- ESP-IDF software components specific advisories are published through the GitHub repository.

Software Updates

Critical security issues in the ESP-IDF components, 3rd party libraries are fixed as and when we find them or when they are reported to us. Gradually, we make the fixes available in all applicable release branches in ESP-IDF.

Applicable security issues and CVEs for the ESP-IDF components, 3rd party libraries are mentioned in the ESP-IDF release notes.

Important: We recommend periodically updating to the latest bugfix version of the ESP-IDF release to have all critical security fixes available.

4.28 Secure Boot

Important: All references in this document are related to Secure Boot V1 (The AES based Secure Boot Scheme). ESP32 Revision 3 onwards, the preferred secure boot scheme is Secure Boot V2. Please refer to Secure Boot V2 document for ESP32 Revision 3 or ESP32-S2.

Secure Boot is a feature for ensuring only your code can run on the chip. Data loaded from flash is verified on each reset.

Secure Boot is separate from the Flash Encryption feature, and you can use secure boot without encrypting the flash contents. However, for a secure environment both should be used simultaneously. See Secure Boot & Flash Encryption for more details.

Important: Enabling secure boot limits your options for further updates of your ESP32. Make sure to read this document throughly and understand the implications of enabling secure boot.

4.28.1 Background

- Most data is stored in flash. Flash access does not need to be protected from physical access in order for secure boot to function, because critical data is stored (non-software-accessible) in Efuses internal to the chip.
- Efuses are used to store the secure bootloader key (in efuse BLOCK2), and also a single Efuse bit (ABS_DONE_0) is burned (written to 1) to permanently enable secure boot on the chip. For more details on Efuses, see ESP32 Technical Reference Manual > eFuse Controller (eFuse) [PDF].
• To understand the secure boot process, first familiarise yourself with the standard ESP-IDF boot process.
• Both stages of the boot process (initial software bootloader load, and subsequent partition & app loading) are verified by the secure boot process, in a “chain of trust” relationship.

4.28.2 Secure Boot Process Overview

This is a high level overview of the secure boot process. Step by step instructions are supplied under How To Enable Secure Boot. Further in-depth details are supplied under Technical Details:

1. The options to enable secure boot are provided in the Project Configuration Menu, under Secure Boot Configuration.
2. Secure Boot defaults to signing images and partition table data during the build process. The Secure boot private signing key config item is a file path to a ECDSA public/private key pair in a PEM format file.
3. The software bootloader image is built by esp-idf with secure boot support enabled and the public key (signature verification) portion of the secure boot signing key compiled in. This software bootloader image is flashed at offset 0x1000.
4. On first boot, the software bootloader follows the following process to enable secure boot:
   • Hardware secure boot support generates a device secure bootloader key (generated via hardware RNG, then stored read/write protected in efuse), and a secure digest. The digest is derived from the key, an IV, and the bootloader image contents.
   • The secure digest is flashed at offset 0x0 in the flash.
   • Depending on Secure Boot Configuration, efuses are burned to disable JTAG and the ROM BASIC interpreter (it is strongly recommended these options are turned on.)
   • Bootloader permanently enables secure boot by burning the ABS_DONE_0 efuse. The software bootloader then becomes protected (the chip will only boot a bootloader image if the digest matches.)
5. On subsequent boots the ROM bootloader sees that the secure boot efuse is burned, reads the saved digest at 0x0 and uses hardware secure boot support to compare it with a newly calculated digest. If the digest does not match then booting will not continue. The digest and comparison are performed entirely by hardware, and the calculated digest is not readable by software. For technical details see Secure Boot Hardware Support.
6. When running in secure boot mode, the software bootloader uses the secure boot signing key (the public key of which is embedded in the bootloader itself, and therefore validated as part of the bootloader) to verify the signature appended to all subsequent partition tables and app images before they are booted.

4.28.3 Keys

The following keys are used by the secure boot process:

• “secure bootloader key” is a 256-bit AES key that is stored in Efuse block 2. The bootloader can generate this key itself from the internal hardware random number generator, the user does not need to supply it (it is optionally possible to supply this key, see Re-Flashable Software Bootloader). The Efuse holding this key is read & write protected (preventing software access) before secure boot is enabled.
  – By default, the Efuse Block 2 Coding Scheme is “None” and a 256 bit key is stored in this block. On some ESP32s, the Coding Scheme is set to 3/4 Encoding (CODING_SCHEME efuse has value 1) and a 192 bit key must be stored in this block.
For more details, see ESP32 Technical Reference Manual > eFuse Controller (eFuse) > System Parameter coding_scheme [PDF].

The algorithm operates on a 256 bit key in all cases, 192 bit keys are extended by repeating some bits (details).

• “secure boot signing key” is a standard ECDSA public/private key pair (see Image Signing Algorithm) in PEM format.
  – The public key from this key pair (for signature verification but not signature creation) is compiled into the software bootloader and used to verify the second stage of booting (partition table, app image) before booting continues. The public key can be freely distributed, it does not need to be kept secret.
  – The private key from this key pair must be securely kept private, as anyone who has this key can authenticate to any bootloader that is configured with secure boot and the matching public key.
4.28.4 Bootloader Size

Enabling Secure boot and/or flash encryption will increase the size of bootloader, which might require updating partition table offset. See Bootloader Size.

4.28.5 How To Enable Secure Boot

1. Open the Project Configuration Menu, navigate to “Secure Boot Configuration” and select the option “One-time Flash”. (To understand the alternative “Reflashable” choice, see Re-Flashable Software Bootloader.)
2. Select a name for the secure boot signing key. This option will appear after secure boot is enabled. The file can be anywhere on your system. A relative path will be evaluated from the project directory. The file does not need to exist yet.
3. Set other menuconfig options (as desired). Pay particular attention to the “Bootloader Config” options, as you can only flash the bootloader once. Then exit menuconfig and save your configuration.
4. The first time you run make, if the signing key is not found then an error message will be printed with a command to generate a signing key via espsecure.py generate_signing_key.

**Important:** A signing key generated this way will use the best random number source available to the OS and its Python installation (/dev/urandom on OSX/Linux and CryptGenRandom() on Windows). If this random number source is weak, then the private key will be weak.

**Important:** For production environments, we recommend generating the keypair using openssl or another industry standard encryption program. See Generating Secure Boot Signing Key for more details.

5. Run idf.py bootloader to build a secure boot enabled bootloader. The build output will include a prompt for a flashing command, using esptool.py write_flash.
6. When you’re ready to flash the bootloader, run the specified command (you have to enter it yourself, this step is not performed by make) and then wait for flashing to complete. **Remember this is a one time flash, you can’t change the bootloader after this!**
7. Run idf.py flash to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 4.

**Note:** idf.py flash doesn’t flash the bootloader if secure boot is enabled.

8. Reset the ESP32 and it will boot the software bootloader you flashed. The software bootloader will enable secure boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32 to verify that secure boot is enabled and no errors have occurred due to the build configuration.

**Note:** Secure boot won’t be enabled until after a valid partition table and app image have been flashed. This is to prevent accidents before the system is fully configured.

**Note:** If the ESP32 is reset or powered down during the first boot, it will start the process again on the next boot.

9. On subsequent boots, the secure boot hardware will verify the software bootloader has not changed (using the secure bootloader key) and then the software bootloader will verify the signed partition table and app image (using the public key portion of the secure boot signing key).
4.28.6 Re-Flashable Software Bootloader

Configuration “Secure Boot: One-Time Flash” is the recommended configuration for production devices. In this mode, each device gets a unique key that is never stored outside the device.

However, an alternative mode Secure Boot: Reflascable is also available. This mode allows you to supply a binary key file that is used for the secure bootloader key. As you have the key file, you can generate new bootloader images and secure boot digests for them.

In the esp-idf build process, this 256-bit key file is derived from the ECDSA app signing key generated by the user (see the Generating Secure Boot Signing Key step below). This private key’s SHA-256 digest is used as the secure bootloader key in efuse (as-is for Coding Scheme None, or truncate to 192 bytes for 3/4 Encoding). This is a convenience so you only need to generate/protect a single private key.

**Note:** Although it’s possible, we strongly recommend not generating one secure boot key and flashing it to every device in a production environment. The “One-Time Flash” option is recommended for production environments.

To enable a reflascable bootloader:

1. In the Project Configuration Menu, select “Bootloader Config” -> CONFIG_SECURE_BOOT -> CONFIG_SECURE_BOOT_V1_ENABLED -> CONFIG_SECURE_BOOTLOADER_MODE -> Reflascable.
2. If necessary, set the CONFIG_SECURE_BOOTLOADER_KEY_ENCODING based on the coding scheme used by the device. The coding scheme is shown in the Features line when esptool.py connects to the chip, or in the esfuse.py summary output.
3. Please follow the steps shown in Generating Secure Boot Signing Key to generate signing key. Path of the generated key file must be specified in “Secure Boot Configuration” menu.
4. Run idf.py bootloader. A binary key file will be created, derived from the private key that is used for signing. Two sets of flashing steps will be printed - the first set of steps includes an esfuse.py burn_key secure_boot_v1 path_to/secure-bootloader-key-xxx.bin command which is used to write the bootloader key to efuse. (Flashing this key is a one-time-only process.) The second set of steps can be used to reflasc the bootloader with a pre-calculated digest (generated during the build process).
5. Resume from Step 6 of the one-time flashing process, to flash the bootloader and enable secure boot. Watch the console log output closely to ensure there were no errors in the secure boot configuration.

4.28.7 Generating Secure Boot Signing Key

The build system will prompt you with a command to generate a new signing key via espsecure.py generate_signing_key. This uses the python-ecdsa library, which in turn uses Python’s os.urandom() as a random number source.

The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source, and using the best available EC key generation utilities.

For example, to generate a signing key using the openssl command line:
```
openssl ecparam -name prime256v1 -genkey -noout -out my_secure_boot_signing_key.pem
```

Remember that the strength of the secure boot system depends on keeping the signing key private.

4.28.8 Remote Signing of Images

For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default esp-idf secure boot configuration). The espsecure.py command line program can be used to sign app images & partition table data for secure boot, on a remote system.
To use remote signing, disable the option “Sign binaries during build”. The private signing key does not need to be present on the build system. However, the public (signature verification) key is required because it is compiled into the bootloader (and can be used to verify image signatures during OTA updates).

To extract the public key from the private key:

```
$ espsecure.py extract_public_key --keyfile PRIVATE_SIGNING_KEY PUBLIC_VERIFICATION_KEY
```

The path to the public signature verification key needs to be specified in the menuconfig under “Secure boot public signature verification key” in order to build the secure bootloader.

After the app image and partition table are built, the build system will print signing steps using espsecure.py:

```
$ espsecure.py sign_data --keyfile PRIVATE_SIGNING_KEY BINARY_FILE
```

The above command appends the image signature to the existing binary. You can use the `--output` argument to write the signed binary to a separate file:

```
$ espsecure.py sign_data --keyfile PRIVATE_SIGNING_KEY --output SIGNED_BINARY_FILE BINARY_FILE
```

### 4.28.9 Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the secure boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all secure boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.
- Use secure boot in combination with flash encryption to prevent local readout of the flash contents.

### 4.28.10 Technical Details

The following sections contain low-level reference descriptions of various secure boot elements:

#### Secure Boot Hardware Support

The first stage of secure boot verification (checking the software bootloader) is done via hardware. The ESP32’s Secure Boot support hardware can perform three basic operations:

1. Generate a random sequence of bytes from a hardware random number generator.
2. Generate a digest from data (usually the bootloader image from flash) using a key stored in Efuse block 2. The key in Efuse can (& should) be read/write protected, which prevents software access. For full details of this algorithm see Secure Bootloader Digest Algorithm. The digest can only be read back by software if Efuse ABS_DONE_0 is not burned (ie still 0).
3. Generate a digest from data (usually the bootloader image from flash) using the same algorithm as step 2 and compare it to a pre-calculated digest supplied in a buffer (usually read from flash offset 0x0). The hardware returns a true/false comparison without making the digest available to software. This function is available even when Efuse ABS_DONE_0 is burned.

#### Secure Bootloader Digest Algorithm

Starting with an “image” of binary data as input, this algorithm generates a digest as output. The digest is sometimes referred to as an “abstract” in hardware documentation.
For a Python version of this algorithm, see the `espsecure.py` tool in the components/esptool_py directory (specifically, the `digest_secure_bootloader` command).

Items marked with (*) are to fulfill hardware restrictions, as opposed to cryptographic restrictions.

1. Read the AES key from efuse block 2, in reversed byte order. If Coding Scheme is set to 3/4 Encoding, extend the 192 bit key to 256 bits using the same algorithm described in *Flash Encryption Algorithm*.
2. Prefix the image with a 128 byte randomly generated IV.
3. If the image length is not modulo 128, pad the image to a 128 byte boundary with 0xFF. (*)
4. For each 16 byte plaintext block of the input image:
   - Reverse the byte order of the plaintext input block (*)
   - Apply AES256 in ECB mode to the plaintext block. - Reverse the byte order of the ciphertext output block. (*)
   - Append to the overall ciphertext output.
5. Byte-swap each 4 byte word of the ciphertext (*)
6. Calculate SHA-512 of the ciphertext.

Output digest is 192 bytes of data: The 128 byte IV, followed by the 64 byte SHA-512 digest.

### Image Signing Algorithm

Deterministic ECDSA as specified by RFC 6979.

- Curve is NIST256p (openssl calls this curve “prime256v1”, it is also sometimes called secp256r1).
- Hash function is SHA256.
- Key format used for storage is PEM.
  - In the bootloader, the public key (for signature verification) is flashed as 64 raw bytes.
- Image signature is 68 bytes - a 4 byte version word (currently zero), followed by 64 bytes of signature data.
  These 68 bytes are appended to an app image or partition table data.

### Manual Commands

Secure boot is integrated into the esp-idf build system, so `make` will automatically sign an app image if secure boot is enabled. `idf.py bootloader` will produce a bootloader digest if menuconfig is configured for it. However, it is possible to use the `espsecure.py` tool to make standalone signatures and digests.

To sign a binary image:

```
espsecure.py sign_data --keyfile ./my_signing_key.pem --output ./image_signed.bin
```

Keyfile is the PEM file containing an ECDSA private signing key.

To generate a bootloader digest:

```
espsecure.py digest_secure_bootloader --keyfile ./securebootkey.bin --output ./bootloader-digest.bin build/bootloader/bootloader.bin
```

Keyfile is the 32 byte raw secure boot key for the device.

The output of the `espsecure.py digest_secure_bootloader` command is a single file which contains both the digest and the bootloader appended to it. To flash the combined digest plus bootloader to the device:

```
esptool.py write_flash 0x0 bootloader-digest.bin
```

### 4.28.1 Secure Boot & Flash Encryption

If secure boot is used without *Flash Encryption*, it is possible to launch “time-of-check to time-of-use” attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both the features together.
4.28.12 Signed App Verification Without Hardware Secure Boot

The integrity of apps can be checked even without enabling the hardware secure boot option. This option uses the same app signature scheme as hardware secure boot, but unlike hardware secure boot it does not prevent the bootloader from being physically updated. This means that the device can be secured against remote network access, but not physical access. Compared to using hardware Secure Boot this option is much simpler to implement. See How To Enable Signed App Verification for step by step instructions.

An app can be verified on update and, optionally, be verified on boot.

- Verification on update: When enabled, the signature is automatically checked whenever the esp OTA API APIs are used for OTA updates. If hardware secure boot is enabled, this option is always enabled and cannot be disabled. If hardware secure boot is not enabled, this option still adds significant security against network-based attackers by preventing spoofing of OTA updates.
- Verification on boot: When enabled, the bootloader will be compiled with code to verify that an app is signed before booting it. If hardware secure boot is enabled, this option is always enabled and cannot be disabled. If hardware secure boot is not enabled, this option doesn’t add significant security by itself so most users will want to leave it disabled.

How To Enable Signed App Verification

1. Open Project Configuration Menu -> Security features -> Enable CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT
2. “Bootloader verifies app signatures” can be enabled, which verifies app on boot.
3. By default, “Sign binaries during build” will be enabled on selecting “Require signed app images” option, which will sign binary files as a part of build process. The file named in “Secure boot private signing key” will be used to sign the image.
4. If you disable “Sign binaries during build” option then you’ll have to enter path of a public key file used to verify signed images in “Secure boot public signature verification key”. In this case, private signing key should be generated by following instructions in Generating Secure Boot Signing Key; public verification key and signed image should be generated by following instructions in Remote Signing of Images.

4.28.13 Advanced Features

JTAG Debugging

By default, when Secure Boot is enabled then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables Secure Boot.

See JTAG with Flash Encryption or Secure Boot for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

4.29 Secure Boot V2

Important: This document is about Secure Boot V2, supported on ESP32 (ECO3 onwards)

For ESP32 before ECO3, refer to Secure Boot. It is recommended that users use Secure Boot V2 if they have a chip version that supports it. Secure Boot V2 is safer and more flexible than Secure Boot V1.

Secure Boot V2 uses RSA-PSS based app and bootloader verification. This document can also be used as a reference for signing apps using the RSA-PSS scheme without signing the bootloader.

Secure Boot V2 and RSA scheme (App Signing Scheme) options are available for ESP32 from ECO3 onwards. To use these options in menuconfig, set CONFIG_ESP32_REV_MIN greater than or equal to Rev 3.
4.29.1 Background

Secure Boot protects a device from running any unauthorized (i.e., unsigned) code by checking that each piece of software that is being booted is signed. On an ESP32, these pieces of software include the second stage bootloader and each application binary. Note that the first stage bootloader does not require signing as it is ROM code thus cannot be changed.

A RSA based Secure Boot verification scheme (Secure Boot V2) is implemented on ESP32 (ECO 3 onwards).

The Secure Boot process on the ESP32 involves the following steps:

1. When the first stage bootloader loads the second stage bootloader, the second stage bootloader’s RSA-PSS signature is verified. If the verification is successful, the second stage bootloader is executed.
2. When the second stage bootloader loads a particular application image, the application’s RSA-PSS signature is verified. If the verification is successful, the application image is executed.

4.29.2 Advantages

- The RSA-PSS public key is stored on the device. The corresponding RSA-PSS private key is kept at a secret place and is never accessed by the device.
- Only one public key can be generated and stored in the chip during manufacturing.
- Same image format and signature verification method is applied for applications and software bootloader.
- No secrets are stored on the device. Therefore, it is immune to passive side-channel attacks (timing or power analysis, etc.)

4.29.3 Secure Boot V2 Process

This is an overview of the Secure Boot V2 Process. Instructions how to enable Secure Boot are supplied in section How To Enable Secure Boot V2.

Secure Boot V2 verifies the bootloader image and application binary images using a dedicated signature block. Each image has a separately generated signature block which is appended to the end of the image.

Only one signature block can be appended to the bootloader or application image in ESP32 ECO3.

Each signature block contains a signature of the preceding image as well as the corresponding RSA-3072 public key. For more details about the format, refer to Signature Block Format. A digest of the RSA-3072 public key is stored in the eFuse.

The application image is not only verified on every boot but also on each over the air (OTA) update. If the currently selected OTA app image cannot be verified, the bootloader will fall back and look for another correctly signed application image.

The Secure Boot V2 process follows these steps:

1. On startup, the ROM code checks the Secure Boot V2 bit in the eFuse. If Secure Boot is disabled, a normal boot will be executed. If Secure Boot is enabled, the boot will proceed according to the following steps.
2. The ROM code verifies the bootloader’s signature block (Verifying a Signature Block). If this fails, the boot process will be aborted.
3. The ROM code verifies the bootloader image using the raw image data, its corresponding signature block(s), and the eFuse (Verifying an Image). If this fails, the boot process will be aborted.
4. The ROM code executes the bootloader.
5. The bootloader verifies the application image’s signature block (Verifying a Signature Block). If this fails, the boot process will be aborted.
6. The bootloader verifies the application image using the raw image data, its corresponding signature blocks and the eFuse (Verifying an Image). If this fails, the boot process will be aborted. If the verification fails but another application image is found, the bootloader will then try to verify that other image using steps 5 to 7. This repeats until a valid image is found or no other images are found.
7. The bootloader executes the verified application image.
4.29.4 Signature Block Format

The signature block starts on a 4KB aligned boundary and has a flash sector of its own. The signature is calculated over all bytes in the image including the padding bytes (Secure Padding).

The content of each signature block is shown in the following table:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Size (bytes)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Magic byte</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Version number byte (currently 0x02), 0x01 is for Secure Boot V1.</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Padding bytes, Reserved. Should be zero.</td>
</tr>
<tr>
<td>4</td>
<td>32</td>
<td>SHA-256 hash of only the image content, not including the signature block.</td>
</tr>
<tr>
<td>36</td>
<td>384</td>
<td>RSA Public Modulus used for signature verification. (value ‘n’ in RFC8017).</td>
</tr>
<tr>
<td>420</td>
<td>4</td>
<td>RSA Public Exponent used for signature verification (value ‘e’ in RFC8017).</td>
</tr>
<tr>
<td>424</td>
<td>384</td>
<td>Pre-calculated R, derived from ‘n’.</td>
</tr>
<tr>
<td>808</td>
<td>4</td>
<td>Pre-calculated M’, derived from ‘n’.</td>
</tr>
<tr>
<td>812</td>
<td>384</td>
<td>RSA-PSS Signature result (section 8.1.1 of RFC8017) of image content, computed using following PSS parameters: SHA256 hash, MGF1 function, salt length 32 bytes, default trailer field (0xBC).</td>
</tr>
<tr>
<td>1196</td>
<td>4</td>
<td>CRC32 of the preceding 1196 bytes.</td>
</tr>
<tr>
<td>1200</td>
<td>16</td>
<td>Zero padding to length 1216 bytes.</td>
</tr>
</tbody>
</table>

Note: R and M’ are used for hardware-assisted Montgomery Multiplication.

The remainder of the signature sector is erased flash (0xFF) which allows writing other signature blocks after previous signature block.

4.29.5 Secure Padding

In Secure Boot V2 scheme, the application image is padded to the flash MMU page size boundary to ensure that only verified contents are mapped in the internal address space. This is known as secure padding. Signature of the image is calculated after padding and then signature block (4KB) gets appended to the image.

- Default flash MMU page size is 64KB
- Secure padding is applied through the option --secure-pad-v2 in the elf2image conversion using esptool.py

Following table explains the Secure Boot V2 signed image with secure padding and signature block appended:

<table>
<thead>
<tr>
<th>Offset</th>
<th>Size (KB)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>580</td>
<td>Unsigned application size (as an example)</td>
</tr>
<tr>
<td>580</td>
<td>60</td>
<td>Secure padding (aligned to next 64KB boundary)</td>
</tr>
<tr>
<td>640</td>
<td>4</td>
<td>Signature block</td>
</tr>
</tbody>
</table>

Note: Please note that the application image always starts on the next flash MMU page size boundary (default 64KB) and hence the space left over after the signature block shown above can be utilized to store any other data partitions.
4.29.6 Verifying a Signature Block

A signature block is “valid” if the first byte is 0xe7 and a valid CRC32 is stored at offset 1196. Otherwise it’s invalid.

4.29.7 Verifying an Image

An image is “verified” if the public key stored in any signature block is valid for this device, and if the stored signature is valid for the image data read from flash.

1. Compare the SHA-256 hash digest of the public key embedded in the bootloader’s signature block with the digest(s) saved in the eFuses. If public key’s hash doesn’t match any of the hashes from the eFuses, the verification fails.
2. Generate the application image digest and match it with the image digest in the signature block. If the digests don’t match, the verification fails.
3. Use the public key to verify the signature of the bootloader image, using RSA-PSS (section 8.1.2 of RFC8017) with the image digest calculated in step (2) for comparison.

4.29.8 Bootloader Size

Enabling Secure boot and/or flash encryption will increase the size of bootloader, which might require updating partition table offset. See Bootloader Size.

In the case when CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES is disabled, the bootloader is sector padded (4KB) using the --pad-to-size option in elf2image command of esptool.

4.29.9 eFuse usage

ESP32-ECO3:

- ABS_DONE_1 - Enables Secure Boot protection on boot.
- BLK2 - Stores the SHA-256 digest of the public key. SHA-256 hash of public key modulus, exponent, pre-calculated R & M’ values (represented as 776 bytes – offsets 36 to 812 - as per the Signature Block Format) is written to an eFuse key block. The write-protection bit must be set, but the read-protection bit must not.

The key(s) must be readable in order to give software access to it. If the key(s) is read-protected then the software reads the key(s) as all zeros and the signature verification process will fail, and the boot process will be aborted.

4.29.10 How To Enable Secure Boot V2

1. Open the Project Configuration Menu, in “Security features” set “Enable hardware Secure Boot in bootloader” to enable Secure Boot.
2. For ESP32, Secure Boot V2 is available only ESP32 ECO3 onwards. To view the “Secure Boot V2” option the chip revision should be changed to revision 3 (ESP32-ECO3). To change the chip revision, set “Minimum Supported ESP32 Revision” to Rev 3 in “Component Config” -> “ESP32- Specific”.
3. Specify the path to Secure Boot signing key, relative to the project directory.
4. Select the desired UART ROM download mode in “UART ROM download mode”. By default the UART ROM download mode has been kept enabled in order to prevent permanently disabling it in the development phase, this option is a potentially insecure option. It is recommended to disable the UART download mode for better security.
5. Set other menuconfig options (as desired). Then exit menuconfig and save your configuration.
Chapter 4. API Guides

6. The first time you run idf.py build, if the signing key is not found then an error message will be printed with a command to generate a signing key via espsecure.py generate_signing_key.

**Important:** A signing key generated this way will use the best random number source available to the OS and its Python installation (/dev/urandom on OSX/Linux and CryptGenRandom() on Windows). If this random number source is weak, then the private key will be weak.

**Important:** For production environments, we recommend generating the key pair using openssl or another industry standard encryption program. See Generating Secure Boot Signing Key for more details.

7. Run idf.py bootloader to build a Secure Boot enabled bootloader. The build output will include a prompt for a flashing command, using esptool.py write_flash.
8. When you’re ready to flash the bootloader, run the specified command (you have to enter it yourself, this step is not performed by the build system) and then wait for flashing to complete.
9. Run idf.py flash to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 6.

**Note:** idf.py flash doesn’t flash the bootloader if Secure Boot is enabled.

10. Reset the ESP32 and it will boot the software bootloader you flashed. The software bootloader will enable Secure Boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32 to verify that Secure Boot is enabled and no errors have occurred due to the build configuration.

**Note:** Secure boot won’t be enabled until after a valid partition table and app image have been flashed. This is to prevent accidents before the system is fully configured.

**Note:** If the ESP32 is reset or powered down during the first boot, it will start the process again on the next boot.

11. On subsequent boots, the Secure Boot hardware will verify the software bootloader has not changed and the software bootloader will verify the signed app image (using the validated public key portion of its appended signature block).

4.29.11 Restrictions after Secure Boot is enabled

- Any updated bootloader or app will need to be signed with a key matching the digest already stored in eFuse.
- After Secure Boot is enabled, no further eFuses can be read protected. (If Flash Encryption is enabled then the bootloader will ensure that any flash encryption key generated on first boot will already be read protected.) If CONFIG_SECURE_BOOT_INSECURE is enabled then this behavior can be disabled, but this is not recommended.
- Please note that enabling Secure Boot or flash encryption disables the USB-OTG USB stack in the ROM, disallowing updates via the serial emulation or Device Firmware Update (DFU) on that port.

4.29.12 Generating Secure Boot Signing Key

The build system will prompt you with a command to generate a new signing key via espsecure.py generate_signing_key.

The --version 2 parameter will generate the RSA 3072 private key for Secure Boot V2. Additionally --scheme rsa3072 can be passed as well to generate RSA 3072 private key
The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source, and using the best available RSA-PSS key generation utilities.

For example, to generate a signing key using the openssl command line:

```bash
openssl genrsa -out my_secure_boot_signing_key.pem 3072
```

Remember that the strength of the Secure Boot system depends on keeping the signing key private.

### 4.29.13 Remote Signing of Images

#### Signing using espsecure.py

For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default esp-idf Secure Boot configuration). The espsecure.py command line program can be used to sign app images & partition table data for Secure Boot, on a remote system.

To use remote signing, disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` and build the firmware. The private signing key does not need to be present on the build system.

After the app image and partition table are built, the build system will print signing steps using espsecure.py:

```bash
espsecure.py sign_data BINARY_FILE --version 2 --keyfile PRIVATE_SIGNING_KEY
```

The above command appends the image signature to the existing binary. You can use the `--output` argument to write the signed binary to a separate file:

```bash
espsecure.py sign_data --version 2 --keyfile PRIVATE_SIGNING_KEY --output SIGNED_BINARY_FILE BINARY_FILE
```

#### Signing using Pre-calculated Signatures

If you have valid pre-calculated signatures generated for an image and their corresponding public keys, you can use these signatures to generate a signature sector and append it to the image. Note that the pre-calculated signature should be calculated over all bytes in the image including the secure-padding bytes.

In such cases, the firmware image should be built by disabling the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES`. This image will be secure-padded and to generate a signed binary use the following command:

```bash
espsecure.py sign_data --version 2 --pub-key PUBLIC_SIGNING_KEY --signature --SIGNATURE_FILE --output SIGNED_BINARY_FILE BINARY_FILE
```

The above command verifies the signature, generates a signature block (refer to [Signature Block Format](#)) and appends it to the binary file.

#### Signing using an External Hardware Security Module (HSM)

For security reasons, you might also use an external Hardware Security Module (HSM) to store your private signing key, which cannot be accessed directly but has an interface to generate the signature of a binary file and its corresponding public key.

In such cases, disable the option `CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES` and build the firmware. This secure-padded image then can be used to supply the external HSM for generating a signature. Refer to [Signing using an External HSM](#) to generate a signed image.
4.29.14 Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all Secure Boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.
- Use Secure Boot in combination with flash encryption to prevent local readout of the flash contents.

4.29.15 Technical Details

The following sections contain low-level reference descriptions of various Secure Boot elements:

Manual Commands

Secure boot is integrated into the esp-idf build system, so `idf.py build` will sign an app image and `idf.py bootloader` will produce a signed bootloader if secure signed binaries on build is enabled.

However, it is possible to use the `espsecure.py` tool to make standalone signatures and digests.

To sign a binary image:

```
espsecure.py sign_data --version 2 --keyfile ./my_signing_key.pem --output ./image_\n  → signed.bin image-unsigned.bin
```

Keyfile is the PEM file containing an RSA-3072 private signing key.

4.29.16 Secure Boot & Flash Encryption

If Secure Boot is used without Flash Encryption, it is possible to launch “time-of-check to time-of-use” attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both the features together.

4.29.17 Signed App Verification Without Hardware Secure Boot

The Secure Boot V2 signature of apps can be checked on OTA update, without enabling the hardware Secure Boot option. This option uses the same app signature scheme as Secure Boot V2, but unlike hardware Secure Boot it does not prevent an attacker who can write to flash from bypassing the signature protection.

This may be desirable in cases where the delay of Secure Boot verification on startup is unacceptable, and/or where the threat model does not include physical access or attackers writing to bootloader or app partitions in flash.

In this mode, the public key which is present in the signature block of the currently running app will be used to verify the signature of a newly updated app. (The signature on the running app isn’t verified during the update process, it’s assumed to be valid.) In this way the system creates a chain of trust from the running app to the newly updated app.

For this reason, it’s essential that the initial app flashed to the device is also signed. A check is run on app startup and the app will abort if no signatures are found. This is to try and prevent a situation where no update is possible. The app should have only one valid signature block in the first position. Note again that, unlike hardware Secure Boot
Chapter 4. API Guides

V2, the signature of the running app isn’t verified on boot. The system only verifies a signature block in the first position and ignores any other appended signatures.

**Note:** In general, it’s recommended to use full hardware Secure Boot unless certain that this option is sufficient for application security needs.

**How To Enable Signed App Verification**

1. Open *Project Configuration Menu* -> Security features
2. Ensure *App Signing Scheme* is RSA. For ESP32 ECO3 chip, select *CONFIG_ESP32_REV_MIN* to Rev 3 to get RSA option available
3. Enable *CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT*
4. By default, “Sign binaries during build” will be enabled on selecting “Require signed app images” option, which will sign binary files as a part of build process. The file named in “Secure boot private signing key” will be used to sign the image.
5. If you disable “Sign binaries during build” option then all app binaries must be manually signed by following instructions in *Remote Signing of Images*.

**Warning:** It is very important that all apps flashed have been signed, either during the build or after the build.

4.29.18 Advanced Features

**JTAG Debugging**

By default, when Secure Boot is enabled then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables Secure Boot.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

4.30 Thread Local Storage

4.30.1 Overview

Thread-local storage (TLS) is a mechanism by which variables are allocated such that there is one instance of the variable per extant thread. ESP-IDF provides three ways to make use of such variables:

- **FreeRTOS Native API**: ESP-IDF FreeRTOS native API.
- **Pthread API**: ESP-IDF’s pthread API.
- **C11 Standard**: C11 standard introduces special keyword to declare variables as thread local.

4.30.2 FreeRTOS Native API

The ESP-IDF FreeRTOS provides the following API to manage thread local variables:

- `vTaskSetThreadLocalStoragePointer()`
- `pvTaskGetThreadLocalStoragePointer()`
- `vTaskSetThreadLocalStoragePointerAndDelCallback()`
In this case maximum number of variables that can be allocated is limited by `CONFIG_FREERTOS_THREAD_LOCAL_STORAGE_POINTERS` configuration value. Variables are kept in the task control block (TCB) and accessed by their index. Note that index 0 is reserved for ESP-IDF internal uses.

Using that API user can allocate thread local variables of an arbitrary size and assign them to any number of tasks. Different tasks can have different sets of TLS variables.

If size of the variable is more then 4 bytes then user is responsible for allocating/deallocating memory for it. Variable’s deallocation is initiated by FreeRTOS when task is deleted, but user must provide function (callback) to do proper cleanup.

### 4.30.3 Pthread API

The ESP-IDF provides the following *pthread API* to manage thread local variables:

- `pthread_key_create()`
- `pthread_key_delete()`
- `pthread_getspecific()`
- `pthread_setspecific()`

This API has all benefits of the one above, but eliminates some its limits. The number of variables is limited only by size of available memory on the heap. Due to the dynamic nature this API introduces additional performance overhead compared to the native one.

### 4.30.4 C11 Standard

The ESP-IDF FreeRTOS supports thread local variables according to C11 standard (ones specified with `__thread` keyword). For details on this GCC feature please see [https://gcc.gnu.org/onlinedocs/gcc-5.5.0/gcc/Thread-Local.html#Thread-Local](https://gcc.gnu.org/onlinedocs/gcc-5.5.0/gcc/Thread-Local.html#Thread-Local). Storage for that kind of variables is allocated on the task’s stack. Note that area for all such variables in the program will be allocated on the stack of every task in the system even if that task does not use such variables at all. For example ESP-IDF system tasks (like `ipc`, `timer` tasks etc.) will also have that extra stack space allocated. So this feature should be used with care. There is a tradeoff: C11 thread local variables are quite handy to use in programming and can be accessed using minimal CPU instructions, but this benefit goes with the cost of additional stack usage for all tasks in the system. Due to static nature of variables allocation all tasks in the system have the same sets of C11 thread local variables.

### 4.31 Tools

#### 4.31.1 IDF Frontend - idf.py

The `idf.py` command-line tool provides a front-end for easily managing your project builds, deployment and debugging, and more. It manages several tools, for example:

- `CMake`, which configures the project to be built.
- `Ninja`, which builds the project.
- `esptool.py`, which flashes the target.

The Step 5. First Steps on ESP-IDF contains a brief introduction on how to set up `idf.py` to configure, build, and flash projects.

**Important:** `idf.py` should be run in an ESP-IDF project directory, i.e., a directory containing a `CMakeLists.txt` file. Older style projects that contain a `Makefile` will not work with `idf.py`. 

Submit Document Feedback
Chapter 4. API Guides

Commands

Start a New Project: create-project

```
idf.py create-project <project name>
```

This command creates a new ESP-IDF project. Additionally, the folder where the project will be created in can be specified by the --path option.

Create a New Component: create-component

```
idf.py create-component <component name>
```

This command creates a new component, which will have a minimum set of files necessary for building. The -C option can be used to specify the directory the component will be created in. For more information about components see the Component CMakeLists Files.

Select the Target Chip: set-target

ESP-IDF supports multiple targets (chips). A full list of supported targets in your version of ESP-IDF can be seen by running idf.py --list-targets.

```
idf.py set-target <target>
```

This command sets the current project target.

**Important:** idf.py set-target will clear the build directory and re-generate the sdkconfig file from scratch. The old sdkconfig file will be saved as sdkconfig.old.

**Note:** The behavior of the idf.py set-target command is equivalent to:

1. clearing the build directory (idf.py fullclean)
2. removing the sdkconfig file (mv sdkconfig sdkconfig.old)
3. configuring the project with the new target (idf.py -DIDF_TARGET=esp32 reconfigure)

It is also possible to pass the desired IDF_TARGET as an environment variable (e.g., export IDF_TARGET=esp32s2) or as a CMake variable (e.g., -DIDF_TARGET=esp32s2 argument to CMake or idf.py). Setting the environment variable is a convenient method if you mostly work with one type of the chip.

To specify the default value of IDF_TARGET for a given project, please add the CONFIG_IDF_TARGET option to the project’s sdkconfig.defaults file. e.g., CONFIG_IDF_TARGET="esp32s2". This value of the option will be used if IDF_TARGET is not specified by other methods, such as using an environment variable, a CMake variable, or the idf.py set-target command.

If the target has not been set by any of these methods, the build system will default to esp32 target.

Start the Graphical Configuration Tool: menuconfig

```
idf.py menuconfig
```

Build the Project: build

```
idf.py build
```

This command builds the project found in the current directory. This can involve multiple steps:

- Create the build directory if needed. The sub-directory build is used to hold build output, although this can be changed with the -B option.
- Run CMake as necessary to configure the project and generate build files for the main build tool.
• Run the main build tool (Ninja or GNU Make). By default, the build tool is automatically detected but it can be explicitly set by passing the \(-G\) option to \texttt{idf.py}.

Building is incremental, so if no source files or configuration has changed since the last build, nothing will be done. Additionally, the command can be run with \texttt{app.bootloader} and \texttt{partition-table} arguments to build only the app, bootloader or partition table as applicable.

**Remove the Build Output: \texttt{clean}**

\texttt{idf.py clean}

This command removes the project build output files from the build directory, and the project will be fully rebuilt on next build. Using this command does not remove the CMake configuration output inside the build folder.

**Delete the Entire Build Contents: \texttt{fullclean}**

\texttt{idf.py fullclean}

This command deletes the entire “build” directory contents, which includes all CMake configuration output. The next time the project is built, CMake will configure it from scratch. Note that this option recursively deletes all files in the build directory, so use with care. Project configuration is not deleted.

**Flash the Project: \texttt{flash}**

\texttt{idf.py flash}

This command automatically builds the project if necessary, and then flash it to the target. You can use \(-p\) and \(-b\) options to set serial port name and flasher baud rate, respectively.

**Note:** The environment variables \texttt{ESPPORT} and \texttt{ESPBAUD} can be used to set default values for the \(-p\) and \(-b\) options, respectively. Providing these options on the command line overrides the default.

Similarly to the \texttt{build} command, the command can be run with \texttt{app.bootloader} and \texttt{partition-table} arguments to flash only the app, bootloader or partition table as applicable.

**Hints on How to Resolve Errors**

\texttt{idf.py} will try to suggest hints on how to resolve errors. It works with a database of hints stored in \texttt{tools/idf_py_actions/hints.yml} and the hints will be printed if a match is found for the given error. The menuconfig target is not supported at the moment by automatic hints on resolving errors.

The \--no-hints argument of \texttt{idf.py} can be used to turn the hints off in case they are not desired.

**Important Notes**

Multiple \texttt{idf.py} commands can be combined into one. For example, \texttt{idf.py \(-p\) COM4 clean flash monitor} will clean the source tree, then build the project and flash it to the target before running the serial monitor.

The order of multiple \texttt{idf.py} commands on the same invocation is not important, as they will automatically be executed in the correct order for everything to take effect (e.g., building before flashing, erasing before flashing).

For commands that are not known to \texttt{idf.py}, an attempt to execute them as a build system target will be made.

The command \texttt{idf.py} supports \texttt{shell autocompletion} for bash, zsh and fish shells.

In order to make \texttt{shell autocompletion} supported, please make sure you have at least Python 3.5 and \texttt{click 7.1} or newer (\textit{Software}).
Chapter 4. API Guides

To enable autocompletion for `idf.py`, use the `export` command (*Step 4. Set up the environment variables*). Autocompletion is initiated by pressing the TAB key. Type `idf.py` - and press the TAB key to autocomplete options.

The autocomplete support for PowerShell is planned in the future.

**Advanced Commands**

**Open the Documentation: docs**

```
idf.py docs
```

This command opens the documentation for the project's target and ESP-IDF version in the browser.

**Show Size: size**

```
idf.py size
```

This command prints app size information including the occupied RAM and flash and section (i.e., .bss) sizes.

```
idf.py size-components
```

Similarly, this command prints the same information for each component used in the project.

```
idf.py size-files
```

This command prints size information per source file in the project.

**Options**

- `--format` specifies the output format with available options: text, csv, json, default being text.
- `--output-file` optionally specifies the name of the file to print the command output to instead of the standard output.

**Reconfigure the Project: reconfigure**

```
idf.py reconfigure
```

This command forces CMake to be rerun regardless of whether it is necessary. It’s unnecessary during normal usage, but can be useful after adding/removing files from the source tree, or when modifying CMake cache variables. For example, `idf.py -DNAME='VALUE' reconfigure` can be used to set variable NAME in CMake cache to value VALUE.

**Clean the Python Byte Code: python-clean**

```
idf.py python-clean
```

This command deletes generated python byte code from the ESP-IDF directory. The byte code may cause issues when switching between ESP-IDF and Python versions. It is advised to run this target after switching versions of Python.

**Generate a UF2 binary: uf2**

```
idf.py uf2
```

This command will generate a UF2 (USB Flashing Format) binary `uf2.bin` in the build directory. This file includes all the necessary binaries (bootloader, app, and partition table) for flashing the target.
This UF2 file can be copied to a USB mass storage device exposed by another ESP running the ESP USB Bridge project. The bridge MCU will use it to flash the target MCU. This is as simple copying (or “drag-and-dropping”) the file to the exposed disk accessed by a file explorer in your machine.

To generate a UF2 binary for the application only (not including the bootloader and partition table), use the `uf2-app` command.

```
elf.py uf2-app
```

### Global Options

To list all available root level options, run `idf.py --help`. To list options that are specific for a subcommand, run `idf.py <command> --help`, e.g., `idf.py monitor --help`. Here is a list of some useful options:

- `-C <dir>` allows overriding the project directory from the default current working directory.
- `-B <dir>` allows overriding the build directory from the default build subdirectory of the project directory.
- `--ccache` enables CCache when compiling source files if the CCache tool is installed. This can dramatically reduce the build time.

**Important:** Note that some older versions of CCache may exhibit bugs on some platforms, so if files are not rebuilt as expected, try disabling CCache and rebuilding the project. To enable CCache by default, set the IDF_CCACHE_ENABLE environment variable to a non-zero value.

- `-v` flag causes both elf.py and the build system to produce verbose build output. This can be useful for debugging build problems.
- `--cmake-warn-uninitialized` (or `-w`) causes CMake to print uninitialized variable warnings found in the project directory only. This only controls CMake variable warnings inside CMake itself, not other types of build warnings. This option can also be set permanently by setting the IDF_CMAKE_WARN_UNINITIALIZED environment variable to a non-zero value.
- `--no-hints` flag disables hints on resolving errors and disable capturing output.

### 4.31.2 IDF Docker Image

IDF Docker image (espressif/idf) is intended for building applications and libraries with specific versions of ESP-IDF, when doing automated builds.

The image contains:

- Common utilities such as git, wget, curl, zip.
- Python 3.7 or newer.
- A copy of a specific version of ESP-IDF (see below for information about versions). IDF_PATH environment variable is set, and points to ESP-IDF location in the container.
- All the build tools required for the specific version of ESP-IDF: CMake, ninja, cross-compiler toolchains, etc.
- All Python packages required by ESP-IDF are installed in a virtual environment.

The image entrypoint sets up PATH environment variable to point to the correct version of tools, and activates the Python virtual environment. As a result, the environment is ready to use the ESP-IDF build system.

The image can also be used as a base for custom images, if additional utilities are required.

### Tags

Multiple tags of this image are maintained:

- `latest`: tracks master branch of ESP-IDF
- `vX.Y`: corresponds to ESP-IDF release vX.Y
- `release-vX.Y`: tracks release/vX.Y branch of ESP-IDF
Chapter 4. API Guides

Note: Versions of ESP-IDF released before this feature was introduced do not have corresponding Docker image versions. You can check the up-to-date list of available tags at https://hub.docker.com/r/espressif/idf/tags.

Usage

Setting up Docker Before using the espressif/idf Docker image locally, make sure you have Docker installed. Follow the instructions at https://docs.docker.com/install/, if it is not installed yet.

If using the image in CI environment, consult the documentation of your CI service on how to specify the image used for the build process.

Building a project with CMake In the project directory, run:

```
docker run --rm -v $PWD:/project -w /project espressif/idf idf.py build
```

The above command explained:

- `docker run`: runs a Docker image. It is a shorter form of the command `docker container run`.
- `--rm`: removes the container when the build is finished
- `-v $PWD:/project`: mounts the current directory on the host ($PWD) as /project directory in the container
- `espressif/idf`: uses Docker image espressif/idf with tag `latest` (implicitly added by Docker when no tag is specified)
- `idf.py build`: runs this command inside the container

To build with a specific Docker image tag, specify it as `espressif/idf:TAG`, for example:

```
docker run --rm -v $PWD:/project -w /project espressif/idf:release-v4.4 idf.py build
```

You can check the up-to-date list of available tags at https://hub.docker.com/r/espressif/idf/tags.

Using the image interactively It is also possible to do builds interactively, to debug build issues or test the automated build scripts. Start the container with `-i -t` flags:

```
docker run --rm -v $PWD:/project -w /project espressif/idf -i -t
```

Then inside the container, use idf.py as usual:

```
idf.py menuconfig
idf.py build
```

Note: Commands which communicate with the development board, such as idf.py flash and idf.py monitor will not work in the container unless the serial port is passed through into the container. This can be done with Docker for Linux with the device option. However currently this is not possible with Docker for Windows (https://github.com/docker/for-win/issues/1018) and Docker for Mac (https://github.com/docker/for-mac/issues/900). This limitation may be overcome by using remote serial ports. An example how to do this can be found in the following using remote serial port section.

Using remote serial port The RFC2217 (Telnet) protocol can be used to remotely connect to a serial port. For more information please see the remote serial ports documentation in the esptool project. This method can also be used to access the serial port inside a Docker container if it cannot be accessed directly. Following is an example how to use the flash command from within a Docker container.

On host install and start esp.rfc2217_server:
• On Windows, package is available as a one-file bundled executable created by pyinstaller and it can be downloaded from the esptool releases page in a zip archive along with other esptool utilities:

```
esp_rfc2217_server -v -p 4000 COM3
```

• On Linux/MacOS, package is available as part of esptool which can be found in ESP-IDF environment or by installing using pip:

```
pip install esptool
```

And then starting the server by executing:

```
esp_rfc2217_server.py -v -p 4000 /dev/ttyUSB0
```

Now the device attached to the host can be flashed from inside a Docker container by using:

```
docker run --rm -v <host_path>:/<container_path> espressif/idf.py --port rfc2217://host.docker.internal:4000?ign_set_control flash
```

Please make sure that <host_path> is properly set to your project path on the host and <container_path> is set as a working directory inside the container with the -w option. The host.docker.internal is a special Docker DNS name to access the host. This can be replaced with host IP if necessary.

### Building custom images

The Dockerfile in ESP-IDF repository provides several build arguments which can be used to customize the Docker image:

- **IDF_CLONE_URL**: URL of the repository to clone ESP-IDF from. Can be set to a custom URL when working with a fork of ESP-IDF. Default is https://github.com/espressif/esp-idf.git.
- **IDF_CLONE_BRANCH_OR_TAG**: Name of a git branch or tag use when cloning ESP-IDF. This value is passed to git clone command using the --branch argument. Default is master.
- **IDF_CHECKOUT_REF**: If this argument is set to a non-empty value, git checkout $IDF_CHECKOUT_REF command will be performed after cloning. This argument can be set to the SHA of the specific commit to checkout, for example if some specific commit on a release branch is desired.
- **IDF_CLONE_SHALLOW**: If this argument is set to a non-empty value, --depth=1 --shallow-submodules arguments will be used when performing git clone. This significantly reduces the amount of data downloaded and the size of the resulting Docker image. However, if switching to a different branch in such a “shallow” repository is necessary, an additional git fetch origin <branch> command must be executed first.
- **IDF_INSTALL_TARGETS**: Comma-separated list of IDF targets to install toolchains for, or all to install toolchains for all targets. Selecting specific targets reduces the amount of data downloaded and the size of the resulting Docker image. Default is all.

To use these arguments, pass them via the --build-arg command line option. For example, the following command will build a Docker image with a shallow clone of ESP-IDF v4.4.1 and tools for ESP32-C3, only:

```
docker build -t idf-custom:v4.4.1-esp32c3 \
  --build-arg IDF_CLONE_BRANCH_OR_TAG=v4.4.1 \
  --build-arg IDF_CLONE_SHALLOW=1 \
  --build-arg IDF_INSTALL_TARGETS=esp32c3 \
  tools/docker
```

### 4.31.3 IDF Windows Installer

#### Command-line parameters

Windows Installer esp-idf-tools-setup provides the following command-line parameters:
Chapter 4. API Guides

- **/CONFIG=[PATH]** - Path to ini configuration file to override default configuration of the installer. Default: config.ini.
- **/GITCLEAN=[yes|no]** - Perform git clean and remove untracked directories in Offline mode installation. Default: yes.
- **/GITREPO=[URL|PATH]** - URL of repository to clone ESP-IDF. Default: https://github.com/espressif/esp-idf.git
- **/GITRESET=[yes|no]** - Enable/Disable git reset of repository during installation. Default: yes.
- **/HELP** - Display command line options provided by Inno Setup installer.
- **/IDFDIR=[PATH]** - Path to directory where it will be installed. Default: {userdesktop}\esp-idf}
- **/IDFVERSION=[v4.3|v4.1|master]** - Use specific IDF version. E.g. v4.1, v4.2, master. Default: empty, pick the first version in the list.
- **/IDFVERSIONSURL=[URL]** - Use URL to download list of IDF versions. Default: https://dl.espressif.com/dl/esp-idf/idf_versions.txt
- **/LOG=[PATH]** - Store installation log file in specific directory. Default: empty.
- **/OFFLINE=[yes|no]** - Execute installation of Python packages by PIP in offline mode. The same result can be achieved by setting the environment variable PIP_NO_INDEX. Default: no.
- **/USEEMBEDDEDPYTHON=[yes|no]** - Use Embedded Python version for the installation. Set to no to allow Python selection screen in the installer. Default: yes.
- **/PYTHONNOUSERSITE=[yes|no]** - Set PYTHONNOUSERSITE variable before launching any Python command to avoid loading Python packages from AppDataRoaming. Default: yes.
- **/PYTHONWHEELSURL=[URL]** - Specify URL to PyPi repositories for resolving binary Python Wheel dependencies. The same result can be achieved by setting the environment variable PIP_EXTRA_INDEX_URL. Default: https://dl.espressif.com/pypi
- **/SKIPSYSTEMCHECK=[yes|no]** - Skip System Check page. Default: no.
- **/VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL** - Perform silent installation.

Unattended installation

The unattended installation of IDF can be achieved by following command-line parameters:

```
esp-idf-tools-setup-x.x.exe /VERYSILENT /SUPPRESSMSGBOXES /SP- /NOCANCEL
```

The installer detaches its process from the command-line. Waiting for installation to finish could be achieved by following PowerShell script:

```
$InstallerProcess = Get-Process esp-idf-tools-setup
Wait-Process -Id $InstallerProcess.Id
```

Custom Python and custom location of Python wheels

The IDF installer is using by default embedded Python with reference to Python Wheel mirror.

Following parameters allows to select custom Python and custom location of Python wheels:

```
esp-idf-tools-setup-x.x.exe /USEEMBEDDEDPYTHON=no /PYTHONWHEELSURL=https://pypi.org/simple/
```

4.3.1.4 IDF Component Manager

The IDF Component manager is a tool that downloads dependencies for any ESP-IDF CMake project. The download happens automatically during a run of CMake. It can source components either from the component registry or from a git repository.

A list of components can be found on https://components.espressif.com/
Chapter 4. API Guides

Using with a project

Dependencies for each component in the project are defined in a separate manifest file named `idf_component.yml` placed in the root of the component. The manifest file template can be created for a component by running `idf.py create-manifest --component=my_component`. When a new manifest is added to one of the components in the project it’s necessary to reconfigure it manually by running `idf.py reconfigure`. Then build will track changes in `idf_component.yml` manifests and automatically triggers CMake when necessary.

There is an example application: `example/build_system/cmake/component_manager` that uses components installed by the component manager.

It’s not necessary to have a manifest for components that don’t need any managed dependencies.

When CMake configures the project (e.g. `idf.py reconfigure`) component manager does a few things:

- Processes `idf_component.yml` manifests for every component in the project and recursively solves dependencies
- Creates a `dependencies.lock` file in the root of the project with a full list of dependencies
- Downloads all dependencies to the `managed_components` directory

The lock-file `dependencies.lock` and content of `managed_components` directory is not supposed to be modified by a user. When the component manager runs it always make sure they are up to date. If these files were accidentally modified it’s possible to re-run the component manager by triggering CMake with `idf.py reconfigure`.

You may set build property `DEPENDENCIES_LOCK` to specify the lock-file path in the top-level CMakeLists.txt. For example, adding `idf_build_set_property(DEPENDENCIES_LOCK dependencies.lock.$(IDF_TARGET))` before `project(PROJECT_NAME)` could help generate different lock files for different targets.

Defining dependencies in the manifest

```yaml
dependencies:
# Required IDF version
idf: ">=4.1"
# Defining a dependency from the registry:
# https://components.espressif.com/component/example/cmp
example/cmp: ">=1.0.0"

# Other ways to define dependencies
#
# For components maintained by Espressif only name can be used.
# Same as `espressif/cmp`
# component: "~1.0.0"
#
# Or in a longer form with extra parameters
# component2:
#   version: ">=2.0.0"
#
# For transient dependencies `public` flag can be set.
# `public` flag doesn't affect the `main` component.
# All dependencies of `main` are public by default.
# public: true
#
# For components hosted on non-default registry:
# service_url: "https://componentregistry.company.com"
#
# For components in git repository:
# test_component:
#   path: test_component
#   git: ssh://git@gitlab.com/user/components.git
```

(continues on next page)
### For test projects during component development

For components can be used from a local directory with relative or absolute path:

```bash
some_local_component:
  path: ../../projects/component
```

#### Disabling the Component Manager

The component manager can be explicitly disabled by setting `IDF_COMPONENT_MANAGER` environment variable to 0.

### 4.31.5 IDF Clang Tidy

The IDF Clang Tidy is a tool that uses `clang-tidy` to run static analysis on your current app.

**Warning:** This functionality and the toolchain it relies on are still under development. There may be breaking changes before a final release.

#### Prerequisites

If you have never run this tool before, take the following steps to get this tool prepared.

1. Run the export scripts (`export.sh` / `export.bat` / ...) to set up the environment variables.
2. Run `pip install --upgrade pyclang` to install this plugin. The extra commands would be activated in `idf.py` automatically.
3. Run `idf_tools.py install esp-clang` to install the clang-tidy required binaries

   **Note:** This toolchain is still under development. After the final release, you don’t have to install them manually.

4. Get file from the [llvm repository](https://llvm.org) and add the folder of this script to the `$PATH`. Or you could pass an optional argument `--run-clang-tidy-py` later when you call `idf.py clang-check`. Please don’t forget to make the script executable.

   **Note:** This file would be bundled in future toolchain releases. This is a temporary workaround.

5. Run the export scripts (`export.sh` / `export.bat` / ...) again to refresh the environment variables.

#### Extra Commands

**clang-check** Run `idf.py clang-check` to re-generate the compilation database and run `clang-tidy` under your current project folder. The output would be written to `<project_dir>/warnings.txt`.

Run `idf.py clang-check --help` to see the full documentation.

**clang-html-report**

1. Run `pip install codereport` to install the additional dependency.
2. Run `idf.py clang-html-report` to generate an HTML report in folder `<project_dir>/html_report` according to the `warnings.txt`. Please open the `<project_dir>/html_report/index.html` in your browser to check the report.
Bug Report

This tool is hosted in espressif/clang-tidy-runner. If you faced any bugs or have any feature request, please report them via github issues.

4.31.6 Downloadable Tools

ESP-IDF build process relies on a number of tools: cross-compiler toolchains, CMake build system, and others. Installing the tools using an OS-specific package manager (like apt, yum, brew, etc.) is the preferred method when the required version of the tool is available. This recommendation is reflected in the Getting Started guide. For example, on Linux and macOS it is recommended to install CMake using an OS package manager.

However, some of the tools are IDF-specific and are not available in OS package repositories. Furthermore, different versions of ESP-IDF require different versions of the tools to operate correctly. To solve these two problems, ESP-IDF provides a set of scripts for downloading and installing the correct versions of tools, and exposing them in the environment.

The rest of the document refers to these downloadable tools simply as “tools”. Other kinds of tools used in ESP-IDF are:

- Python scripts bundled with ESP-IDF (such as idf.py)
- Python packages installed from PyPI.

The following sections explain the installation method, and provide the list of tools installed on each platform.

Note: This document is provided for advanced users who need to customize their installation, users who wish to understand the installation process, and ESP-IDF developers.

If you are looking for instructions on how to install the tools, see the Getting Started Guide.

Tools metadata file

The list of tools and tool versions required for each platform is located in tools/tools.json. The schema of this file is defined by tools/tools_schema.json.

This file is used by tools/idf_tools.py script when installing the tools or setting up the environment variables.

Tools installation directory

IDF_TOOLS_PATH environment variable specifies the location where the tools are to be downloaded and installed. If not set, IDF_TOOLS_PATH defaults to HOME/.espressif on Linux and macOS, and %USER_PROFILE%\espressif on Windows.

Inside IDF_TOOLS_PATH, the scripts performing tools installation create the following directories and files:

- dist —where the archives of the tools are downloaded.
- tools —where the tools are extracted. The tools are extracted into subdirectories: tools/TOOL_NAME/VERSION/. This arrangement allows different versions of tools to be installed side by side.
- idf-env.json —user install options (targets, features) are stored in this file. Targets are selected chip targets for which tools are installed and kept up-to-date. Features determine the Python package set which should be installed. These options will be discussed later.
- python_env —not tools related; virtual Python environments are installed in the sub-directories. Note that the Python environment directory can be placed elsewhere by setting the IDF_PYTHON_ENV_PATH environment variable.
- espidf.constraints.*.txt —one constraint file for each ESP-IDF release containing Python package version requirements.
GitHub Assets Mirror

Most of the tools downloaded by the tools installer are GitHub Release Assets, which are files attached to a software release on GitHub.

If GitHub downloads are inaccessible or slow to access, it’s possible to configure a GitHub assets mirror.

To use Espressif’s download server, set the environment variable IDF_GITHUB_ASSETS to dl.espressif.com/github_assets. When the install process is downloading a tool from github.com, the URL will be rewritten to use this server instead.

Any mirror server can be used provided the URL matches the github.com download URL format: the install process will replace https://github.com with https://${IDF_GITHUB_ASSETS} for any GitHub asset URL that it downloads.

Note: The Espressif download server doesn’t currently mirror everything from GitHub, it only mirrors files attached as Assets to some releases as well as source archives for some releases.

idf_tools.py script

tools/idf_tools.py script bundled with ESP-IDF performs several functions:

- install: Download the tool into ${IDF_TOOLS_PATH}/dist directory, extract it into ${IDF_TOOLS_PATH}/tools/TOOL_NAME/VERSION.  
  install command accepts the list of tools to install, in TOOL_NAME or TOOL_NAME@VERSION format.  
  If all is given, all the tools (required and optional ones) are installed. If no argument or required is given, only the required tools are installed.
- download: Similar to install but doesn’t extract the tools. An optional --platform argument may be used to download the tools for the specific platform.
- export: Lists the environment variables which need to be set to use the installed tools. For most of the tools, setting PATH environment variable is sufficient, but some tools require extra environment variables.
  The environment variables can be listed in either of shell or key-value formats, set by --format parameter:
  - export optional parameters:
    - --unset Creates statement that unset some global variables, so the environment gets to the state it was before calling export.(sh/fish).
    - --add_paths_extras Adds extra ESP-IDF-related paths of $PATH to ${IDF_TOOLS_PATH}/esp-idf.json, which is used to remove global variables when the active ESP-IDF environment is deactivated. Example: While processing export.(sh/fish) script, new paths are added to global variable $PATH. This option is used to save these new paths to the ${IDF_TOOLS_PATH}/esp-idf.json.
  - shell produces output suitable for evaluation in the shell. For example,

```bash
export PATH="/home/user/.espressif/tools/tool/v1.0.0/bin:$PATH"
```

on Linux and macOS, and

```bash
set "PATH=C:\Users\user\.espressif\tools\v1.0.0\bin;%PATH%"
```

on Windows.

Note: Exporting environment variables in Powershell format is not supported at the moment. key-value format may be used instead.

The output of this command may be used to update the environment variables, if the shell supports this. For example:

```bash
eval $(IDF_PATH/tools/idf_tools.py export)
```

- key-value produces output in VARIABLE=VALUE format, suitable for parsing by other scripts:
PATH=/home/user/.espressif/tools/tool/v1.0.0:$PATH

Note that the script consuming this output has to perform expansion of $VAR or %VAR% patterns found in the output.

- **list**: Lists the known versions of the tools, and indicates which ones are installed.
  Following options are available to customize the output.
  - **--outdated**: List only outdated versions of tools installed in IDF_TOOLS_PATH.
- **check**: For each tool, checks whether the tool is available in the system path and in IDF_TOOLS_PATH.
- **install-python-env**: Create a Python virtual environment in the $(IDF_TOOLS_PATH)/python_env directory (or directly in the directory set by the IDF_PYTHON_ENV_PATH environment variable) and install there the required Python packages. An optional --features argument allows one to specify a comma-separated list of features to be added or removed. Feature that begins with - will be removed and features with + or without any sign will be added. Example syntax for removing feature XY is --features=-XY and for adding --features=+XY or --features=XY. If both removing and adding options are provided with the same feature, no operation is performed. For each feature a requirements file must exist. For example, feature XYZ is a valid feature if $(IDF_PATH)/tools/requirements/requirements.XYZ.txt is an existing file with a list of Python packages to be installed. There is one mandatory core feature ensuring core functionality of ESP-IDF (build, flash, monitor, debug in console). There can be an arbitrary number of optional features. The selected list of features is stored in idf-env.json. The requirement files contain a list of the desired Python packages to be installed and espidf.constraints.*.txt downloaded from https://dl.espressif.com and stored in $(IDF_TOOLS_PATH) the package version requirements for a given ESP-IDF version. Although it is not recommended, the download and use of constraint files can be disabled with the --no-constraints argument or setting the IDF_PYTHON_CHECK_CONSTRAINTS environment variable to no.
- **check-python-dependencies**: Checks if all required Python packages are installed. Packages from $(IDF_PATH)/tools/requirements/requirements.*.txt files selected by the feature list of idf-env.json are checked with the package versions specified in the espidf.constraints.*.txt file. The constraint file is downloaded with install-python-env command. The use of constraints files can be disabled similarly to the install-python-env command.
- **uninstall**: Print and remove tools, that are currently not used by active ESP-IDF version.
  - **--dry-run**: Print installed unused tools.
  - **--remove-archives**: Additionally remove all older versions of previously downloaded installation packages.

**Install scripts**

Shell-specific user-facing scripts are provided in the root of ESP-IDF repository to facilitate tools installation. These are:

- **install.bat** for Windows Command Prompt
- **install.ps1** for Powershell
- **install.sh** for Bash
- **install.fish** for Fish

Aside from downloading and installing the tools into IDF_TOOLS_PATH, these scripts prepare a Python virtual environment, and install the required packages into that environment.

These scripts accept optionally a comma separated list of chip targets and --enable-* arguments for enabling features. These arguments are passed to the idf_tools.py script which stores them in idf-env.json. Therefore, chip targets and features can be enabled incrementally.

Running the scripts without any optional arguments will install tools for all chip targets (by running idf_tools.py install --targets=all) and Python packages for core ESP-IDF functionality (by running idf_tools.py install-python-env --features=core).

Or for example, install.sh esp32 will install tools only for ESP32. See the Getting Started Guide for more examples.

install.sh --enable-XY will enable feature XY (by running idf_tools.py install-python-env --features=core,XY).
Chapter 4. API Guides

Export scripts

Since the installed tools are not permanently added into the user or system PATH environment variable, an extra step is required to use them in the command line. The following scripts modify the environment variables in the current shell to make the correct versions of the tools available:

- **export.bat** for Windows Command Prompt
- **export.ps1** for Powershell
- **export.sh** for Bash
- **export.fish** for Fish

**Note:** To modify the shell environment in Bash, `export.sh` must be “sourced” :: . ./export.sh (note the leading dot and space).

`export.sh` may be used with shells other than Bash (such as zsh). However in this case the IDF_PATH environment variable must be set before running the script. When used in Bash, the script will guess the IDF_PATH value from its own location.

In addition to calling `idf_tools.py`, these scripts list the directories which have been added to the PATH.

Other installation methods

Depending on the environment, more user-friendly wrappers for `idf_tools.py` are provided:

- **IDF Tools installer for Windows** can download and install the tools. Internally the installer uses `idf_tools.py`.
- **Eclipse Plugin** includes a menu item to set up the tools. Internally the plugin calls `idf_tools.py`.
- **VSCode Extension** for ESP-IDF includes an onboarding flow. This flow helps setting up the tools. Although the extension does not rely on `idf_tools.py`, the same installation method is used.

Custom installation

Although the methods above are recommended for ESP-IDF users, they are not a must for building ESP-IDF applications. ESP-IDF build system expects that all the necessary tools are installed somewhere, and made available in the PATH.

4.32 Unit Testing in ESP32

ESP-IDF provides the following methods to test software.

- **Target based tests** using a central unit test application which runs on the esp32. These tests use the Unity unit test framework. They can be integrated into an ESP-IDF component by placing them in the component’s `test` subdirectory. This document mainly introduces this target based tests.
- **Linux-host based unit tests** in which part of the hardware can be abstracted via mocks. Currently, Linux-host based tests are still under development and only a small fraction of IDF components support them. More information on running IDF applications on the host can be found here: [Running Applications on the Host Machine](#).

4.32.1 Normal Test Cases

Unit tests are located in the `test` subdirectory of a component. Tests are written in C, and a single C source file can contain multiple test cases. Test files start with the word “test”.

Each test file should include the `unity.h` header and the header for the C module to be tested.

Tests are added in a function in the C file as follows:

```c
TEST_CASE("test name", 
        "[module name]"
) {
  // Add test here
}
```

- The first argument is a descriptive name for the test.
- The second argument is an identifier in square brackets. Identifiers are used to group related test, or tests with specific properties.

**Note:** There is no need to add a main function with `UNITY_BEGIN()` and `UNITY_END()` in each test case. `unity_platform.c` will run `UNITY_BEGIN()` autonomously, and run the test cases, then call `UNITY_END()`.

The `test` subdirectory should contain a component `CMakeLists.txt`, since they are themselves components (i.e., a test component). ESP-IDF uses the Unity test framework located in the `unity` component. Thus, each test component should specify the `unity` component as a component requirement using the `REQUIRES` argument. Normally, components **should list their sources manually**; for component tests however, this requirement is relaxed and the use of the `SRC_DIRS` argument in `idf_component_register` is advised.

Overall, the minimal `test` subdirectory `CMakeLists.txt` file should contain the following:
See [http://www.throwtheswitch.org/unity](http://www.throwtheswitch.org/unity) for more information about writing tests in Unity.

### 4.3.22 Multi-device Test Cases

The normal test cases will be executed on one DUT (Device Under Test). However, components that require some form of communication (e.g., GPIO, SPI) require another device to communicate with, thus cannot be tested through normal test cases. Multi-device test cases involve writing multiple test functions, and running them on multiple DUTs.

The following is an example of a multi-device test case:

```c
void gpio_master_test()
{
    gpio_config_t slave_config = {
        .pin_bit_mask = 1 << MASTER_GPIO_PIN,
        .mode = GPIO_MODE_INPUT,
    };
    gpio_config(&slave_config);
    unity_wait_for_signal("output high level");
    TEST_ASSERT(gpio_get_level(MASTER_GPIO_PIN) == 1);}

void gpio_slave_test()
{
    gpio_config_t master_config = {
        .pin_bit_mask = 1 << SLAVE_GPIO_PIN,
        .mode = GPIO_MODE_OUTPUT,
    };
    gpio_config(&master_config);
    gpio_set_level(SLAVE_GPIO_PIN, 1);
    unity_send_signal("output high level");
}
```

The macro `TEST_CASE_MULTIPLE_DEVICES` is used to declare a multi-device test case.

- The first argument is test case name.
- The second argument is test case description.
- From the third argument, up to 5 test functions can be defined, each function will be the entry point of tests running on each DUT.

Running test cases from different DUTs could require synchronizing between DUTs. We provide `unity_wait_for_signal` and `unity_send_signal` to support synchronizing with UART. As the scenario in the above example, the slave should get GPIO level after master set level. DUT UART console will prompt and user interaction is required:

DUT1 (master) console:

```
Waiting for signal: [output high level]!
Please press "Enter" key to once any board send this signal.
```

DUT2 (slave) console:

```
Send signal: [output high level]!
```

Once the signal is sent from DUT2, you need to press “Enter” on DUT1, then DUT1 unblocks from `unity_wait_for_signal` and starts to change GPIO level.
4.32.3 Multi-stage Test Cases

The normal test cases are expected to finish without reset (or only need to check if reset happens). Sometimes we expect to run some specific tests after certain kinds of reset. For example, we want to test if the reset reason is correct after a wake up from deep sleep. We need to create a deep-sleep reset first and then check the reset reason. To support this, we can define multi-stage test cases, to group a set of test functions:

```c
static void trigger_deepsleep(void)
{
    esp_sleep_enable_timer_wakeup(2000);
    esp_deep_sleep_start();
}

void check_deepsleep_reset_reason()
{
    soc_reset_reason_t reason = esp_rom_get_reset_reason(0);
    TEST_ASSERT(reason == RESET_REASON_CORE_DEEP_SLEEP);
}
```

Multi-stage test cases present a group of test functions to users. It needs user interactions (select cases and select different stages) to run the case.

4.32.4 Tests For Different Targets

Some tests (especially those related to hardware) cannot run on all targets. Below is a guide how to make your unit tests run on only specified targets.

1. Wrap your test code by `!(TEMPORARY_)DISABLED_FOR_TARGETS()` macros and place them either in the original test file, or separate the code into files grouped by functions, but make sure all these files will be processed by the compiler. E.g.:

```c
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
TEST_CASE("a test that is not ready for esp32 and esp8266 yet", "[]")
{
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
```

Once you need one of the tests to be compiled on a specified target, just modify the targets in the disabled list. It’s more encouraged to use some general conception that can be described in `soc_caps.h` to control the disabling of tests. If this is done but some of the tests are not ready yet, use both of them (and remove `!(TEMPORARY_)DISABLED_FOR_TARGETS()` later). E.g.:

```c
#if SOC_SDIODE_SLAVE_SUPPORTED
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
TEST_CASE("a s dio slave tests that is not ready for esp64 yet", "[s dio_slave]")
{
    // available for esp32 now, and will be available for esp64 in the future
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
#endif //SOC_SDIODE_SLAVE_SUPPORTED
```

2. For test code that you are 100% for sure that will not be supported (e.g. no peripheral at all), use `DISABLED_FOR_TARGETS();` for test code that should be disabled temporarily, or due to lack of runners, etc., use `TEMPORARY_DISABLED_FOR_TARGETS()`.

Some old ways of disabling unit tests for targets, that have obvious disadvantages, are deprecated:

- DON’T put the test code under `test/target` folder and use `CMakeLists.txt` to choose one of the target folder. This is prevented because test code is more likely to be reused than the implementations. If you put
something into test/esp32 just to avoid building it on esp32s2, it’s hard to make the code tidy if you want to enable the test again on esp32s3.

- DON’T use CONFIG_IDF_TARGET_xxx macros to disable the test items any more. This makes it harder to track disabled tests and enable them again. Also, a black-list style #if !disabled is preferred to white-list style #if CONFIG_IDF_TARGET_xxx, since you will not silently disable cases when new targets are added in the future. But for test implementations, it’s allowed to use #if CONFIG_IDF_TARGET_xxx to pick one of the implementation code.
  - Test item: some test items that will be performed on some targets, but skipped on other targets. E.g. There are three test items SD 1-bit, SD 4-bit and SDSPI. For ESP32-S2, which doesn’t have SD host, among the tests only SDSPI is enabled on ESP32-S2.
  - Test implementation: some code will always happen, but in different ways. E.g. There is no SDIO PKT_LEN register on ESP8266. If you want to get the length from the slave as a step in the test process, you can have different implementation code protected by #if CONFIG_IDF_TARGET_xxx_reading in different ways. But please avoid using #else macro. When new target is added, the test case will fail at building stage, so that the maintainer will be aware of this, and choose one of the implementations explicitly.

4.32.5 Building Unit Test App

Follow the setup instructions in the top-level esp-idf README. Make sure that IDF_PATH environment variable is set to point to the path of esp-idf top-level directory.

Change into tools/unit-test-app directory to configure and build it:

- idf.py menuconfig - configure unit test app.
- idf.py -T all build - build unit test app with tests for each component having tests in the test subdirectory.
- idf.py -T "xxx yyy" build - build unit test app with tests for some space-separated specific components (For instance: idf.py -T heap build - build unit tests only for heap component directory).
- idf.py -T all -E "xxx yyy" build - build unit test app with all unit tests, except for unit tests of some components (For instance: idf.py -T all -E "ulp mbedtls" build - build all unit tests excludes ulp and mbedtls components).

**Note:** Due to inherent limitations of Windows command prompt, following syntax has to be used in order to build unit-test-app with multiple components: idf.py -T xxxx -T yyyy build or with escaped quotes: idf.py -T "\xxxx yyyy\" build in PowerShell or idf.py -T "\ssd1306 hts221\" build in Windows command prompt.

When the build finishes, it will print instructions for flashing the chip. You can simply run idf.py flash to flash all build output.

You can also run idf.py -T all flash or idf.py -T xxxx flash to build and flash. Everything needed will be rebuilt automatically before flashing.

Use menuconfig to set the serial port for flashing. For more information, see tools/unit-test-app/README.md.

4.32.6 Running Unit Tests

After flashing reset the ESP32 and it will boot the unit test app.

When unit test app is idle, press “Enter” will make it print test menu with all available tests:

```plaintext
Here's the test menu, pick your combo:
(1) "esp_ota_begin() verifies arguments" [ota]
(2) "esp_ota_get_next_update_partition logic" [ota]
(3) "Verify bootloader image in flash" [bootloader_support]
(4) "Verify unit test app image" [bootloader_support]
(5) "can use new and delete" [cxx]
```

(continues on next page)
The normal case will print the case name and description. Master-slave cases will also print the sub-menu (the registered test function names).

Test cases can be run by inputting one of the following:

- Test case name in quotation marks to run a single test case
- Test case index to run a single test case
- Module name in square brackets to run all test cases for a specific module
- An asterisk to run all test cases

[multi_device] and [multi_stage] tags tell the test runner whether a test case is a multiple devices or multiple stages of test case. These tags are automatically added by `TEST_CASE_MULTIPLE_DEVICES` and `TEST_CASE_MULTIPLE_STAGES` macros.

After you select a multi-device test case, it will print sub-menu:

**Running gpio master/slave test example...**

**gpio master/slave test example**

1. "gpio_master_test"
2. "gpio_slave_test"

Running reset reason check for deepsleep...  
reset reason check for deepsleep

1. "trigger_deepsleep"
2. "check_deepsleep_reset_reason"

First time you execute this case, input 1 to run first stage (trigger deepsleep). After DUT is rebooted and able to run test cases, select this case again and input 2 to run the second stage. The case only passes if the last stage passes and all previous stages trigger reset.

### 4.32.7 Timing Code with Cache Compensated Timer

Instructions and data stored in external memory (e.g. SPI Flash and SPI RAM) are accessed through the CPU’s unified instruction and data cache. When code or data is in cache, access is very fast (i.e., a cache hit).

"can call virtual functions" [cxx]
"can use static initializers for non-POD types" [cxx]
"can use std::vector" [cxx]
"static initialization guards work as expected" [cxx]
"global initializers run in the correct order" [cxx]
"before scheduler has started, static initializers work correctly" [cxx]
"adc2 work with wifi" [adc]
"gpio master/slave test example" [ignore][misc][test_env=UT_T2_1][multi_→device]
1. "gpio_master_test"
2. "gpio_slave_test"

"SPI Master clockdiv calculation routines" [spi]
"SPI Master test" [spi][ignore]
"SPI Master test, interaction of multiple devs" [spi][ignore]
"SPI Master no response when switch from host1 (SPI2) to host2 (SPI3)"...

"SPI Master DMA test, TX and RX in different regions" [spi]
"SPI Master DMA test: length, start, not aligned" [spi]
"reset reason check for deepsleep" [esp32][test_env=UT_T2_1][multi_stage]
1. "trigger_deepsleep"
2. "check_deepsleep_reset_reason"

"adc2 work with wifi" [adc]
However, if the instruction or data is not in cache, it needs to be fetched from external memory (i.e., a cache miss). Access to external memory is significantly slower, as the CPU must execute stall cycles whilst waiting for the instruction or data to be retrieved from external memory. This can cause the overall code execution speed to vary depending on the number of cache hits or misses.

Code and data placements can vary between builds, and some arrangements may be more favorable with regards to cache access (i.e., minimizing cache misses). This can technically affect execution speed, however these factors are usually irrelevant as their effect ‘average out’ over the device’s operation.

The effect of the cache on execution speed, however, can be relevant in benchmarking scenarios (especially micro benchmarks). There might be some variability in measured time between runs and between different builds. A technique for eliminating for some of the variability is to place code and data in instruction or data RAM (IRAM/DRAM), respectively. The CPU can access IRAM and DRAM directly, eliminating the cache out of the equation. However, this might not always be viable as the size of IRAM and DRAM is limited.

The cache compensated timer is an alternative to placing the code/data to be benchmarked in IRAM/DRAM. This timer uses the processor’s internal event counters in order to determine the amount of time spent on waiting for code/data in case of a cache miss, then subtract that from the recorded wall time.

```c
// Start the timer
ccomp_timer_start();

// Function to time
func_code_to_time();

// Stop the timer, and return the elapsed time in microseconds relative to
// ccomp_timer_start
int64_t t = ccomp_timer_stop();
```

One limitation of the cache compensated timer is that the task that benchmarked functions should be pinned to a core. This is due to each core having its own event counters that are independent of each other. For example, if `ccomp_timer_start` gets called on one core, put to sleep by the scheduler, wakes up, and gets rescheduled on the other core, then the corresponding `ccomp_timer_stop` will be invalid.

### 4.32.8 Mocks

**Note:** Currently, mocking is only possible with some selected components when running on the Linux host. In the future, we plan to make essential components in IDF mock-able. This will also include mocking when running on the ESP32.

One of the biggest problems regarding unit testing on embedded systems are the strong hardware dependencies. Running unit tests directly on the ESP32 can be especially difficult for higher layer components for the following reasons:

- Decreased test reliability due to lower layer components and/or hardware setup.
- Increased difficulty in testing edge cases due to limitations of lower layer components and/or hardware setup
- Increased difficulty in identifying the root cause due to the large number of dependencies influencing the behavior

When testing a particular component, (i.e., the component under test), mocking allows the dependencies of the component under test to be substituted (i.e., mocked) entirely in software. Through mocking, hardware details are emulated and specified at run time, but only if necessary. To allow mocking, ESP-IDF integrates the CMock mocking framework as a component. With the addition of some CMake functions in the ESP-IDF build system, it is possible to conveniently mock the entirety (or a part) of an IDF component.

Ideally, all components that the component under test is dependent on should be mocked, thus allowing the test environment complete control over all interactions with the component under test. However, if mocking all dependent components becomes too complex or too tedious (e.g. because you need to mock too many function calls) you have the following options:
• Include more “real” IDF code in the tests. This may work but increases the dependency on the “real” code’s behavior. Furthermore, once a test fails, you may not know if the failure is in your actual code under test or the “real” IDF code.

• Re-evaluate the design of the code under test and attempt to reduce its dependencies by dividing the code under test into more manageable components. This may seem burdensome but it is quite common that unit tests expose software design weaknesses. Fixing design weaknesses will not only help with unit testing in the short term, but will help future code maintenance as well.

Refer to cmock/CMock/docs/CMock_Summary.md for more details on how CMock works and how to create and use mocks.

Requirements

Mocking with CMock requires Ruby on the host machine. Furthermore, since mocking currently only works on the Linux target, the requirements of the latter also need to be fulfilled:

• Installed ESP-IDF including all ESP-IDF requirements
• System package requirements (libbsd, libbsd-dev)
• A recent enough Linux or macOS version and GCC compiler
• All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the COMPONENTS variable to main in the CMakeLists.txt of the application’s root directory:

```make
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

Mock a Component

If a mocked component, called a component mock, is already available in ESP-IDF, then it can be used right away as long as it satisfies the required functionality. Refer to Component Linux/Mock Support Overview to see which components are mocked already. Then refer to Adjustments in Unit Test in order to use the component mock.

It is necessary to create component mocks if they are not yet provided in ESP-IDF. To create a component mock, the component needs to be overwritten in a particular way. Overriding a component entails creating a component with the exact same name as the original component, then letting the build system discover it later than the original component (see Multiple components with the same name for more details).

In the component mock, the following parts are specified:

- The headers providing the functions to generate mocks for
- Include paths of the aforementioned headers
- Dependencies of the mock component (this is necessary e.g. if the headers include files from other components)

All these parts have to be specified using the IDF build system function `idf_component_mock`. You can use the IDF build system function `idf_component_get_property` with the tag `COMPONENT_OVERRIDEN_DIR` to access the component directory of the original component and then register the mock component parts using `idf_component_mock`:

```make
idf_component_get_property(original_component_dir <original-component-name>_<COMPONENT_OVERRIDEN_DIR)
...
idf_component_mock(INCLUDE_DIRS "${original_component_dir}/include"
```

(continues on next page)
The component mock also requires a separate mock directory containing a `mock_config.yaml` file that configures CMock. A simple `mock_config.yaml` could look like this:

```yaml
:cmock:
  :plugins:
    - expect
    - expect_any_args
```

For more details about the CMock configuration yaml file, have a look at `cmock/CMock/docs/CMock_Summary.md`.

Note that the component mock does not have to mock the original component in its entirety. As long as the test project’s dependencies and dependencies of other code to the original components are satisfied by the component mock, partial mocking is adequate. In fact, most of the component mocks in IDF in `tools/mocks` are only partially mocking the original component.

Examples of component mocks can be found under `tools/mocks` in the IDF directory. General information on how to override an IDF component can be found in *Multiple components with the same name*. There are several examples for testing code while mocking dependencies with CMock (non-exhaustive list):

- unit test for the NVS Page class.
- unit test for esp_event.
- unit test for mqtt.

### Adjustments in Unit Test

The unit test needs to inform the cmake build system to mock dependent components (i.e., it needs to override the original component with the mock component). This is done by either placing the component mock into the project’s `$components` directory or adding the mock component’s directory using the following line in the project’s root CMakeLists.txt:

```cmake
list(APPEND EXTRA_COMPONENT_DIRS "<mock_component_dir>")
```

Both methods will override existing components in ESP-IDF with the component mock. The latter is particularly convenient if you use component mocks that are already supplied by IDF.

Users can refer to the `esp_event` host-based unit test and its `esp_event/host_test/esp_event_unit_test/CMakeLists.txt` as an example of a component mock.

## 4.33 Running Applications on Host

### Note:

Running IDF applications on host is currently still an experimental feature, thus there is no guarantee for API stability. However, user feedback via the ESP-IDF GitHub repository or the ESP32 forum is highly welcome, and may help influence the future of design of the IDF host-based applications.

This document provides an overview of the methods to run IDF applications on Linux, and what type of IDF applications can typically be run on Linux.

### 4.33.1 Introduction

Typically, an IDF application is built (cross-compiled) on a host machine, uploaded (i.e., flashed) to an ESP chip for execution, and monitored by the host machine via a UART/USB port. However, execution of an IDF application on
an ESP chip (hence forth referred to as “running on target”) can be limiting in various development/usage/testing scenarios.

Therefore, it is possible for an IDF application to be built and executed entirely within the same Linux host machine (hence forth referred to as “running on host”). Running ESP-IDF applications on host has several advantages:

- No need to upload to a target.
- Faster execution on a host machine, compared to running on an ESP chip.
- No requirements for any specific hardware, except the host machine itself.
- Easier automation and setup for software testing.
- Large number of tools for code and runtime analysis (e.g. Valgrind).

A large number of IDF components depend on chip-specific hardware. These hardware dependencies must be mocked or simulated when running on host. ESP-IDF currently supports the following mocking and simulation approaches:

1. Using the FreeRTOS POSIX/Linux simulator that simulates FreeRTOS scheduling. On top of this simulation, other APIs are also simulated or implemented when running on host.
2. Using CMock to mock all dependencies and run the code in complete isolation.

In principle, it is possible to mix both approaches (POSIX/Linux simulator and mocking using CMock), but this has not been done yet in ESP-IDF. Note that despite the name, the FreeRTOS POSIX/Linux simulator currently also works on MacOS. Running IDF applications on host machines is often used for testing. However, simulating the environment and mocking dependencies does not fully represent the target device. Thus, testing on the target device is still necessary, though with a different focus that usually puts more weight on integration and system testing.

**Note:** Another possibility to run applications on the host is to use the QEMU simulator. However, QEMU development for IDF applications is currently work in progress and has not been documented yet.

**CMock-Based Approach**

This approach uses the CMock framework to solve the problem of missing hardware and software dependencies. CMock-based applications running on the host machine have the added advantage that they usually only compile the necessary code, i.e., the (mostly mocked) dependencies instead of the entire system. For a general introduction toMocks and how to configure and use them in ESP-IDF, please refer to *Mocks*.

**POSIX/Linux Simulator Approach**

The FreeRTOS POSIX/Linux simulator is available on ESP-IDF as a preview target already. It is the base for the Linux target which is already available as a preview. Using this simulator, IDF components can be implemented on the host to make them available to IDF applications when running on host. Currently, only a limited number of components are ready to be built on Linux. Furthermore the functionality of each component ported to Linux may also be limited or different compared to the functionality when building that component for a chip target. For more information if the desired components are supported on Linux, please refer to *Component Linux/Mock Support Overview*.

**4.33.2 Requirements**

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (libbsd, libbsd-dev)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the COMPONENTS variable to main in the CMakeLists.txt of the application’s root directory:
set(COMPONENTS main)

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

If any mocks are used, then Ruby is required, too.

### 4.33.3 Build and Run

To build the application on Linux, the target has to be set to `linux` and then it can be built and run:

```bash
idf.py --preview set-target linux
idf.py build
idf.py monitor
```

### 4.33.4 Component Linux/Mock Support Overview

Note that any “Yes” here does not necessarily mean a full implementation or mocking. It can also mean a partial implementation or mocking of functionality. Usually, the implementation or mocking is done to a point where enough functionality is provided to build and run a test application.

### 4.34 Wi-Fi Driver

#### 4.34.1 ESP32 Wi-Fi Feature List

The following features are supported:

- 4 virtual Wi-Fi interfaces, which are STA, AP, Sniffer and reserved.
- Station-only mode, AP-only mode, station/AP-coexistence mode
- IEEE 802.11b, IEEE 802.11g, IEEE 802.11n, and APIs to configure the protocol mode
- WPA/WPA2/WPA3/WPA2-Enterprise/WPA3-Enterprise/WAPI/WPS and DPP
Chapter 4. API Guides

- AMSDU, AMPDU, HT40, QoS, and other key features
- Modem-sleep
- The Espressif-specific ESP-NOW protocol and Long Range mode, which supports up to 1 km of data traffic
- Up to 20 MBit/s TCP throughput and 30 MBit/s UDP throughput over the air
- Sniffer
- Both fast scan and all-channel scan
- Multiple antennas
- Channel state information
- Wi-Fi Aware (NAN)

4.3.4.2 How To Write a Wi-Fi Application

Preparation

Generally, the most effective way to begin your own Wi-Fi application is to select an example which is similar to your
own application, and port the useful part into your project. It is not a MUST, but it is strongly recommended that you
take some time to read this article first, especially if you want to program a robust Wi-Fi application.

This article is supplementary to the Wi-Fi APIs/Examples. It describes the principles of using the Wi-Fi APIs, the
limitations of the current Wi-Fi API implementation, and the most common pitfalls in using Wi-Fi. This article also
reveals some design details of the Wi-Fi driver. We recommend you to select an example.

Setting Wi-Fi Compile-time Options

Refer to Wi-Fi Menuconfig.

Init Wi-Fi

Refer to ESP32 Wi-Fi station General Scenario and ESP32 Wi-Fi AP General Scenario.

Start/Connect Wi-Fi

Refer to ESP32 Wi-Fi station General Scenario and ESP32 Wi-Fi AP General Scenario.

Event-Handling

Generally, it is easy to write code in “sunny-day” scenarios, such as WIFI_EVENT_STA_START and
WIFI_EVENT_STA_CONNECTED. The hard part is to write routines in “rainy-day” scenarios, such as
WIFI_EVENT_STA_DISCONNECTED. Good handling of “rainy-day” scenarios is fundamental to robust Wi-Fi
applications. Refer to ESP32 Wi-Fi Event Description, ESP32 Wi-Fi station General Scenario, and ESP32 Wi-Fi AP
General Scenario. See also the overview of the Event Loop Library in ESP-IDF.

Write Error-Recovery Routines Correctly at All Times

Just like the handling of “rainy-day” scenarios, a good error-recovery routine is also fundamental to robust Wi-Fi
applications. Refer to ESP32 Wi-Fi API Error Code.

4.3.4.3 ESP32 Wi-Fi API Error Code

All of the ESP32 Wi-Fi APIs have well-defined return values, namely, the error code. The error code can be cate-
gorized into:

- No errors, e.g., ESP_OK means that the API returns successfully.
• Recoverable errors, such as `ESP_ERR_NO_MEM`.
• Non-recoverable, non-critical errors.
• Non-recoverable, critical errors.

Whether the error is critical or not depends on the API and the application scenario, and it is defined by the API user.

The primary principle to write a robust application with Wi-Fi API is to always check the error code and write the error-handling code. Generally, the error-handling code can be used:

• For recoverable errors, in which case you can write a recoverable-error code. For example, when `esp_wifi_start()` returns `ESP_ERR_NO_MEM`, the recoverable-error code `vTaskDelay` can be called in order to get a microsecond’s delay for another try.
• For non-recoverable, yet non-critical errors, in which case printing the error code is a good method for error handling.
• For non-recoverable and also critical errors, in which case “assert” may be a good method for error handling. For example, if `esp_wifi_set_mode()` returns `ESP_ERR_WIFI_NOT_INIT`, it means that the Wi-Fi driver is not initialized by `esp_wifi_init()` successfully. You can detect this kind of error very quickly in the application development phase.

In `esp_common/include/esp_err.h`, `ESP_ERROR_CHECK` checks the return values. It is a rather commonplace error-handling code and can be used as the default error-handling code in the application development phase. However, it is strongly recommended that API users write their own error-handling code.

### 4.3.4 ESP32 Wi-Fi API Parameter Initialization

When initializing struct parameters for the API, one of two approaches should be followed:

• Explicitly set all fields of the parameter.
• Use get API to get current configuration first, then set application specific fields.

Initializing or getting the entire structure is very important, because most of the time the value 0 indicates that the default value is used. More fields may be added to the struct in the future and initializing these to zero ensures the application will still work correctly after ESP-IDF is updated to a new release.

### 4.3.5 ESP32 Wi-Fi Programming Model

The ESP32 Wi-Fi programming model is depicted as follows:

![Wi-Fi Programming Model](image)

**Fig. 57: Wi-Fi Programming Model**

The Wi-Fi driver can be considered a black box that knows nothing about high-layer code, such as the TCP/IP stack, application task, and event task. The application task (code) generally calls *Wi-Fi driver APIs* to initialize Wi-Fi.
and handles Wi-Fi events when necessary. Wi-Fi driver receives API calls, handles them, and posts events to the application.

Wi-Fi event handling is based on the `esp_event library`. Events are sent by the Wi-Fi driver to the `default event loop`. Application may handle these events in callbacks registered using `esp_event_handler_register()`. Wi-Fi events are also handled by `esp_netif component` to provide a set of default behaviors. For example, when Wi-Fi station connects to an AP, `esp_netif` will automatically start the DHCP client by default.

### 4.34.6 ESP32 Wi-Fi Event Description

#### WIFI_EVENT_WIFI_READY

The Wi-Fi driver will never generate this event, which, as a result, can be ignored by the application event callback. This event may be removed in future releases.

#### WIFI_EVENT_SCAN_DONE

The scan-done event is triggered by `esp_wifi_scan_start()` and will arise in the following scenarios:

- The scan is completed, e.g., the target AP is found successfully, or all channels have been scanned.
- The scan is stopped by `esp_wifi_scan_stop()`.
- The `esp_wifi_scan_start()` is called before the scan is completed. A new scan will override the current scan and a scan-done event will be generated.

The scan-done event will not arise in the following scenarios:

- It is a blocked scan.
- The scan is caused by `esp_wifi_connect()`.

Upon receiving this event, the event task does nothing. The application event callback needs to call `esp_wifi_scan_get_ap_num()` and `esp_wifi_scan_get_ap_records()` to fetch the scanned AP list and trigger the Wi-Fi driver to free the internal memory which is allocated during the scan (do not forget to do this!). Refer to `ESP32 Wi-Fi Scan` for a more detailed description.

#### WIFI_EVENT_STA_START

If `esp_wifi_start()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will initialize the LwIP network interface (netif). Generally, the application event callback needs to call `esp_wifi_connect()` to connect to the configured AP.

#### WIFI_EVENT_STA_STOP

If `esp_wifi_stop()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will release the station’s IP address, stop the DHCP client, remove TCP/UDP-related connections, and clear the LwIP station netif, etc. The application event callback generally does not need to do anything.

#### WIFI_EVENT_STA_CONNECTED

If `esp_wifi_connect()` returns `ESP_OK` and the station successfully connects to the target AP, the connection event will arise. Upon receiving this event, the event task starts the DHCP client and begins the DHCP process of getting the IP address. Then, the Wi-Fi driver is ready for sending and receiving data. This moment is good for beginning the application work, provided that the application does not depend on LwIP, namely the IP address. However, if the application is LwIP-based, then you need to wait until the `got ip` event comes in.
**WIFI_EVENT_STA_DISCONNECTED**

This event can be generated in the following scenarios:

- When `esp_wifi_disconnect()` or `esp_wifi_stop()` is called and the station is already connected to the AP.
- When `esp_wifi_connect()` is called, but the Wi-Fi driver fails to set up a connection with the AP due to certain reasons, e.g., the scan fails to find the target AP or the authentication times out. If there are more than one AP with the same SSID, the disconnected event will be raised after the station fails to connect all of the found APs.
- When the Wi-Fi connection is disrupted because of specific reasons, e.g., the station continuously loses N beacons, the AP kicks off the station, or the AP’s authentication mode is changed.

Upon receiving this event, the default behaviors of the event task are:

- Shutting down the station’s LwIP netif.
- Notifying the LwIP task to clear the UDP/TCP connections which cause the wrong status to all sockets. For socket-based applications, the application callback can choose to close all sockets and re-create them, if necessary, upon receiving this event.

The most common event handle code for this event in application is to call `esp_wifi_connect()` to reconnect the Wi-Fi. However, if the event is raised because `esp_wifi_disconnect()` is called, the application should not call `esp_wifi_connect()` to reconnect. It is the application’s responsibility to distinguish whether the event is caused by `esp_wifi_disconnect()` or other reasons. Sometimes a better reconnection strategy is required. Refer to **Wi-Fi Reconnect** and **Scan When Wi-Fi Is Connecting**.

Another thing that deserves attention is that the default behavior of LwIP is to abort all TCP socket connections on receiving the disconnect. In most cases, it is not a problem. However, for some special applications, this may not be what they want. Consider the following scenarios:

- The application creates a TCP connection to maintain the application-level keep-alive data that is sent out every 60 seconds.
- Due to certain reasons, the Wi-Fi connection is cut off, and the `WIFI_EVENT_STA_DISCONNECTED` is raised. According to the current implementation, all TCP connections will be removed and the keep-alive socket will be in a wrong status. However, since the application designer believes that the network layer should **ignore** this error at the Wi-Fi layer, the application does not close the socket.
- Five seconds later, the Wi-Fi connection is restored because `esp_wifi_connect()` is called in the application event callback function. **Moreover, the station connects to the same AP and gets the same IPV4 address as before.**
- Sixty seconds later, when the application sends out data with the keep-alive socket, the socket returns an error and the application closes the socket and re-creates it when necessary.

In above scenarios, ideally, the application sockets and the network layer should not be affected, since the Wi-Fi connection only fails temporarily and recovers very quickly. The application can enable “Keep TCP connections when IP changed” via LwIP menuconfig.

**IP_EVENT_STA_GOT_IP**

This event arises when the DHCP client successfully gets the IPV4 address from the DHCP server, or when the IPV4 address is changed. The event means that everything is ready and the application can begin its tasks (e.g., creating sockets).

The IPV4 may be changed because of the following reasons:

- The DHCP client fails to renew/rebind the IPV4 address, and the station’s IPV4 is reset to 0.
- The DHCP client rebinds to a different address.
- The static-configured IPV4 address is changed.

Whether the IPV4 address is changed or not is indicated by the field `ip_change` of `ip_event_got_ip_t`. The socket is based on the IPV4 address, which means that, if the IPV4 changes, all sockets relating to this IPV4 will become abnormal. Upon receiving this event, the application needs to close all sockets and recreate the application when the IPV4 changes to a valid one.
Chapter 4. API Guides

**IP_EVENT_GOT_IP6**

This event arises when the IPV6 SLAAC support auto-configures an address for the ESP32, or when this address changes. The event means that everything is ready and the application can begin its tasks, e.g., creating sockets.

**IP_EVENT_STA_LOST_IP**

This event arises when the IPV4 address becomes invalid. IP_EVENT_STA_LOST_IP does not arise immediately after the Wi-Fi disconnects. Instead, it starts an IPV4 address lost timer. If the IPV4 address is got before ip lost timer expires, IP_EVENT_STA_LOST_IP does not happen. Otherwise, the event arises when the IPV4 address lost timer expires.

Generally, the application can ignore this event, because it is just a debug event to inform that the IPV4 address is lost.

**WIFI_EVENT_AP_START**

Similar to **WIFI_EVENT_STA_START**.

**WIFI_EVENT_AP_STOP**

Similar to **WIFI_EVENT_STA_STOP**.

**WIFI_EVENT_AP_STACONNECTED**

Every time a station is connected to ESP32 AP, the WIFI_EVENT_AP_STACONNECTED will arise. Upon receiving this event, the event task will do nothing, and the application callback can also ignore it. However, you may want to do something, for example, to get the info of the connected STA.

**WIFI_EVENT_AP_STADISCONNECTED**

This event can happen in the following scenarios:

- The application calls `esp_wifi_disconnect()`, or `esp_wifi_deauth_sta()`, to manually disconnect the station.
- The Wi-Fi driver kicks off the station, e.g., because the AP has not received any packets in the past five minutes. The time can be modified by `esp_wifi_set_inactive_time()`.
- The station kicks off the AP.

When this event happens, the event task will do nothing, but the application event callback needs to do something, e.g., close the socket which is related to this station.

**WIFI_EVENT_AP_PROBEREQRECVED**

This event is disabled by default. The application can enable it via API `esp_wifi_set_event_mask()`. When this event is enabled, it will be raised each time the AP receives a probe request.

**WIFI_EVENT_STA_BEACON_TIMEOUT**

If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens, the WIFI_EVENT_STA_BEACON_TIMEOUT will arise. The application can set inactive time via API `esp_wifi_set_inactive_time()`.
WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START

The WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START will arise at the start of connectionless module Interval. See connectionless module power save.

4.34.7 ESP32 Wi-Fi Station General Scenario

Below is a “big scenario” which describes some small scenarios in station mode:

1. Wi-Fi/LwIP Init Phase
   - s1.1: The main task calls esp_netif_init() to create an LwIP core task and initialize LwIP-related work.
   - s1.2: The main task calls esp_event_loop_create() to create a system Event task and initialize an application event’s callback function. In the scenario above, the application event’s callback function does nothing but relaying the event to the application task.
   - s1.3: The main task calls esp_netif_create_default_wifi_ap() or esp_netif_create_default_wifi_sta() to create default network interface instance binding station or AP with TCP/IP stack.
   - s1.4: The main task calls esp_wifi_init() to create the Wi-Fi driver task and initialize the Wi-Fi driver.
   - s1.5: The main task calls OS API to create the application task.

Step 1.1 ~ 1.5 is a recommended sequence that initializes a Wi-Fi-/LwIP-based application. However, it is NOT a must-follow sequence, which means that you can create the application task in step 1.1 and put all other initialization in the application task. Moreover, you may not want to create the application task in the initialization phase if the application task depends on the sockets. Rather, you can defer the task creation until the IP is obtained.

2. Wi-Fi Configuration Phase

Once the Wi-Fi driver is initialized, you can start configuring the Wi-Fi driver. In this scenario, the mode is station, so you may need to call esp_wifi_set_mode() (WIFI_MODE_STA) to configure the Wi-Fi mode as station. You can call other esp_wifi_set_xxx APIs to configure more settings, such as the protocol mode, the country code, and the bandwidth. Refer to ESP32 Wi-Fi Configuration.

Generally, the Wi-Fi driver should be configured before the Wi-Fi connection is set up. But this is NOT mandatory, which means that you can configure the Wi-Fi connection anytime, provided that the Wi-Fi driver is initialized successfully. However, if the configuration does not need to change after the Wi-Fi connection is set up, you should configure the Wi-Fi driver at this stage, because the configuration APIs (such as esp_wifi_set_protocol()) will cause the Wi-Fi to reconnect, which may not be desirable.

If the Wi-Fi NVS flash is enabled by menuconfig, all Wi-Fi configuration in this phase, or later phases, will be stored into flash. When the board powers on/reboots, you do not need to configure the Wi-Fi driver from scratch. You only need to call esp_wifi_get_xxx APIs to fetch the configuration stored in flash previously. You can also configure the Wi-Fi driver if the previous configuration is not what you want.

3. Wi-Fi Start Phase
   - s3.1: Call esp_wifi_start() to start the Wi-Fi driver.
   - s3.2: The Wi-Fi driver posts WIFI_EVENT_STA_START to the event task; then, the event task will do some common things and will call the application event callback function.
   - s3.3: The application event callback function relays the WIFI_EVENT_STA_START to the application task. We recommend that you call esp_wifi_connect(). However, you can also call esp_wifi_connect() in other phrases after the WIFI_EVENT_STA_START arises.
Chapter 4. API Guides

Fig. 58: Sample Wi-Fi Event Scenarios in Station Mode

1. Init Phase
   1.1> Create / init LwIP
   1.2> Create / init event
   1.3> Create / init Wi-Fi
   1.4> Create app task

2. Configure Phase
   2> Configure Wi-Fi

3. Start Phase
   3.1> Start Wi-Fi
   3.2> WIFI_EVENT_STA_START
   3.3> WIFI_EVENT_STA_START

4. Connect Phase
   4.1> Connect Wi-Fi
   4.2> WIFI_EVENT_STA_CONNECTED
   4.3> WIFI_EVENT_STA_CONNECTED

5. Get IP Phase
   5.1> Start DHCP client
   5.2> IP_EVENT_STA_GOT_IP
   5.3> IP_EVENT_STA_GOT_IP
   5.4> socket ready init

6. Disconnect Phase
   6.1> WIFI_EVENT_STA_DISCONNECTED
   6.2> WIFI_EVENT_STA_DISCONNECTED
   6.3> disconnect handling

7. IP Change Phase
   7.1> IP_EVENT_STA_GOT_IP
   7.2> IP_EVENT_STA_GOT_IP
   7.3> Socket error handling

8. Deinit Phase
   8.1> Disconnect Wi-Fi
   8.2> Stop Wi-Fi
   8.3> Deinit Wi-Fi
4. Wi-Fi Connect Phase

- s4.1: Once `esp_wifi_connect()` is called, the Wi-Fi driver will start the internal scan/connection process.
- s4.2: If the internal scan/connection process is successful, the `WIFI_EVENT_STA_CONNECTED` will be generated. In the event task, it starts the DHCP client, which will finally trigger the DHCP process.
- s4.3: In the above-mentioned scenario, the application event callback will relay the event to the application task. Generally, the application needs to do nothing, and you can do whatever you want, e.g., print a log.

In step 4.2, the Wi-Fi connection may fail because, for example, the password is wrong, or the AP is not found. In a case like this, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason for such a failure will be provided. For handling events that disrupt Wi-Fi connection, please refer to phase 6.

5. Wi-Fi ‘Got IP’ Phase

- s5.1: Once the DHCP client is initialized in step 4.2, the got IP phase will begin.
- s5.2: If the IP address is successfully received from the DHCP server, then `IP_EVENT_STA_GOT_IP` will arise and the event task will perform common handling.
- s5.3: In the application event callback, `IP_EVENT_STA_GOT_IP` is relayed to the application task. For LwIP-based applications, this event is very special and means that everything is ready for the application to begin its tasks, e.g., creating the TCP/UDP socket. A very common mistake is to initialize the socket before `IP_EVENT_STA_GOT_IP` is received. **DO NOT start the socket-related work before the IP is received.**

6. Wi-Fi Disconnect Phase

- s6.1: When the Wi-Fi connection is disrupted, e.g., the AP is powered off or the RSSI is poor, `WIFI_EVENT_STA_DISCONNECTED` will arise. This event may also arise in phase 3. Here, the event task will notify the LwIP task to clear/remove all UDP/TCP connections. Then, all application sockets will be in a wrong status. In other words, no socket can work properly when this event happens.
- s6.2: In the scenario described above, the application event callback function relays `WIFI_EVENT_STA_DISCONNECTED` to the application task. The recommended actions are: 1) call `esp_wifi_connect()` to reconnect the Wi-Fi, 2) close all sockets, and 3) re-create them if necessary. For details, please refer to `WIFI_EVENT_STA_DISCONNECTED`.

7. Wi-Fi IP Change Phase

- s7.1: If the IP address is changed, the `IP_EVENT_STA_GOT_IP` will arise with “ip_change” set to true.
- s7.2: This event is important to the application. When it occurs, the timing is good for closing all created sockets and recreating them.

8. Wi-Fi Deinit Phase

- s8.1: Call `esp_wifi_disconnect()` to disconnect the Wi-Fi connectivity.
- s8.2: Call `esp_wifi_stop()` to stop the Wi-Fi driver.
- s8.3: Call `esp_wifi_deinit()` to unload the Wi-Fi driver.

4.34.8 ESP32 Wi-Fi AP General Scenario

Below is a “big scenario” which describes some small scenarios in AP mode:
Fig. 59: Sample Wi-Fi Event Scenarios in AP Mode
4.34.9 ESP32 Wi-Fi Scan

Currently, the `esp_wifi_scan_start()` API is supported only in station or station/AP mode.

**Scan Type**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active Scan</td>
<td>Scan by sending a probe request. The default scan is an active scan.</td>
</tr>
<tr>
<td>Passive Scan</td>
<td>No probe request is sent out. Just switch to the specific channel and wait for a beacon. Application can enable it via the scan_type field of <code>wifi_scan_config_t</code>.</td>
</tr>
<tr>
<td>Foreground Scan</td>
<td>This scan is applicable when there is no Wi-Fi connection in station mode. Foreground or background scanning is controlled by the Wi-Fi driver and cannot be configured by the application.</td>
</tr>
<tr>
<td>Background Scan</td>
<td>This scan is applicable when there is a Wi-Fi connection in station mode or in station/AP mode. Whether it is a foreground scan or background scan depends on the Wi-Fi driver and cannot be configured by the application.</td>
</tr>
<tr>
<td>All-Channel Scan</td>
<td>It scans all of the channels. If the channel field of <code>wifi_scan_config_t</code> is set to 0, it is an all-channel scan.</td>
</tr>
<tr>
<td>Specific Channel Scan</td>
<td>It scans specific channels only. If the channel field of <code>wifi_scan_config_t</code> set to 1-14, it is a specific-channel scan.</td>
</tr>
</tbody>
</table>

The scan modes in above table can be combined arbitrarily, so there are in total 8 different scans:

- All-Channel Background Active Scan
- All-Channel Background Passive Scan
- All-Channel Foreground Active Scan
- All-Channel Foreground Passive Scan
- Specific-Channel Background Active Scan
- Specific-Channel Background Passive Scan
- Specific-Channel Foreground Active Scan
- Specific-Channel Foreground Passive Scan

**Scan Configuration**

The scan type and other per-scan attributes are configured by `esp_wifi_scan_start()`. The table below provides a detailed description of `wifi_scan_config_t`. 
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssid</td>
<td>If the SSID is not NULL, it is only the AP with the same SSID that can be scanned.</td>
</tr>
<tr>
<td>bssid</td>
<td>If the BSSID is not NULL, it is only the AP with the same BSSID that can be scanned.</td>
</tr>
<tr>
<td>channel</td>
<td>If “channel” is 0, there will be an all-channel scan; otherwise, there will be a specific-channel scan.</td>
</tr>
<tr>
<td>show_hidden</td>
<td>If “show_hidden” is 0, the scan ignores the AP with a hidden SSID; otherwise, the scan considers the hidden AP a normal one.</td>
</tr>
<tr>
<td>scan_type</td>
<td>If “scan_type” is WIFI_SCAN_TYPE_ACTIVE, the scan is “active”; otherwise, it is a “passive” one.</td>
</tr>
</tbody>
</table>
| scan_time     | This field is used to control how long the scan dwells on each channel. For passive scans, scan_time.passive designates the dwell time for each channel. For active scans, dwell times for each channel are listed in the table below. Here, min is short for scan_time.active.min and max is short for scan_time.active.max.  
  • min=0, max=0: scan dwells on each channel for 120 ms.  
  • min>0, max=0: scan dwells on each channel for 120 ms.  
  • min=0, max>0: scan dwells on each channel for max ms.  
  • min>0, max>0: the minimum time the scan dwells on each channel is min ms. If no AP is found during this time frame, the scan switches to the next channel. Otherwise, the scan dwells on the channel for max ms.  
If you want to improve the performance of the scan, you can try to modify these two parameters. |

There are also some global scan attributes which are configured by API esp_wifi_set_config(), refer to Station Basic Configuration.

Scan All APs on All Channels (Foreground)

Scenario:
The scenario above describes an all-channel, foreground scan. The foreground scan can only occur in station mode where the station does not connect to any AP. Whether it is a foreground or background scan is totally determined by the Wi-Fi driver, and cannot be configured by the application.

Detailed scenario description:

Scan Configuration Phase

- s1.1: Call esp_wifi_set_country() to set the country info if the default country info is not what you want. Refer to Wi-Fi Country Code.  
- s1.2: Call esp_wifi_scan_start() to configure the scan. To do so, you can refer to Scan Configuration. Since this is an all-channel scan, just set the SSID/BSSID/channel to 0.

Wi-Fi Driver’s Internal Scan Phase

- s2.1: The Wi-Fi driver switches to channel 1. In this case, the scan type is WIFI_SCAN_TYPE_ACTIVE, and a probe request is broadcasted. Otherwise, the Wi-Fi will wait for a beacon from the APs. The Wi-Fi driver will stay in channel 1 for some time. The dwell time is configured in min/max time, with the default value being 120 ms.  
- s2.2: The Wi-Fi driver switches to channel 2 and performs the same operation as in step 2.1.  
- s2.3: The Wi-Fi driver scans the last channel N, where N is determined by the country code which is configured in step 1.1.

Scan-Done Event Handling Phase

- s3.1: When all channels are scanned, WIFI_EVENT_SCAN_DONE will arise.
Fig. 60: Foreground Scan of all Wi-Fi Channels
s3.2: The application’s event callback function notifies the application task that WIFI_EVENT_SCAN_DONE is received. esp_wifi_scan_get_ap_num() is called to get the number of APs that have been found in this scan. Then, it allocates enough entries and calls esp_wifi_scan_get_ap_records() to get the AP records. Please note that the AP records in the Wi-Fi driver will be freed once esp_wifi_scan_get_ap_records() is called. Do not call esp_wifi_scan_get_ap_records() twice for a single scan-done event. If esp_wifi_scan_get_ap_records() is not called when the scan-done event occurs, the AP records allocated by the Wi-Fi driver will not be freed. So, make sure you call esp_wifi_scan_get_ap_records(), yet only once.

Scan All APs on All Channels (Background)

Scenario:
The scenario above is an all-channel background scan. Compared to Scan All APs on All Channels (Foreground), the difference in the all-channel background scan is that the Wi-Fi driver will scan the back-to-home channel for 30 ms before it switches to the next channel to give the Wi-Fi connection a chance to transmit/receive data.

Scan for Specific AP on All Channels

Scenario:
This scan is similar to Scan All APs on All Channels (Foreground). The differences are:

- **s1.1**: In step 1.2, the target AP will be configured to SSID/BSSID.
- **s2.1 ~ s2.N**: Each time the Wi-Fi driver scans an AP, it will check whether it is a target AP or not. If the scan is WIFI_FAST_SCAN scan and the target AP is found, then the scan-done event will arise and scanning will end; otherwise, the scan will continue. Please note that the first scanned channel may not be channel 1, because the Wi-Fi driver optimizes the scanning sequence.

It is a possible situation that there are multiple APs that match the target AP info, e.g., two APs with the SSID of “ap” are scanned. In this case, if the scan is WIFI_FAST_SCAN, then only the first scanned “ap” will be found. If the scan is WIFI_ALL_CHANNEL_SCAN, both “ap” will be found and the station will connect the “ap” according to the configured strategy. Refer to Station Basic Configuration.

You can scan a specific AP, or all of them, in any given channel. These two scenarios are very similar.

Scan in Wi-Fi Connect

When esp_wifi_connect() is called, the Wi-Fi driver will try to scan the configured AP first. The scan in “Wi-Fi Connect” is the same as Scan for Specific AP On All Channels, except that no scan-done event will be generated when the scan is completed. If the target AP is found, the Wi-Fi driver will start the Wi-Fi connection; otherwise, WIFI_EVENT_STA_DISCONNECTED will be generated. Refer to Scan for Specific AP On All Channels.

Scan in Blocked Mode

If the block parameter of esp_wifi_scan_start() is true, then the scan is a blocked one, and the application task will be blocked until the scan is done. The blocked scan is similar to an unblocked one, except that no scan-done event will arise when the blocked scan is completed.

Parallel Scan

Two application tasks may call esp_wifi_scan_start() at the same time, or the same application task calls esp_wifi_scan_start() before it gets a scan-done event. Both scenarios can happen. However, the Wi-Fi driver does not support multiple concurrent scans adequately. As a result, concurrent scans should be avoided. Support for concurrent scan will be enhanced in future releases, as the ESP32’s Wi-Fi functionality improves continuously.
Fig. 61: Background Scan of all Wi-Fi Channels

1.1 > Configure country code
1.2 > Scan configuration

2.1 > Scan channel 1
2.2 > Back to home channel H
2.3 > Scan channel 2
2.4 > Back to home channel H
...
2.x-1 > Scan channel N
2.x > Back to home channel H

3.1 > WIFI_EVENT_SCAN_DONE
3.2 > WIFI_EVENT_SCAN_DONE

Chapter 4. API Guides
Fig. 62: Scan of specific Wi-Fi Channels
Scan When Wi-Fi Is Connecting

The \texttt{esp_wifi_scan_start()} fails immediately if the Wi-Fi is connecting, because the connecting has higher priority than the scan. If scan fails because of connecting, the recommended strategy is to delay for some time and retry scan again. The scan will succeed once the connecting is completed.

However, the retry/delay strategy may not work all the time. Considering the following scenarios:

- The station is connecting a non-existing AP or it connects the existing AP with a wrong password, it always raises the event \texttt{WIFI_EVENT_STA_DISCONNECTED}.
- The application calls \texttt{esp_wifi_connect()} to reconnect on receiving the disconnect event.
- Another application task, e.g., the console task, calls \texttt{esp_wifi_scan_start()} to do scan, the scan always fails immediately because the station keeps connecting.
- When scan fails, the application simply delays for some time and retry the scan.

In the above scenarios, the scan will never succeed because the connecting is in process. So if the application supports similar scenario, it needs to implement a better reconnection strategy. For example:

- The application can choose to define a maximum continuous reconnection counter and stop reconnecting once the counter reaches the maximum.
- The application can choose to reconnect immediately in the first N continuous reconnection, then give a delay sometime and reconnect again.

The application can define its own reconnection strategy to avoid the scan starve to death. Refer to \texttt{<Wi-Fi Reconnect>}. 

4.34.10 ESP32 Wi-Fi Station Connecting Scenario

This scenario depicts the case if only one target AP is found in the scan phase. For scenarios where more than one AP with the same SSID is found, refer to \texttt{ESP32 Wi-Fi Station Connecting When Multiple APs Are Found}.

Generally, the application can ignore the connecting process. Below is a brief introduction to the process for those who are really interested.

Scenario:

**Scan Phase**

- s1.1: The Wi-Fi driver begins scanning in “Wi-Fi Connect”. Refer to \texttt{Scan in Wi-Fi Connect} for more details.
- s1.2: If the scan fails to find the target AP, \texttt{WIFI_EVENT_STA_DISCONNECTED} will arise and the reason code will be \texttt{WIFI_REASON_NO_AP_FOUND}. Refer to \texttt{Wi-Fi Reason Code}.

**Auth Phase**

- s2.1: The authentication request packet is sent and the auth timer is enabled.
- s2.2: If the authentication response packet is not received before the authentication timer times out, \texttt{WIFI_EVENT_STA_DISCONNECTED} will arise and the reason code will be \texttt{WIFI_REASON_AUTH_EXPIRE}. Refer to \texttt{Wi-Fi Reason Code}.
- s2.3: The auth-response packet is received and the auth-timer is stopped.
- s2.4: The AP rejects authentication in the response and \texttt{WIFI_EVENT_STA_DISCONNECTED} arises, while the reason code is \texttt{WIFI_REASON_AUTH_FAIL} or the reasons specified by the AP. Refer to \texttt{Wi-Fi Reason Code}.

**Association Phase**

- s3.1: The association request is sent and the association timer is enabled.
- s3.2: If the association response is not received before the association timer times out, \texttt{WIFI_EVENT_STA_DISCONNECTED} will arise and the reason code will be \texttt{WIFI_REASON_ASSOC_EXPIRE}. Refer to \texttt{Wi-Fi Reason Code}. 

Espressif Systems 2564 Release v5.1.1
Fig. 63: Wi-Fi Station Connecting Process

1. **Scan Phase**
   - 1.1 > Scan
   - 1.2 > WIFI_EVENT_STA_DISCONNECTED

2. **Auth Phase**
   - 2.1 > Auth request
   - 2.2 > WIFI_EVENT_STA_DISCONNECTED
   - 2.3 > Auth response
   - 2.4 > WIFI_EVENT_STA_DISCONNECTED

3. **Assoc Phase**
   - 3.1 > Assoc request
   - 3.2 > WIFI_EVENT_STA_DISCONNECTED
   - 3.3 > Assoc response
   - 3.4 > WIFI_EVENT_STA_DISCONNECTED

4. **4-way Handshake Phase**
   - 4.1 > WIFI_EVENT_STA_DISCONNECTED
   - 4.2 > 1/4 EAPOL
   - 4.3 > 2/4 EAPOL
   - 4.4 > WIFI_EVENT_STA_DISCONNECTED
   - 4.5 > 3/4 EAPOL
   - 4.6 > 4/4 EAPOL
   - 4.7 > WIFI_EVENT_STA_CONNECTED
• s3.3: The association response is received and the association timer is stopped.
• s3.4: The AP rejects the association in the response and `WIFI_EVENT_STA_DISCONNECTED` arises, while the reason code is the one specified in the association response. Refer to `Wi-Fi Reason Code`.

Four-way Handshake Phase

• s4.1: The handshake timer is enabled, and the 1/4 EAPOL is not received before the handshake timer expires. `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to `Wi-Fi Reason Code`.
• s4.2: The 1/4 EAPOL is received.
• s4.3: The station replies 2/4 EAPOL.
• s4.4: If the 3/4 EAPOL is not received before the handshake timer expires, `WIFI_EVENT_STA_DISCONNECTED` will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to `Wi-Fi Reason Code`.
• s4.5: The 3/4 EAPOL is received.
• s4.6: The station replies 4/4 EAPOL.
• s4.7: The station raises `WIFI_EVENT_STA_CONNECTED`.

Wi-Fi Reason Code

The table below shows the reason-code defined in ESP32. The first column is the macro name defined in `esp_wifi/include/esp_wifi_types.h`. The common prefix `WIFI_REASON` is removed, which means that `UNSPECIFIED` actually stands for `WIFI_REASON_UNSPECIFIED` and so on. The second column is the value of the reason. The third column is the standard value to which this reason is mapped in section 9.4.1.7 of IEEE 802.11-2020. (For more information, refer to the standard mentioned above.) The last column describes the reason.

<table>
<thead>
<tr>

### 4.34.11 ESP32 Wi-Fi Station Connecting When Multiple APs Are Found

This scenario is similar as ESP32 Wi-Fi Station Connecting Scenario. The difference is that the station will not raise the event `WIFI_EVENT_STA_DISCONNECTED` unless it fails to connect all of the found APs.

### 4.34.12 Wi-Fi Reconnect

The station may disconnect due to many reasons, e.g., the connected AP is restarted. It is the application’s responsibility to reconnect. The recommended reconnection strategy is to call `esp_wifi_connect()` on receiving event `WIFI_EVENT_STA_DISCONNECTED`.

Sometimes the application needs more complex reconnection strategy:

- If the disconnect event is raised because the `esp_wifi_disconnect()` is called, the application may not want to do the reconnection.
- If the `esp_wifi_scan_start()` may be called at anytime, a better reconnection strategy is necessary. Refer to Scan When Wi-Fi Is Connecting.

Another thing that need to be considered is that the reconnection may not connect the same AP if there are more than one APs with the same SSID. The reconnection always select current best APs to connect.

### 4.34.13 Wi-Fi Beacon Timeout

The beacon timeout mechanism is used by ESP32 station to detect whether the AP is alive or not. If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens. The application can set inactive time via API `esp_wifi_set_inactive_time()`.

After the beacon times out, the station sends 5 probe requests to the AP. If still no probe response or beacon is received from AP, the station disconnects from the AP and raises the event `WIFI_EVENT_STA_DISCONNECTED`.

It should be considered that the timer used for beacon timeout will be reset during the scanning process. It means that the scan process will affect the triggering of the event `WIFI_EVENT_STA_BEACON_TIMEOUT`.

### 4.34.14 ESP32 Wi-Fi Configuration

All configurations will be stored into flash when the Wi-Fi NVS is enabled; otherwise, refer to Wi-Fi NVS Flash.

#### Wi-Fi Mode

Call `esp_wifi_set_mode()` to set the Wi-Fi mode.
### Mode Description

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIFI_MODE_NULL</td>
<td>NULL mode: in this mode, the internal data struct is not allocated to the station and the AP, while both the station and AP interfaces are not initialized for RX/TX Wi-Fi data. Generally, this mode is used for Sniffer, or when you only want to stop both the station and the AP without calling esp_wifi_deinit() to unload the whole Wi-Fi driver.</td>
</tr>
<tr>
<td>WIFI_MODE_STA</td>
<td>Station mode: in this mode, esp_wifi_start() will init the internal station data, while the station’s interface is ready for the RX and TX Wi-Fi data. After esp_wifi_connect(), the station will connect to the target AP.</td>
</tr>
<tr>
<td>WIFI_MODE_AP</td>
<td>AP mode: in this mode, esp_wifi_start() will init the internal AP data, while the AP’s interface is ready for RX/TX Wi-Fi data. Then, the Wi-Fi driver starts broad-casting beacons, and the AP is ready to get connected to other stations.</td>
</tr>
<tr>
<td>WIFI_MODE_APSTA</td>
<td>Station/AP coexistence mode: in this mode, esp_wifi_start() will simultaneously initialize both the station and the AP. This is done in station mode and AP mode. Please note that the channel of the external AP, which the ESP station is connected to, has higher priority over the ESP AP channel.</td>
</tr>
</tbody>
</table>

### Station Basic Configuration

API esp_wifi_set_config() can be used to configure the station. And the configuration will be stored in NVS. The table below describes the fields in detail.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssid</td>
<td>This is the SSID of the target AP, to which the station wants to connect.</td>
</tr>
<tr>
<td>password</td>
<td>Password of the target AP.</td>
</tr>
<tr>
<td>scan_method</td>
<td>For WIFI_FAST_SCAN scan, the scan ends when the first matched AP is found. For WIFI_ALL_CHANNEL_SCAN, the scan finds all matched APs on all channels. The default scan is WIFI_FAST_SCAN.</td>
</tr>
<tr>
<td>bssid_set</td>
<td>If bssid_set is 0, the station connects to the AP whose SSID is the same as the field “ssid”, while the field “bssid” is ignored. In all other cases, the station connects to the AP whose SSID is the same as the “ssid” field, while its BSSID is the same the “bssid” field.</td>
</tr>
<tr>
<td>bssid</td>
<td>This is valid only when bssid_set is 1; see field “bssid_set”.</td>
</tr>
<tr>
<td>channel</td>
<td>If the channel is 0, the station scans the channel 1～N to search for the target AP; otherwise, the station starts by scanning the channel whose value is the same as that of the “channel” field, and then scans the channel 1～N but skip the specific channel to find the target AP. For example, if the channel is 3, the scan order will be 3, 1, 2, 4, 5, 6, N. If you do not know which channel the target AP is running on, set it to 0.</td>
</tr>
<tr>
<td>sort_method</td>
<td>This field is only for WIFI_ALL_CHANNEL_SCAN. If the sort_method is WIFI_CONNECT_AP_BY_SIGNAL, all matched APs are sorted by signal, and the AP with the best signal will be connected firstly. For example, the station wants to connect an AP whose SSID is “apxx”. If the scan finds two APs whose SSID equals to “apxx”, and the first AP’s signal is -90 dBm while the second AP’s signal is -30 dBm, the station connects the second AP firstly, and it would not connect the first one unless it fails to connect the second one. If the sort_method is WIFI_CONNECT_AP_BY_SECURITY, all matched APs are sorted by security. For example, the station wants to connect an AP whose SSID is “apxx”. If the scan finds two APs whose SSID is “apxx”, and the security of the first found AP is open while the second one is WPA2, the station connects to the second AP firstly, and it would not connect the first one unless it fails to connect the second one.</td>
</tr>
<tr>
<td>threshold</td>
<td>The threshold is used to filter the found AP. If the RSSI or security mode is less than the configured threshold, the AP will be discarded. If the RSSI is set to 0, it means the default threshold and the default RSSI threshold are -127 dBm. If the authmode threshold is set to 0, it means the default threshold and the default authmode threshold are open.</td>
</tr>
</tbody>
</table>
**Attention:** WEP/WPA security modes are deprecated in IEEE 802.11-2016 specifications and are recommended not to be used. These modes can be rejected using authmode threshold by setting threshold as WPA2 by threshold.authmode as WIFI_AUTH_WPA2_PSK.

**AP Basic Configuration**

API `esp_wifi_set_config()` can be used to configure the AP. And the configuration will be stored in NVS. The table below describes the fields in detail.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ssid</td>
<td>SSID of AP; if the ssid[0] is 0xFF and ssid[1] is 0xFF, the AP defaults the SSID to ESP_aabbcc, where “aabbcc” is the last three bytes of the AP MAC.</td>
</tr>
<tr>
<td>password</td>
<td>Password of AP; if the auth mode is WIFI_AUTH_OPEN, this field will be ignored.</td>
</tr>
<tr>
<td>ssid_len</td>
<td>Length of SSID; if ssid_len is 0, check the SSID until there is a termination character. If ssid_len &gt; 32, change it to 32; otherwise, set the SSID length according to ssid_len.</td>
</tr>
<tr>
<td>channel</td>
<td>Channel of AP; if the channel is out of range, the Wi-Fi driver defaults to channel 1. So, please make sure the channel is within the required range. For more details, refer to Wi-Fi Country Code.</td>
</tr>
<tr>
<td>authmode</td>
<td>Auth mode of ESP AP; currently, ESP AP does not support AUTH_WEP. If the authmode is an invalid value, AP defaults the value to WIFI_AUTH_OPEN.</td>
</tr>
<tr>
<td>ssid_hidden</td>
<td>If ssid_hidden is 1, AP does not broadcast the SSID; otherwise, it does broadcast the SSID.</td>
</tr>
<tr>
<td>max_connection</td>
<td>The max number of stations allowed to connect in, the default value is 10. ESP Wi-Fi supports up to 15 (ESP_WIFI_MAX_CONN_NUM) Wi-Fi connections. Please note that ESP AP and ESP-NOW share the same encryption hardware keys, so the max_connection parameter will be affected by the CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM. The total number of encryption hardware keys is 17, if <code>CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM</code> &lt;= 2, the max_connection can be set up to 15, otherwise the max_connection can be set up to <code>(17 - CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM)</code>.</td>
</tr>
<tr>
<td>beacon_interval</td>
<td>Beacon interval; the value is 100 ~ 60000 ms, with default value being 100 ms. If the value is out of range, AP defaults it to 100 ms.</td>
</tr>
</tbody>
</table>

**Wi-Fi Protocol Mode**

Currently, the ESP-IDF supports the following protocol modes:
<table>
<thead>
<tr>
<th>Protocol Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>802.11b</td>
<td>Call <code>esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_11B</code> to set the station/AP to 802.11b-only mode.</td>
</tr>
<tr>
<td>802.11bg</td>
<td>Call `esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_11B</td>
</tr>
<tr>
<td>802.11g</td>
<td>Call `esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_11B</td>
</tr>
<tr>
<td>802.11bgn</td>
<td>Call `esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_11B</td>
</tr>
<tr>
<td>802.11gn</td>
<td>Call `esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_11B</td>
</tr>
<tr>
<td>802.11 BGNLR</td>
<td>Call `esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_11B</td>
</tr>
<tr>
<td>802.11 LR</td>
<td>Call <code>esp_wifi_set_protocol@ifx, WIFI_PROTOCOL_LR</code> to set the station/AP only to the LR mode. <strong>This mode is an Espressif-patented mode which can achieve a one-kilometer line of sight range. Please make sure both the station and the AP are connected to an ESP device.</strong></td>
</tr>
</tbody>
</table>

**Long Range (LR)**

Long Range (LR) mode is an Espressif-patented Wi-Fi mode which can achieve a one-kilometer line of sight range. Compared to the traditional 802.11b mode, it has better reception sensitivity, stronger anti-interference ability, and longer transmission distance.

**LR Compatibility** Since LR is Espressif-unique Wi-Fi mode, only ESP32 chip series devices (except ESP32-C2) can transmit and receive the LR data. In other words, the ESP32 chip series devices (except ESP32-C2) should **NOT** transmit the data in LR data rate if the connected device does not support LR. The application can achieve this by configuring a suitable Wi-Fi mode. If the negotiated mode supports LR, the ESP32 chip series devices (except ESP32-C2) may transmit data in LR rate. Otherwise, ESP32 chip series devices (except ESP32-C2) will transmit all data in the traditional Wi-Fi data rate.

The following table depicts the Wi-Fi mode negotiation:

<table>
<thead>
<tr>
<th>AP STA</th>
<th>BG</th>
<th>B</th>
<th>BGNLR</th>
<th>BGLR</th>
<th>BLR</th>
<th>LR</th>
</tr>
</thead>
<tbody>
<tr>

<td>BLR</td>
<td>LR</td>
</tr>
<tr>
<td>LR</td>
<td>*</td>
<td>*</td>
<td>LR</td>
<td>LR</td>
<td>LR</td>
<td>LR</td>
</tr>
</tbody>
</table>
In the above table, the row is the Wi-Fi mode of AP and the column is the Wi-Fi mode of station. The “-” indicates Wi-Fi mode of the AP and station are not compatible.

According to the table, the following conclusions can be drawn:

- For LR-enabled AP of ESP32, it is incompatible with traditional 802.11 mode, because the beacon is sent in LR mode.
- For LR-enabled station of ESP32 whose mode is NOT LR-only mode, it is compatible with traditional 802.11 mode.
- If both station and AP are ESP32 series chips devices (except ESP32-C2) and both of them have enabled LR mode, the negotiated mode supports LR.

If the negotiated Wi-Fi mode supports both traditional 802.11 mode and LR mode, it is the Wi-Fi driver’s responsibility to automatically select the best data rate in different Wi-Fi modes and the application can ignore it.

**LR Impacts to Traditional Wi-Fi Device**  The data transmission in LR rate has no impacts on the traditional Wi-Fi device because:

- The CCA and backoff process in LR mode are consistent with 802.11 specification.
- The traditional Wi-Fi device can detect the LR signal via CCA and do backoff.

In other words, the transmission impact in LR mode is similar to that in 802.11b mode.

**LR Transmission Distance**  The reception sensitivity gain of LR is about 4 dB larger than that of the traditional 802.11b mode. Theoretically, the transmission distance is about 2 to 2.5 times the distance of 11B.

**LR Throughput**  The LR rate has very limited throughput, because the raw PHY data rate LR is 1/2 Mbps and 1/4 Mbps.

**When to Use LR**  The general conditions for using LR are:

- Both the AP and station are Espressif devices.
- Long distance Wi-Fi connection and data transmission is required.
- Data throughput requirements are very small, such as remote device control.

**Wi-Fi Country Code**

Call `esp_wifi_set_country()` to set the country info. The table below describes the fields in detail. Please consult local 2.4 GHz RF operating regulations before configuring these fields.
### Field | Description
--- | ---
cc[3] | Country code string. This attribute identifies the country or noncountry entity in which the station/AP is operating. If it is a country, the first two octets of this string is the two-character country info as described in the document ISO/IEC3166-1. The third octet is one of the following:
- an ASCII space character, which means the regulations under which the station/AP is operating encompass all environments for the current frequency band in the country.
- an ASCII ‘O’ character, which means the regulations under which the station/AP is operating are for an outdoor environment only.
- an ASCII ‘I’ character, which means the regulations under which the station/AP is operating are for an indoor environment only.
- an ASCII ‘X’ character, which means the station/AP is operating under a non-country entity. The first two octets of the noncountry entity is two ASCII ‘XX’ characters.
- the binary representation of the Operating Class table number currently in use. Refer to Annex E of IEEE Std 802.11-2020.
schan | Start channel. It is the minimum channel number of the regulations under which the station/AP can operate.
nchan | Total number of channels as per the regulations. For example, if the schan=1, nchan=13, then the station/AP can send data from channel 1 to 13.
policy | Country policy. This field controls which country info will be used if the configured country info is in conflict with the connected AP’s. For more details on related policies, see the following section.

The default country info is:

```c
wifi_country_t config = {
    .cc = "01",
    .schan = 1,
    .nchan = 11,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

If the Wi-Fi Mode is station/AP coexist mode, they share the same configured country info. Sometimes, the country info of AP, to which the station is connected, is different from the country info of configured. For example, the configured station has country info:

```c
wifi_country_t config = {
    .cc = "JP",
    .schan = 1,
    .nchan = 14,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

but the connected AP has country info:

```c
wifi_country_t config = {
    .cc = "CN",
    .schan = 1,
    .nchan = 13,
};
```

then country info of connected AP’s is used.

The following table depicts which country info is used in different Wi-Fi modes and different country policies, and it also describes the impact on active scan.
<table>
<thead>
<tr>
<th>Wi-Fi Mode</th>
<th>Policy</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Station</strong></td>
<td>WIFI_COUNTRY_POLICY_AUTO</td>
<td>If the connected AP has country IE in its beacon, the country info equals to the country info in beacon. Otherwise, use the default country info. For scan: Use active scan from 1 to 11 and use passive scan from 12 to 14. Always keep in mind that if an AP with hidden SSID and station is set to a passive scan channel, the passive scan will not find it. In other words, if the application hopes to find the AP with hidden SSID in every channel, the policy of country info should be configured to WIFI_COUNTRY_POLICY_MANUAL.</td>
</tr>
<tr>
<td><strong>Station</strong></td>
<td>WIFI_COUNTRY_POLICY_MANUAL</td>
<td>Always use the configured country info. For scan: Use active scan from schan to schan+nchan-1.</td>
</tr>
<tr>
<td><strong>AP</strong></td>
<td>WIFI_COUNTRY_POLICY_AUTO</td>
<td>Always use the configured country info.</td>
</tr>
<tr>

<td>WIFI_COUNTRY_POLICY_MANUAL</td>
<td>Always use the configured country info.</td>
</tr>
<tr>
<td><strong>Station/AP-coexistence</strong></td>
<td>WIFI_COUNTRY_POLICY_AUTO</td>
<td>Same as station mode with policy WIFI_COUNTRY_POLICY_AUTO. AP: If the station does not connect to any external AP, the AP uses the configured country info. If the station connects to an external AP, the AP has the same country info as the station.</td>
</tr>
<tr>
<td><strong>Station/AP-coexistence</strong></td>
<td>WIFI_COUNTRY_POLICY_MANUAL</td>
<td>Same as station mode with policy WIFI_COUNTRY_POLICY_MANUAL. AP: Same as AP mode with policy WIFI_COUNTRY_POLICY_MANUAL.</td>
</tr>
</tbody>
</table>

**Home Channel**  In AP mode, the home channel is defined as the AP channel. In station mode, home channel is defined as the channel of AP which the station is connected to. In station/AP-coexistence mode, the home channel of AP and station must be the same, and if they are different, the station’s home channel is always in priority. For example, assume that the AP is on channel 6, and the station connects to an AP whose channel is 9. Since the station’s home channel has higher priority, the AP needs to switch its channel from 6 to 9 to make sure that it has the same home channel as the station. While switching channel, the ESP32 in AP mode will notify the connected stations about the channel migration using a Channel Switch Announcement (CSA). Station that supports channel switching will transit without disconnecting and reconnecting to the AP.

**Wi-Fi Vendor IE Configuration**

By default, all Wi-Fi management frames are processed by the Wi-Fi driver, and the application can ignore them. However, some applications may have to handle the beacon, probe request, probe response, and other management frames. For example, if you insert some vendor-specific IE into the management frames, it is only the management frames which contain this vendor-specific IE that will be processed. In ESP32, `esp_wifi_set_vendor_ie()` and `esp_wifi_set_vendor_ie_cb()` are responsible for this kind of tasks.

### 4.34.15 Wi-Fi Easy Connect™ (DPP)

Wi-Fi Easy Connect™ (or Device Provisioning Protocol) is a secure and standardized provisioning protocol for configuring Wi-Fi devices. More information can be found in `esp_dpp`. 
WPA2-Enterprise

WPA2-Enterprise is the secure authentication mechanism for enterprise wireless networks. It uses RADIUS server for authentication of network users before connecting to the Access Point. The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, and PEAP. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both. When ESP32 in station mode tries to connect an AP in enterprise mode, it sends authentication request to AP which is sent to RADIUS server by AP for authenticating the station. Based on different EAP methods, the parameters can be set in configuration which can be opened using `idf.py menuconfig`. WPA2 Enterprise is supported by ESP32 only in station mode.

For establishing a secure connection, AP and station negotiate and agree on the best possible cipher suite to be used. ESP32 supports 802.1X/EAP (WPA) method of AKM and Advanced encryption standard with Counter Mode Cipher Block Chaining Message Authentication protocol (AES-CCM) cipher suite. It also supports the cipher suites supported by mbedtls if `USE_MBEDTLS_CRYPTO` flag is set.

ESP32 currently supports the following EAP methods:

- **EAP-TLS**: This is a certificate-based method and only requires SSID and EAP-IDF.
- **PEAP**: This is a Protected EAP method. Username and Password are mandatory.
- **EAP-TTLS**: This is a credential-based method. Only server authentication is mandatory while user authentication is optional. Username and Password are mandatory. It supports different Phase2 methods, such as:
  - MSCHAP and MSCHAP-V2.
- **EAP-FAST**: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, `USE_MBEDTLS_CRYPTO` flag should be disabled to use this feature.

Detailed information on creating certificates and how to run wpa2_enterprise example on ESP32 can be found in `wifi/wifi_enterprise`.

4.34.16 Wi-Fi Aware™ (NAN)

Wi-Fi Aware™ or NAN (Neighbor Awareness Networking) is a protocol that allows Wi-Fi devices to discover services in their proximity. NAN uses direct device-to-device communication and does not require any Internet or AP connection.

Multiple NAN devices in the vicinity will form a NAN cluster which allows them to communicate with each other. NAN devices in a cluster synchronise their clocks and listen to each other periodically on Channel 6. Devices can advertise (Publish) or seek for (Subscribe) services within their NAN Cluster using Service Discovery protocols. Matching of services is done by service name and optionally matching filters. Once a Subscriber gets a match with a Publisher, it can either send a message (Follow-up) or establish a datapath (NDP) with the Publisher. After NDP is setup both devices will obtain an IPv6 address and can use it for communication.

Please note that NAN Datapath security is not supported i.e. the data packets will go out unencrypted. NAN uses a separate interface for Discovery and Datapath, which is other than that used for STA and AP. NAN operates in standalone mode, which means co-existence with STA or AP interface is not supported.

Refer to ESP-IDF examples `examples/wifi/wifi_aware/nan_publisher/README.md` and `examples/wifi/wifi_aware/nan_subscriber/README.md` to setup a NAN Publisher and Subscriber.

4.34.17 Wireless Network Management

Wireless Network Management allows client devices to exchange information about the network topology, including information related to RF environment. This makes each client network-aware, facilitating overall improvement in the performance of the wireless network. It is part of 802.11v specification. It also enables the client to support Network assisted Roaming. - Network assisted Roaming: Enables WLAN to send messages to associated clients, resulting clients to associate with APs with better link metrics. This is useful for both load balancing and in directing poorly connected clients.
Current implementation of 802.11v includes support for BSS transition management frames.

4.34.18 Radio Resource Measurement

Radio Resource Measurement (802.11k) is intended to improve the way traffic is distributed within a network. In a WLAN, each device normally connects to the access point (AP) that provides the strongest signal. Depending on the number and geographic locations of the subscribers, this arrangement can sometimes lead to excessive demand on one AP and underutilization of others, resulting in degradation of overall network performance. In a network conforming to 802.11k, if the AP having the strongest signal is loaded to its full capacity, a wireless device can be moved to one of the underutilized APs. Even though the signal may be weaker, the overall throughput is greater because more efficient use is made of the network resources.

Current implementation of 802.11k includes support for beacon measurement report, link measurement report, and neighbor request.

Refer ESP-IDF example examples/wifi/roaming/README.md to set up and use these APIs. Example code only demonstrates how these APIs can be used, and the application should define its own algorithm and cases as required.

4.34.19 ESP32 Wi-Fi Power-saving Mode

Station Sleep

Currently, ESP32 Wi-Fi supports the Modem-sleep mode which refers to the legacy power-saving mode in the IEEE 802.11 protocol. Modem-sleep mode works in station-only mode and the station must connect to the AP first. If the Modem-sleep mode is enabled, station will switch between active and sleep state periodically. In sleep state, RF, PHY and BB are turned off in order to reduce power consumption. Station can keep connection with AP in modem-sleep mode.

Modem-sleep mode includes minimum and maximum power-saving modes. In minimum power-saving mode, station wakes up every DTIM to receive beacon. Broadcast data will not be lost because it is transmitted after DTIM. However, it cannot save much more power if DTIM is short for DTIM is determined by AP.

In maximum power-saving mode, station wakes up in every listen interval to receive beacon. This listen interval can be set to be longer than the AP DTIM period. Broadcast data may be lost because station may be in sleep state at DTIM time. If listen interval is longer, more power is saved, but broadcast data is more easy to lose. Listen interval can be configured by calling API `esp_wifi_set_config()` before connecting to AP.

Call `esp_wifi_set_ps(WIFI_PS_MIN_MODEM)` to enable Modem-sleep minimum power-saving mode or `esp_wifi_set_ps(WIFI_PS_MAX_MODEM)` to enable Modem-sleep maximum power-saving mode after calling `esp_wifi_init()`. When station connects to AP, Modem-sleep will start. When station disconnects from AP, Modem-sleep will stop.

Call `esp_wifi_set_ps(WIFI_PS_NONE)` to disable Modem-sleep mode entirely. Disabling it increases power consumption, but minimizes the delay in receiving Wi-Fi data in real time. When Modem-sleep mode is enabled, the delay in receiving Wi-Fi data may be the same as the DTIM cycle (minimum power-saving mode) or the listening interval (maximum power-saving mode).

Note that in coexist mode, Wi-Fi will remain active only during Wi-Fi time slice, and sleep during non Wi-Fi time slice even if `esp_wifi_set_ps(WIFI_PS_NONE)` is called. Please refer to coexist policy.

The default Modem-sleep mode is WIFI_PS_MIN_MODEM.

AP Sleep

Currently, ESP32 AP does not support all of the power-saving feature defined in Wi-Fi specification. To be specific, the AP only caches unicast data for the stations connect to this AP, but does not cache the multicast data for the stations. If stations connected to the ESP32 AP are power-saving enabled, they may experience multicast packet loss.

In the future, all power-saving features will be supported on ESP32 AP.
Disconnected State Sleep

Disconnected state is the duration without Wi-Fi connection between `esp_wifi_start()` to `esp_wifi_stop()`.

Currently, ESP32 Wi-Fi supports sleep mode in disconnected state if running at station mode. This feature could be configured by Menuconfig choice `CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE`.

If `CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE` is enabled, RF, PHY and BB would be turned off in disconnected state when IDLE. The current would be same with current at modem-sleep.

The choice `CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE` would be selected by default, while it would be selected forcefully in Menuconfig at coexistence mode.

Connectionless Modules Power-saving

Connectionless modules are those Wi-Fi modules not relying on Wi-Fi connection, e.g ESP-NOW, DPP, FTM. These modules start from `esp_wifi_start()`, working until `esp_wifi_stop()`.

Currently, if ESP-NOW works at station mode, it's supported to sleep at both connected state and disconnected state.

Connectionless Modules TX  For each connectionless module, its supported to TX at any sleeping time without any extra configuration.

Meanwhile, `esp_wifi_80211_tx()` is supported at sleep as well.

Connectionless Modules RX  For each connectionless module, two parameters shall be configured to RX at sleep, which are `Window` and `Interval`.

At the start of `Interval` time, RF, PHY, BB would be turned on and kept for `Window` time. Connectionless Module could RX in the duration.

**Interval**

- There is only one `Interval`. Its configured by `esp_wifi_set_connectionless_interval()`. The unit is milliseconds.
- The default value of `Interval` is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE`.
- Event `WIFI_EVENT_CONNECTIONLESSMODULE_WAKE_INTERVAL_START` would be posted at the start of `Interval`. Since `Window` also starts at that moment, it's recommended to TX in that event.
- At connected state, the start of `Interval` would be aligned with TBTT.

**Window**

- Each connectionless module has its own `Window` after start. Connectionless Modules Power-saving would work with the max one among them.
- `Window` is configured by `module_name_set_wake_window()`. The unit is milliseconds.
- The default value of `Window` is the maximum.

<table>
<thead>
<tr>
<th>Interval</th>
<th>ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>not used</td>
</tr>
<tr>
<td>1 - max</td>
<td>default mode</td>
</tr>
<tr>
<td></td>
<td>used periodically (Window &lt; Interval) / used</td>
</tr>
<tr>
<td></td>
<td>all time (Window ≥ Interval)</td>
</tr>
</tbody>
</table>

Table 33: RF, PHY and BB usage under different circumstances

**Default mode**  If `Interval` is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE` with non-zero `Window`, Connectionless Modules Power-saving would work in default mode.

In default mode, RF, PHY, BB would be kept on if no coexistence with non-Wi-Fi protocol.
With coexistence, RF, PHY, BB resources are allocated by coexistence module to Wi-Fi connectionless module and non-Wi-Fi module, using time-division method. In default mode, Wi-Fi connectionless module is allowed to use RF, BB, PHY periodically under a stable performance.

Its recommended to configure Connectionless Modules Power-saving to default mode if there is Wi-Fi connectionless module coexists with non-Wi-Fi module.

### 4.34.20 ESP32 Wi-Fi Throughput

The table below shows the best throughput results gained in Espressif’s lab and in a shielded box.

<table>
<thead>
<tr>
<th>Type/Throughput</th>
<th>Air In Lab</th>
<th>Shield-box</th>
<th>Test Tool</th>
<th>IDF Version (commit ID)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raw 802.11 Packet RX</td>
<td>N/A</td>
<td><strong>130 MBit/s</strong></td>
<td>Internal tool</td>
<td>NA</td>
</tr>
<tr>
<td>Raw 802.11 Packet TX</td>
<td>N/A</td>
<td><strong>130 MBit/s</strong></td>

<td>15575346</td>
</tr>
<tr>
<td>TCP TX</td>
<td>20 MBit/s</td>
<td>75 MBit/s</td>
<td>iperf example</td>
<td>15575346</td>
</tr>
</tbody>
</table>

When the throughput is tested by iperf example, the sdkconfig is examples/wifi/iperf/sdkconfig.defaults.esp32.

### 4.34.21 Wi-Fi 80211 Packet Send

The `esp_wifi_80211_tx()` API can be used to:

- Send the beacon, probe request, probe response, and action frame.
- Send the non-QoS data frame.

It cannot be used for sending encrypted or QoS frames.

#### Preconditions of Using `esp_wifi_80211_tx()`

- The Wi-Fi mode is station, or AP, or station/AP.
- Either `esp_wifi_set_promiscuous(true)`, or `esp_wifi_start()`, or both of these APIs return `ESP_OK`. This is because Wi-Fi hardware must be initialized before `esp_wifi_80211_tx()` is called. In ESP32, both `esp_wifi_set_promiscuous(true)` and `esp_wifi_start()` can trigger the initialization of Wi-Fi hardware.
- The parameters of `esp_wifi_80211_tx()` are hereby correctly provided.

#### Data Rate

- The default data rate is 1 Mbps.
- Can set any rate through `esp_wifi_config_80211_tx_rate()` API.
- Can set any bandwidth through `esp_wifi_set_bandwidth()` API.

#### Side-Effects to Avoid in Different Scenarios

Theoretically, if the side-effects the API imposes on the Wi-Fi driver or other stations/APs are not considered, a raw 802.11 packet can be sent over the air with any destination MAC, any source MAC, any BSSID, or any other types of packet. However, robust or useful applications should avoid such side-effects. The table below provides some tips and recommendations on how to avoid the side-effects of `esp_wifi_80211_tx()` in different scenarios.
<table>
<thead>
<tr>
<th>Scenario</th>
<th>Description</th>
</tr>
</thead>
</table>
| No Wi-Fi connection          | In this scenario, no Wi-Fi connection is set up, so there are no side-effects on the Wi-Fi driver. If `en_sys_seq==true`, the Wi-Fi driver is responsible for the sequence control. If `en_sys_seq==false`, the application needs to ensure that the buffer has the correct sequence. Theoretically, the MAC address can be any address. However, this may impact other stations/APs with the same MAC/BSSID. Side-effect example#1 The application calls `esp_wifi_80211_tx()` to send a beacon with `BSSID == mac_x` in AP mode, but the `mac_x` is not the MAC of the AP interface. Moreover, there is another AP, e.g., “other-AP”, whose BSSID is `mac_x`. If this happens, an “unexpected behavior” may occur, because the stations which connect to the “other-AP” cannot figure out whether the beacon is from the “other-AP” or the `esp_wifi_80211_tx()`. To avoid the above-mentioned side-effects, it is recommended that:  
  - If `esp_wifi_80211_tx()` is called in station mode, the first MAC should be a multicast MAC or the exact target-device’s MAC, while the second MAC should be that of the station interface.  
  - If `esp_wifi_80211_tx()` is called in AP mode, the first MAC should be a multicast MAC or the exact target-device’s MAC, while the second MAC should be that of the AP interface.  
  The recommendations above are only for avoiding side-effects and can be ignored when there are good reasons. |
| Have Wi-Fi connection        | When the Wi-Fi connection is already set up, and the sequence is controlled by the application, the latter may impact the sequence control of the Wi-Fi connection as a whole. So, the `en_sys_seq` need to be true, otherwise `ESP_ERR_WIFI_ARG` is returned. The MAC-address recommendations in the “No Wi-Fi connection” scenario also apply to this scenario. If the Wi-Fi mode is station mode, the MAC address1 is the MAC of AP to which the station is connected, and the MAC address2 is the MAC of station interface, it is said that the packet is sent from the station to AP. Otherwise, if the Wi-Fi is in AP mode, the MAC address1 is the MAC of the station that connects to this AP, and the MAC address2 is the MAC of AP interface, it is said that the packet is sent from the AP to station. To avoid conflicting with Wi-Fi connections, the following checks are applied:  
  - If the packet type is data and is sent from the station to AP, the ToDS bit in IEEE 80211 frame control should be 1 and the FromDS bit should be 0. Otherwise, the packet will be discarded by Wi-Fi driver.  
  - If the packet type is data and is sent from the AP to station, the ToDS bit in IEEE 80211 frame control should be 0 and the FromDS bit should be 1. Otherwise, the packet will be discarded by Wi-Fi driver.  
  - If the packet is sent from station to AP or from AP to station, the Power Management, More Data, and Re-Transmission bits should be 0. Otherwise, the packet will be discarded by Wi-Fi driver.  
  `ESP_ERR_WIFI_ARG` is returned if any check fails. |

### 4.34.22 Wi-Fi Sniffer Mode

The Wi-Fi sniffer mode can be enabled by `esp_wifi_set_promiscuous()`. If the sniffer mode is enabled, the following packets can be dumped to the application:

- 802.11 Management frame.
- 802.11 Data frame, including MPDU, AMPDU, and AMSDU.
- 802.11 MIMO frame, for MIMO frame, the sniffer only dumps the length of the frame.
- 802.11 Control frame.
- 802.11 CRC error frame.

The following packets will NOT be dumped to the application:

- Other 802.11 error frames.
For frames that the sniffer can dump, the application can additionally decide which specific type of packets can be filtered to the application by using `esp_wifi_set_promiscuous_filter()` and `esp_wifi_set_promiscuous_ctrl_filter()`. By default, it will filter all 802.11 data and management frames to the application.

The Wi-Fi sniffer mode can be enabled in the Wi-Fi mode of `WIFI_MODE_NULL`, `WIFI_MODE_STA`, `WIFI_MODE_AP`, or `WIFI_MODE_APSTA`. In other words, the sniffer mode is active when the station is connected to the AP, or when the AP has a Wi-Fi connection. Please note that the sniffer has a great impact on the throughput of the station or AP Wi-Fi connection. Generally, the sniffer should be enabled only if the station/AP Wi-Fi connection does not experience heavy traffic.

Another noteworthy issue about the sniffer is the callback `wifi_promiscuous_cb_t`. The callback will be called directly in the Wi-Fi driver task, so if the application has a lot of work to do for each filtered packet, the recommendation is to post an event to the application task in the callback and defer the real work to the application task.

### 4.34.23 Wi-Fi Multiple Antennas

The Wi-Fi multiple antennas selecting can be depicted as following picture:

```
<table>
<thead>
<tr>
<th>Enabled</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Antenna 0</td>
<td></td>
</tr>
</tbody>
</table>
```

ESP32 supports up to sixteen antennas through external antenna switch. The antenna switch can be controlled by up to four address pins - `antenna_select[0:3]`. Different input value of `antenna_select[0:3]` means selecting different antenna. For example, the value `m0b1011` means the antenna 11 is selected. The default value of `antenna_select[3:0]` is `m0b0000`, which means the antenna 0 is selected by default.

Up to four GPIOs are connected to the four active high `antenna_select` pins. ESP32 can select the antenna by control the GPIO[0:3]. The API `esp_wifi_set_ant_gpio()` is used to configure which GPIOs are connected to `antenna_select`. If GPIO[x] is connected to antenna_select[x], then gpio_config->gpio_cfg[x].gpio_select should be set to 1 and gpio_config->gpio_cfg[x].gpio_num should be provided.

For the specific implementation of the antenna switch, there may be illegal values in `antenna_select[0:3]`. It means that ESP32 may support less than sixteen antennas through the switch. For example, ESP32-WROOM-DA which uses RTC6603SP as the antenna switch, supports two antennas. Two GPIOs are connected to two active high antenna selection inputs. The value `m0b01` means the antenna 0 is selected, the value `m0b10` means the antenna 1 is selected. Values `m0b00` and `m0b11` are illegal.

Although up to sixteen antennas are supported, only one or two antennas can be simultaneously enabled for RX/TX. The API `esp_wifi_set_ant()` is used to configure which antennas are enabled.

The enabled antennas selecting algorithm is also configured by `esp_wifi_set_ant()`. The RX/TX antenna mode can be `WIFI_ANT_MODE_ANT0`, `WIFI_ANT_MODE_ANT1`, or `WIFI_ANT_MODE_AUTO`. If the antenna mode is `WIFI_ANT_MODE_ANT0`, the enabled antenna 0 is selected for RX/TX data. If the antenna mode is `WIFI_ANT_MODE_ANT1`, the enabled antenna 1 is selected for RX/TX data. Otherwise, Wi-Fi automatically selects the enabled antenna that has better signal.

If the RX antenna mode is `WIFI_ANT_MODE_AUTO`, the default antenna mode also needs to be set, because the RX antenna switching only happens when some conditions are met. For example, the RX antenna starts to switch if
the RSSI is lower than -65 dBm or another antenna has better signal. RX uses the default antenna if the conditions are not met. If the default antenna mode is WIFIANT_MODE_ANT1, the enabled antenna 1 is used as the default RX antenna, otherwise the enabled antenna 0 is used.

Some limitations need to be considered:

- The TX antenna can be set to WIFIANT_MODE_AUTO only if the RX antenna mode is WIFIANT_MODE_AUTO, because TX antenna selecting algorithm is based on RX antenna in WIFIANT_MODE_AUTO type.
- Currently, Bluetooth® does not support the multiple antennas feature, so please do not use multiple antennas related APIs.

Following is the recommended scenarios to use the multiple antennas:

- In Wi-Fi mode WIFIMODE_STA, both RX/TX antenna modes are configured to WIFIANT_MODE_AUTO. The Wi-Fi driver selects the better RX/TX antenna automatically.
- The RX antenna mode is configured to WIFIANT_MODE_AUTO. The TX antenna mode is configured to WIFIANT_MODE_ANT0 or WIFIANT_MODE_ANT1. The applications can choose to always select a specified antenna for TX, or implement their own TX antenna selecting algorithm, e.g., selecting the TX antenna mode based on the channel switch information.
- Both RX/TX antenna modes are configured to WIFIANT_MODE_ANT0 or WIFIANT_MODE_ANT1.

**Wi-Fi Multiple Antennas Configuration**

Generally, following steps can be taken to configure the multiple antennas:

- Configure which GPIOs are connected to the antenna_selects. For example, if four antennas are supported and GPIO20/GPIO21 are connected to antenna_select[0]/antenna_select[1], the configurations look like:

```c
wifi_ant_gpio_config_t ant_gpio_config = {
    .gpio_cfg[0] = { .gpio_select = 1, .gpio_num = 20 },
    .gpio_cfg[1] = { .gpio_select = 1, .gpio_num = 21 }
};
```

- Configure which antennas are enabled and how RX/TX use the enabled antennas. For example, if antenna1 and antenna3 are enabled, the RX needs to select the better antenna automatically and uses antenna1 as its default antenna, the TX always selects the antenna3. The configuration looks like:

```c
wifi_ant_config_t config = {
    .rx_ant_mode = WIFIANT_MODE_AUTO,
    .rx_ant_default = WIFIANT_ANT0,
    .tx_ant_mode = WIFIANT_MODE_ANT1,
    .enabled_ant0 = 1,
    .enabled_ant1 = 3
};
```

### 4.34.24 Wi-Fi Channel State Information

Channel state information (CSI) refers to the channel information of a Wi-Fi connection. In ESP32, this information consists of channel frequency responses of sub-carriers and is estimated when packets are received from the transmitter. Each channel frequency response of sub-carrier is recorded by two bytes of signed characters. The first one is imaginary part and the second one is real part. There are up to three fields of channel frequency responses according to the type of received packet. They are legacy long training field (LLTF), high throughput LTF (HT-LTF), and space time block code HT-LTF (STBC-HT-LTF). For different types of packets which are received on channels with different state, the sub-carrier index and total bytes of signed characters of CSI are shown in the following table.
All of the information in the table can be found in the structure `wifi_csi_info_t`.

- Secondary channel refers to `secondary_channel` field of `rx_ctrl` field.
- Signal mode of packet refers to `sig_mode` field of `rx_ctrl` field.
- Channel bandwidth refers to `cwb` field of `rx_ctrl` field.
- STBC refers to `stbc` field of `rx_ctrl` field.
- Total bytes refers to `len` field.

The CSI data corresponding to each Long Training Field (LTF) type is stored in a buffer starting from the buffer field. Each item is stored as two bytes: imaginary part followed by real part. The order of each item is the same as the sub-carrier in the table. The order of LTF is: LLTF, HT-LTF, STBC-HT-LTF. However, all 3 LTFs may not be present, depending on the channel and packet information (see above).

- If `first_word_invalid` field of `wifi_csi_info_t` is true, it means that the first four bytes of CSI data is invalid due to a hardware limitation in ESP32.
- More information like RSSI, noise floor of RF, receiving time and antenna is in the `rx_ctrl` field.

When imaginary part and real part data of sub-carrier are used, please refer to the table below.

<table>

<td>-53,-25,-11,+11,+25,+53</td>
<td>114 total, 108 usable</td>
</tr>
</tbody>
</table>

Note:

- For STBC packet, CSI is provided for every space-time stream without CSD (cyclic shift delay). As each cyclic shift on the additional chains shall be -200 ns, only the CSD angle of first space-time stream is recorded in sub-carrier 0 of HT-LTF and STBC-HT-LTF for there is no channel frequency response in sub-carrier 0. CSD[10:0] is 11 bits, ranging from -π to π.
- If LLTF, HT-LTF, or STBC-HT-LTF is not enabled by calling API `esp_wifi_set_csi_config()`, the total bytes of CSI data will be fewer than that in the table. For example, if LLTF and HT-LTF is not enabled
and STBC-HT-LTF is enabled, when a packet is received with the condition above/HT/40MHz/STBC, the total bytes of CSI data is 244 \((61 + 60) \times 2 + 2 = 244\). The result is aligned to four bytes, and the last two bytes are invalid.

### 4.34.25 Wi-Fi Channel State Information Configure

To use Wi-Fi CSI, the following steps need to be done.

- Select Wi-Fi CSI in menuconfig. Go to Menuconfig > Components config > Wi-Fi > Wi-Fi CSI (Channel State Information).
- Set CSI receiving callback function by calling API `esp_wifi_set_csi_rx_cb()`.
- Configure CSI by calling API `esp_wifi_set_csi_config()`.
- Enable CSI by calling API `esp_wifi_set_csi()`.

The CSI receiving callback function runs from Wi-Fi task. So, do not do lengthy operations in the callback function. Instead, post necessary data to a queue and handle it from a lower priority task. Because station does not receive any packet when it is disconnected and only receives packets from AP when it is connected, it is suggested to enable sniffer mode to receive more CSI data by calling `esp_wifi_set_promiscuous()`.

### 4.34.26 Wi-Fi HT20/40

ESP32 supports Wi-Fi bandwidth HT20 or HT40 and does not support HT20/40 coexist. `esp_wifi_set_bandwidth()` can be used to change the default bandwidth of station or AP. The default bandwidth for ESP32 station and AP is HT40.

In station mode, the actual bandwidth is firstly negotiated during the Wi-Fi connection. It is HT40 only if both the station and the connected AP support HT40, otherwise it is HT20. If the bandwidth of connected AP is changes, the actual bandwidth is negotiated again without Wi-Fi disconnecting.

Similarly, in AP mode, the actual bandwidth is negotiated between AP and the stations that connect to the AP. It is HT40 if the AP and one of the stations support HT40, otherwise it is HT20.

In station/AP coexist mode, the station/AP can configure HT20/40 seperately. If both station and AP are negotiated to HT40, the HT40 channel should be the channel of station because the station always has higher priority than AP in ESP32. For example, the configured bandwidth of AP is HT40, the configured primary channel is 6, and the configured secondary channel is 10. The station is connected to an router whose primary channel is 6 and secondary channel is 2, then the actual channel of AP is changed to primary 6 and secondary 2 automatically.

Theoretically, the HT40 can gain better throughput because the maximum raw physical (PHY) data rate for HT40 is 150 Mbps while it is 72 Mbps for HT20. However, if the device is used in some special environment, e.g., there are too many other Wi-Fi devices around the ESP32 device, the performance of HT40 may be degraded. So if the applications need to support same or similar scenarios, it is recommended that the bandwidth is always configured to HT20.

### 4.34.27 Wi-Fi QoS

ESP32 supports all the mandatory features required in WFA Wi-Fi QoS Certification.

Four ACs (Access Category) are defined in Wi-Fi specification, and each AC has its own priority to access the Wi-Fi channel. Moreover, a map rule is defined to map the QoS priority of other protocol, e.g., 802.11D or TCP/IP precedence is mapped to Wi-Fi AC.

The table below describes how the IP Precedences are mapped to Wi-Fi ACs in ESP32. It also indicates whether the AMPDU is supported for this AC. The table is sorted from high to low priority. That is to say, the AC_VO has the highest priority.
The application can make use of the QoS feature by configuring the IP precedence via socket option IP_TOS. Here is an example to make the socket to use VI queue:

```c
const int ip_precedence_vi = 4;
const int ip_precedence_offset = 5;
int priority = (ip_precedence_vi << ip_precedence_offset);
setsockopt(socket_id, IPPROTO_IP, IP_TOS,

Theoretically, the higher priority AC has better performance than the lower priority AC. However, it is not always true. Here are some suggestions about how to use the Wi-Fi QoS:

- Some really important application traffic can be put into the AC_VO queue. But avoid using the AC_VO queue for heavy traffic, as it may impact the management frames which also use this queue. Eventually, it is worth noting that the AC_VO queue does not support AMPDU, and its performance with heavy traffic is no better than other queues.
- Avoid using more than two precedences supported by different AMPDUs, e.g., when socket A uses precedence 0, socket B uses precedence 1, and socket C uses precedence 2. This can be a bad design because it may need much more memory. To be specific, the Wi-Fi driver may generate a Block Ack session for each precedence and it needs more memory if the Block Ack session is set up.

### 4.34.28 Wi-Fi AMSDU

ESP32 supports receiving and transmitting AMSDU. AMSDU TX is disabled by default, since enable AMSDU TX need more memory. Select `CONFIG_ESP_WIFI_AMSDU_TX_ENABLED` to enable AMSDU Tx feature, it depends on `CONFIG_SPIRAM`.

### 4.34.29 Wi-Fi Fragment

supports Wi-Fi receiving fragment, but does not support Wi-Fi transmitting fragment.

### 4.34.30 WPS Enrollee

ESP32 supports WPS enrollee feature in Wi-Fi mode `WIFI_MODE_STA` or `WIFI_MODE_APSTA`. Currently, ESP32 supports WPS enrollee type PBC and PIN.

### 4.34.31 Wi-Fi Buffer Usage

This section is only about the dynamic buffer configuration.

**Why Buffer Configuration Is Important**

In order to get a high-performance system, consider the memory usage/configuration carefully for the following reasons:

- the available memory in ESP32 is limited.
- currently, the default type of buffer in LwIP and Wi-Fi drivers is “dynamic”, which means that both the LwIP and Wi-Fi share memory with the application. Programmers should always keep this in mind; otherwise, they will face a memory issue, such as “running out of heap memory”.
it is very dangerous to run out of heap memory, as this will cause ESP32 an “undefined behavior”. Thus, enough heap memory should be reserved for the application, so that it never runs out of it.

- the Wi-Fi throughput heavily depends on memory-related configurations, such as the TCP window size and Wi-Fi RX/TX dynamic buffer number.
- the peak heap memory that the ESP32 LwIP/Wi-Fi may consume depends on a number of factors, such as the maximum TCP/UDP connections that the application may have.
- the total memory that the application requires is also an important factor when considering memory configuration.

Due to these reasons, there is not a good-for-all application configuration. Rather, it is recommended to consider memory configurations separately for every different application.

### Dynamic vs. Static Buffer

The default type of buffer in Wi-Fi drivers is “dynamic”. Most of the time the dynamic buffer can significantly save memory. However, it makes the application programming a little more difficult, because in this case the application needs to consider memory usage in Wi-Fi.

LwIP also allocates buffers at the TCP/IP layer, and this buffer allocation is also dynamic. See [LwIP documentation section about memory use and performance](https://lwip.org/).

### Peak Wi-Fi Dynamic Buffer

The Wi-Fi driver supports several types of buffer (refer to [Wi-Fi Buffer Configure](https://lwip.org/)). However, this section is about the usage of the dynamic Wi-Fi buffer only. The peak heap memory that Wi-Fi consumes is the theoretically-maximum memory that the Wi-Fi driver consumes. Generally, the peak memory depends on:

- $b_{rx}$ the number of dynamic RX buffers that are configured
- $b_{tx}$ the number of dynamic TX buffers that are configured
- $m_{rx}$ the maximum packet size that the Wi-Fi driver can receive
- $m_{tx}$ the maximum packet size that the Wi-Fi driver can send

So, the peak memory that the Wi-Fi driver consumes ($p$) can be calculated with the following formula:

$$p = (b_{rx} \times m_{rx}) + (b_{tx} \times m_{tx})$$

Generally, the dynamic TX long buffers and dynamic TX long long buffers can be ignored, because they are management frames which only have a small impact on the system.

### 4.34.32 How to Improve Wi-Fi Performance

The performance of ESP32 Wi-Fi is affected by many parameters, and there are mutual constraints between each parameter. A proper configuration cannot only improve performance, but also increase available memory for applications and improve stability.

This section briefly explains the operating mode of the Wi-Fi/LwIP protocol stack and the role of each parameter. It also gives several recommended configuration ranks to help choose the appropriate rank according to the usage scenario.

### Protocol Stack Operation Mode

The ESP32 protocol stack is divided into four layers: Application, LwIP, Wi-Fi, and Hardware.

- During receiving, hardware puts the received packet into DMA buffer, and then transfers it into the RX buffer of Wi-Fi and LwIP in turn for related protocol processing, and finally to the application layer. The Wi-Fi RX buffer and the LwIP RX buffer shares the same buffer by default. In other words, the Wi-Fi forwards the packet to LwIP by reference by default.
During sending, the application copies the messages to be sent into the TX buffer of the LwIP layer for TCP/IP encapsulation. The messages will then be passed to the TX buffer of the Wi-Fi layer for MAC encapsulation and wait to be sent.

**Parameters**

Increasing the size or number of the buffers mentioned above properly can improve Wi-Fi performance. Meanwhile, it will reduce available memory to the application. The following is an introduction to the parameters that users need to configure:

**RX direction:**

- **CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM** This parameter indicates the number of DMA buffer at the hardware layer. Increasing this parameter will increase the sender’s one-time receiving throughput, thereby improving the Wi-Fi protocol stack ability to handle burst traffic.
- **CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM** This parameter indicates the number of RX buffer in the Wi-Fi layer. Increasing this parameter will improve the performance of packet reception. This parameter needs to match the RX buffer size of the LwIP layer.
- **CONFIG_ESP_WIFI_RX_BA_WIN** This parameter indicates the size of the AMPDU BA Window at the receiving end. This parameter should be configured to the smaller value between twice of **CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM** and **CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM**.
- **CONFIG_LWIP_TCP_WND_DEFAULT** This parameter represents the RX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_RX_BUFFER_NUM (KB) to reach a high and stable performance. Meanwhile, in case of multiple streams, this value needs to be reduced proportionally.

**TX direction:**

- **CONFIG_ESP_WIFI_TX_BUFFER** This parameter indicates the type of TX buffer, it is recommended to configure it as a dynamic buffer, which can make full use of memory.
- **CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM** This parameter indicates the number of TX buffer on the Wi-Fi layer. Increasing this parameter will improve the performance of packet sending. The parameter value needs to match the TX buffer size of the LwIP layer.
- **CONFIG_LWIP_TCP_SND_BUF_DEFAULT** This parameter represents the TX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_TX_BUFFER_NUM (KB) to reach a high and stable performance. In case of multiple streams, this value needs to be reduced proportionally.

**Throughput optimization by placing code in IRAM:**
Chapter 4. API Guides

- **CONFIG_ESP_WIFI_IRAM_OPT** If this option is enabled, some Wi-Fi functions are moved to IRAM, improving throughput. This increases IRAM usage by 15 kB.
- **CONFIG_ESP_WIFI_RX_IRAM_OPT** If this option is enabled, some Wi-Fi RX functions are moved to IRAM, improving throughput. This increases IRAM usage by 16 kB.
- **CONFIG_LWIP_IRAM_OPTIMIZATION** If this option is enabled, some LwIP functions are moved to IRAM, improving throughput. This increases IRAM usage by 13 kB.

**Note:** The buffer size mentioned above is fixed as 1.6 KB.

### How to Configure Parameters

The memory of ESP32 is shared by protocol stack and applications. Here, several configuration ranks are given. In most cases, the user should select a suitable rank for parameter configuration according to the size of the memory occupied by the application.

The parameters not mentioned in the following table should be set to the default.

<table>
<thead>
<tr>
<th>Rank</th>
<th>Iperf</th>
<th>TX prior</th>
<th>High-performance</th>
<th>RX prior</th>
<th>Default</th>
<th>Memory saving</th>
<th>Minimum</th>
</tr>
</thead>
<tbody>
<tr>

<td>46.5</td>
<td>39.9</td>
<td>44.2</td>
<td>33.8</td>
<td>25.6</td>
</tr>
<tr>
<td>TCP RX throughput (Mbit/s)</td>
<td>63.6</td>
<td>35.5</td>
<td>42.3</td>
<td>48.5</td>
<td>40.5</td>
<td>30.1</td>
<td>27.8</td>
</tr>
<tr>
<td>UDP TX throughput (Mbit/s)</td>
<td>76.2</td>
<td>75.1</td>
<td>74.1</td>
<td>72.4</td>
<td>69.6</td>
<td>64.1</td>
<td>36.5</td>
</tr>
<tr>
<td>UDP RX throughput (Mbit/s)</td>
<td>83.1</td>
<td>66.3</td>
<td>75.1</td>
<td>75.6</td>
<td>73.1</td>
<td>65.3</td>
<td>54.7</td>
</tr>
</tbody>
</table>

**Note:** The test was performed with a single stream in a shielded box using an ASUS RT-N66U router. ESP32’s CPU is dual core with 240 MHz. ESP32’s flash is in QIO mode with 80 MHz.

**Ranks:**

- **Iperf rank** ESP32 extreme performance rank used to test extreme performance.
- **High-performance rank** The ESP32’s high-performance configuration rank, suitable for scenarios where the application occupies less memory and has high-performance requirements. In this rank, users can choose to use the RX prior rank or the TX prior rank according to the usage scenario.
- **Default rank**  ESP32’s default configuration rank, the available memory, and performance are in balance.
- **Memory saving rank** This rank is suitable for scenarios where the application requires a large amount of memory, and the transceiver performance will be reduced in this rank.
- **Minimum rank** This is the minimum configuration rank of ESP32. The protocol stack only uses the necessary memory for running. It is suitable for scenarios where there is no requirement for performance and the application requires lots of space.

### Using PSRAM

PSRAM is generally used when the application takes up a lot of memory. In this mode, the `CONFIG_ESP_WIFI_TX_BUFFER` is forced to be static. `CONFIG_ESP_WIFI_STATIC_TX_BUFFER_NUM` indicates the number of DMA buffers at the hardware layer, and increasing this parameter can improve performance. The following are the recommended ranks for using PSRAM:

<table>
<thead>
<tr>
<th>Rank</th>
<th>Iperf</th>
<th>Default</th>
<th>Memory saving</th>
<th>Minimum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available memory (KB)</td>
<td>113.8</td>
<td>152.4</td>
<td>181.2</td>
<td>202.6</td>
</tr>
<tr>
<td>WIFI_STATIC_RX_BUFFER_NUM</td>
<td>8</td>
<td>4</td>
<td></td>
<td>2</td>
</tr>
<tr>

</table>

### 4.34.33 Wi-Fi Menuconfig

**Wi-Fi Buffer Configure**

If you are going to modify the default number or type of buffer, it would be helpful to also have an overview of how the buffer is allocated/freed in the data path. The following diagram shows this process in the TX direction:

![Fig. 65: TX Buffer Allocation](image)
Description:

- The application allocates the data which needs to be sent out.
- The application calls TCPIP-/Socket-related APIs to send the user data. These APIs will allocate a PBUF used in LwIP, and make a copy of the user data.
- When LwIP calls a Wi-Fi API to send the PBUF, the Wi-Fi API will allocate a “Dynamic Tx Buffer” or “Static Tx Buffer”, make a copy of the LwIP PBUF, and finally send the data.

The following diagram shows how buffer is allocated/freed in the RX direction:

![Fig. 66: RX Buffer Allocation](image)

Description:

- The Wi-Fi hardware receives a packet over the air and puts the packet content to the “Static Rx Buffer”, which is also called “RX DMA Buffer”.
- The Wi-Fi driver allocates a “Dynamic Rx Buffer”, makes a copy of the “Static Rx Buffer”, and returns the “Static Rx Buffer” to hardware.
- The Wi-Fi driver delivers the packet to the upper-layer (LwIP), and allocates a PBUF for holding the “Dynamic Rx Buffer”.
- The application receives data from LwIP.

The diagram shows the configuration of the Wi-Fi internal buffer.
<table>
<thead>
<tr>
<th>Buffer Type</th>
<th>Alloc Type</th>
<th>Default</th>
<th>Configurable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Static RX Buffer</td>
<td>Static</td>
<td>10 * 1600 Bytes</td>
<td>Yes</td>
<td>This is a kind of DMA memory. It is initialized in <code>esp_wifi_init()</code> and freed in <code>esp_wifi_deinit()</code>. The ‘Static Rx Buffer’ forms the hardware receiving list. Upon receiving a frame over the air, hardware writes the frame into the buffer and raises an interrupt to the CPU. Then, the Wi-Fi driver reads the content from the buffer and returns the buffer back to the list. If needs be, the application can reduce the memory statically allocated by Wi-Fi. It can reduce this value from 10 to 6 to save 6400 Bytes of memory. It is not recommended to reduce the configuration to a value less than 6 unless the AMPDU feature is disabled.</td>
</tr>
<tr>
<td>Dynamic RX Buffer</td>
<td>Dynamic</td>
<td>32</td>
<td>Yes</td>
<td>The buffer length is variable and it depends on the received frames’ length. When the Wi-Fi driver receives a frame from the ‘Hardware Rx Buffer’, the ‘Dynamic Rx Buffer’ needs to be allocated from the heap. The number of the Dynamic Rx Buffer, configured in the menu-config, is used to limit the total un-freed Dynamic Rx Buffer number.</td>
</tr>
<tr>
<td>Dynamic TX Buffer</td>
<td>Dynamic</td>
<td>32</td>
<td>Yes</td>
<td>This is a kind of DMA memory. It is allocated to the heap. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a ‘Dynamic TX Buffer’ and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffers are mutually exclusive.</td>
</tr>
<tr>
<td>Static TX Buffer</td>
<td>Static</td>
<td>16 * 1600Bytes</td>
<td>Yes</td>
<td>This is a kind of DMA memory. It is initialized in <code>esp_wifi_init()</code> and freed in <code>esp_wifi_deinit()</code>. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a ‘Static TX Buffer’ and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffers are mutually exclusive.</td>

<td>Dynamic</td>
<td>32</td>
<td>NO</td>
<td>Wi-Fi driver’s internal buffer.</td>
</tr>
</tbody>
</table>
Wi-Fi NVS Flash

If the Wi-Fi NVS flash is enabled, all Wi-Fi configurations set via the Wi-Fi APIs will be stored into flash, and the Wi-Fi driver will start up with these configurations the next time it powers on/reboots. However, the application can choose to disable the Wi-Fi NVS flash if it does not need to store the configurations into persistent memory, or has its own persistent storage, or simply due to debugging reasons, etc.

Wi-Fi Aggregate MAC Protocol Data Unit (AMPDU)

ESP32 supports both receiving and transmitting AMPDU, and the AMPDU can greatly improve the Wi-Fi throughput.

Generally, the AMPDU should be enabled. Disabling AMPDU is usually for debugging purposes.

4.34.34 Troubleshooting

Please refer to a separate document with Espresif Wireshark User Guide.

Espresif Wireshark User Guide

1. Overview

1.1 What is Wireshark? Wireshark (originally named “Ethereal”) is a network packet analyzer that captures network packets and displays the packet data as detailed as possible. It uses WinPcap as its interface to directly capture network traffic going through a network interface controller (NIC).

You could think of a network packet analyzer as a measuring device used to examine what is going on inside a network cable, just like a voltmeter is used by an electrician to examine what is going on inside an electric cable.

In the past, such tools were either very expensive, proprietary, or both. However, with the advent of Wireshark, all that has changed.

Wireshark is released under the terms of the GNU General Public License, which means you can use the software and the source code free of charge. It also allows you to modify and customize the source code.

Wireshark is, perhaps, one of the best open source packet analyzers available today.

1.2 Some Intended Purposes Here are some examples of how Wireshark is typically used:

• Network administrators use it to troubleshoot network problems.
• Network security engineers use it to examine security problems.
• Developers use it to debug protocol implementations.
• People use it to learn more about network protocol internals.

Beside these examples, Wireshark can be used for many other purposes.

1.3 Features The main features of Wireshark are as follows:

• Available for UNIX and Windows
• Captures live packet data from a network interface
• Displays packets along with detailed protocol information
• Opens/saves the captured packet data
• Imports/exports packets into a number of file formats, supported by other capture programs
• Advanced packet filtering
• Searches for packets based on multiple criteria
• Colorizes packets according to display filters
• Calculates statistics
• …and a lot more!

1.4 Wireshark Can or Can’t Do
• Live capture from different network media.
  Wireshark can capture traffic from different network media, including wireless LAN.
• Import files from many other capture programs.
  Wireshark can import data from a large number of file formats, supported by other capture programs.
• Export files for many other capture programs.
  Wireshark can export data into a large number of file formats, supported by other capture programs.
• Numerous protocol dissectors.
  Wireshark can dissect, or decode, a large number of protocols.
• Wireshark is not an intrusion detection system.
  It will not warn you if there are any suspicious activities on your network. However, if strange things happen, Wireshark might help you figure out what is really going on.
• Wireshark does not manipulate processes on the network, it can only perform “measurements” within it.
  Wireshark does not send packets on the network or influence it in any other way, except for resolving names (converting numerical address values into a human readable format), but even that can be disabled.

2. Where to Get Wireshark
You can get Wireshark from the official website: https://www.wireshark.org/download.html
Wireshark can run on various operating systems. Please download the correct version according to the operating system you are using.

This demonstration uses Wireshark 2.2.6 on Linux.

a) Start Wireshark
On Linux, you can run the shell script provided below. It starts Wireshark, then configures NIC and the channel for packet capture.

```bash
ifconfig $1 down
iwconfig $1 mode monitor
iwconfig $1 channel $2
ifconfig $1 up
Wireshark&
```

In the above script, the parameter $1 represents NIC and $2 represents channel. For example, wlan0 in ./xxx.sh wlan0 6, specifies the NIC for packet capture, and 6 identifies the channel of an AP or Soft-AP.

b) Run the Shell Script to Open Wireshark and Display Capture Interface
c) Select the Interface to Start Packet Capture
As the red markup shows in the picture above, many interfaces are available. The first one is a local NIC and the second one is a wireless NIC.

Please select the NIC according to your requirements. This document will use the wireless NIC to demonstrate packet capture.

Double click wlan0 to start packet capture.

d) Set up Filters
Since all packets in the channel will be captured, and many of them are not needed, you have to set up filters to get the packets that you need.

Please find the picture below with the red markup, indicating where the filters should be set up.
Chapter 4. API Guides

Fig. 67: Wireshark Capture Interface

Fig. 68: Setting up Filters in Wireshark
Click **Filter**, the top left blue button in the picture below. The *display filter* dialogue box will appear.

![Display Filter Dialogue Box](image)

Fig. 69: **Display Filter** Dialogue Box

Click the **Expression** button to bring up the *Filter Expression* dialogue box and set the filter according to your requirements.

**The quickest way**: enter the filters directly in the toolbar.

Click on this area to enter or modify the filters. If you enter a wrong or unfinished filter, the built-in syntax check turns the background red. As soon as the correct expression is entered, the background becomes green.

The previously entered filters are automatically saved. You can access them anytime by opening the drop down list.

For example, as shown in the picture below, enter two MAC addresses as the filters and click **Apply** (the blue arrow). In this case, only the packet data transmitted between these two MAC addresses will be captured.

e) **Packet List**

You can click any packet in the packet list and check the detailed information about it in the box below the list. For example, if you click the first packet, its details will appear in that box.

f) **Stop/Start Packet Capture**

As shown in the picture below, click the red button to stop capturing the current packet.

Click the top left blue button to start or resume packet capture.

g) **Save the Current Packet**

On Linux, go to **File -> Export Packet Dissections -> As Plain Text File** to save the packet.

Please note that **All packets, Displayed and All expanded** must be selected.

By default, Wireshark saves the captured packet in a libpcap file. You can also save the file in other formats, e.g. txt, to analyze it in other tools.

### 4.35 Wi-Fi Security

#### 4.35.1 ESP32 Wi-Fi Security Features

- Support for Protected Management Frames (PMF)
- Support for WPA3-Personal

In addition to traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), ESP32 Wi-Fi supports state-of-the-art security protocols, namely Protected Management Frames based on 802.11w standard and Wi-Fi Protected Access.
Fig. 70: *Filter Expression* Dialogue Box

Fig. 71: Filter Toolbar

Fig. 72: Example of MAC Addresses applied in the Filter Toolbar
Fig. 73: Example of Packet List Details

Fig. 74: Stopping Packet Capture

Fig. 75: Starting or Resuming the Packets Capture
3. Together, PMF and WPA3 provide better privacy and robustness against known attacks on traditional modes.

### 4.35.2 Protected Management Frames (PMF)

#### Introduction

In Wi-Fi, management frames such as beacons, probes, (de)authentication, (dis)association are used by non-AP stations to scan and connect to an AP. Unlike data frames, these frames are sent unencrypted. An attacker can use eavesdropping and packet injection to send spoofed (de)authentication/(dis)association frames at the right time, leading to the following attacks in case of unprotected management frame exchanges.

- DOS attack on one or all clients in the range of the attacker.
- Tearing down existing association on AP side by sending association request.
- Forcing a client to perform 4-way handshake again in case PSK is compromised in order to get PTK.
- Getting SSID of hidden network from association request.
- Launching man-in-the-middle attack by forcing clients to deauth from legitimate AP and associating to a rogue one.

PMF provides protection against these attacks by encrypting unicast management frames and providing integrity checks for broadcast management frames. These include deauthentication, disassociation and robust management frames. It also provides Secure Association (SA) teardown mechanism to prevent spoofed association/authentication frames from disconnecting already connected clients.

**There are 3 types of PMF configuration modes on both station and AP side -**

- PMF Optional
- PMF Required
- PMF Disabled

Depending on PMF configurations on Station and AP side, the resulting connection will behave differently. The table below summarises all possible outcomes -
### API & Usage

ESP32 supports PMF in both Station and SoftAP mode. For both, the default mode is PMF Optional. For even higher security, PMF required mode can be enabled by setting the `required` flag in `pmf_cfg` while using the `esp_wifi_set_config()` API. This will result in the device only connecting to a PMF enabled device and rejecting others. PMF optional can be disabled using `esp_wifi_disable_pmf_config()` API. If softAP is started in WPA3 or WPA2/WPA3 mixed mode trying to disable PMF will result in error.

<table>
<thead>
<tr>
<th>STA Setting</th>
<th>AP Setting</th>
<th>Outcome</th>
</tr>
</thead>
<tbody>
<tr>
<td>PMF Optional</td>
<td>PMF Optional/Required</td>
<td>Mgmt Frames Protected</td>
</tr>
<tr>
<td>PMF Optional</td>
<td>PMF Disabled</td>
<td>Mgmt Frames Not Protected</td>
</tr>
<tr>
<td>PMF Required</td>
<td>PMF Optional/Required</td>
<td>Mgmt Frames Protected</td>
</tr>
<tr>
<td>PMF Required</td>
<td>PMF Disabled</td>
<td>STA refuses Connection</td>

<tr>
<td>PMF Disabled</td>
<td>PMF Optional/Disabled</td>
<td>Mgmt Frames Not Protected</td>
</tr>
<tr>
<td>PMF Disabled</td>
<td>PMF Required</td>
<td>AP refuses Connection</td>
</tr>
</tbody>
</table>

**Attention:** The `capable` flag in `pmf_cfg` is deprecated and set to true internally. This is to take the additional security benefit of PMF whenever possible.

### 4.35.3 WPA3-Personal

#### Introduction

Wi-Fi Protected Access-3 (WPA3) is a set of enhancements to Wi-Fi access security intended to replace the current WPA2 standard. It includes new features and capabilities that offer significantly better protection against different types of attacks. It improves upon WPA2-Personal in following ways:

- WPA3 uses Simultaneous Authentication of Equals (SAE), which is password-authenticated key agreement method based on Diffie-Hellman key exchange. Unlike WPA2, the technology is resistant to offline-dictionary attack, where the attacker attempts to determine shared password based on captured 4-way handshake without any further network interaction.
- Disallows outdated protocols such as TKIP, which is susceptible to simple attacks like MIC key recovery attack.
- Mandates Protected Management Frames (PMF), which provides protection for unicast and multicast robust management frames which include Disassoc and Deauth frames. This means that the attacker cannot disrupt an established WPA3 session by sending forged Assoc frames to the AP or Deauth/Disassoc frames to the Station.
- Provides forward secrecy, which means the captured data cannot be decrypted even if password is compromised after data transmission.

Please refer to Security section of Wi-Fi Alliance’s official website for further details.

#### Setting up WPA3 with ESP32

In IDF Menuconfig under Wi-Fi component, a config option “Enable WPA3-Personal” is provided to Enable/Disable WPA3 for station. By default it is kept enabled, if disabled ESP32 will not be able to establish a WPA3 connection. Also under WI-FI component a config option “ESP_WIFI_SOFTAP_SAE_SUPPORT” is provided to Enable/Disable WPA3 for softAP. Additionally, since PMF is mandated by WPA3 protocol, PMF Mode Optional is set by default for station and softAP. PMF Required can be configured using WiFi config. For WPA3 softAP, PMF required is mandatory and will be configured and stored in NVS implicitly if not specified by user.

Refer to Protected Management Frames (PMF) on how to set this mode.

After configuring all required settings for WPA3-Personal station, application developers need not worry about the underlying security mode of the AP. WPA3-Personal is now the highest supported protocol in terms of security, so it will be automatically selected for the connection whenever available. For example, if an AP is configured to be
in WPA3 Transition Mode, where it will advertise as both WPA2 and WPA3 capable, Station will choose WPA3 for the connection with above settings. Note that Wi-Fi stack size requirement will increase 3kB when “Enable WPA3-Personal” is used.

After configuring all required setting for WPA3-Personal softAP, application developers have to set WIFI_AUTH_WPA3_PSK as WiFi config authmode to start AP in softAP. SoftAP can be also configured to use WIFI_AUTH_WPA2_WPA3_PSK mixed mode. Note that flash size will be increased by 6kB after enabling “ESP_WIFI_SOFTAP_SAE_SUPPORT”.
Chapter 5

Migration Guides

5.1 ESP-IDF 5.x Migration Guide

5.1.1 Migration from 4.4 to 5.0

Bluetooth Classic

Bluedroid

- bt/host/bluedroid/api/include/api/esp_hf_defs.h
  - In esp_hf_cme_err_t
    - ESP_HF_CME_MEMEORY_FULL renamed to ESP_HF_CME_MEMORY_FULL
    - ESP_HF_CME_MEMEORY_FAILURE renamed to ESP_HF_CME_MEMORY_FAILURE
- bt/host/bluedroid/api/include/api/esp_hf_ag_api.h
  - esp_bt_hf_init(esp_bd_addr_t remote_addr) changes into esp_hf_ag_init(void)
  - esp_bt_hf_deinit(esp_bd_addr_t remote_addr) changes into esp_hf_ag_deinit(void)
  - esp_bt_hf_register_callback changes into esp_hf_ag_register_callback
  - esp_bt_hf_connect changes into esp_hf_ag_slc_connect
  - esp_bt_hf_disconnect changes into esp_hf_ag_slc_disconnect
  - esp_bt_hf_connect_audio changes into esp_hf_ag_audio_connect
  - esp_bt_hf_disconnect_audio changes into esp_hf_ag_audio_disconnect
  - esp_bt_hf_vra changes into esp_hf_ag_vra_control
  - esp_bt_hf_volume_control changes into esp_hf_ag_volume_control
  - esp_hf_unat_response changes into esp_hf_ag_unknown_at_send
  - esp_hf_cmee_response changes into esp_hf_ag_cmee_send
  - esp_bt_hf_indchange_notification changes into esp_hf_ag_devices_status_indchange
  - esp_bt_hf_cind_response changes into esp_hf_ag_cind_response
  - esp_bt_hf_cops_response changes into esp_hf_ag_cops_response
  - esp_bt_hf_clcc_response changes into esp_hf_ag_clcc_response
  - esp_bt_hf_cnum_response changes into esp_hf_ag_cnum_response
Chapter 5. Migration Guides

- esp_bt_hf_bsir changes into esp_hf_ag_bsir
- esp_bt_hf_answer_call changes into esp_hf_ag_answer_call
- esp_bt_hf_reject_call changes into esp_hf_ag_reject_call
- esp_bt_hf_out_call changes into esp_hf_ag_out_call
- esp_hf_register_data_callback changes into esp_hf_ag_register_data_callback
- esp_hf_outgoing_data_ready changes into esp_hf_ag_outgoing_data_ready

Bluetooth Low Energy

Bluedroid

The following Bluedroid macros, types, and functions have been renamed:

- bt/host/bluedroid/api/include/api/esp_gap_ble_api.h
  - In esp_gap_ble_cb_event_t:
    * ESP_GAP_BLE_SET_PREFERED_DEFAULT_PHY_COMPLETE_EVT renamed to ESP_GAP_BLE_SET_PREFERRED_DEFAULT_PHY_COMPLETE_EVT
    * ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT renamed to ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT
  - esp_ble_wl_operation_t renamed to esp_ble_wl_operation_t
  - esp_ble_gap_cb_param_t.pkt_data_length_cmpl renamed to pkt_data_length_cmpl
  - esp_ble_gap_cb_param_t.update_whitelist_cmpl.wl_opration renamed to wl_operation
  - esp_ble_gap_set_prefered_default_phy renamed to esp_ble_gap_set_preferred_default_phy()

- bt/host/bluedroid/api/include/api/esp_gatt_defs.h
  - In esp_gatt_status_t:
    * ESP_GATT_ENCRYPED_MITM renamed to ESP_GATT_ENCRYPTED_MITM
    * ESP_GATT_ENCRYPTED_NO_MITM renamed to ESP_GATT_ENCRYPTED_NO_MITM

Nimble

The following Nimble APIs have been removed:

- bt/host/nimble/esp-hci/include/esp_nimble_hci.h
  - Remove esp_err_t esp_nimble_hci_and_controller_init(void)
    - Controller initialization, enable and HCI initialization calls have been moved to nimble_port_init. This function can be deleted directly.
  - Remove esp_err_t esp_nimble_hci_and_controller_deinit(void)
    - Controller deinitialization, disable and HCI deinitialization calls have been moved to nimble_port_deinit. This function can be deleted directly.

ESP-BLE-MESH

The following ESP-BLE-MESH macro has been renamed:

- bt/esp_ble_mesh/api/esp_ble_mesh_defs.h
  - In esp_ble_mesh_prov_cb_event_t:
    * ESP_BLE_MESH_PROVISIONER_DRIECT_ERASE_SETTINGS_COMP_EVT renamed to ESP_BLE_MESH_PROVISIONERDIRECT_ERASE_SETTINGS_COMP_EVT
Build System

Migrating from GNU Make Build System  ESP-IDF v5.0 no longer supports GNU make-based projects. Please follow the build system guide for migration.

Update Fragment File Grammar  Please follow the migrate linker script fragment files grammar chapter for migrating v3.x grammar to the new one.

Specify Component Requirements Explicitly  In previous versions of ESP-IDF, some components were always added as public requirements (dependencies) to every component in the build, in addition to the common component requirements:

- driver
- efuse
- esp_timer
- lwip
- vfs
- esp_wifi
- esp_event
- esp_netif
- esp_eth
- esp_phy

This means that it was possible to include header files of those components without specifying them as requirements in idf_component_register. This behavior was caused by transitive dependencies of various common components.

In ESP-IDF v5.0, this behavior is fixed and these components are no longer added as public requirements by default. Every component depending on one of the components which isn’t part of common requirements has to declare this dependency explicitly. This can be done by adding REQUIRES <component_name> or PRIV_REQUIRES <component_name> in idf_component_register call inside component’s CMakeLists.txt. See Component Requirements for more information on specifying requirements.

Setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS Variables  ESP-IDF v5.0 includes a number of improvements to support building projects with space characters in their paths. To make that possible, there are some changes related to setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS variables in project CMakeLists.txt files.

Adding non-existent directories to COMPONENT_DIRS or EXTRA_COMPONENT_DIRS is no longer supported and will result in an error.

Using string concatenation to define COMPONENT_DIRS or EXTRA_COMPONENT_DIRS variables is now deprecated. These variables should be defined as CMake lists, instead. For example, use:

```
set(EXTRA_COMPONENT_DIRS path1 path2)
list(APPEND EXTRA_COMPONENT_DIRS path3)
```

instead of:

```
set(EXTRA_COMPONENT_DIRS "path1 path2")
set(EXTRA_COMPONENT_DIRS "${EXTRA_COMPONENT_DIRS} path3")
```

Defining these variables as CMake lists is compatible with previous ESP-IDF versions.

Update Usage of target_link_libraries with project_elf  ESP-IDF v5.0 fixes CMake variable propagation issues for components. This issue caused compiler flags and definitions that were supposed to apply to one component to be applied to every component in the project.
Chapter 5. Migration Guides

As a side effect of this, user projects from ESP-IDF v5.0 onwards must use `target_link_libraries` with `project_elf` explicitly and custom CMake projects must specify `PRIVATE`, `PUBLIC`, or `INTERFACE` arguments. This is a breaking change and is not backward compatible with previous ESP-IDF versions.

For example:

```
target_link_libraries(${project_elf} PRIVATE "-Wl,--wrap=esp_panic_handler")
```

instead of:

```
target_link_libraries(${project_elf} "-Wl,--wrap=esp_panic_handler")
```

**Update CMake Version**  
In ESP-IDF v5.0 minimal CMake version was increased to 3.16 and versions lower than 3.16 are not supported anymore. Run `tools/idf_tools.py install cmake` to install a suitable version if your OS version doesn’t have one.

This affects ESP-IDF users who use system-provided CMake and custom CMake.

**Reorder the Applying of the Target-Specific Config Files**  
ESP-IDF v5.0 reorders the applying order of target-specific config files and other files listed in `SDKCONFIG_DEFAULTS`. Now, target-specific files will be applied right after the file brings it in, before all latter files in `SDKCONFIG_DEFAULTS`.

For example:

```
If `''SDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig_devkit1"'`, and there is a file `''sdkconfig.defaults.esp32''` in the same folder, then the files will be applied in the following order: (1) sdkconfig.defaults (2) sdkconfig.defaults.esp32 (3) sdkconfig_devkit1.
```

If you have a key with different values in the target-specific files of the former item (e.g., `sdkconfig.defaults.esp32` above) and the latter item (e.g., `sdkconfig_devkit1.esp32` above), please note the latter will override the target-specific file of the former.

If you do want to have some target-specific config values, please put it into the target-specific file of the latter item (e.g., `sdkconfig_devkit1.esp32`).

**GCC**

**GCC Version**  
The previous GCC version was GCC 8.4.0. This has now been upgraded to GCC 11.2.0 on all targets. Users that need to port their code from GCC 8.4.0 to 11.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 9
- Porting to GCC 10
- Porting to GCC 11

**Warnings**  
The upgrade to GCC 11.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user’s code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter, and ways to suppress them.

**Warning:**  
Users are advised to check that a warning is indeed a false positive before attempting to suppress it.
Chapter 5. Migration Guides

-Wstringop-overflow, -Wstringop-overread, -Wstringop-truncation, and -Warray-bounds  Users that use memory/string copy/compare functions will run into one of the -Wstringop warnings if the compiler cannot properly determine the size of the memory/string. The examples below demonstrate code that triggers these warnings and how to suppress them.

```c
#pragma GCC diagnostic push
#pragma GCC diagnostic ignored "-Wstringop-overflow"
#pragma GCC diagnostic ignored "-Warray-bounds"
    memset(RTC_SLOW_MEM, 0, CONFIG_ULP_COPROC_RESERVE_MEM);  // <<<-- This line leads to warnings
#pragma GCC diagnostic pop
```

-Waddress-of-packed-member  GCC will issue this warning when accessing an unaligned member of a packed struct due to the incurred penalty of unaligned memory access. However, all ESP chips (on both Xtensa and RISC-V architectures) allow for unaligned memory access and incur no extra penalty. Thus, this warning can be ignored in most cases.

```c
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c: In function 'btc_to_bta_gatt_id':
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c:105:21: warning: taking address of packed member of 'struct <anonymous>' may result in an unaligned pointer value [-Waddress-of-packed-member]
   105 |     btc_to_bta_uuid(&p_dest->uuid, &p_src->uuid);
       | ^~~~~~~~~~~~~
```

If the warning occurs in multiple places across multiple source files, users can suppress the warning at the CMake level as demonstrated below.

```c
set_source_files_properties(
    "host/bluedroid/btc/gatt/btc_gatto_act.c"
    "host/bluedroid/btc/gatt/btc_gatto_cache.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatts.c"
    PROPERTIES COMPILE_FLAGS -Wno-address-of-packed-member)
```

However, if there are only one or two instances, users can suppress the warning directly in the source code itself as demonstrated below.

```c
#pragma GCC diagnostic push
#if __GNUC__ >= 9
#pragma GCC diagnostic ignored "-Waddress-of-packed-member"  // <<<-- This key had been introduced since GCC 9
#endif
uint32_t* reg_ptr = (uint32_t*)src;
#pragma GCC diagnostic pop
```

llabs() for 64-bit Integers  The function abs() from stdlib.h takes int argument. Please use llabs() for types that are intended to be 64-bit. It is particularly important for time_t.
Espressif Toolchain Changes

**int32_t and uint32_t for Xtensa Compiler**  The types `int32_t` and `uint32_t` have been changed from the previous `int` and `unsigned int` to `long` and `unsigned long` respectively for the Xtensa compiler. This change now matches upstream GCC which uses `long` integers for `int32_t` and `uint32_t` on Xtensa, RISC-V, and other architectures.

<table>
<thead>
<tr>
<th></th>
<th>2021r2 and older, GCC 8</th>
<th>2022r1, GCC 11</th>
</tr>
</thead>
<tbody>
<tr>
<td>Xtensa</td>
<td>(unsigned) int</td>
<td>(unsigned) long</td>
</tr>
<tr>
<td>riscv32</td>
<td>(unsigned) long</td>
<td>(unsigned) long</td>
</tr>
</tbody>
</table>

The change mostly affects code that formats strings using types provided by `<inttypes.h>`. Users will need to replace placeholders such as `%i` and `%x` with `PRIi32` and `PRIxx` respectively.

In other cases, it should be noted that enums have the `int` type.

In common, `int32_t` and `int`, as well as `uint32_t` and `unsigned int`, are different types.

If users do not make the aforementioned updates to format strings in their applications, the following error will be reported during compilation:

```c
/Users/name/esp/esp-rainmaker/components/esp-insights/components/esp_diagnostics/
#include/esp_diagnostics.h:238:29: error: format '%u' expects argument of type
    unsigned int', but argument 3 has type 'uint32_t' {aka 'long unsigned int'} [-
    Werror=format=]
238 | esp_diag_log_event(tag, "EV (%u) %s: " format, esp_log_timestamp(), tag,
    __FILE_ARGS__); \
| ^~~~~~~~~~~~~~ ~~~~~~~~~~~~~~~~~~~
```

Removing CONFIG_COMPILER_DISABLE_GCC8_WARNINGS Build Option  The `CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` option was introduced to allow building of legacy code dating from the rigid GCC 5 toolchain. However, enough time has passed to allow for the warnings to be fixed, thus this option has been removed.

For now in GCC 11, users are advised to review their code and fix the compiler warnings where possible.

Networking

Wi-Fi

**Callback function type esp_now_recv_cb_t**  Previously, the first parameter of `esp_now_recv_cb_t` was of type `const uint8_t *mac_addr`, which only included the address of ESP-NOW peer device.

This now changes. The first parameter is of type `esp_now_recv_info_t`, which has members `src_addr`, `des_addr` and `rx_ctrl`. Therefore, the following updates are required:

- Redefine ESP-NOW receive callback function.
- `src_addr` can be used to replace original `mac_addr`.
- `des_addr` is the destination MAC address of ESP-NOW packet, which can be unicast or broadcast address.
  With `des_addr`, the user can distinguish unicast and broadcast ESP-NOW packets where broadcast ESP-NOW packets can be non-encrypted even when encryption policy is configured for the ESP-NOW.
- `rx_ctrl` is Rx control info of the ESP-NOW packet, which provides more information about the packet.
Please refer to the ESP-NOW example: wifi/espnnow/main/espnnow_example_main.c

**Ethernet**

*esp_eth_ioctl() API*  
Previously, the *esp_eth_ioctl() API had the following issues:

- The third parameter (which is of type void *) would accept an int/bool type arguments (i.e., not pointers) as input in some cases. However, these cases were not documented properly.
- To pass int/bool type argument as the third parameter, the argument had to be “unnaturally” casted to a void * type, to prevent a compiler warning as demonstrated in the code snippet below. This casting could lead to misuse of the *esp_eth_ioctl() function.

```c
esp_eth_ioctl(eth_handle, ETH_CMD_S_FLOW_CTRL, (void *)true);
```

Therefore, the usage of *esp_eth_ioctl()* is now unified. Arguments to the third parameter must be passed as pointers to a specific data type to/from where data will be stored/read by *esp_eth_ioctl()*.

Usage example to set Ethernet configuration:

```c
eth_duplex_t new_duplex_mode = ETH_DUPLEX_HALF;
esp_eth_ioctl(eth_handle, ETH_CMD_S_DUPLEX_MODE, &new_duplex_mode);
```

Usage example to get Ethernet configuration:

```c
eth_duplex_t duplex_mode;
esp_eth_ioctl(eth_handle, ETH_CMD_G_DUPLEX_MODE, &duplex_mode);
```

**KSZ8041/81 and LAN8720 Driver Update**  
The KSZ8041/81 and LAN8720 drivers are updated to support more devices (i.e., generations) from their associated product families. The drivers can recognize particular chip numbers and their potential support by the driver.

As a result, the specific “chip number” functions calls are replaced by generic ones as follows:

- Removed esp_eth_phy_new_ksz8041() and esp_eth_phy_new_ksz8081(), and use esp_eth_phy_new_ksz80xx() instead
- Removed esp_eth_phy_new_lan8720(), and use esp_eth_phy_new_lan87xx() instead

**ESP NETIF Glue Event Handlers**  
*esp_eth_set_default_handlers() and esp_eth_clear_default_handlers() functions are removed.* Registration of the default IP layer handlers for Ethernet is now handled automatically. If you have already followed the suggestion to fully initialize the Ethernet driver and network interface before registering their Ethernet/IP event handlers, then no action is required (except for deleting the affected functions). Otherwise, you may start the Ethernet driver right after they register the user event handler.

**PHY Address Auto-detect**  
The Ethernet PHY address auto-detect function esp_eth_detect_phy_addr() is renamed to esp_eth_phy_802_3_detect_phy_addr() and its header declaration is moved to esp_eth/include/esp_eth_phy_802_3.h.

**SPI-Ethernet Module Initialization**  
The SPI-Ethernet Module initialization is now simplified. Previously, you had to manually allocate an SPI device using spi_bus_add_device() before instantiating the SPI-Ethernet MAC.

Now, you no longer need to call spi_bus_add_device() as SPI devices are allocated internally. As a result, the eth_dm9051_config_t, eth_w5500_config_t, and eth_ksz8851an1l_config_t configuration structures are updated to include members for SPI device configuration (e.g., to allow fine tuning of SPI timing which may be dependent on PCB design). Likewise, the ETH_DM9051_DEFAULT_CONFIG,
ETW5500_DEFAULT_CONFIG, and ETH_KSZ8851SNL_DEFAULT_CONFIG configuration initialization macros are updated to accept new input parameters. Refer to Ethernet API Reference Guide for an example of SPI-Ethernet Module initialization.

TCP/IP Adapter  The TCP/IP Adapter was a network interface abstraction component used in ESP-IDF prior to v4.1. This section outlines migration from tcpip_adapter API to its successor ESP-NETIF.

Updating Network Connection Code

Network Stack Initialization

• You may simply replace tcpip_adapter_init() with esp_netif_init(). However, please should note that the esp_netif_init() function now returns standard error codes. See ESP-NETIF for more details.
• The esp_netif_deinit() function is provided to de-initialize the network stack.
• You should also replace #include "tcpip_adapter.h" with #include "esp_netif.h".

Network Interface Creation  Previously, the TCP/IP Adapter defined the following network interfaces statically:

• WiFi Station
• WiFi Access Point
• Ethernet

This now changes. Network interface instance should be explicitly constructed, so that the ESP-NETIF can connect to the TCP/IP stack. For example, after the TCP/IP stack and the event loop are initialized, the initialization code for WiFi must explicitly call esp_netif_create_default_wifi_sta(); or esp_netif_create_default_wifi_ap();.

Please refer to the example initialization code for these three interfaces:

• WiFi Station: wifi/getting_started/station/main/station_example_main.c
• WiFi Access Point: wifi/getting_started/softAP/main/softap_example_main.c
• Ethernet: ethernet/basic/main/ethernet_example_main.c

Other tcpip_adapter API Replacement  All the tcpip_adapter functions have their esp_netif counter-part. Please refer to the esp_netif.h grouped into these sections:

• Setters/Getters
• DHCP
• DNS
• IP address

Default Event Handlers  Event handlers are moved from tcpip_adapter to appropriate driver code. There is no change from application code perspective, as all events should be handled in the same way. Please note that for IP-related event handlers, application code usually receives IP addresses in the form of an esp_netif specific struct instead of the LwIP structs. However, both structs are binary compatible.

This is the preferred way to print the address:

ESP_LOGI(TAG, "got ip: \n", IPSTR(event->ip_info.ip));

Instead of

ESP_LOGI(TAG, "got ip:%\n", ip4addr_ntoa(event->ip_info.ip));

Since ip4addr_ntoa() is a LwIP API, the esp-netif provides esp_ip4addr_ntoa() as a replacement. However, the above method using IP2STR() is generally preferred.
IP Addresses  You are advised to use esp-netif defined IP structures. Please note that with default compatibility enabled, the LwIP structs will still work.
  * esp-netif IP address definitions

Peripherals

Peripheral Clock Gating  As usual, peripheral clock gating is still handled by driver itself, users don’t need to take care of the peripheral module clock gating.

However, for advanced users who implement their own drivers based on hal and soc components, the previous clock gating include path has been changed from driver/periph_ctrl.h to esp_private/periph_ctrl.h.

RTC Subsystem Control  RTC control APIs have been moved from driver/rtc_cntl.h to esp_private/rtc_ctrl.h.

ADC

ADC Oneshot & Continuous Mode drivers  The ADC oneshot mode driver has been redesigned.
  * The new driver is in esp_adc component and the include path is esp_adc/adc_oneshot.h.
  * The legacy driver is still available in the previous include path driver/adc.h.

The ADC continuous mode driver has been moved from driver component to esp_adc component.
  * The include path has been changed from driver/adc.h to esp_adc/adc_continuous.h.

Attempting to use the legacy include path driver/adc.h of either driver will trigger the build warning below by default. However, the warning can be suppressed by enabling the CONFIG_ADC_SUPPRESS_DEPRECATE_WARN Kconfig option.

```
legacy adc driver is deprecated, please migrate to use esp_adc/adc_oneshot.h and
  esp_adc/adc_continuous.h for oneshot mode and continuous mode drivers...
```

ADC Calibration Driver  The ADC calibration driver has been redesigned.
  * The new driver is in esp_adc component and the include path is esp_adc/adc_cali.h and esp_adc/
    adc_cali_scheme.h.

Legacy driver is still available by including esp_adc_cal.h. However, if users still would like to use the include path of the legacy driver, users should add esp_adc component to the list of component requirements in CMakeLists.txt.

Attempting to use the legacy include path esp_adc_cal.h will trigger the build warning below by default. However, the warning can be suppressed by enabling the CONFIG_ADC_CALI_SUPPRESS_DEPRECATE_WARN Kconfig option.

```
legacy adc calibration driver is deprecated, please migrate to use esp_adc/adc_
  --cali.h and esp_adc/adc_cali_scheme.h
```
Chapter 5. Migration Guides

API Changes

- The ADC power management APIs `adc_power_acquire` and `adc_power_release` have made private and moved to `esp_private/adc_share_hw_ctrl.h`.
  - The two APIs were previously made public due to a HW errata workaround.
  - Now, ADC power management is completely handled internally by drivers.
  - Users who still require this API can include `esp_private/adc_share_hw_ctrl.h` to continue using these functions.
- `driver/adc2_wifi_private.h` has been moved to `esp_private/adc_share_hw_ctrl.h`.
- Enums `ADC_UNIT_BOTH`, `ADC_UNIT_ALTER` and `ADC_UNIT_MAX` in `adc_unit_t` have been removed.
- The following enumerations have been removed as some of their enumeration values are not supported on all chips. This would lead to the driver triggering a runtime error if an unsupported value is used.
  - Enum `ADC_CHANNEL_MAX`
  - Enum `ADC_ATTEN_MAX`
  - Enum `ADC_CONV_UNIT_MAX`
- API `hall_sensor_read` on ESP32 has been removed. Hall sensor is no longer supported on ESP32.
- API `adc_set_i2s_data_source` and `adc_i2s_mode_init` have been deprecated. Related enum `adc_i2s_source_t` has been deprecated. Please migrate to use `esp_adc/adc_continuous.h`.
- API `adc_digi_filter_reset`, `adc_digi_filter_set_config`, `adc_digi_filter_get_config` and `adc_digi_filter_enable` have been removed. These APIs behaviours are not guaranteed. Enum `adc_digi_filter_idx_t`, `adc_digi_filter_mode_t` and structure `adc_digi_iir_filter_t` have been removed as well.
- API `esp_adc_cal_characterize` has been deprecated, please migrate to `adc_cali_create_scheme_curve_fitting` or `adc_cali_create_scheme_line_fitting` instead.
- API `esp_adc_cal_raw_to_voltage` has been deprecated, please migrate to `adc_oneshot_get_calibrated_result` instead.

GPIO

- The previous Kconfig option `RTCIO_SUPPORT_RTC_GPIO_DESC` has been removed, thus the `rtc_gpio_desc` array is unavailable. Please use `rtc_io_desc` array instead.
- The user callback of a GPIO interrupt should no longer read the GPIO interrupt status register to get the GPIO’s pin number of triggering the interrupt. You should use the callback argument to determine the GPIO’s pin number instead.
  - Previously, when a GPIO interrupt occurs, the GPIO’s interrupt status register is cleared after calling the user callbacks. Thus, it was possible for users to read the GPIO’s interrupt status register inside the callback to determine which GPIO was used to trigger the interrupt.
  - However, clearing the interrupt status register after calling the user callbacks can potentially cause edge-triggered interrupts to be lost. For example, if an edge-triggered interrupt (re)is triggered while the user callbacks are being called, that interrupt will be cleared without its registered user callback being handled.
  - Now, the GPIO’s interrupt status register is cleared before invoking the user callbacks. Thus, users can no longer read the GPIO interrupt status register to determine which pin has triggered the interrupt. Instead, users should use the callback argument to pass the pin number.

Sigma-Delta Modulator

- The Sigma-Delta Modulator driver has been redesigned into SDM.
- The new driver implements a factory pattern, where the SDM channels are managed in a pool internally, thus users don’t have to fix a SDM channel to a GPIO manually.
- All SDM channels can be allocated dynamically.

Although it’s recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/sigmadelta.h`. However, by default, including `driver/sigmadelta.h` will trigger the build warning below. The warning can be suppressed by Kconfig option `CONFIG_SDM_SUPPRESS_DEPRECATE_WARN`. 
The legacy sigma-delta driver is deprecated, please use driver/sdm.h

The major breaking changes in concept and usage are listed as follows:

**Breaking Changes in Concepts**

- SDM channel representation has changed from `sigmadelta_channel_t` to `sdm_channel_handle_t`, which is an opaque pointer.
- SDM channel configurations are stored in `sdm_config_t` now, instead of the previous `sigmadelta_config_t`.
- In the legacy driver, users don’t have to set the clock source for SDM channel. But in the new driver, users need to set a proper one in the `sdm_config_t::clk_src`. The available clock sources are listed in the `soc_periph_sdm_clk_src_t`.
- In the legacy driver, users need to set a prescale for the channel, which reflects the frequency in which the modulator outputs a pulse. In the new driver, users should use `sdm_config_t::sample_rate_hz` to set the over sample rate.
- In the legacy driver, users set duty to decide the output analog value, it’s now renamed to a more appropriate name `density`.

**Breaking Changes in Usage**

- Channel configuration was done by channel allocation, in `sdm_new_channel()`. In the new driver, only the density can be changed at runtime, by `sdm_channel_set_pulse_density()`. Other parameters like gpio number and prescale are only allowed to set during channel allocation.
- Before further channel operations, users should enable the channel in advance, by calling `sdm_channel_enable()`. This function will help to manage some system level services, like Power Management.

**Timer Group Driver**

Timer Group driver has been redesigned into **GPTimer**, which aims to unify and simplify the usage of general purpose timer.

Although it’s recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/timer.h`. However, by default, including `driver/timer.h` will trigger the build warning below. The warning can be suppressed by the Kconfig option `CONFIG_GPTIMER_SUPPRESS_DEPRECATE_WARN`.

The major breaking changes in concept and usage are listed as follows:

**Breaking Changes in Concepts**

- `timer_group_t` and `timer_idx_t` which used to identify the hardware timer are removed from user’s code. In the new driver, a timer is represented by `gptimer_handle_t`.
- Definition of timer clock source is moved to `gptimer_clock_source_t`, the previous `timer_src_clk_t` is not used.
- Definition of timer count direction is moved to `gptimer_count_direction_t`, the previous `timer_count_dir_t` is not used.
- Only level interrupt is supported, `timer_intr_t` and `timer_intr_mode_t` are not used.
- Auto-reload is enabled by set the `gptimer_alarm_config_t::auto_reload_on_alarm` flag. `timer_autoreload_t` is not used.

**Breaking Changes in Usage**

- Timer initialization is done by creating a timer instance from `gptimer_new_timer()`. Basic configurations like clock source, resolution and direction should be set in `gptimer_config_t`. Note that, specific configurations of alarm events are not needed during the installation stage of the driver.
- Alarm event is configured by `gptimer_set_alarm_action()`, with parameters set in the `gptimer_alarm_config_t`.
- Setting and getting count value are done by `gptimer_get_raw_count()` and `gptimer_set_raw_count()`. The driver doesn’t help convert the raw value into UTC time-stamp. Instead, the conversion should be done from user’s side as the timer resolution is also known to the user.
- The driver will install the interrupt service as well if `gptimer_event_callbacks_t::on_alarm` is set to a valid callback function. In the callback, users do not have to deal with the low level registers (like “clear interrupt status”, “re-enable alarm event” and so on). So functions like `timer_group_get_intr_status_in_isr` and `timer_group_get_auto_reload_in_isr` are not used anymore.
- To update the alarm configurations when alarm event happens, one can call `gptimer_set_alarm_action()` in the interrupt callback, then the alarm will be re-enabled again.
- Alarm will always be re-enabled by the driver if `gptimer_alarm_config_t::auto_reload_on_alarm` is set to true.

Pulse Counter Driver  

Pulse counter driver has been redesigned (see PCNT), which aims to unify and simplify the usage of PCNT peripheral.

Although it’s recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/pcnt.h`. However, including `driver/pcnt.h` will trigger the build warning below by default. The warning can be suppressed by the Kconfig option `CONFIG_PCNT_SUPPRESS_DEPRECATED_WARN`.

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- `pcnt_port_t`, `pcnt_unit_t` and `pcnt_channel_t` which used to identify the hardware unit and channel are removed from user’s code. In the new driver, PCNT unit is represented by `pcnt_unit_handle_t`, likewise, PCNT channel is represented by `pcnt_channel_handle_t`. Both of them are opaque pointers.
- `pcnt_evt_type_t` is not used any more, they have been replaced by a universal Watch Point Event. In the event callback `pcnt_watch_cb_t`, it’s still possible to distinguish different watch points from `pcnt_watch_event_data_t`.
- `pcnt_count_mode_t` is replaced by `pcnt_channel_edge_action_t`, and `pcnt_ctrl_mode_t` is replaced by `pcnt_channel_level_action_t`.

Breaking Changes in Usage

- Previously, the PCNT unit configuration and channel configuration were combined into a single function: `pcnt_unit_config`. They are now split into the two factory APIs: `pcnt_new_unit()` and `pcnt_new_channel()` respectively.
  - Only the count range is necessary for initializing a PCNT unit. GPIO number assignment has been moved to `pcnt_new_channel()`.
  - High/Low control mode and positive/negative edge count mode are set by stand-alone functions: `pcnt_channel_set_edge_action()` and `pcnt_channel_set_level_action()`.
- `pcnt_get_counter_value` is replaced by `pcnt_unit_get_count()`.
- `pcnt_counter_pause` is replaced by `pcnt_unit_stop()`.
- `pcnt_counter_resume` is replaced by `pcnt_unit_start()`.
- `pcnt_counter_clear` is replaced by `pcnt_unit_clear_count()`.
- `pcnt_input_enable` and `pcnt_input_disable` are removed. In the new driver, the interrupt is enabled by registering event callbacks `pcnt_unit_register_event_callbacks()`.
- `pcnt_event_enable` and `pcnt_event_disable` are removed. In the new driver, the PCNT events are enabled/disabled by adding/removing watch points `pcnt_unit_add_watch_point()`, `pcnt_unit_remove_watch_point()`.
- `pcnt_isr_register` and `pcnt_isr_unregister` are removed. Register of the ISR handler from user’s code is no longer permitted. Users should register event callbacks instead by calling `pcnt_unit_register_event_callbacks()`.
- `pcnt_set_pin` is removed and the new driver no longer allows the switching of the GPIO at runtime. If users want to change to other GPIOs, please delete the existing PCNT channel by `pcnt_del_channel()` and reinstall with the new GPIO number by `pcnt_new_channel()`.
- `pcnt_filter_enable`, `pcnt_filter_disable` and `pcnt_set_filter_value` are replaced by `pcnt_unit_set_glitch_filter()`. Meanwhile, `pcnt_get_filter_value` has been removed.
- `pcnt_set_mode` is replaced by `pcnt_channel_set_edge_action()` and `pcnt_channel_set_level_action()`.
- `pcnt_isr_service_install`, `pcnt_isr_service_uninstall`, `pcnt_isr_handler_add` and `pcnt_isr_handler_remove` are replaced by
pcnt_unit_register_event_callbacks(). The default ISR handler is lazy installed in the new driver.

**RMT Driver**  RMT driver has been redesigned (see RMT transceiver), which aims to unify and extend the usage of RMT peripheral.

Although it’s recommended to use the new driver APIs, the legacy driver is still available in the previous include path driver/rmt.h. However, including driver/rmt.h will trigger the build warning below by default. The warning can be suppressed by the Kconfig option CONFIG_RMT_SUPPRESS_DEPRECATE_WARN.

The legacy RMT driver is deprecated, please use driver/rmt_tx.h and/or driver/rmt_rx.h

The major breaking changes in concept and usage are listed as follows:

### Breaking Changes in Concepts

- **rmt_channel_t** which used to identify the hardware channel are removed from user space. In the new driver, RMT channel is represented by **rmt_channel_handle_t**. The channel is dynamically allocated by the driver, instead of designated by user.
- **rmt_item32_t** is replaced by **rmt_symbol_word_t**, which avoids a nested union inside a struct.
- **rmt_mem_t** is removed, as we don’t allow users to access RMT memory block (a.k.a an RMTMEM) directly. Direct access to RMTMEM doesn’t make sense but make mistakes, especially when the RMT channel also connected with a DMA channel.
- **rmt_mem_owner_t** is removed, as the ownership is controlled by driver, not by user anymore.
- **rmt_source_clk_t** is replaced by **rmt_clock_source_t**, and note they’re not binary compatible.
- **rmt_data_mode_t** is removed, the RMT memory access mode is configured to always use Non-FIFO and DMA mode.
- **rmt_idle_level_t** is removed, as the driver has stand alone install functions for TX and RX channels.
- **rmt_idle_level_t** is removed, setting IDLE level for TX channel is available in **rmt_transmit_config_t::eot_level**.
- **rmt_carrier_level_t** is removed, setting carrier polarity is available in **rmt_carrier_config_t::polarity_active_low**.
- **rmt_channel_status_t** and **rmt_channel_status_result_t** are removed, they’re not used anywhere.
- Transmitting by RMT channel doesn’t expect user to prepare the RMT symbols, instead, user needs to provide an RMT Encoder to tell the driver how to convert user data into RMT symbols.

### Breaking Changes in Usage

- Channel installation has been separated for TX and RX channels into **rmt_new_tx_channel()** and **rmt_new_rx_channel()**.
- rmt_set_clk_div and rmt_get_clk_div are removed. Channel clock configuration can only be done during channel installation.
- **rmt_set_rx_idle_thresh** and **rmt_get_rx_idle_thresh** are removed. In the new driver, the RX channel IDLE threshold is redesigned into a new concept **rmt_receive_config_t::signal_range_max_ns**.
- **rmt_set_mem_block_num** and **rmt_get_mem_block_num** are removed. In the new driver, the memory block number is determined by **rmt_tx_channel_config_t::mem_block_symbols** and **rmt_rx_channel_config_t::mem_block_symbols**.
- **rmt_set_tx_carrier** is removed, the new driver uses **rmt_apply_carrier()** to set carrier behavior.
- **rmt_set_mem_pd** and **rmt_get_mem_pd** are removed. The memory power is managed by the driver automatically.
- **rmt_memory_rw_rst, rmt_tx_memory_reset** and **rmt_rx_memory_reset** are removed. Memory reset is managed by the driver automatically.
- **rmt_tx_start** and **rmt_rx_start** are merged into a single function **rmt_enable()**, for both TX and RX channels.
Chapter 5. Migration Guides

- \texttt{rmt\_tx\_stop} and \texttt{rmt\_rx\_stop} are merged into a single function \texttt{rmt\_disable()}, for both TX and RX channels.
- \texttt{rmt\_set\_memory\_owner} and \texttt{rmt\_get\_memory\_owner} are removed. RMT memory owner guard is added automatically by the driver.
- \texttt{rmt\_set\_tx\_loop\_mode} and \texttt{rmt\_get\_tx\_loop\_mode} are removed. In the new driver, the loop mode is configured in \texttt{rmt\_transmit\_config\_t::loop\_count}.
- \texttt{rmt\_set\_source\_clk} and \texttt{rmt\_get\_source\_clk} are removed. Configuring clock source is only possible during channel installation by \texttt{rmt\_tx\_channel\_config\_t::clk\_src} and \texttt{rmt\_rx\_channel\_config\_t::clk\_src}.
- \texttt{rmt\_set\_tx\_loop\_count} is removed. The loop count in the new driver is configured in \texttt{rmt\_transmit\_config\_t::loop\_count}.
- \texttt{rmt\_set\_intr\_enable\_mask} and \texttt{rmt\_clr\_intr\_enable\_mask} are removed, as the interrupt is handled by the driver, user doesn’t need to take care of it.

LCD

- The LCD panel initialization flow is slightly changed. Now the \texttt{esp\_lcd\_panel\_init()} won’t turn on the display automatically. User needs to call \texttt{esp\_lcd\_panel\_disp\_on\_off()} to manually turn on the display. Note, this is different from turning on backlight. With this breaking change, user can flash a predefined pattern to the screen before turning on the screen. This can help avoid random noise on the screen after a power on reset.
- \texttt{esp\_lcd\_panel\_disp\_off()} is deprecated, please use \texttt{esp\_lcd\_panel\_disp\_on\_off()} instead.
- \texttt{dc\_as\_cmd\_phase} is removed. The SPI LCD driver currently doesn’t support a 9-bit SPI LCD. Please always use a dedicated GPIO to control the LCD D/C line.
- The way to register RGB panel event callbacks has been moved from \texttt{esp\_lcd\_rgb\_panel\_config\_t} into a separate API.
esp_lcd_rgb_panel_register_event_callbacks(). However, the event callback signature is not changed.

- Previous `relax_on_idle` flag in `esp_lcd_rgb_panel_config_t` has been renamed into `esp_lcd_rgb_panel_config_t::refresh_on_demand`, which expresses the same meaning but with a clear name.
- If the RGB LCD is created with the `refresh_on_demand` flag enabled, the driver won’t start a refresh in the `esp_lcd_panel_draw_bitmap()`. Now users have to call `esp_lcd_rgb_panel_refresh()` to refresh the screen by themselves.
- `esp_lcd_color_space_t` is deprecated, please use `lcd_color_space_t` to describe the color space, and use `lcd_color_rgb_endian_t` to describe the data order of RGB color.

**MCPWM** MCPWM driver was redesigned (see _MCPWM_), meanwhile, the legacy driver is deprecated.

The new driver’s aim is to make each MCPWM submodule independent to each other, and give the freedom of resource connection back to users.

Although it’s recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/mcpwm.h`. However, using legacy driver will rigger the build warning below by default. This warning can be suppressed by the Kconfig option `CONFIG_MCPWM_SUPPRESS_DEPRECATE_WARN`.

```c
# legacy MCPWM driver is deprecated, please migrate to the new driver (include...
→ driver/mcpwm_prelude.h)
```

The major breaking changes in concept and usage are listed as follows:

**Breaking Changes in Concepts** The new MCPWM driver is object-oriented, where most of the MCPWM submodule has a driver object associated with it. The driver object is created by factory function like `mcpwm_new_timer()`. IO control function always needs an object handle, in the first place.

The legacy driver has an inappropriate assumption, that is the MCPWM operator should be connected to different MCPWM timer. In fact, the hardware doesn’t have such limitation. In the new driver, a MCPWM timer can be connected to multiple operators, so that the operators can achieve the best synchronization performance.

The legacy driver presets the way to generate a PWM waveform into a so called `mcpwm_duty_type_t`. However, the duty cycle modes listed there are far from sufficient. Likewise, legacy driver has several preset `mcpwm_deadtime_type_t`, which also doesn’t cover all the use cases. What’s more, user usually gets confused by the name of the duty cycle mode and dead-time mode. In the new driver, there’re no such limitation, but user has to construct the generator behavior from scratch.

In the legacy driver, the ways to synchronize the MCPWM timer by GPIO, software and other timer module are not unified. It increased learning costs for users. In the new driver, the synchronization APIs are unified.

The legacy driver has mixed the concepts of “Fault detector” and “Fault handler”. Which make the APIs very confusing to users. In the new driver, the fault object just represents a failure source, and we introduced a new concept – `brake` to express the concept of “Fault handler”. What’s more, the new driver supports software fault.

The legacy drive only provides callback functions for the capture submodule. The new driver provides more useful callbacks for various MCPWM submodules, like timer stop, compare match, fault enter, brake, etc.

- `mcpwm_io_signals_t` and `mcpwm_pin_config_t` are not used. GPIO configuration has been moved into submodule’s configuration structure.
- `mcpwm_timer_t`, `mcpwm_generator_t` are not used. Timer and generator are represented by `mcpwm_timer_handle_t` and `mcpwm_gen_handle_t`.
- `mcpwm_fault_signal_t` and `mcpwm_sync_signal_t` are not used. Fault and sync source are represented by `mcpwm_fault_handle_t` and `mcpwm_sync_handle_t`.
- `mcpwm_capture_signal_t` is not used. A capture channel is represented by `mcpwm_cap_channel_handle_t`.

**Breaking Changes in Usage**
• `mcpwm_gpio_init` and `mcpwm_set_pin`: GPIO configurations are moved to submodule’s own configuration. e.g. set the PWM GPIO in `mcpwm_generator_config_t::gen_gpio_num`.

• `mcpwm_init`: To get an expected PWM waveform, users need to allocate at least one MCPWM timer and MCPWM operator, then connect them by calling `mcpwm_operator_connect_timer()`. After that, users should set the generator’s actions on various events by calling e.g. `mcpwm_generator_set_actions_on_timer_event()`, `mcpwm_generator_set_actions_on_compare_event()`.

• `mcpwm_group_set_resolution`: in the new driver, the group resolution is fixed to the maximum, usually it’s 80MHz.

• `mcpwm_timer_set_resolution`: MCPWM Timer resolution is set in `mcpwm_timer_config_t::resolution_hz`.

• `mcpwm_set_frequency`: PWM frequency is determined by `mcpwm_timer_config_t::resolution_hz`, `mcpwm_timer_config_t::count_mode` and `mcpwm_timer_config_t::period_ticks`.

• `mcpwm_set_duty`: To set the PWM duty cycle, users should call `mcpwm_comparator_set_compare_value()` to change comparator’s threshold.

• `mcpwm_set_signal_high` and `mcpwm_set_signal_low` are replaced by `mcpwm_generator_set_force_level()`. In the new driver, it’s implemented by setting force action for the generator, instead of changing the duty cycle to 0% or 100% at the background.

• `mcpwm_start` and `mcpwm_stop` are replaced by `mcpwm_timer_start_stop()`. You have more modestos to start and stop the MCPWM timer, see `mcpwm_timer_start_stop_cmd_t`.

• `mcpwm_carrier_init` is replaced by `mcpwm_operator_apply_carrier()`.

• `mcpwm_carrier_set_period` is replaced by `mcpwm_carrier_config_t::frequency_hz`.

• `mcpwm_carrier_set_duty_cycle` is replaced by `mcpwm_carrier_config_t::duty_cycle`.

• `mcpwm_carrier_oneshot_mode_enable` is replaced by `mcpwm_carrier_config_t::first_pulse_duration_us`.

• `mcpwm_carrier_oneshot_mode_disable` is removed. Disabling the first pulse (a.k.a the one-shot pulse) in the carrier is never supported by the hardware.

• `mcpwm_carrier_output_invert` is replaced by `mcpwm_carrier_config_t::invert_before_modulate` and `mcpwm_carrier_config_t::invert_after_modulate`.

• `mcpwm_capture_enable` and `mcpwm_capture_disable` are removed. It’s duplicated to `mcpwm_capture_enable_channel()` and `mcpwm_capture_disable_channel()`.

• `mcpwm_capture_signal_get_value` and `mcpwm_capture_signal_get_edge`: Capture timer count value and capture edge are provided in the capture event callback, via `mcpwm_capture_event_data_t`. Capture data are only valuable when capture event happens. Providing single API to fetch capture data is meaningless.

• `mcpwm_sync_enable` is removed. It’s duplicated to `mcpwm_sync_configure()` and `mcpwm_sync_disable` is equivalent to setting `mcpwm_timer_sync_phase_config_t::sync_src` to NULL.

• `mcpwm_timer_trigger_soft_sync` is replaced by `mcpwm_soft_sync_activate()`.

• `mcpwm_isr_register` is removed. You can register various event callbacks instead. For example, to register capture event callback, users can use `mcpwm_capture_channel_register_event_callbacks()`.
I2S driver  The I2S driver has been redesigned (see I2S Driver), which aims to rectify the shortcomings of the driver that were exposed when supporting all the new features of ESP32-C3 & ESP32-S3. The new driver’s APIs are available by including corresponding I2S mode’s header files driver/i2s/include/driver/i2s_std.h, driver/i2s/include/driver/i2s_pdm.h, or driver/i2s/include/driver/i2s_tdm.h.

Meanwhile, the old driver’s APIs in driver/deprecated/driver/i2s.h are still supported for backward compatibility. But there will be warnings if users keep using the old APIs in their projects, these warnings can be suppressed by the Kconfig option CONFIG_I2S_SUPPRESS_DEPRECATED_WARN.

Here is the general overview of the current I2S files:

![I2S Files Diagram]

#### Breaking changes in Concepts

**Independent TX/RX channels**  The minimum control unit in new I2S driver are now individual TX/RX channels instead of an entire I2S controller (that consists of multiple channels).

- The TX and RX channels of the same I2S controller can be controlled separately, meaning that they are configured such that they can be started or stopped separately.
- The c-type: `i2s_chan_handle_t` handle type is used to uniquely identify I2S channels. All the APIs will require the channel handle and users need to maintain the channel handles by themselves.
- On the ESP32-C3 and ESP32-S3, TX and RX channels in the same controller can be configured to different clocks or modes.
- However, on the ESP32 and ESP32-S2, the TX and RX channels of the same controller still share some hardware resources. Thus, configurations may cause one channel to affect another channel in the same controller.
- The channels can be registered to an available I2S controller automatically by setting `i2s_port_t::I2S_NUM_AUTO` as I2S port ID which will cause the driver to search for the available TX/RX channels. However, the driver also supports registering channels to a specific port.
- In order to distinguish between TX/RX channels and sound channels, the term ‘channel’ in the context of the I2S driver will only refer to TX/RX channels. Meanwhile, sound channels will be referred to as “slots”.

#### I2S Mode Categorization  I2S communication modes are categorized into the following three modes. Note that:

- **Standard mode**: Standard mode always has two slots, it can support Philips, MSB, and PCM (short frame sync) formats. Please refer to `driver/i2s/include/driver/i2s_std.h` for more details.
- **PDM mode**: PDM mode only supports two slots with 16-bit data width, but the configurations of PDM TX and PDM RX are slightly different. For PDM TX, the sample rate...
can be set by `i2s_pdm_tx_clk_config_t::sample_rate`, and its clock frequency depends on the up-sampling configuration. For PDM RX, the sample rate can be set by `i2s_pdm_rx_clk_config_t::sample_rate`, and its clock frequency depends on the down-sampling configuration. Please refer to `driver/i2s/include/driver/i2s_pdm.h` for details.

- **TDM mode**: TDM mode can support up to 16 slots. It can work in Philips, MSB, PCM (short frame sync), and PCM (long frame sync) formats. Please refer to `driver/i2s/include/driver/i2s_tdm.h` for details.

When allocating a new channel in a specific mode, users should initialize that channel by its corresponding function. It is strongly recommended to use the helper macros to generate the default configurations in case the default values are changed in the future.

### Independent Slot and Clock Configuration

The slot configurations and clock configurations can be configured separately.

- Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()`, or `i2s_channel_init_tdm_mode()` to initialize the slot/clock/gpio pin configurations.
- Calling `i2s_channel_reconfig_std_slot()`, `i2s_channel_reconfig_pdm_rx_slot()`, `i2s_channel_reconfig_pdm_tx_slot()`, or `i2s_channel_reconfig_tdm_slot()` can change the slot configurations after initialization.
- Calling `i2s_channel_reconfig_std_clock()`, `i2s_channel_reconfig_pdm_rx_clock()`, `i2s_channel_reconfig_pdm_tx_clock()`, or `i2s_channel_reconfig_tdm_clock()` can change the clock configurations after initialization.
- Calling `i2s_channel_reconfig_std_gpio()`, `i2s_channel_reconfig_pdm_rx_gpio()`, `i2s_channel_reconfig_pdm_tx_gpio()`, or `i2s_channel_reconfig_tdm_gpio()` can change the GPIO configurations after initialization.

### Misc

- States and state-machine are adopted in the new I2S driver to avoid APIs called in wrong state.
- ADC and DAC modes are removed. They will only be supported in their own drivers and the legacy I2S driver.

### Breaking Changes in Usage

To use the new I2S driver, please follow these steps:

1. Call `i2s_new_channel()` to acquire channel handles. We should specify the work role and I2S port in this step. Besides, the TX or RX channel handle will be generated by the driver. Inputting both two TX and RX channel handles is not necessary but at least one handle is needed. In the case of inputting both two handles, the driver will work at the duplex mode. Both TX and RX channels will be available on a same port, and they will share the MCLK, BCLK and WS signal. But if only one of the TX or RX channel handle is inputted, this channel will only work in the simplex mode.
2. Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()` or `i2s_channel_init_tdm_mode()` to initialize the channel to the specified mode. Corresponding slot, clock and GPIO configurations are needed in this step.
3. (Optional) Call `i2s_channel_register_event_callback()` to register the ISR event callback functions. I2S events now can be received by the callback function synchronously, instead of from the event queue asynchronously.
4. Call `i2s_channel_enable()` to start the hardware of I2S channel. In the new driver, I2S won’t start automatically after installed, and users are supposed to know clearly whether the channel has started or not.
5. Read or write data by `i2s_channel_read()` or `i2s_channel_write()`. Certainly, only the RX channel handle is supposed to be inputted in `i2s_channel_read()` and the TX channel handle in `i2s_channel_write()`.
6. (Optional) The slot, clock and GPIO configurations can be changed by corresponding ‘reconfig’ functions, but `i2s_channel_disable()` must be called before updating the configurations.
7. Call `i2s_channel_disable()` to stop the hardware of I2S channel.
8. Call `i2s_del_channel()` to delete and release the resources of the channel if it is not needed any more, but the channel must be disabled before deleting it.
**TWAI Driver**  The deprecated CAN peripheral driver is removed. Please use TWAI driver instead (i.e., include `driver/twai.h` in your application).

**Register Access Macros**  Previously, all register access macros could be used as expressions, so the following was allowed:

```
uint32_t val = REG_SET_BITS(reg, mask);
```

In ESP-IDF v5.0, register access macros which write or read-modify-write the register can no longer be used as expressions, and can only be used as statements. This applies to the following macros: `REG_WRITE`, `REG_SET_BIT`, `REG_CLR_BIT`, `REG_SET_BITS`, `REG_SET_FIELD`, `WRITE_PERI_REG`, `CLEAR_PERI_REG_MASK`, `SET_PERI_REG_MASK`, `SET_PERI_REG_BITS`.

To store the value which would have been written into the register, split the operation as follows:

```
uint32_t new_val = REG_READ(reg) | mask;
REG_WRITE(reg, new_val);
```

To get the value of the register after modification (which may be different from the value written), add an explicit read:

```
REG_SET_BITS(reg, mask);
uint32_t new_val = REG_READ(reg);
```

**Protocols**

**Mbed TLS**  For ESP-IDF v5.0, Mbed TLS has been updated from v2.x to v3.1.0.

For more details about Mbed TLS’s migration from version 2.x to version 3.0 or greater, please refer to the official guide.

**Breaking Changes (Summary)**

**Most structure fields are now private**
- Direct access to fields of structures (struct types) declared in public headers is no longer supported.
- Appropriate accessor functions (getter/setter) must be used for the same. A temporary workaround would be to use `MBEDTLS_PRIVATE` macro (not recommended).
- For more details, refer to the official guide.

**SSL**
- Removed support for TLS 1.0, 1.1, and DTLS 1.0
- Removed support for SSL 3.0

**Deprecated Functions Were Removed from Cryptography Modules**
- The functions `mbedtls_*_ret()` (related to MD, SHA, RIPEMD, RNG, HMAC modules) was renamed to replace the corresponding functions without `_ret` appended and updated return value.
- For more details, refer to the official guide.
Chapter 5. Migration Guides

Deprecated Config Options  Following are some of the important config options deprecated by this update. The configs related to and/or dependent on these have also been deprecated.

- **MBEDTLS_SSL_PROTO_SSL3**: Support for SSL 3.0
- **MBEDTLS_SSL_PROTO_TLS1**: Support for TLS 1.0
- **MBEDTLS_SSL_PROTO_TLS1_1**: Support for TLS 1.1
- **MBEDTLS_SSL_PROTO_DTLS**: Support for DTLS 1.1 (Only DTLS 1.2 is supported now)
- **MBEDTLS_DES_C**: Support for 3DES ciphersuites
- **MBEDTLS_RC4_MODE**: Support for RC4-based ciphersuites

Note: This list includes only major options configurable through `idf.py menuconfig`. For more details on deprecated options, refer to the official guide.

Miscellaneous

Disabled Diffie-Hellman Key Exchange Modes  The Diffie-Hellman Key Exchange modes have now been disabled by default due to security risks (see warning text here). Related configs are given below:

- **MBEDTLS_DHM_C**: Support for the Diffie-Hellman-Merkle module
- **MBEDTLS_KEY_EXCHANGE_DHE_PSK**: Support for Diffie-Hellman PSK (pre-shared-key) TLS authentication modes
- **MBEDTLS_KEY_EXCHANGE_DHE_RSA**: Support for cipher suites with the prefix `TLS-DHE-RSA-WITH-`

Note: During the initial step of the handshake (i.e. `client_hello`), the server selects a cipher from the list that the client publishes. As the DHE_PSK/DHE_RSA ciphers have now been disabled by the above change, the server would fall back to an alternative cipher; if in a rare case, it does not support any other cipher, the handshake would fail. To retrieve the list of ciphers supported by the server, one must attempt to connect with the server with a specific cipher from the client-side. Few utilities can help do this, e.g. `sslscan`.

Remove certs Module from X509 Library

- The `mbedtls/certs.h` header is no longer available in mbedtls 3.1. Most applications can safely remove it from the list of includes.

Breaking Change for `esp_crt_bundle_set` API

- The `esp_crt_bundle_set()` API now requires one additional argument named `bundle_size`. The return type of the API has also been changed to `esp_err_t` from `void`.

Breaking Change for `esp_ds_rsa_sign` API

- The `esp_ds_rsa_sign()` API now requires one less argument. The argument `mode` is no longer required.

HTTPS Server

Breaking Changes (Summary)  Names of variables holding different certs in `httpd_ssl_config_t` structure have been updated.

- **httpd_ssl_config::servercert** variable inherits role of `cacert_pem` variable.
- **httpd_ssl_config::servercert_len** variable inherits role of `cacert_len` variable
- **httpd_ssl_config::cacert_pem** variable inherits role of `client_verify_cert_pem` variable
• `httpd_ssl_config::cacert_len` variable inherits role of `client_verify_cert_len` variable

The return type of the `httpd_ssl_stop()` API has been changed to `esp_err_t` from `void`.

**ESP HTTPS OTA**

**Breaking Changes (Summary)**

• The function `esp_https_ota()` now requires pointer to `esp_https_ota_config_t` as argument instead of pointer to `esp_http_client_config_t`.

**ESP-TLS**

**Breaking Changes (Summary)**

**esp_tls_t Structure is Now Private** The `esp_tls_t` has now been made completely private. You cannot access its internal structures directly. Any necessary data that needs to be obtained from the ESP-TLS handle can be done through respective getter/setter functions. If there is a requirement of a specific getter/setter function, please raise an issue on ESP-IDF.

The list of newly added getter/setter function is as as follows:

• `esp_tls_get_ssl_context()` - Obtain the ssl context of the underlying ssl stack from the ESP-TLS handle.

**Function Deprecations And Recommended Alternatives** Following table summarizes the deprecated functions removed and their alternatives to be used from ESP-IDF v5.0 onwards.

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>esp_tls_conn_new()</code></td>
<td><code>esp_tls_conn_new_sync()</code></td>
</tr>
<tr>
<td><code>esp_tls_conn_delete()</code></td>
<td><code>esp_tls_conn_destroy()</code></td>
</tr>
</tbody>
</table>

• The function `esp_tls_conn_http_new()` has now been termed as deprecated. Please use the alternative function `esp_tls_conn_http_new_sync()` (or its asynchronous `esp_tls_conn_http_new_async()`). Note that the alternatives need an additional parameter `esp_tls_t`, which has to be initialized using the `esp_tls_init()` function.

**HTTP Server**

**Breaking Changes (Summary)**

• `http_server.h` header is no longer available in `esp_http_server`. Please use `esp_http_server.h` instead.

**ESP HTTP Client**

**Breaking Changes (Summary)**

• The functions `esp_http_client_read()` and `esp_http_client_fetch_headers()` now return an additional return value -`ESP_ERR_HTTP_EAGAIN` for timeout errors - call timed-out before any data was ready.
Chapter 5. Migration Guides

TCP Transport

Breaking Changes (Summary)

- The function `esp_transport_read()` now returns 0 for a connection timeout and < 0 for other errors. Please refer `esp_tcp_transport_err_t` for all possible return values.

MQTT Client

Breaking Changes (Summary)

- `esp_mqtt_client_config_t` have all fields grouped in sub structs.

Most common configurations are listed below:

- Broker address now is set in `esp_mqtt_client_config_t::broker::address::uri`
- Security related to broker verification in `esp_mqtt_client_config_t::broker::verification`
- Client username is set in `esp_mqtt_client_config_t::credentials::username`
- `esp_mqtt_client_config_t` no longer supports the `user_context` field. Please use `esp_mqtt_client_register_event()` instead for registering an event handler; the last argument `event_handler_arg` can be used to pass user context to the handler.

ESP-Modbus

Breaking Changes (Summary) The ESP-IDF component `freemodbus` has been removed from ESP-IDF and is supported as a separate component. Additional information for the ESP-Modbus component can be found in the separate repository:

- ESP-Modbus component on GitHub

The main component folder of the new application shall include the component manager manifest file `idf_component.yml` as in the example below:

```yaml
dependencies:
espressif/esp-modbus:
  version: "^1.0"
```

The `esp-modbus` component can be found in component manager registry. Refer to component manager documentation for more information on how to set up the component manager.

For applications targeting v4.x releases of ESP-IDF that need to use new `esp-modbus` component, adding the component manager manifest file `idf_component.yml` will be sufficient to pull in the new component. However, users should also exclude the legacy `freemodbus` component from the build. This can be achieved using the statement below in the project’s `CMakeLists.txt`:

```cmake
set(EXCLUDE_COMPONENTS freemodbus)
```

Provisioning

Protocomm The `pop` field in the `protocomm_set_security()` API is now deprecated. Please use the `sec_params` field instead of `pop`. This parameter should contain the structure (including the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` parameter should contain the pointer to the structure of type `protocomm_security2_params_t`. 

Espressif Systems 2625 Release v5.1.1
Submit Document Feedback
Wi-Fi Provisioning

- The `pop` field in the `wifi_prov_mgr_start_provisioning()` API is now deprecated. For backward compatibility, `pop` can be still passed as a string for security version 1. However, for security version 2, the `wifi_prov_sec_params` argument needs to be passed instead of `pop`. This parameter should contain the structure (containing the security parameters) as required by the protocol version used. For example, when using security version 2, the `wifi_prov_sec_params` parameter should contain the pointer to the structure of type `wifi_prov_security2_params_t`. For security 1, the behaviour and the usage of the API remain the same.

- The API `wifi_prov_mgr_is_provisioned()` does not return `ESP_ERR_INVALID_STATE` error any more. This API now works without any dependency on provisioning manager initialization state.

ESP Local Control

The `pop` field in the `esp_local_ctrl_proto_sec_cfg_t` API is now deprecated. Please use the `sec_params` field instead of `pop`. This field should contain the structure (containing the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` field should contain pointer to the structure of type `esp_local_ctrl_security2_params_t`.

Removed or Deprecated Components

**Components Moved to IDF Component Registry**

Following components are removed from ESP-IDF and moved to IDF Component Registry:

- libsodium
- cbor
- jsmn
- esp_modem
- nghttp
- mdns
- esp_websocket_client
- asio
- freemodbus
- sh2lib
- expat
- coap
- esp-cryptoauthlib
- qrcode
- tjpgd
- esp_serial_slave_link
- tinyusb

**Note:** Please note that http parser functionality which was previously part of `nghttp` component is now part of `http_parser` component.

These components can be installed using `idf.py add-dependency` command.

For example, to install libsodium component with the exact version X.Y, run `idf.py add-dependency libsodium==X.Y`.

To install libsodium component with the latest version compatible to X.Y according to semver rules, run `idf.py add-dependency libsodium~X.Y`.

To find out which versions of each component are available, open `https://components.espressif.com`, search for the component by its name and check the versions listed on the component page.
Chapter 5. Migration Guides

Deprecated Components  The following components are removed since they were deprecated in IDF v4.x:

- tcpip_adapter. Please use the ESP-NETIF component instead; you can follow the TCP/IP Adapter.

Note: OpenSSL-API component is no longer supported. It is not available in the IDF Component Registry, either. Please use ESP-TLS or mbedtls API directly.

Note: esp_adc_cal component is no longer supported. New adc calibration driver is in esp_adc component. Legacy adc calibration driver has been moved into esp_adc component. To use legacy esp_adc_cal driver APIs, you should add esp_adc component to the list of component requirements in CMakeLists.txt. Also check Peripherals Migration Guide for more details.

The targets components are no longer necessary after refactoring and have been removed:

- esp32
- esp32s2
- esp32s3
- esp32c2
- esp32c3
- esp32h2

Storage

New Component for the Partition APIs  Breaking change: all the Partition API code has been moved to a new component esp_partition. For the complete list of affected functions and data-types, see header file esp_partition.h.

These API functions and data-types were previously a part of the spi_flash component, and thus possible dependencies on the spi_flash in existing applications may cause the build failure, in case of direct esp_partition_* APIs/data-types use (for instance, fatal error: esp_partition.h: No such file or directory at lines with #include "esp_partition.h"). If you encounter such an issue, please update your project’s CMakeLists.txt file as follows:

Original dependency setup:

```c
idf_component_register(...
  REQUIRES spi_flash)
```

Updated dependency setup:

```c
idf_component_register(...
  REQUIRES spi_flash esp_partition)
```

Note: Please update relevant REQUIRES or PRIV_REQUIRES section according to your project. The above-presented code snippet is just an example.

If the issue persists, please let us know and we will assist you with your code migration.

SDMMC/SDSPI  SD card frequency on SDMMC/SDSPI interface can be now configured through sdmcc_host_t.max_freq_khz to a specific value, not only SDMMC_FREQ_PROBING (400 kHz), SDMMC_FREQ_DEFAULT (20 MHz), or SDMMC_FREQ_HIGHSPEED (40 MHz). Previously, in case you have specified a custom frequency other than any of the above-mentioned values, the closest lower-or-equal one was selected anyway.

Now, the underlaying drivers calculate the nearest fitting value, given by available frequency dividers instead of an enumeration item selection. This could cause troubles in communication with your SD card without a change of the existing application code. If you encounter such an issue, please, keep trying different frequencies around your desired...
value unless you find the one working well. To check the frequency value calculated and actually applied, use void
sdmmc_card_print_info(FILE* stream, const sdmmc_card_t* card) function.

**FatFs** FatFs is now updated to v0.14. As a result, the function signature of f_mkfs() has changed. The new
signature is `RESULT f_mkfs (const TCHAR* path, const MKFS_PARM* opt, void* work, UINT len);` which uses MKFS_PARM struct as a second argument.

**Partition Table** The partition table generator no longer supports misaligned partitions. When generating a partition
table, ESP-IDF only accepts partitions with offsets that align to 4 KB. This change only affects generating new
partition tables. Reading and writing to already existing partitions remains unchanged.

**VFS** The `esp_vfs_semihost_register()` function signature is changed as follows:

- The new signature is `esp_err_t esp_vfs_semihost_register(const char* base_path);`
- The `host_path` parameter of the old signature no longer exists. Instead, the OpenOCD command
  ESP_SEMIHOST_BASEDIR should be used to set the full path on the host.

**Function Signature Changes** The following functions now return `esp_err_t` instead of `void` or
`nvs_iterator_t`. Previously, when parameters were invalid or when something goes wrong internally, these
functions would `assert()` or return a `nullptr`. With an `esp_err_t` returned, you can get better error reporting.

- `nvs_entry_find()`
- `nvs_entry_next()`
- `nvs_entry_info()`

Because the `esp_err_t` return type changes, the usage patterns of `nvs_entry_find()` and
`nvs_entry_next()` become different. Both functions now modify iterators via parameters instead of
returning an iterator.

The old programming pattern to iterate over an NVS partition was as follows:

```c
nvs_iterator_t it = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY);
while (it != NULL) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info);
    it = nvs_entry_next(it);
    printf("key '%s', type '%d'\n", info.key, info.type);
}
```

The new programming pattern to iterate over an NVS partition is now:

```c
nvs_iterator_t it = nullptr;
esp_err_t res = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY, &it);
while (res == ESP_OK) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info); // Can omit error check if parameters are guaranteed to be non-NULL
    printf("key '%s', type '%d'\n", info.key, info.type);
    res = nvs_entry_next(&it);
}
nvs_release_iterator(it);
```

**Iterator Validity** Note that because the function signature changes, if there is a parameter error, you
may get an invalid iterator from `nvs_entry_find()`. Hence, it is important to initialize the iterator
to NULL before using nvs_entry_find(), so that you can avoid complex error checking before calling nvs_release_iterator(). A good example is the programming pattern above.

**Removed SDSPI Deprecated API** Structure sdspi_slot_config_t and function sdspi_host_init_slot() are removed, and replaced by structure sdspi_device_config_t and function sdspi_host_init_device() respectively.

**ROM SPI Flash** In versions before v5.0, ROM SPI flash functions were included via esp32**/rom/spi_flash.h. Thus, code written to support different ESP chips might be filled with ROM headers of different targets. Furthermore, not all of the APIs could be used on all ESP chips.

Now, the common APIs are extracted to esp_rom_spiflash.h. Although it is not a breaking change, you are strongly recommended to only use the functions from this header (i.e., prefixed with esp_rom_spiflash and included by esp_rom_spiflash.h) for better cross-compatibility between ESP chips.

To make ROM SPI flash APIs clearer, the following functions are also renamed:

- `esp_rom_spiflash_lock()` to `esp_rom_spiflash_set_bp()`
- `esp_rom_spiflash_unlock()` to `esp_rom_spiflash_clear_bp()`

**SPI Flash Driver** The esp_flash_speed_t enum type is now deprecated. Instead, you may now directly pass the real clock frequency value to the flash configuration structure. The following example demonstrates how to configure a flash frequency of 80MHz:

```c
esp_flash_spi_device_config_t dev_cfg = {
    .freq_mhz = 80,
    // Other members
};
```

**Legacy SPI Flash Driver** To make SPI flash drivers more stable, the legacy SPI flash driver is removed from v5.0. The legacy SPI flash driver refers to default spi_flash driver since v3.0, and the SPI flash driver with configuration option CONFIG_SPI_FLASH_USE_LEGACY_IMPL enabled since v4.0. The major breaking change here is that the legacy spi_flash driver is no longer supported from v5.0. Therefore, the legacy driver APIs and the CONFIG_SPI_FLASH_USE_LEGACY_IMPL configuration option are both removed. Please use the new spi_flash driver’s APIs instead.

<table>
<thead>
<tr>
<th>Removed Items</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>spi_flash_erase_sector()</td>
<td>esp_flash_erase_region()</td>
</tr>
<tr>
<td>spi_flash_erase_range()</td>
<td>esp_flash_erase_region()</td>
</tr>
<tr>
<td>spi_flash_write()</td>
<td>esp_flash_write()</td>
</tr>
<tr>
<td>spi_flash_read()</td>
<td>esp_flash_read()</td>
</tr>
<tr>
<td>spi_flash_write_encrypted()</td>
<td>esp_flash_write_encrypted()</td>
</tr>
<tr>
<td>spi_flash_read_encrypted()</td>
<td>esp_flash_read_encrypted()</td>
</tr>
</tbody>
</table>

**Note:** New functions with prefix esp_flash accept an additional esp_flash_t* parameter. You can simply set it to NULL. This will make the function to run the main flash (esp_flash_default_chip).

The esp_spi_flash.h header is deprecated as system functions are no longer public. To use flash memory mapping APIs, you may include spi_flash_mmap.h instead.

**System**
Chapter 5. Migration Guides

**Inter-Processor Call**  
IPC (Inter-Processor Call) feature is no longer a stand-alone component and has been integrated into the `esp_system` component.  
Thus, any project presenting a `CMakeLists.txt` file with the parameters `PRIV_REQUIRES esp_ipc` or `REQUIRES esp_ipc` should be modified to simply remove these options as the `esp_system` component is included by default.

**ESP Clock**  
The ESP Clock API (functions/types/macros prefixed with `esp_clk`) has been made into a private API. Thus, the previous include paths `#include "ESP32/clk.h"` and `#include "esp_clk.h"` have been removed. If users still require usage of the ESP Clock API (though this is not recommended), it can be included via `#include "esp_private/esp_clk.h"`.

**Cache Error Interrupt**  
The Cache Error Interrupt API (functions/types/macros prefixed with `esp_cache_err`) has been made into a private API. Thus, the previous include path `#include "ESP32/cache_err_int.h"` has been removed. If users still require usage of the Cache Error Interrupt API (though this is not recommended), it can be included via `#include "esp_private/cache_err_int.h"`.

**bootloader_support**  
- The function `bootloader_common_get_reset_reason()` has been removed. Please use the function `esp_rom_get_reset_reason()` in the ROM component.
- The functions `esp_secure_boot_verify_sha2_signature_block()` and `esp_secure_boot_verify_rsa_signature_block()` have been removed without replacement. We do not expect users to use these directly. If they are indeed still necessary, please open a feature request on GitHub explaining why these functions are necessary to you.

**Brownout**  
The Brownout API (functions/types/macros prefixed with `esp_brownout`) has been made into a private API. Thus, the previous include path `#include "brownout.h"` has been removed. If users still require usage of the Brownout API (though this is not recommended), it can be included via `#include "esp_private/brownout.h"`.

**Trax**  
The Trax API (functions/types/macros prefixed with `trax_`) has been made into a private API. Thus, the previous include path `#include "trax.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/trax.h"`.

**ROM**  
The previously deprecated ROM-related header files located in `components/esp32/rom/` (old include path: `rom/*.h`) have been moved. Please use the new target-specific path from `components/esp_rom/include/ESP32/` (new include path: `ESP32/rom/*.h`).

**esp_hw_support**  
- The header files `soc/cpu.h` have been deleted and deprecated CPU util functions have been removed. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header files `hal/cpu_ll.h`, `hal/cpu_hal.h`, `hal/soc_ll.h`, `hal/soc_hal.h` and `interrupt_controller_hal.h` CPU API functions have been deprecated. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header file `compare_set.h` have been deleted. ESP-IDF developers should use `esp_cpu_compare_and_set()` function provided in `esp_cpu.h` instead.
• `esp_cpu_get_ccount()`, `esp_cpu_set_ccount()` and `esp_cpu_in OCD_debug_mode()` were removed from `esp_cpu.h`. ESP-IDF developers should use respectively `esp_cpu_get_cycle_count()`, `esp_cpu_set_cycle_count()` and `esp_cpu_dbg_is_attached()` instead.

• The header file `esp_intr.h` has been deleted. Please include `esp_intr_alloc.h` to allocate and manipulate interrupts.

• The Panic API (functions/types/macros prefixed with `esp_panic`) has been made into a private API. Thus, the previous include path `#include "esp_panic.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/panic_reason.h"`. Besides, developers should include `esp_debug_helpers.h` instead to use any debug-related helper functions, e.g., print backtrace.

• The header file `soc_log.h` is now renamed to `esp_hw_log.h` and has been made private. Users are encouraged to use logging APIs provided under `esp_log.h` instead.

• The header files `spinlock.h`, `clk_ctrl_os.h`, and `rtc_wdt.h` must now be included without the `soc` prefix. For example, `#include "spinlock.h"`.

• `esp_chip_info()` returns the chip version in the format `= 100 * major eFuse version + minor eFuse version`. Thus, the revision in the `esp_chip_info_t` structure is expanded to `uint16_t` to fit the new format.

PSRAM

• The target-specific header file `spiram.h` and the header file `esp_spiram.h` have been removed. A new component `esp_psram` is created instead. For PSRAM/SPIRAM-related functions, users now include `esp_psram.h` and set the `esp_psram` component as a component requirement in their `CMakeLists.txt` project files.

• `esp_spiram_get_chip_size` and `esp_spiram_get_size` have been deleted. You should use `esp_psram_get_size` instead.

eFuse

• The parameter type of function `esp_secure_boot_read_key_digests()` changed from `ets_secure_boot_key_digests_t*` to `esp_secure_boot_key_digests_t*`. The new type is the same as the old one, except that the `allow_key_revoke` flag has been removed. The latter was always set to `true` in current code, not providing additional information.

• Added eFuse wafer revisions: major and minor. The `esp_efuse_get_chip_ver()` API is not compatible with these changes, so it was removed. Instead, please use the following APIs: `efuse_hal_get_major_chip_version()`, `efuse_hal_get_minor_chip_version()` or `efuse_hal_chip_revision()`.

esp_common

`EXT_RAM_ATTR` is deprecated. Use the new macro `EXT_RAM_BSS_ATTR` to put `.bss` on PSRAM.

esp_system

• The header files `esp_random.h`, `esp_mac.h`, and `esp_chip_info.h`, which were all previously indirectly included via the header file `esp_system.h`, must now be included directly. These indirect inclusions from `esp_system.h` have been removed.

• The Backtrace Parser API (functions/types/macros prefixed with `esp_eh_frame_`) has been made into a private API. Thus, the previous include path `#include "eh_frame_parser.h"` has been removed. If users still require usage of the Backtrace Parser API (though this is not recommended), it can be included via `#include "esp_private/eh_frame_parser.h"`.

• The Interrupt Watchdog API (functions/types/macros prefixed with `esp_int_wdt_`) has been made into a private API. Thus, the previous include path `#include "esp_int_wdt.h"` has been removed. If users still require usage of the Interrupt Watchdog API (though this is not recommended), it can be included via `#include "esp_private/esp_int_wdt.h"`. 
SOC Dependency

- Public API headers listed in the Doxyfiles will not expose unstable and unnecessary soc header files, such as `soc/soc.h` and `soc/rtc.h`. That means the user has to explicitly include them in their code if these “missing” header files are still wanted.
- Kconfig option `LEGACY_INCLUDE_COMMON_HEADERS` is also removed.
- The header file `soc/soc_memory_types.h` has been deprecated. Users should use the `esp_memory_utils.h` instead. Including `soc/soc_memory_types.h` will bring a build warning like `soc_memory_types.h is deprecated, please migrate to esp_memory_utils.h`.

APP Trace

One of the timestamp sources has changed from the legacy timer group driver to the new `GPTimer`. Kconfig choices like `APPTTRACE_SV_TS_SOURCE_TIMER00` has been changed to `APPTTRACE_SV_TS_SOURCE_GPTIMER`. User no longer need to choose the group and timer ID.

esp_timer

The FRC2-based legacy implementation of esp_timer available on ESP32 has been removed. The simpler and more efficient implementation based on the LAC timer is now the only option.

ESP Image

The image SPI speed enum definitions have been renamed.

- Enum `ESP_IMAGE_SPI_SPEED_80M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_1`.
- Enum `ESP_IMAGE_SPI_SPEED_40M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_2`.
- Enum `ESP_IMAGE_SPI_SPEED_26M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_3`.
- Enum `ESP_IMAGE_SPI_SPEED_20M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_4`.

Task Watchdog Timers

- The API for `esp_task_wdt_init()` has changed as follows:
  - Configuration is now passed as a configuration structure.
  - The function will now handle subscribing of the idle tasks if configured to do so.
- The former `CONFIG_ESP_TASK_WDT` configuration option has been renamed to `CONFIG_ESP_TASK_WDT_INIT` and a new `CONFIG_ESP_TASK_WDT_EN` option has been introduced.

FreeRTOS

Legacy API and Data Types

Previously, the `configENABLE_BACKWARD_COMPATIBILITY` option was set by default, thus allowing pre FreeRTOS v8.0.0 function names and data types to be used. The `configENABLE_BACKWARD_COMPATIBILITY` is now disabled by default, thus legacy FreeRTOS names/types are no longer supported by default. Users should do one of the followings:

- Update their code to remove usage of legacy FreeRTOS names/types.
- Enable the `CONFIG_FREERTOS_ENABLE_BACKWARD_COMPATIBILITY` to explicitly allow the usage of legacy names/types.

Tasks Snapshot

The header `task_snapshot.h` has been removed from `freertos/task.h`. ESP-IDF developers should include `freertos/task_snapshot.h` if they need tasks snapshot API.

The function `vTaskGetSnapshot()` now returns `BaseType_t`. Return value shall be `pdTRUE` on success and `pdFALSE` otherwise.

FreeRTOS Asserts

Previously, FreeRTOS asserts were configured separately from the rest of the system using the `FREERTOS_ASSERT` kconfig option. This option has now been removed and the configuration is now done through `COMPILER_OPTIMIZATION_ASSERTION_LEVEL`.
Port Macro API  The file `portmacro_deprecated.h` which was added to maintain backward compatibility for deprecated APIs is removed. Users are advised to use the alternate functions for the deprecated APIs as listed below:

- `portENTER_CRITICAL_NESTED()` is removed. Users should use the `port_SET_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `portEXIT_CRITICAL_NESTED()` is removed. Users should use the `port_CLEAR_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `vPortCPUInitializeMutex()` is removed. Users should use the `spinlock_initialize()` function instead.
- `vPortCPUAcquireMutex()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUAcquireMutexTimeout()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUReleaseMutex()` is removed. Users should use the `spinlock_release()` function instead.

App Update

- The functions `esp_ota_get_app_description()` and `esp_ota_get_app_elf_sha256()` have been termed as deprecated. Please use the alternative functions `esp_app_get_description()` and `esp_app_get_elf_sha256()` respectively. These functions have now been moved to a new component `esp_app_format`. Please refer to the header file `esp_app_desc.h`.

Bootloader Support

- The `esp_app_desc_t` structure, which used to be declared in `esp_app_format.h`, is now declared in `esp_app_desc.h`.
- The function `bootloader_common_get_partition_description()` has now been made private. Please use the alternative function `esp_ota_get_partition_description()`. Note that this function takes `esp_partition_t` as its first argument instead of `esp_partition_pos_t`.

Chip Revision  The bootloader checks the chip revision at the beginning of the application loading. The application can only be loaded if the version is >= `CONFIG_ESP32_REV_MIN` and < `CONFIG_ESP32_REV_MAX_FULL`.

During the OTA upgrade, the version requirements and chip revision in the application header are checked for compatibility. The application can only be updated if the version is >= `CONFIG_ESP32_REV_MIN` and < `CONFIG_ESP32_REV_MAX_FULL`.

Tools

IDF Monitor  IDF Monitor makes the following changes regarding baud-rate:

- IDF monitor now uses the custom console baud-rate (`CONFIG_ESP_CONSOLE_UART_BAUDRATE`) by default instead of 115200.
- Setting a custom baud from menuconfig is no longer supported.
- A custom baud-rate can be specified from command line with the `idf.py monitor -b <baud>` command or through setting environment variables.
- Please note that the baud-rate argument has been renamed from `-B` to `-b` in order to be consistent with the global baud-rate `idf.py -b <baud>`. Run `idf.py monitor --help` for more information.
**Deprecated Commands**  
`idf.py` sub-commands and `cmake` target names have been unified to use hyphens (-) instead of underscores (_). Using a deprecated sub-command or target name will produce a warning. Users are advised to migrate to using the new sub-commands and target names. The following changes have been made:

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>efuse_common_table</td>
<td>efuse-common-table</td>
</tr>
<tr>
<td>efuse_custom_table</td>
<td>efuse-custom-table</td>
</tr>
<tr>
<td>erase_flash</td>
<td>erase-flash</td>
</tr>
<tr>
<td>partition_table</td>
<td>partition-table</td>
</tr>
<tr>
<td>partition_table-flash</td>
<td>partition-table-flash</td>
</tr>
<tr>
<td>post_debug</td>
<td>post-debug</td>
</tr>
<tr>
<td>show_efuse_table</td>
<td>show-efuse-table</td>
</tr>
<tr>
<td>erase_otadata</td>
<td>erase-otadata</td>
</tr>
<tr>
<td>read_otadata</td>
<td>read-otadata</td>
</tr>
</tbody>
</table>

**Esptool**  
The `CONFIG_ESPTOOLPY_FLASHSIZE_DETECT` option has been renamed to `CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE` and has been disabled by default. New and existing projects migrated to ESP-IDF v5.0 will have to set `CONFIG_ESPTOOLPY_FLASHSIZE`. If this is not possible due to an unknown flash size at build time, then `CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE` can be enabled. However, once enabled, to keep the digest valid, a SHA256 digest will no longer be appended to the image when updating the binary header with the flash size during flashing.

**Windows Environment**  
The Msys/Mingw-based Windows environment support got deprecated in ESP-IDF v4.0 and was entirely removed in v5.0. Please use ESP-IDF Tools Installer to set up a compatible environment. The options include Windows Command Line, Power Shell and the graphical user interface based on Eclipse IDE. In addition, a VS Code-based environment can be set up with the supported plugin: https://github.com/espressif/vscode-esp-idf-extension.

### 5.1.2 Migration from 5.0 to 5.1

**GCC**

**GCC Version**  
The previous GCC version was GCC 11.2.0. This has now been upgraded to GCC 12.2.0 on all targets. Users that need to port their code from GCC 11.2.0 to 12.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 12

**Warnings**  
The upgrade to GCC 12.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user’s code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter and ways to fix them.
-Wuse-after-free  Typically, this warning should not produce false-positives for release-level code. But this may appear in test cases. There is an example of how it was fixed in IDF’s test_realloc.c.

```c
void *x = malloc(64);
void *y = realloc(x, 48);
TEST_ASSERT_EQUAL_PTR(x, y);
```

Pointers may be converted to int to avoid warning -Wuse-after-free.

```c
int x = (int) malloc(64);
int y = (int) realloc((void *) x, 48);
TEST_ASSERT_EQUAL_UINT32((uint32_t) x, (uint32_t) y);
```

-Waddress  GCC 12.2.0 introduces an enhanced version of the -Waddress warning option, which is now more eager in detecting the checking of pointers to an array in if-statements.

The following code will trigger the warning:

```c
char array[8];
...
if (array)
    memset(array, 0xff, sizeof(array));
```

Eliminating unnecessary checks resolves the warning.

```c
char array[8];
...
memset(array, 0xff, sizeof(array));
```

RISC-V Builds Outside of IDF  The RISC-V extensions zicsr and zifencei have been separated from the I extension. GCC 12 reflects this change, and as a result, when building for RISC-V ESP32 chips outside of the IDF framework, you must include the _zicsr_zifencei postfix when specifying the -march option in your build system.

Example:

```
riscv32-esp-elf-gcc main.c -march=rv32imac
```

Now is replaced with:

```
riscv32-esp-elf-gcc main.c -march=rv32imac_zicsr_zifencei
```

Peripherals

DAC  DAC driver has been redesigned (see DAC API Reference), which aims to unify the interface and extend the usage of DAC peripheral. Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path driver/dac.h. However, by default, including driver/dac.h will bring a build warning like The legacy DAC driver is deprecated, please use 'driver/dac_oneshot.h', 'driver/dac_cosine.h' or 'driver/dac_continuous.h' instead. The warning can be suppressed by the Kconfig option CONFIG_DAC_SUPPRESS_DEPRECATED_WARN.

The major breaking changes in concept and usage are listed as follows:
Breaking Changes in Concepts

- `dac_channel_t` which was used to identify the hardware channel are removed from user space. The channel index now starts from 0, so please use `DAC_CHAN_0` and `DAC_CHAN_1` instead. And in the new driver, DAC channels can be selected by using `dac_channel_mask_t`. And these channels can be allocated in a same channel group which is represented by `dac_channels_handle_t`.
- `dac_cw_scale_t` is replaced by `dac_cosine_atten_t` to decouple the legacy driver and the new driver.
- `dac_cw_phase_t` is replaced by `dac_cosine_phase_t`. The enumerate value is now the phase angle directly.
- `dac_cw_config_t` is replaced by `dac_cosine_config_t`, but the `en_ch` field is removed because it should be specified while allocating the channel group.

Breaking Changes in Usage

- `dac_pad_get_io_num` is removed.
- `dac_output_voltage` is replaced by `dac_oneshot_output_voltage()`.
- `dac_output_enable` is removed. For oneshot mode, it will be enabled after the channel is allocated.
- `dac_output_disable` is removed. For oneshot mode, it will be disabled before the channel is deleted.
- `dac_cw_generator_enable` is replaced by `dac_cosine_start()`.
- `dac_cw_generator_disable` is replaced by `dac_cosine_stop()`.
- `dac_cw_generator_config` is replaced by `dac_cosine_new_channel()`.
- `dac_i2s_enable` is replaced by `dac_continuous_enable()`, but it needs to allocate the continuous DAC channel first by `dac_continuous_new_channels()`.
- `dac_i2s_disable` is replaced by `dac_continuous_disable()`.

GPSPI  Following items are deprecated. Since ESP-IDF v5.1, GPSPI clock source is configurable.

- `spi_get_actual_clock` is deprecated, you should use `spi_device_get_actual_freq()` instead.

LEDC

- `soc_periph_ledc_clk_src_legacy_t::LEDC_USE_RTC8M_CLK` is deprecated. Please use `LEDC_USE_RC_FAST_CLK` instead.

Storage

FatFs  `esp_vfs_fat_sdmcc_unmount()` is now deprecated, you can use `esp_vfs_fat_sdcard_unmount()` instead. This API is deprecated in previous IDF versions, but without deprecation warning and migration guide. Since IDF v5.1, calling this `esp_vfs_fat_sdmcc_unmount()` API will generate deprecation warning.

SPI_FLASH

- `spi_flash_get_counters()` is deprecated, please use `esp_flash_get_counters()` instead.
- `spi_flash_dump_counters()` is deprecated, please use `esp_flash_dump_counters()` instead.
- `spi_flash_reset_counters()` is deprecated, please use `esp_flash_reset_counters()` instead.
Networking

SNTP  SNTP module now provides thread safe APIs to access lwIP functionality. It’s recommended to use ESP_NETIF API. Please refer to the chapter SNTP API for more details.

System

FreeRTOS

Dynamic Memory Allocation  Previously, most FreeRTOS dynamic allocation would eventually call to malloc(). Thus, if an application was configured to allow malloc() to allocate from external RAM (i.e., CONFIG_SPIRAM_USE was set CONFIG_SPIRAM_USE_MALLOC), then there was a possibility that FreeRTOS could allocate dynamic memory from external RAM, with the exact placement being decided by the heap allocator.

Note:  Dynamic memory allocation for tasks (which are likely to consume the most memory) were an exception to the scenario above. FreeRTOS would use a separate memory allocation function to guarantee that dynamic memory allocate for a task was always placed in internal RAM.

Allowing FreeRTOS objects (such as queues and semaphores) to be placed in external RAM becomes an issue if those objects are accessed while the cache is disabled (such as during SPI Flash write operations) and would lead to a cache access errors (see Fatal Errors for more details).

Therefore, FreeRTOS has been updated to always use internal memory (i.e., DRAM) for dynamic memory allocation. Calling FreeRTOS creation functions (e.g., xTaskCreate(), xQueueCreate()) will guarantee that the memory allocated for those tasks/objects is from internal memory (see FreeRTOS Heap for more details).

Warning:  For users that previously relied on CONFIG_SPIRAM_USE to place FreeRTOS objects into external memory, this change will lead to increased usage of internal memory due the FreeRTOS objects now being allocated there.

Users that want to place a FreeRTOS task/object into external memory will now need to do so explicitly. Users can use one of the following methods:

• Allocate the task/object using one of the ...CreateWithCaps() API such as xTaskCreateWithCaps() and xQueueCreateWithCaps() (see IDF Additional API for more details).
• Manually allocate external memory for those objects using heap_caps_malloc(), then create the objects from the allocated memory using one of the ...CreateStatic() FreeRTOS functions.

Power Management

• esp_pm_config.esp32xx_t is deprecated, use esp_pm_config_t instead.
• esp32xx/pm.h is deprecated, use esp_pm.h instead.
Chapter 6

Libraries and Frameworks

6.1 Cloud Frameworks

ESP32 supports multiple cloud frameworks using agents built on top of ESP-IDF. Here are the pointers to various supported cloud frameworks’ agents and examples:

6.1.1 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. ESP RainMaker on GitHub.

6.1.2 AWS IoT

https://github.com/espressif/esp-aws-iot is an open source repository for ESP32 based on Amazon Web Services’ aws-iot-device-sdk-embedded-C.

6.1.3 Azure IoT

https://github.com/espressif/esp-azure is an open source repository for ESP32 based on Microsoft Azure’s azure-iot-sdk-c SDK.

6.1.4 Google IoT Core

https://github.com/espressif/esp-google-iot is an open source repository for ESP32 based on Google’s iot-device-sdk-embedded-c SDK.

6.1.5 Aliyun IoT

https://github.com/espressif/esp-aliyun is an open source repository for ESP32 based on Aliyun’s iotkit-embedded SDK.

6.1.6 Joylink IoT

https://github.com/espressif/esp-joylink is an open source repository for ESP32 based on Joylink’s joylink_dev_sdk SDK.
Chapter 6. Libraries and Frameworks

6.1.7 Tencent IoT

https://github.com/espressif/esp-welink is an open source repository for ESP32 based on Tencent’s welink SDK.

6.1.8 Tencentyun IoT

https://github.com/espressif/esp-qcloud is an open source repository for ESP32 based on Tencentyun’s qcloud-iot-sdk-embedded-c SDK.

6.1.9 Baidu IoT

https://github.com/espressif/esp-baidu-iot is an open source repository for ESP32 based on Baidu’s iot-sdk-c SDK.

6.2 Espressif’s Frameworks

Here you will find a collection of the official Espressif libraries and frameworks.

6.2.1 Espressif Audio Development Framework

The ESP-ADF is a comprehensive framework for audio applications including:

- CODEC’s HAL
- Music Players and Recorders
- Audio Processing
- Bluetooth Speakers
- Internet Radios
- Hands-free devices
- Speech Recognition

This framework is available at GitHub: ESP-ADF.

6.2.2 ESP-CSI

ESP-CSI is an experimental implementation that uses the Wi-Fi Channel State Information to detect the presence of a human body.

See ESP-CSI project for more information about it.

6.2.3 Espressif DSP Library

The library provides algorithms optimized specifically for digital signal processing applications. This library supports:

- Matrix multiplication
- Dot product
- FFT (Fast Fourier Transform)
- IIR (Infinite Impulse Response)
- FIR (Finite Impulse Response)
- Vector math operations

This library is available here: ESP-DSP library.
6.2.4 ESP-WIFI-MESH Development Framework

This framework is based on the ESP-WIFI-MESH protocol with the following features:

- Fast network configuration
- Stable upgrade
- Efficient debugging
- LAN control
- Various application demos

ESP-MDF.

6.2.5 ESP-WHO

The ESP-WHO is a face detection and recognition framework using the ESP32 and camera. To know more about the project, see ESP-WHO on GitHub.

6.2.6 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. Using ESP RainMaker, you can create AIoT devices from the firmware to the integration with voice-assistant, phone apps and cloud backend.

ESP RainMaker on GitHub.

6.2.7 ESP-IoT-Solution

ESP-IoT-Solution contains commonly used device drivers and code frameworks when developing IoT systems. The device drivers and code frameworks within the ESP-IoT-Solution are organized as separate components, allowing them to be easily integrated into an ESP-IDF project.

ESP-IoT-Solution includes:

- Device drivers for sensors, display, audio, GUI, input, actuators, etc.
- Framework and documentation for low power, security, storage, etc.
- Guide for Espressif open source solutions from practical application point.

ESP-IoT-Solution on GitHub.

6.2.8 ESP-Protocols

ESP-Protocols repository contains collection of protocol components for ESP-IDF. The code within the ESP-Protocols is organized into separate components, allowing them to be easily integrated into an ESP-IDF project. In addition to that, each component is available in IDF Component Registry.

ESP-Protocols components:

- esp_modem enables connectivity with GSM/LTE modems using AT commands or PPP protocol, see the esp_modem documentation.
- mdns (mDNS) is a multicast UDP service that is used to provide local network service and host discovery, see the mdns documentation.
- esp_websocket_client is a managed component for esp-idf that contains implementation of [WebSocket protocol client](https://datatracker.ietf.org/doc/html/rfc6455) for ESP32, see the esp_websocket_client documentation.
- asio is a cross-platform C++ library, see [https://think-async.com/Asio/](https://think-async.com/Asio/). It provides a consistent asynchronous model using a modern C++ approach. , see the asio documentation.
6.2.9 ESP-BSP

ESP-BSP repository contains Board Support Packages (BSPs) for various Espressif’s and 3rd party development boards. BSPs are useful for quick start on a supported board. Usually they contain pinout definition and helper functions, that will initialize peripherals for the specific board. Additionally, the BSP would contain drivers for external chips populated on the development board, such as sensors, displays, audio codecs etc.

6.2.10 ESP-IDF-CXX

ESP-IDF-CXX contains C++ wrappers for part of ESP-IDF. The focus is on ease of use, safety, automatic resource management and shifting checks to compile time instead of failing at run time. There are C++ classes for ESP-Timer, I2C, SPI, GPIO and other peripherals or features of ESP-IDF. ESP-IDF-CXX is available as a component from the component registry. Please check the project’s README.md for more information.
Chapter 7

Contributions Guide

We welcome contributions to the esp-idf project!

7.1 How to Contribute

Contributions to esp-idf - fixing bugs, adding features, adding documentation - are welcome. We accept contributions via Github Pull Requests.

7.2 Before Contributing

Before sending us a Pull Request, please consider this list of points:

• Is the contribution entirely your own work, or already licensed under an Apache License 2.0 compatible Open Source License? If not then we unfortunately cannot accept it. Please check the Copyright Header Guide for additional information.
• Does any new code conform to the esp-idf Style Guide?
• Have you installed the pre-commit hook for esp-idf project?
• Does the code documentation follow requirements in Documenting Code?
• Is the code adequately commented for people to understand how it is structured?
• Is there documentation or examples that go with code contributions? There are additional suggestions for writing good examples in examples readme.
• Are comments and documentation written in clear English, with no spelling or grammar errors?
• Example contributions are also welcome. Please check the Creating Examples guide for these.
• If the contribution contains multiple commits, are they grouped together into logical changes (one major change per pull request)? Are any commits with names like “fixed typo” squashed into previous commits?
• If you’re unsure about any of these points, please open the Pull Request anyhow and then ask us for feedback.

7.3 Pull Request Process

After you open the Pull Request, there will probably be some discussion in the comments field of the request itself. Once the Pull Request is ready to merge, it will first be merged into our internal git system for in-house automated testing. If this process passes, it will be merged onto the public github repository.
7.4 Legal Part

Before a contribution can be accepted, you will need to sign our *Contributor Agreement*. You will be prompted for this automatically as part of the Pull Request process.

7.5 Related Documents

7.5.1 Espressif IoT Development Framework Style Guide

About This Guide

Purpose of this style guide is to encourage use of common coding practices within the ESP-IDF.

Style guide is a set of rules which are aimed to help create readable, maintainable, and robust code. By writing code which looks the same way across the code base we help others read and comprehend the code. By using same conventions for spaces and newlines we reduce chances that future changes will produce huge unreadable diffs. By following common patterns for module structure and by using language features consistently we help others understand code behavior.

We try to keep rules simple enough, which means that they can not cover all potential cases. In some cases one has to bend these simple rules to achieve readability, maintainability, or robustness.

When doing modifications to third-party code used in ESP-IDF, follow the way that particular project is written. That will help propose useful changes for merging into upstream project.

C Code Formatting

Naming

- Any variable or function which is only used in a single source file should be declared `static`.
- Public names (non-static variables and functions) should be namespaced with a per-component or per-unit prefix, to avoid naming collisions. ie `esp_vfs_register()` or `esp_console_run()`. Starting the prefix with `esp_` for Espressif-specific names is optional, but should be consistent with any other names in the same component.
- Static variables should be prefixed with `s_` for easy identification. For example, `static bool s_invert`.
- Avoid unnecessary abbreviations (ie shortening `data` to `dat`), unless the resulting name would otherwise be very long.

Indentation

Use 4 spaces for each indentation level. Don’t use tabs for indentation. Configure the editor to emit 4 spaces each time you press tab key.

Vertical Space

Place one empty line between functions. Don’t begin or end a function with an empty line.

```c
void function1()
{
    do_one_thing();
    do_another_thing();
    // INCORRECT, don't place empty line here
}

void function2()
{
    // INCORRECT, don't use an empty line here
    int var = 0;
    while (var < SOME_CONSTANT) {
        do_stuff(&var);
    }

    // place empty line here
}
```

(continues on next page)
The maximum line length is 120 characters as long as it doesn’t seriously affect the readability.

**Horizontal Space** Always add single space after conditional and loop keywords:

```c
if (condition) { // correct
  // ...
}
switch (n) { // correct
  case 0:
    // ...
}
for (int i = 0; i < CONST; ++i) { // INCORRECT
  // ...
}
```

Add single space around binary operators. No space is necessary for unary operators. It is okay to drop space around multiply and divide operators:

```c
const int y = y0 + (x - x0) * (y1 - y0) / (x1 - x0); // correct
const int y = y0 + (x - x0)*(y1 - y0)/(x1 - x0); // also okay
int y_cur = -y;
++y_cur;
const int y = y0+(x-x0)*(y1-y0)/(x1-x0); // INCORRECT
```

No space is necessary around . and -> operators.

Sometimes adding horizontal space within a line can help make code more readable. For example, you can add space to align function arguments:

```c
esp_rom_gpio_connect_in_signal(PIN_CAM_D6, I2S0I_DATA_IN14_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_D7, I2S0I_DATA_IN15_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_HREF, I2S0I_H_ENABLE_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_PCLK, I2S0I_DATA_IN15_IDX, false);
```

Note however that if someone goes to add new line with a longer identifier as first argument (e.g. PIN_CAM_VSYNC), it will not fit. So other lines would have to be realigned, adding meaningless changes to the commit.

Therefore, use horizontal alignment sparingly, especially if you expect new lines to be added to the list later.

Never use TAB characters for horizontal alignment.

Never add trailing whitespace at the end of the line.

**Braces**

- Function definition should have a brace on a separate line:

```c
// This is correct:
void function(int arg)
{
}
```

(continues on next page)
• Within a function, place opening brace on the same line with conditional and loop statements:

```c
if {condition} {
    do_one();
} else if {other_condition} {
    do_two();
}
```

**Comments** Use `//` for single line comments. For multi-line comments it is okay to use either `//` on each line or a `/* */` block.

Although not directly related to formatting, here are a few notes about using comments effectively.

• Don’t use single comments to disable some functionality:

```c
void init_something()
{
    setup_dma();
    // load_resources(); // WHY is this thing commented, asks-the reader?
    start_timer();
}
```

• If some code is no longer required, remove it completely. If you need it you can always look it up in git history of this file. If you disable some call because of temporary reasons, with an intention to restore it in the future, add explanation on the adjacent line:

```c
void init_something()
{
    setup_dma();
    // TODO: we should load resources here, but loader is not fully integrated-yet.
    // load_resources();
    start_timer();
}
```

• Same goes for `#if 0 ... #endif` blocks. Remove code block completely if it is not used. Otherwise, add comment explaining why the block is disabled. Don’t use `#if 0 ... #endif` or comments to store code snippets which you may need in the future.

• Don’t add trivial comments about authorship and change date. You can always look up who modified any given line using git. E.g. this comment adds clutter to the code without adding any useful information:

```c
void init_something()
{
    setup_dma();
    // XXX add 2016-09-01
    init_dma_list();
    fill_dma_item(0);
    // end XXX add
    start_timer();
}
```

**Line Endings** Commits should only contain files with LF (Unix style) endings.

Windows users can configure git to check out CRLF (Windows style) endings locally and commit LF endings by setting the `core.autocrlf` setting. [Github has a document about setting this option](https://help.github.com/articles/setting-up-git-to-work-with-both-crlf-and-lf/).
If you accidentally have some commits in your branch that add LF endings, you can convert them to Unix by running this command in an MSYS2 or Unix terminal (change directory to the IDF working directory and check the correct branch is currently checked out, beforehand):

```
git rebase --exec 'git diff-tree --no-commit-id --name-only -r HEAD | xargs --dos2unix &
git commit --amend --no-edit --allow-empty' master
```

(Note that this line rebases on master, change the branch name at the end to rebase on another branch.)

For updating a single commit, it’s possible to run `dos2unix FILENAME` and then run `git commit --amend`

### Formatting Your Code

You can use `astyle` program to format your code according to the above recommendations.

If you are writing a file from scratch, or doing a complete rewrite, feel free to re-format the entire file. If you are changing a small portion of file, don’t re-format the code you didn’t change. This will help others when they review your changes.

To re-format a file, run:

```
tools/format.sh components/my_component/file.c
```

### Type Definitions

Should be snake_case, ending with `_t` suffix:

```c
typedef int signed_32_bit_t;
```

### Enum

Enums should be defined through the `typedef` and be namespaced:

```c
typedef enum
{
    MODULE_FOO_ONE,
    MODULE_FOO_TWO,
    MODULE_FOO_THREE
} module_foo_t;
```

### Assertions

The standard C `assert()` function, defined in `assert.h` should be used to check conditions that should be true in source code. In the default configuration, an assertion that returns `false` or `0` will call `abort()` and trigger a **Fatal Error**.

`assert()` should only be used to detect unrecoverable errors due to a serious internal logic bug or corruption, where it’s not possible for the program to continue. For recoverable errors, including errors that are possible due to invalid external input, an **error value should be returned**.

**Note:** When asserting a value of type `esp_err_t` is equal to `ESP_OK`, use the `ESP_ERROR_CHECK` macro instead of an `assert()`.

It’s possible to configure ESP-IDF projects with assertions disabled (see `CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL`). Therefore, functions called in an `assert()` statement should not have side-effects.

It’s also necessary to use particular techniques to avoid “variable set but not used” warnings when assertions are disabled, due to code patterns such as:

```c
int res = do_something();
assert(res == 0);
```
Once the `assert` is optimized out, the `res` value is unused and the compiler will warn about this. However the function `do_something()` must still be called, even if assertions are disabled.

When the variable is declared and initialized in a single statement, a good strategy is to cast it to `void` on a new line. The compiler will not produce a warning, and the variable can still be optimized out of the final binary:

```c
int res = do_something();
assert(res == 0);
(void)res;
```

If the variable is declared separately, for example if it is used for multiple assertions, then it can be declared with the GCC attribute `__attribute__((unused))`. The compiler will not produce any unused variable warnings, but the variable can still be optimized out:

```c
int res __attribute__((unused));
res = do_something();
assert(res == 0);
res = do_something_else();
assert(res != 0);
```

Header file guards

All public facing header files should have preprocessor guards. A `#pragma` is preferred:

```c
#pragma once
```

over the following pattern:

```c
#ifndef FILE_NAME_H
#define FILE_NAME_H
...
#endif // FILE_NAME_H
```

In addition to guard macros, all C header files should have `extern "C"` guards to allow the header to be used from C++ code. Note that the following order should be used: `#pragma once`, then any `#include` statements, then `extern "C"` guards:

```c
#pragma once
#include <stdint.h>
#ifdef __cplusplus
extern "C" {
#endif
/* declarations go here */
#ifdef __cplusplus
}
#endif
```

Include statements

When writing `#include` statements, try to maintain the following order:

- C standard library headers.
- Other POSIX standard headers and common extensions to them (such as `sys/queue.h`.)
- Common IDF headers (`esp_log.h`, `esp_system.h`, `esp_timer.h`, `esp_sleep.h`, etc.)
• Headers of other components, such as FreeRTOS.
• Public headers of the current component.
• Private headers.

Use angle brackets for C standard library headers and other POSIX headers (\#include <stdio.h>).
Use double quotes for all other headers (\#include "esp_log.h").

**C++ Code Formatting**

The same rules as for C apply. Where they are not enough, apply the following rules.

**File Naming**  C++ Header files have the extension .hpp. C++ source files have the extension .cpp. The latter is important for the compiler to distinguish them from normal C source files.

**Naming**

• **Class and struct** names shall be written in CamelCase with a capital letter as beginning. Member variables and methods shall be in snake_case. An exception from CamelCase is if the readability is severely decreased, e.g. in GPIOOutput, then an underscore _ is allowed to make it more readable: GPIO_Output.
• **Namespaces** shall be in lower snake_case.
• **Templates** are specified in the line above the function declaration.
• Interfaces in terms of Object-Oriented Programming shall be named without the suffix ...Interface. Later, this makes it easier to extract interfaces from normal classes and vice versa without making a breaking change.

**Member Order in Classes**  In order of precedence:

• First put the public members, then the protected, then private ones. Omit public, protected or private sections without any members.
• First put constructors/destructors, then member functions, then member variables.

For example:

```cpp
class ForExample {
public:
    // first constructors, then default constructor, then destructor
    ForExample(double example_factor_arg);
    ForExample();
    ~ForExample();

    // then remaining public methods
    set_example_factor(double example_factor_arg);

    // then public member variables
    uint32_t public_data_member;

private:
    // first private methods
    void internal_method();

    // then private member variables
    double example_factor;
};
```

**Spacing**

• Don’t indent inside namespaces.
• Put public, protected and private labels at the same indentation level as the corresponding class label.

Simple Example

```c++
// file spaceship.h
#ifndef SPACESHIP_H_
#define SPACESHIP_H_
#include <cstdlib>
namespace spaceships {

class SpaceShip {
public:
    SpaceShip(size_t crew);
    size_t get_crew_size() const;

private:
    const size_t crew;
};

class SpaceShuttle: public SpaceShip {
public:
    SpaceShuttle();
};

class Sojuz: public SpaceShip {
public:
    Sojuz();
};
template<typename T>
class CargoShip {
public:
    CargoShip(const T &cargo);

private:
    T cargo;
};
} // namespace spaceships
#endif // SPACESHIP_H_

// file spaceship.cpp
#include "spaceship.h"
namespace spaceships {

// Putting the curly braces in the same line for constructors is OK if it only initializes
// values in the initializer list
SpaceShip::SpaceShip(size_t crew) : crew(crew) { }

size_t SpaceShip::get_crew_size() const
{
    return crew;
}

SpaceShuttle::SpaceShuttle() : SpaceShip(7)
{
    // doing further initialization
}  
```

CMake Code Style

- Indent with four spaces.
- Maximum line length 120 characters. When splitting lines, try to focus on readability where possible (for example, by pairing up keyword/argument pairs on individual lines).
- Don’t put anything in the optional parentheses after endforeach(), endif(), etc.
- Use lowercase (with underscores) for command, function, and macro names.
- For locally scoped variables, use lowercase (with underscores).
- For globally scoped variables, use uppercase (WITH_UNDERSCORES).
- Otherwise follow the defaults of the cmake-lint project.

Configuring the Code Style for a Project Using EditorConfig

EditorConfig helps developers define and maintain consistent coding styles between different editors and IDEs. The EditorConfig project consists of a file format for defining coding styles and a collection of text editor plugins that enable editors to read the file format and adhere to defined styles. EditorConfig files are easily readable and they work nicely with version control systems.

For more information, see EditorConfig Website.

Third Party Component Code Styles

ESP-IDF integrates a number of third party components where these components may have differing code styles.

FreeRTOS  The code style adopted by FreeRTOS is described in the FreeRTOS style guide. Formatting of FreeRTOS source code is automated using Uncrustify, thus a copy of the FreeRTOS code style’s Uncrustify configuration (uncrustify.cfg) is stored within ESP-IDF FreeRTOS component.

If a FreeRTOS source file is modified, the updated file can be formatted again by following the steps below:

1. Ensure that Uncrustify (v0.69.0) is installed on your system
2. Run the following command on the update FreeRTOS source file (where source.c is the path to the source file that requires formatting).

```
uncrustify --c $IDF_PATH/components/freertos/FreeRTOS-Kernel/uncrustify.cfg --replace source.c --no-backup
```

Documenting Code

Please see the guide here: Documenting Code.
Chapter 7. Contributions Guide

Structure
To be written.

Language Features
To be written.

7.5.2 Install pre-commit Hook for ESP-IDF Project

Required Dependency
Python 3.7.* or above. This is our recommended python version for IDF developers.
If you still have python versions not compatible, update your python versions before installing the pre-commit hook.

Install pre-commit

Run `pip install pre-commit`

Install pre-commit hook

1. Go to the IDF Project Directory
2. Run `pre-commit install --allow-missing-config`. Install hook by this approach will let you commit successfully even in branches without the `.pre-commit-config.yaml`
3. `pre-commit` hook will run automatically when you’re running `git commit` command

Uninstall pre-commit

Run `pre-commit uninstall`

What’s More?

For detailed usage, please refer to the documentation of `pre-commit`.

Common Problems For Windows Users

/\usr/bin/env: python: Permission denied.
If you’re in Git Bash, please check the python executable location by run `which python`.
If the executable is under ~/AppData/Local/Microsoft/WindowsApps/; then it’s a link to Windows AppStore, not a real one.
Please install python manually and update this in your PATH environment variable.
Your %USERPROFILE% contains non-ASCII characters
`pre-commit` may fail when initializing an environment for a particular hook when the path of `pre-commit`’s cache contains non-ASCII characters. The solution is to set `PRE_COMMIT_HOME` to a path containing only standard characters before running pre-commit.

• CMD: `set PRE_COMMIT_HOME=C:\somepath\pre-commit`
• PowerShell: `$Env:PRE_COMMIT_HOME = "C:\somepath\pre-commit"
• git bash: `export PRE_COMMIT_HOME="/c/somepath/pre-commit"`
7.5.3 Documenting Code

The purpose of this description is to provide quick summary on documentation style used in `espressif/esp-idf` repository and how to add new documentation.

**Introduction**

When documenting code for this repository, please follow Doxygen style. You are doing it by inserting special commands, for instance `@param`, into standard comments blocks, for example:

```cpp
/**
 * @param ratio this is oxygen to air ratio
 */
```

Doxygen is phrasing the code, extracting the commands together with subsequent text, and building documentation out of it.

Typical comment block, that contains documentation of a function, looks like below.

Doxygen supports couple of formatting styles. It also gives you great flexibility on level of details to include in documentation. To get familiar with available features, please check data rich and very well organized Doxygen Manual.

**Why we need it?**

The ultimate goal is to ensure that all the code is consistently documented, so we can use tools like Sphinx and Breathe to aid preparation and automatic updates of API documentation when the code changes.

With these tools the above piece of code renders like below:
Go for it!

When writing code for this repository, please follow guidelines below.

1. Document all building blocks of code: functions, structs, typedefs, enums, macros, etc. Provide enough information about purpose, functionality and limitations of documented items, as you would like to see them documented when reading the code by others.

2. Documentation of function should describe what this function does. If it accepts input parameters and returns some value, all of them should be explained.

3. Do not add a data type before parameter or any other characters besides spaces. All spaces and line breaks are compressed into a single space. If you like to break a line, then break it twice.

4. If function has void input or does not return any value, then skip @param or @return.
5. When documenting a `define` as well as members of a `struct` or `enum`, place specific comment like below after each member.

```
/* <![CDATA[ */
/*!< how to documented members */
```

6. To provide well formatted lists, break the line after command (like `@return` in example below).

```
* @return
*   - ESP_OK if erase operation was successful
*   - ESP_ERR_NVS_INVALID_HANDLE if handle has been closed or is NULL
*   - ESP_ERR_NVS_READ_ONLY if handle was opened as read only
*   - ESP_ERR_NVS_NOT_FOUND if the requested key doesn't exist
*   - other error codes from the underlying storage driver
```

7. Overview of functionality of documented header file, or group of files that make a library, should be placed in a separate `README.rst` file of the same directory. If this directory contains header files for different APIs, then the file name should be `apiname-readme.rst`.

Go one extra mile

Here are a couple of tips on how you can make your documentation even better and more useful to the reader and writer.

When writing codes, please follow the guidelines below:

1. Add code snippets to illustrate implementation. To do so, enclose snippet using `@code(c)` and `@endcode` commands.

```
* @code(c)
* // Example of using nvs_get_i32:
* int32_t max_buffer_size = 4096; // default value
* esp_err_t err = nvs_get_i32(my_handle, "max_buffer_size", &max_buffer_size);
* assert(err == ESP_OK || err == ESP_ERR_NVS_NOT_FOUND);
* // if ESP_ERR_NVS_NOT_FOUND was returned, max_buffer_size will still
* // have its default value.
```

(continues on next page)
The code snippet should be enclosed in a comment block of the function that it illustrates.

2. To highlight some important information use command `@attention` or `@note`.

```
/*
* @attention
* 1. This API only impact WIFI_MODE_STA or WIFI_MODE_APSTA mode
* 2. If the ESP32 is connected to an AP, call esp_wifi_disconnect to disconnect.
*/
```

Above example also shows how to use a numbered list.

3. To provide common description to a group of similar functions, enclose them using `/**@{*/ and `/** @}*/` markup commands:

```
/**@{*/
/**
* @brief common description of similar functions
*
*/
void first_similar_function (void);
void second_similar_function (void);
/** @}*/
```

For practical example see `nvs_flash/include/nvs.h`.

4. You may want to go even further and skip some code like repetitive defines or enumerations. In such case, enclose the code within `/** @cond */ ` and `/** @endcond */ ` commands. Example of such implementation is provided in `driver/gpio/include/driver/gpio.h`.

5. Use markdown to make your documentation even more readable. You will add headers, links, tables and more.

```
```

**Note:** Code snippets, notes, links, etc. will not make it to the documentation, if not enclosed in a comment block associated with one of documented objects.

6. Prepare one or more complete code examples together with description. Place description to a separate file `README.md` in specific folder of `examples` directory.

**Standardize Document Format**

When it comes to text, please follow guidelines below to provide well formatted Markdown (.md) or reST (.rst) documents.

1. Please ensure that one paragraph is written in one line. Don’t break lines like below. Breaking lines to enhance readability is only suitable for writing codes. To make the text easier to read, it is recommended to place an empty line to separate the paragraph.

2. Please make the line number of CN and EN documents consistent like below. The benefit of this approach is that it can save time for both writers and translators. When non-bilingual writers need to update text, they only need to update the same line in the corresponding CN or EN document. For translators, if documents are updated in English, then translators can quickly locate where to update in the corresponding CN document later. Besides, by comparing the total number of lines in EN and CN documents, you can quickly find out whether the CN version lags behind the EN version.
Chapter 7. Contributions Guide

Fig. 1: One line for one paragraph (click to enlarge)

Fig. 2: No line breaks within the same paragraph (click to enlarge)

Fig. 3: Keep the line number for EN and CN documents consistent (click to enlarge)
Building Documentation

The documentation is built with the `esp-docs` Python package, which is a wrapper around Sphinx. To install it simply do:

```
pip install esp-docs
```

After a successful install then the documentation can be built from the docs folder with:

```
build-docs build
```

or for specific target and language with:

```
build-docs -t esp32 -l en build
```

For more in-depth documentation about `esp-docs` features please see the documentation at `esp-docs`.

Wrap up

We love good code that is doing cool things. We love it even better, if it is well documented, so we can quickly make it run and also do the cool things.

Go ahead, contribute your code and documentation!

- `API Documentation Template`

7.5.4 Creating Examples

Each ESP-IDF example is a complete project that someone else can copy and adapt the code to solve their own problem. Examples should demonstrate ESP-IDF functionality, while keeping this purpose in mind.

Structure

- The main directory should contain a source file named `(something)_example_main.c` with the main functionality.
- If the example has additional functionality, split it logically into separate C or C++ source files under `main` and place a corresponding header file in the same directory.
- If the example has a lot of additional functionality, consider adding a `components` directory to the example project and make some example-specific components with library functionality. Only do this if the components are specific to the example, if they’re generic or common functionality then they should be added to ESP-IDF itself.
- The example should have a `README.md` file. Use the `template example README` and adapt it for your particular example.
- Examples should have a `pytest_<example name>.py` file for running an automated example test. If submitting a GitHub Pull Request which includes an example, it’s OK not to include this file initially. The details can be discussed as part of the Pull Request. Please refer to `IDF Tests with Pytest Guide` for details.

General Guidelines

Example code should follow the `Espressif IoT Development Framework Style Guide`. 
Chapter 7. Contributions Guide

Checklist

Checklist before submitting a new example:

• Example project name (in README.md) uses the word “example”. Use “example” instead of “demo”, “test” or similar words.
• Example does one distinct thing. If the example does more than one thing at a time, split it into two or more examples.
• Example has a README.md file which is similar to the template example README.
• Functions and variables in the example are named according to naming section of the style guide. (For non-static names which are only specific to the example’s source files, you can use example or something similar as a prefix.)
• All code in the example is well structured and commented.
• Any unnecessary code (old debugging logs, commented-out code, etc.) is removed from the example.
• Options in the example (like network names, addresses, etc) are not hard-coded. Use configuration items if possible, or otherwise declare macros or constants)
• Configuration items are provided in a KConfig.projbuild file with a menu named “Example Configuration”. See existing example projects to see how this is done.
• All original example code has a license header saying it is “in the public domain / CC0”, and a warranty disclaimer clause. Alternatively, the example is licensed under Apache License 2.0. See existing examples for headers to adapt from.
• Any adapted or third party example code has the original license header on it. This code must be licensed compatible with Apache License 2.0.

7.5.5 API Documentation Template

Note: INSTRUCTIONS

1. Use this file (docs/en/api-reference/template.rst) as a template to document API.
2. Change the file name to the name of the header file that represents documented API.
3. Include respective files with descriptions from the API folder using ..include::
   • README.rst
   • example.rst
   • ...
4. Optionally provide description right in this file.
5. Once done, remove all instructions like this one and any superfluous headers.

Overview

Note: INSTRUCTIONS

1. Provide overview where and how this API may be used.
2. Where applicable include code snippets to illustrate functionality of particular functions.
3. To distinguish between sections, use the following heading levels:
   • # with overline, for parts
   • * with overline, for chapters
   • =,, for sections
   • –,, for subsections
   • ^, for subsubsections
   • “, for paragraphs
Application Example

Note: **INSTRUCTIONS**

1. Prepare one or more practical examples to demonstrate functionality of this API.
2. Each example should follow pattern of projects located in `esp-idf/examples/` folder.
3. Place example in this folder complete with README.md file.
4. Provide overview of demonstrated functionality in README.md.
5. With good overview reader should be able to understand what example does without opening the source code.
6. Depending on complexity of example, break down description of code into parts and provide overview of functionality of each part.
7. Include flow diagram and screenshots of application output if applicable.
8. Finally add in this section synopsis of each example together with link to respective folder in `esp-idf/examples/`.

API Reference

Note: **INSTRUCTIONS**

1. This repository provides for automatic update of API reference documentation using code markup retrieved by Doxygen from header files.
2. Update is done on each documentation build by invoking Sphinx extension `esp_extensions/run_doxygen.py` for all header files listed in the INPUT statement of `docs/doxygen/Doxyfile`.
3. Each line of the INPUT statement (other than a comment that begins with `##`) contains a path to header file `*.h` that will be used to generate corresponding `*.inc` files:

```plaintext
## Wi-Fi - API Reference
../components/esp32/include/esp_wifi.h \ 
../components/esp32/include/esp_smartconfig.h \ 
```

4. When the headers are expanded, any macros defined by default in `sdkconfig.h` as well as any macros defined in SOC-specific include/soc/*_caps.h headers will be expanded. This allows the headers to include/exclude material based on the IDF_TARGET value.
5. The `*.inc` files contain formatted reference of API members generated automatically on each documentation build. All `*.inc` files are placed in Sphinx _build directory. To see directives generated for e.g. `esp_wifi.h`, run `python gen-dxd.py esp32/include/esp_wifi.h`.
6. To show contents of `*.inc` file in documentation, include it as follows:

```plaintext
.. include-build-file:: inc/esp_wifi.inc
```

For example see `docs/en/api-reference/network/esp_wifi.rst`

7. Optionally, rather that using `*.inc` files, you may want to describe API in you own way. See `docs/en/api-reference/storage/fatfs.rst` for example.

Below is the list of common `.doxygen...::` directives:

• Functions -. doxygenfunction:: name_of_function
• Unions -. doxyguneunion:: name_of_union
• Structures -. doxygenstruct:: name_of_structure together with :members:
• Macros -. doxygendefine:: name_of_define
• Type Definitions -. doxygentypedef:: name_of_type
• Enumerations -. doxygenenum:: name_of Enumeration

See Breathe documentation for additional information.

To provide a link to header file, use the `link custom role` directive as follows:

```plaintext
* :component_file:`path_to/header_file.h`
```
8. In any case, to generate API reference, the file `docs/doxygen/Doxyfile` should be updated with paths to `*.h` headers that are being documented.
9. When changes are committed and documentation is build, check how this section has been rendered. Correct annotations in respective header files, if required.

### 7.5.6 Contributor Agreement

**Individual Contributor Non-Exclusive License Agreement including the Traditional Patent License OPTION**

Thank you for your interest in contributing to this Espressif project hosted on GitHub ("We" or "Us").

The purpose of this contributor agreement ("Agreement") is to clarify and document the rights granted by contributors to Us. To make this document effective, please follow the instructions in the Contributions Guide.

1. **DEFINITIONS**
   - "You" means the Individual Copyright owner who submits a Contribution to Us. If You are an employee and submit the Contribution as part of your employment, You have had Your employer approve this Agreement or sign the Entity version of this document.
   - "Contribution" means any original work of authorship (software and/or documentation) including any modifications or additions to an existing work, Submitted by You to Us, in which You own the Copyright. If You do not own the Copyright in the entire work of authorship, please contact Us by submitting a comment on GitHub.
   - "Copyright" means all rights protecting works of authorship owned or controlled by You, including copyright, moral and neighboring rights, as appropriate, for the full term of their existence including any extensions by You.
   - "Material" means the software or documentation made available by Us to third parties. When this Agreement covers more than one software project, the Material means the software or documentation to which the Contribution was Submitted. After You Submit the Contribution, it may be included in the Material.
   - "Submit" means any form of physical, electronic, or written communication sent to Us, including but not limited to electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, Us, but excluding communication that is conspicuously marked or otherwise designated in writing by You as "Not a Contribution."
   - "Submission Date" means the date You Submit a Contribution to Us.
   - "Documentation" means any non-software portion of a Contribution.

2. **LICENSE GRANT**
   2.1 Copyright License to Us

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, NON-exclusive, perpetual and irrevocable license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, under the Copyright covering the Contribution to use the Contribution by all means, including, but not limited to:

- to publish the Contribution,
- to modify the Contribution, to prepare derivative works based upon or containing the Contribution and to combine the Contribution with other software code,
- to reproduce the Contribution in original or modified form,
- to distribute, to make the Contribution available to the public, display and publicly perform the Contribution in original or modified form.

2.2 Moral Rights remain unaffected to the extent they are recognized and not waivable by applicable law. Notwithstanding, You may add your name in the header of the source code files of Your Contribution and We will respect this attribution when using Your Contribution.
3. PATENTS

3.1 Patent License

Subject to the terms and conditions of this Agreement You hereby grant to us a worldwide, royalty-free, non-exclusive, perpetual and irrevocable (except as stated in Section 3.2) patent license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, to make, have made, use, sell, offer for sale, import and otherwise transfer the Contribution and the Contribution in combination with the Material (and portions of such combination). This license applies to all patents owned or controlled by You, whether already acquired or hereafter acquired, that would be infringed by making, having made, using, selling, offering for sale, importing or otherwise transferring of Your Contribution(s) alone or by combination of Your Contribution(s) with the Material.

3.2 Revocation of Patent License

You reserve the right to revoke the patent license stated in section 3.1 if we make any infringement claim that is targeted at your Contribution and not asserted for a Defensive Purpose. An assertion of claims of the Patents shall be considered for a “Defensive Purpose” if the claims are asserted against an entity that has filed, maintained, threatened, or voluntarily participated in a patent infringement lawsuit against Us or any of Our licensees.

4. DISCLAIMER

THE CONTRIBUTION IS PROVIDED “AS IS”, MORE PARTICULARLY, ALL EXPRESS OR IMPLIED WARRANTIES INCLUDING, WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT ARE EXPRESSLY DISCLAIMED BY YOU TO US AND BY US TO YOU. TO THE EXTENT THAT ANY SUCH WARRANTIES CANNOT BE DISCLAIMED, SUCH WARRANTY IS LIMITED IN DURATION TO THE MINIMUM PERIOD PERMITTED BY LAW.

5. Consequential Damage Waiver

TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT WILL YOU OR US BE LIABLE FOR ANY LOSS OF PROFITS, LOSS OF ANTICIPATED SAVINGS, LOSS OF DATA, INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL AND EXEMPLARY DAMAGES ARISING OUT OF THIS AGREEMENT REGARDLESS OF THE LEGAL OR EQUITABLE THEORY (CONTRACT, TORT OR OTHERWISE) UPON WHICH THE CLAIM IS BASED.

6. Approximation of Disclaimer and Damage Waiver

IF THE DISCLAIMER AND DAMAGE WAIVER MENTIONED IN SECTION 4 AND SECTION 5 CANNOT BE GIVEN LEGAL EFFECT UNDER APPLICABLE LOCAL LAW, REVIEWING COURTS SHALL APPLY LOCAL LAW THAT MOST CLOSELY APPROXIMATES AN ABSOLUTE WAIVER OF ALL CIVIL LIABILITY IN CONNECTION WITH THE CONTRIBUTION.

7. Term

7.1 This Agreement shall come into effect upon Your acceptance of the terms and conditions.

7.2 In the event of a termination of this Agreement Sections 4, 5, 6, 7 and 8 shall survive such termination and shall remain in full force thereafter. For the avoidance of doubt, Contributions that are already licensed under a free and open source license at the date of the termination shall remain in full force after the termination of this Agreement.

8. Miscellaneous

8.1 This Agreement and all disputes, claims, actions, suits or other proceedings arising out of this agreement or relating in any way to it shall be governed by the laws of People’s Republic of China excluding its private international law provisions.

8.2 This Agreement sets out the entire agreement between You and Us for Your Contributions to Us and overrides all other agreements or understandings.

8.3 If any provision of this Agreement is found void and unenforceable, such provision will be replaced to the extent possible with a provision that comes closest to the meaning of the original provision and that is enforceable. The terms and conditions set forth in this Agreement shall apply notwithstanding any failure of essential purpose of this Agreement or any limited remedy to the maximum extent possible under law.

8.4 You agree to notify Us of any facts or circumstances of which you become aware that would make this Agreement inaccurate in any respect.
7.5.7 Copyright Header Guide

ESP-IDF is released under the Apache License 2.0 with some additional third-party copyrighted code released under various licenses. For further information please refer to the list of copyrights and licenses.

This page explains how the source code should be properly marked with a copyright header. ESP-IDF uses The Software Package Data Exchange (SPDX) format which is short and can be easily read by humans or processed by automated tools for copyright checks.

How to Check the Copyright Headers

Please make sure you have installed the pre-commit hooks which contain a copyright header checker as well. The checker can suggest a header if it is not able to detect a properly formatted SPDX header.

What if the Checker’s Suggestion is Incorrect?

No automated checker (no matter how good is) can replace humans. So the developer’s responsibility is to modify the offered header to be in line with the law and the license restrictions of the original code on which the work is based on. Certain licenses are not compatible between each other. Such corner cases will be covered by the following examples.

The checker can be configured with the tools/ci/check_copyright_config.yaml configuration file. Please check the options it offers and consider updating it in order to match the headers correctly.

Common Examples of Copyright Headers

The simplest case is when the code is not based on any licensed previous work, e.g. it was written completely from scratch. Such code can be decorated with the following copyright header and put under the license of ESP-IDF:

```c
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * *
 * SPDX-License-Identifier: Apache-2.0
 */
```
Less restrictive parts of ESP-IDF

Some parts of ESP-IDF are deliberately under less restrictive licenses in order to ease their re-use in commercial closed source projects. This is the case for ESP-IDF examples which are in Public domain or under the Creative Commons Zero Universal (CC0) license. The following header can be used in such source files:

```c
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * SPDX-License-Identifier: Unlicense OR CC0-1.0
 */
```

The option allowing multiple licenses joined with the OR keyword from the above example can be achieved with the definition of multiple allowed licenses in the `tools/ci/check_copyright_config.yaml` configuration file. Please use this option with care and only selectively for a limited part of ESP-IDF.

Third party licenses

Code licensed under different licenses, modified by Espressif Systems and included in ESP-IDF cannot be licensed under Apache License 2.0 not even if the checker suggests it. It is advised to keep the original copyright header and add an SPDX before it.

The following example is a suitable header for a code licensed under the “GNU General Public License v2.0 or later” held by John Doe with some additional modifications done by Espressif Systems:

```c
/*
 * SPDX-FileCopyrightText: 1991 John Doe
 * SPDX-License-Identifier: GPL-2.0-or-later
 * SPDX-FileContributor: 2019-2023 Espressif Systems (Shanghai) CO LTD
 */
```

The licenses can be identified and the short SPDX identifiers can be found in the official SPDX license list. Other very common licenses are the GPL-2.0-only, the BSD-3-Clause, and the BSD-2-Clause.

In exceptional case, when a license is not present on the SPDX license list, it can be expressed by using the LicenseRef-[idString] custom license identifier, for example LicenseRef-Special-License. The full license text must be added into the LICENSES directory under Special-License filename.

```c
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * SPDX-License-Identifier: LicenseRef-Special-License
 */
```

Dedicated LicenseRef-Included custom license identifier can be used to express a situation when the custom license is included directly in the source file.

```c
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 * SPDX-License-Identifier: LicenseRef-Included
 * <Full custom license text>
 */
```

The configuration stored in `tools/ci/check_copyright_config.yaml` offers features useful for third party licenses:

- A different license can be defined for the files part of a third party library.
- The check for a selected set of files can be permanently disabled. Please use this option with care and only in cases when none of the other options are suitable.
7.5.8 ESP-IDF Tests with Pytest Guide

This documentation is a guide that introduces the following aspects:

1. The basic idea of different test types in ESP-IDF
2. How to apply the pytest framework to the test python scripts to make sure the apps are working as expected.
3. ESP-IDF CI target test process
4. Run ESP-IDF tests with pytest locally
5. Tips and tricks on pytest

Disclaimer

In ESP-IDF, we use the following plugins by default:

- pytest-embedded with default services esp, idf
- pytest-rerunfailures

All the introduced concepts and usages are based on the default behavior in ESP-IDF. Not all of them are available in vanilla pytest.

Installation

All dependencies could be installed by running the install script with the `--enable-pytest` argument, e.g., `$ install.sh --enable-pytest`

Common Issues During Installation

No Package ‘dbus-1’ found If you’re facing an error message like:

```
configure: error: Package requirements (dbus-1 >= 1.8) were not met:
No package 'dbus-1' found
Consider adjusting the PKG_CONFIG_PATH environment variable if you
installed software in a non-standard prefix.
```

If you’re running under ubuntu system, you may need to run:

```
sudo apt-get install libdbus-glib-1-dev
```

or

```
sudo apt-get install libdbus-1-dev
```

For other linux distros, you may Google the error message and find the solution. This issue could be solved by installing the related header files.

Invalid command ‘bdist_wheel’ If you’re facing an error message like:

```
error: invalid command 'bdist_wheel'
```

You may need to run:

```
python -m pip install -U pip
```

Or
Before running the pip commands, please make sure you’re using the IDF python virtual environment.

**Basic Concepts**

**Component-based Unit Tests** Component-based unit tests are our recommended way to test your component. All the test apps should be located under `${IDF_PATH}/components/<COMPONENT_NAME>/test_apps`. For example:

```bash
components/
|-- my_component/
    |-- include/
    |   `-- ...
    `-- test_apps/
        |-- test_app_1
        |   `-- main/
        |       `-- ...
        `-- CMakeLists.txt
        `-- pytest_my_component_app_1.py
    `-- test_app_2
        `-- ...
        `-- pytest_my_component_app_2.py
    `-- parent_folder
        `-- test_app_3
            `-- ...
            `-- pytest_my_component_app_3.py
                `-- ...
        `-- my_component.c
    `-- CMakeLists.txt
```

**Example Tests** Example Tests are tests for examples that are intended to demonstrate parts of the ESP-IDF functionality to our customers. All the test apps should be located under `${IDF_PATH}/examples`. For more information please refer to the **Examples Readme**.

For example:

```bash
examples/
|-- parent_folder/
    |-- example_1/
        `-- main/
            `-- ...
            `-- CMakeLists.txt
                `-- pytest_example_1.py
```

**Custom Tests** Custom Tests are tests that aim to run some arbitrary test internally. They are not intended to demonstrate the ESP-IDF functionality to our customers in any way. All the test apps should be located under `${IDF_PATH}/tools/test_apps`. For more information please refer to the **Custom Test Readme**.

**Pytest in ESP-IDF**

**Pytest Execution Process**
1. Bootstrapping Phase
   Create session-scoped caches:
   • port-target cache
   • port-app cache

2. Collection Phase
   1. Get all the python files with the prefix `pytest_`
   2. Get all the test functions with the prefix `test_`
   3. Apply the `params`, and duplicate the test functions.
   4. Filter the test cases with CLI options. Introduced detailed usages here

3. Test Running Phase
   1. Construct the fixtures. In ESP-IDF, the common fixtures are initialized in this order:
      1. `pexpect_proc`: `pexpect` instance
      2. `app`: `IdfApp` instance
         The information of the app, like sdkconfig, flash_files, partition_table, etc., would be parsed at this phase.
      3. `serial`: `IdfSerial` instance
         The port of the host which connected to the target type parsed from the app would be auto-detected.
         The flash files would be auto flashed.
      4. `dut`: `IdfDut` instance
   2. Run the real test function
   3. Deconstruct the fixtures in this order:
      1. `dut`
         1. close the serial port
      2. (Only for apps with `unity test framework`) generate junit report of the unity test cases
      2. `serial`
      3. `app`
      4. `pexpect_proc`: Close the file descriptor
      4. (Only for apps with `unity test framework`) Raise `AssertionError` when detected unity test failed if you call `dut.expect_from UNITY_output()` in the test function.

4. Reporting Phase
   1. Generate junit report of the test functions
   2. Modify the junit report test case name into ESP-IDF test case ID format: `<target>.<config>.<test function name>

5. Finalizing Phase (Only for apps with `unity test framework`)
   Combine the junit reports if the junit reports of the unity test cases are generated.

Getting Started Example  This code example is taken from `pytest_console_basic.py`

```python
@ pytest.mark.esp32
@ pytest.mark.esp32c3
@ pytest.mark.generic
@ pytest.mark.parametrize('config', [ 'history', 'nohistory', ], indirect=True)
def test_console_advanced(config: str, dut: IdfDut) -> None:
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```

Let’s go through this simple test case line by line in the following subsections.

Use Markers to Specify the Supported Targets

```python
@ pytest.mark.esp32  # <-- support esp32
@ pytest.mark.esp32c3 # <-- support esp32c3
```

(continues on next page)
The above lines indicate that this test case supports target esp32 and esp32c3, the target board type should be "generic". If you want to know what is the "generic" type refers to, you may run pytest --markers to get the detailed information of all markers.

**Note:** If the test case supports all officially ESP-IDF supported targets (You may check the value via `idf.py ⚶ list-targets`), you can use a special marker `supported_targets` to apply all of them in one line.

**Use Params to Specify the sdkconfig Files** You can use `pytest.mark.parametrize` with `config` to apply the same test to different apps with different sdkconfig files. For more information about `sdkconfig.ci.xxx` files, please refer to the Configuration Files section under this readme.

```
@ pytest.mark.parametrize('config', [
    'history', # <-- run with app built by sdkconfig.ci.history
    'nohistory', # <-- run with app built by sdkconfig.ci.nohistory
], indirect=True) # <-- 'indirect=True' is required
```

Overall, this test function would be replicated to 4 test cases:

- esp32.history.test_console_advanced
- esp32.nohistory.test_console_advanced
- esp32c3.history.test_console_advanced
- esp32c3.nohistory.test_console_advanced

**Expect From the Serial output**

```
def test_console_advanced(config: str, dut: IdfDut) -> None:
    # The value of argument `config` is assigned by the parametrization.
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```

When we’re using `dut.expect(...), the string would be compiled into regex at first, and then seeks through the serial output until the compiled regex is matched, or a timeout is exceeded. You may have to pay extra attention when the string contains regex keyword characters, like parentheses, or square brackets.

Actually using `dut.expect_exact(...)` here is better, since it would seek until the string is matched. For further reading about the different types of `expect` functions, please refer to the `pytest-embedded Expecting documentation`.

**Advanced Examples**

**Multi Dut Tests with the Same App**

```
@pytest.mark.esp32s2
@pytest.mark.esp32s3
@pytest.mark.usb_host
@pytest.mark.parametrize('count', [2], indirect=True)
def test_usb_host(dut: Tuple[IdfDut, IdfDut]) -> None:
    device = dut[0] # <-- assume the first dut is the device
    host = dut[1] # <-- and the second dut is the host
    ...
```
After setting the param `count` to 2, all these fixtures are changed into tuples.

**Multi Dut Tests with Different Apps**  
This code example is taken from `pytest_wifi_getting_started.py`.

```python
@ ESP32
@ pytest.mark.multi_dut_generic
@ pytest.mark.parametrize(
    'count, app_path', [
    (2, 
    f'(os.path.join(os.path.dirname(__file__), "softAP")||os.path.join(os.
    path.dirname(__file__), "station"))', 
    ),
    indirect=True
)  
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]
    ...
```

Here the first dut was flashed with the app `softap`, and the second dut was flashed with the app `station`.

**Note:** Here the `app_path` should be set with absolute path. the `__file__` macro in python would return the absolute path of the test script itself.

---

**Multi Dut Tests with Different Apps, and Targets**  
This code example is taken from `pytest_wifi_getting_started.py`. As the comment says, for now it’s not running in the ESP-IDF CI.

```python
@ pytest.mark.parametrize(
    'count, app_path, target', [
    (2, 
    f'(os.path.join(os.path.dirname(__file__), "softAP")||os.path.join(os.
    path.dirname(__file__), "station"))', 
    'esp32|esp32s2',
    ),
    indirect=True,
)  
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]
    ...
```

Overall, this test function would be replicated to 2 test cases:

- softap with esp32 target, and station with esp32s2 target
- softap with esp32s2 target, and station with esp32 target

**Support different targets with different sdkconfig files**  
This code example is taken from `pytest_panic.py` as an advanced example.

```python
CONFIGS = [
    pytest.param('coredump_flash_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
    esp32s2]),
    pytest.param('coredump_flash_elf_sha', marks=[pytest.mark.esp32]), # sha256.
    only supported on esp32
    pytest.param('coredump_uart_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
    esp32s2]),
]  
```

(continues on next page)
Use Custom Class  Usually, you can write a custom class in these conditions:

1. Add more reusable functions for a certain number of DUTs
2. Add custom setup and teardown functions in different phases described here

This code example is taken from panic/conftest.py

```python
class PanicTestDut(IdfDut):
    ...

@fixture(scope='module')
def monkeypatch_module(request: FixtureRequest) -> MonkeyPatch:
    mp = MonkeyPatch()
    request.addfinalizer(mp.undo)
    return mp

@fixture(scope='module', autouse=True)
def replace_dut_class(monkeypatch_module: MonkeyPatch) -> None:
    monkeypatch_modulesetattr('pytest_embedded_idf.dut.IdfDut', PanicTestDut)
```

monkeypatch_module provide a module-scoped monkeypatch fixture.
replace_dut_class is a module-scoped autouse fixture. This function replaces the IdfDut class with your custom class.

Mark Flaky Tests  Sometimes, our test is based on ethernet or wifi. The network may cause the test flaky. We could mark the single test case within the code repo.

This code example is taken from pytest_esp Eth.py

```python
@fixture(reruns=3, reruns_delay=5)
def test_esp Eth_ip101(dut: IdfDut) -> None:
    ...
```

This flaky marker means that if the test function failed, the test case would rerun for a maximum of 3 times with 5 seconds delay.

Mark Known Failure Cases  Sometimes a test couldn’t pass for the following reasons:

- Has a bug
- The success ratio is too low because of environment issue, such as network issue. Retry couldn’t help

Now you may mark this test case with marker xfail with a user-friendly readable reason.

This code example is taken from pytest_panic.py

```python
@fixture(reason='raised IllegalInstruction instead')
def test_cache_error(dut: PanicTestDut, config: str, test_func_name: str) -> None:
    ...
```

This marker means that if the test would be a known failure one on esp32s2.
Mark Nightly Run Test Cases  Some test cases are only triggered in nightly run pipelines due to a lack of runners.

```python
@ pytest.mark.nightly_run
```

This marker means that the test case would only be run with env var NIGHTLY_RUN or INCLUDE_NIGHTLY_RUN.

Mark Temp Disabled in CI  Some test cases which can pass locally may need to be temporarily disabled in CI due to a lack of runners.

```python
@ pytest.mark.temp_skip_ci(targets=['esp32', 'esp32s2'], reason='lack of runners')
```

This marker means that the test case could still be run locally with pytest --target esp32, but will not run in CI.

Run Unity Test Cases  For component-based unit test apps, one line could do the trick to run all single-board test cases, including normal test cases and multi-stage test cases:

```python
def test_component_ut(dut: IdfDut):
    dut.run_all_single_board_cases()
```

It would also skip all the test cases with [ignore] mark.

If you need to run a group of test cases, you may run:

```python
def test_component_ut(dut: IdfDut):
    dut.run_all_single_board_cases(group='psram')
```

It would trigger all test cases with module name [psram].

You may also see that there are some test scripts with the following statements, which are deprecated. Please use the suggested one as above.

```python
def test_component_ut(dut: IdfDut):
    dut.expect_exact('Press ENTER to see the list of tests')
    dut.write('*')
    dut.expect_unity_test_output()
```

For further reading about our unit testing in ESP-IDF, please refer to our unit testing guide.

Run the Tests in CI

The workflow in CI is simple, build jobs -> target test jobs.

Build Jobs

Build Job Names

- Component-based Unit Tests: build_pytest_components_<target>
- Example Tests: build_pytest_examples_<target>
- Custom Tests: build_pytest_test_apps_<target>

Build Job Commands  The command used by CI to build all the relevant tests is: python $IDF_PATH/tools/ci/ci_build_apps.py <parent_dir> --target <target> -vv --pytest-apps

All apps which supported the specified target would be built with all supported sdkconfig files under build_<target>_<config>.
For example, if you run `python $IDF_PATH/tools/ci/ci_build_apps.py $IDF_PATH/examples/system/console/basic --target esp32 --pytest-apps`, the folder structure would be like this:

```
basic
│   └── build_esp32_history/
│       └── ...
│   └── build_esp32_nohistory/
│       └── ...
│   └── main/
│       └── CMakeLists.txt
│   └── pytest_console_basic.py
└── ...
```

All the binaries folders would be uploaded as artifacts under the same directories.

**Target Test Jobs**

**Target Test Job Names**

- Component-based Unit Tests: `component_ut_pytest_<target>_<test_env>`
- Example Tests: `example_test_pytest_<target>_<test_env>`
- Custom Tests: `test_app_test_pytest_<target>_<test_env>`

**Target Test Job Commands**  
The command used by CI to run all the relevant tests is: `pytest <parent_dir> --target <target> -m <test_env_marker>`

All test cases with the specified target marker and the test env marker under the parent folder would be executed.

The binaries in the target test jobs are downloaded from build jobs, the artifacts would be placed under the same directories.

**Run the Tests Locally**

First you need to install ESP-IDF with additional python requirements:

```
$ cd $IDF_PATH
$ bash install.sh --enable-pytest
$ . ./export.sh
```

By default, the pytest script will look for the build directory in this order:

- `build_<target>_<sdkconfig>`
- `build_<target>`
- `build_<sdkconfig>`
- `build`

Which means, the simplest way to run pytest is calling `idf.py build`.

For example, if you want to run all the esp32 tests under the `$IDF_PATH/examples/get-started/hello_world` folder, you should run:

```
$ cd examples/get-started/hello_world
$ idf.py build
$ pytest --target esp32
```

If you have multiple sdkconfig files in your test app, like those `sdkconfig.ci.*` files, the simple `idf.py build` won’t apply the extra sdkconfig files. Let’s take `$IDF_PATH/examples/system/console/basic` as an example.

If you want to test this app with config history, and build with `idf.py build`, you should run
If you want to build and test with all `sdkconfig` files at the same time, you should use our CI script as an helper script:

```bash
$ cd examples/system/console/basic
$ python ${IDF_PATH}/tools/ci/ci_build_apps.py . --target esp32 -vv --pytest-apps
$ pytest --target esp32
```

The app with `sdkconfig.ci.history` will be built in `build_esp32_history`, and the app with `sdkconfig.ci.nohistory` will be built in `build_esp32_nohistory`. pytest --target esp32 will run tests on both apps.

### Tips and Tricks

#### Filter the Test Cases

- Filter by target with `pytest --target <target>`
  `pytest` would run all the test cases that support specified target.
- Filter by `sdkconfig` file with `pytest --sdkconfig <sdkconfig>`
  if `<sdkconfig>` is default, `pytest` would run all the test cases with the `sdkconfig` file `sdkconfig.defaults`.
  In other cases, `pytest` would run all the test cases with `sdkconfig` file `sdkconfig.ci.<sdkconfig>`.

#### Add New Markers

We’re using two types of custom markers, target markers which indicate that the test cases should support this target, and env markers which indicate that the test case should be assigned to runners with these tags in CI.

You can add new markers by adding one line under the `${IDF_PATH}/conftest.py`. If it’s a target marker, it should be added into `TARGET_MARKERS`. If it’s a marker that specifies a type of test environment, it should be added into `ENV_MARKERS`. The grammar should be: `<marker_name>: <marker_description>`.

#### Generate JUnit Report

You can call `pytest` with `--junitxml <filepath>` to generate the JUnit report. In ESP-IDF, the test case name would be unified as “<target>.<config>.<function_name>”.

#### Skip Auto Flash Binary

Skipping auto-flash binary every time would be useful when you’re debugging your test script.

You can call `pytest` with `--skip-autoflash y` to achieve it.

#### Record Statistics

Sometimes you may need to record some statistics while running the tests, like the performance test statistics.

You can use `record_xml_attribute` fixture in your test script, and the statistics would be recorded as attributes in the JUnit report.

#### Logging System

Sometimes you may need to add some extra logging lines while running the test cases.

You can use `python logging module` to achieve this.

### Useful Logging Functions (as Fixture)
log_performance

def test_hello_world(
   dut: IdfDut,
   log_performance: Callable[[str, object], None],
) -> None:
   log_performance('test', 1)

The above example would log the performance item with pre-defined format: “[performance][test]: 1” and record it under the properties tag in the junit report if --junitxml <filepath> is specified. The junit test case node would look like:

```
<testcase classname="examples.get-started.hello_world.pytest_hello_world" file="examples/get-started/hello_world/pytest_hello_world.py" line="13" name="esp32.
default.test_hello_world" time="8.389">
   <properties>
      <property name="test" value="1"/>
   </properties>
</testcase>
```

check_performance We provide C macros TEST_PERFORMANCE_LESS_THAN and TEST_PERFORMANCE_GREATER_THAN to log the performance item and check if the value is in the valid range. Sometimes the performance item value could not be measured in C code, so we also provide a python function for the same purpose. Please note that using C macros is the preferred approach, since the python function couldn’t recognize the threshold values of the same performance item under different ifdef blocks well.

def test_hello_world(
   dut: IdfDut,
   check_performance: Callable[[str, float, str], None],
) -> None:
   check_performance('RSA_2048KEY_PUBLIC_OP', 123, 'esp32')
   check_performance('RSA_2048KEY_PUBLIC_OP', 19001, 'esp32')

The above example would first get the threshold values of the performance item RSA_2048KEY_PUBLIC_OP from components/idf_test/include/idf_performance.h and the target-specific one components/idf_test/include/esp32/idf_performance_target.h, then check if the value reached the minimum limit or exceeded the maximum limit.

Let’s assume the value of IDF_PERFORMANCE_MAX_RSA_2048KEY_PUBLIC_OP is 19000. so the first check_performance line would pass and the second one would fail with warning: [Performance] RSA_2048KEY_PUBLIC_OP value is 19001, doesn’\t meet pass standard 19000.0

Chapter 8

ESP-IDF Versions

The ESP-IDF GitHub repository is updated regularly, especially the master branch where new development takes place.
For production use, there are also stable releases available.

8.1 Releases

The documentation for the current stable release version can always be found at this URL:

Documentation for the latest version (master branch) can always be found at this URL:

The full history of releases can be found on the GitHub repository Releases page. There you can find release notes, links to each version of the documentation, and instructions for obtaining each version.

8.2 Which Version Should I Start With?

- For production purposes, use the current stable version. Stable versions have been manually tested, and are updated with “bugfix releases” which fix bugs without changing other functionality (see Versioning Scheme for more details). Every stable release version can be found on the Releases page.
- For prototyping, experimentation or for developing new ESP-IDF features, use the latest version (master branch in Git). The latest version in the master branch has all the latest features and has passed automated testing, but has not been completely manually tested (“bleeding edge”).
- If a required feature is not yet available in a stable release, but you do not want to use the master branch, it is possible to check out a pre-release version or a release branch. It is recommended to start from a stable version and then follow the instructions for Updating to a Pre-Release Version or Updating to a Release Branch.
- If you plan to use another project which is based on ESP-IDF, please check the documentation of that project to determine the version(s) of ESP-IDF it is compatible with.

See Updating ESP-IDF if you already have a local copy of ESP-IDF and wish to update it.

8.3 Versioning Scheme

ESP-IDF uses Semantic Versioning. This means that:
• Major Releases, like v3.0, add new functionality and may change functionality. This includes removing deprecated functionality.
  If updating to a new major release (for example, from v2.1 to v3.0), some of your project’s code may need updating and functionality may need to be re-tested. The release notes on the Releases page include lists of Breaking Changes to refer to.
• Minor Releases like v3.1 add new functionality and fix bugs but will not change or remove documented functionality, or make incompatible changes to public APIs.
  If updating to a new minor release (for example, from v3.0 to v3.1), your project’s code does not require updating, but you should re-test your project. Pay particular attention to the items mentioned in the release notes on the Releases page.
• Bugfix Releases like v3.0.1 only fix bugs and do not add new functionality.
  If updating to a new bugfix release (for example, from v3.0 to v3.0.1), you do not need to change any code in your project, and you only need to re-test the functionality directly related to bugs listed in the release notes on the Releases page.

8.4 Support Periods

Each ESP-IDF major and minor release version has an associated support period. After this period, the release is End of Life and no longer supported.

The ESP-IDF Support Period Policy explains this in detail, and describes how the support periods for each release are determined.

Each release on the Releases page includes information about the support period for that particular release.

As a general guideline:

• If starting a new project, use the latest stable release.
• If you have a GitHub account, click the “Watch” button in the top-right of the Releases page and choose “Releases only”. GitHub will notify you whenever a new release is available. Whenever a bug fix release is available for the version you are using, plan to update to it.
• If possible, periodically update the project to a new major or minor ESP-IDF version (for example, once a year.) The update process should be straightforward for Minor updates, but may require some planning and checking of the release notes for Major updates.
• Always plan to update to a newer release before the release you are using becomes End of Life.

Each ESP-IDF major and minor release (V4.1, V4.2, etc) is supported for 30 months after the initial stable release date.

Supported means that the ESP-IDF team will continue to apply bug fixes, security fixes, etc to the release branch on GitHub, and periodically make new bugfix releases as needed.

Support period is divided into “Service” and “Maintenance” period:

<table>
<thead>
<tr>
<th>Period</th>
<th>Duration</th>
<th>Recommended for new projects?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>12 months</td>
<td>Yes</td>
</tr>
<tr>
<td>Maintenance</td>
<td>18 months</td>
<td>No</td>
</tr>
</tbody>
</table>

During the Service period, bugfixes releases are more frequent. In some cases, support for new features may be added during the Service period (this is reserved for features which are needed to meet particular regulatory requirements or standards for new products, and which carry a very low risk of introducing regressions.)

During the Maintenance period, the version is still supported but only bugfixes for high severity issues or security issues will be applied.

Using an “In Service” version is recommended when starting a new project.

Users are encouraged to upgrade all projects to a newer ESP-IDF release before the support period finishes and the release becomes End of Life (EOL). It is our policy to not continue fixing bugs in End of Life releases.
Pre-release versions (betas, previews, -rc and -dev versions, etc) are not covered by any support period. Sometimes a particular feature is marked as “Preview” in a release, which means it is also not covered by the support period.

The ESP-IDF Programming Guide has information about the different versions of ESP-IDF (major, minor, bugfix, etc).

8.5 Checking the Current Version

The local ESP-IDF version can be checked by using idf.py:

```bash
idf.py --version
```

The ESP-IDF version is also compiled into the firmware and can be accessed (as a string) via the macro `IDF_VER`. The default ESP-IDF bootloader will print the version on boot (the version information is not always updated if the code in the GitHub repo is updated, it only changes if there is a clean build or if that particular source file is recompiled).

If writing code that needs to support multiple ESP-IDF versions, the version can be checked at compile time using `compile-time macros`.

Examples of ESP-IDF versions:
### Chapter 8. ESP-IDF Versions

<table>
<thead>
<tr>
<th>Version String</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>v3.2-dev-306-gbeb3611ca</td>
<td>Master branch pre-release.</td>
</tr>
<tr>
<td></td>
<td>- v3.2-dev - in development for version 3.2.</td>
</tr>
<tr>
<td></td>
<td>- 306 - number of commits after v3.2 development started.</td>
</tr>
<tr>
<td></td>
<td>- beb3611ca - commit identifier.</td>
</tr>
<tr>
<td>v3.0.2</td>
<td>Stable release, tagged v3.0.2.</td>
</tr>
<tr>
<td>v3.1-beta1-75-g346d6b0ea</td>
<td>Beta version in development (on a release branch).</td>
</tr>
<tr>
<td></td>
<td>- v3.1-beta1 - pre-release tag.</td>
</tr>
<tr>
<td></td>
<td>- 75 - number of commits after the pre-release beta tag was assigned.</td>
</tr>
<tr>
<td></td>
<td>- 346d6b0ea - commit identifier.</td>
</tr>
<tr>
<td>v3.0.1-dirty</td>
<td>Stable release, tagged v3.0.1.</td>
</tr>
<tr>
<td></td>
<td>- dirty means that there are modifications in the local ESP-IDF directory.</td>
</tr>
</tbody>
</table>

### 8.6 Git Workflow

The development (Git) workflow of the Espressif ESP-IDF team is as follows:

- New work is always added on the master branch (latest version) first. The ESP-IDF version on master is always tagged with "dev" (for “in development”), for example v3.1-dev.
- Changes are first added to an internal Git repository for code review and testing but are pushed to GitHub after automated testing passes.
- When a new version (developed on master) becomes feature complete and “beta” quality, a new branch is made for the release, for example release/v3.1. A pre-release tag is also created, for example v3.1-beta1. You can see a full list of branches and a list of tags on GitHub. Beta pre-releases have release notes which may include a significant number of Known Issues.
- As testing of the beta version progresses, bug fixes will be added to both the master branch and the release branch. New features for the next release may start being added to master at the same time.
- Once testing is nearly complete a new release candidate is tagged on the release branch, for example v3.1-rc1. This is still a pre-release version.
- If no more significant bugs are found or reported, then the final Major or Minor Version is tagged, for example v3.1. This version appears on the Releases page.
- As bugs are reported in released versions, the fixes will continue to be committed to the same release branch.
- Regular bugfix releases are made from the same release branch. After manual testing is complete, a bugfix release is tagged (i.e. v3.1.1) and appears on the Releases page.

### 8.7 Updating ESP-IDF

Updating ESP-IDF depends on which version(s) you wish to follow:

- *Updating to Stable Release* is recommended for production use.
Chapter 8. ESP-IDF Versions

- Updating to Master Branch is recommended for the latest features, development use, and testing.
- Updating to a Release Branch is a compromise between the first two.

Note: These guides assume that you already have a local copy of ESP-IDF cloned. To get one, check Step 2 in the Getting Started guide for any ESP-IDF version.

8.7.1 Updating to Stable Release

To update to a new ESP-IDF release (recommended for production use), this is the process to follow:

- Check the Releases page regularly for new releases.
- When a bugfix release for the version you are using is released (for example, if using v3.0.1 and v3.0.2 is released), check out the new bugfix version into the existing ESP-IDF directory.
- In Linux or macOS system, please run the following commands to update the local branch to vX.Y.Z:

```bash
    cd $IDF_PATH
    git fetch
    git checkout vX.Y.Z
    git submodule update --init --recursive
```

- In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.
- When major or minor updates are released, check the Release Notes on the releases page and decide if you want to update or to stay with your current release. Updating is via the same Git commands shown above.

Note: If you installed the stable release via zip file instead of using git, it might not be possible to update versions using the commands. In this case, update by downloading a new zip file and replacing the entire IDF_PATH directory with its contents.

8.7.2 Updating to a Pre-Release Version

It is also possible to `git checkout` a tag corresponding to a pre-release version or release candidate, the process is the same as Updating to Stable Release.

Pre-release tags are not always found on the Releases page. Consult the list of tags on GitHub for a full list. Caveats for using a pre-release are similar to Updating to a Release Branch.

8.7.3 Updating to Master Branch

Note: Using Master branch means living “on the bleeding edge” with the latest ESP-IDF code.

To use the latest version on the ESP-IDF master branch, this is the process to follow:

- In Linux or macOS system, please run the following commands to check out to the master branch locally:

```bash
    cd $IDF_PATH
    git checkout master
    git pull
    git submodule update --init --recursive
```

- In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.
- Periodically, re-run `git pull` to pull the latest version of master. Note that you may need to change your project or report bugs after updating your master branch.
• To switch from master to a release branch or stable version, run `git checkout` as shown in the other sections.

**Important:** It is strongly recommended to regularly run `git pull` and then `git submodule update --init --recursive` so a local copy of master does not get too old. Arbitrary old master branch revisions are effectively unsupportable “snapshots” that may have undocumented bugs. For a semi-stable version, try *Updating to a Release Branch* instead.

### 8.7.4 Updating to a Release Branch

In terms of stability, using a release branch is part-way between using the master branch and only using stable releases. A release branch is always beta quality or better, and receives bug fixes before they appear in each stable release.

You can find a list of branches on GitHub.

For example, in Linux or macOS system, you can execute the following commands to follow the branch for ESP-IDF v3.1, including any bugfixes for future releases like v3.1.1, etc:

```
cd $IDF_PATH
git fetch
git checkout release/v3.1
git pull
git submodule update --init --recursive
```

In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.

Each time you `git pull` this branch, ESP-IDF will be updated with fixes for this release.

**Note:** There is no dedicated documentation for release branches. It is recommended to use the documentation for the closest version to the branch which is currently checked out.
Chapter 9

Resources

9.1 PlatformIO

- What is PlatformIO?
- Installation
- Configuration
- Tutorials
- Project Examples
- Next Steps

9.1.1 What is PlatformIO?

PlatformIO is a cross-platform embedded development environment with out-of-the-box support for ESP-IDF.

Since ESP-IDF support within PlatformIO is not maintained by the Espressif team, please report any issues with PlatformIO directly to its developers in the official PlatformIO repositories.

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in the official PlatformIO documentation.

9.1.2 Installation

- PlatformIO IDE is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms
- PlatformIO Core (CLI) is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services
9.1.3 Configuration

Please go through the official PlatformIO configuration guide for ESP-IDF.

9.1.4 Tutorials

- ESP-IDF and ESP32-DevKitC: debugging, unit testing, project analysis

9.1.5 Project Examples

Please check ESP-IDF page in the official PlatformIO documentation

9.1.6 Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Learn more about integrations with other IDEs/Text Editors
- Get help from PlatformIO community

9.2 Useful Links

- The esp32.com forum is a place to ask questions and find community resources.
- Check the Issues section on GitHub if you find a bug or have a feature request. Please check existing Issues before opening a new one.
- A comprehensive collection of solutions, practical applications, components and drivers based on ESP-IDF is available in ESP IoT Solution repository. In most of cases descriptions are provided both in English and in 中文.
- To develop applications using Arduino platform, refer to Arduino core for the ESP32, ESP32-S2 and ESP32-C3.
- Several books have been written about ESP32 and they are listed on Espressif web site.
- If you’re interested in contributing to ESP-IDF, please check the Contributions Guide.
- For additional ESP32 product related information, please refer to documentation section of Espressif site.
- Download latest and previous versions of this documentation in PDF and HTML format.
Chapter 10

Copyrights and Licenses

10.1 Software Copyrights

All original source code in this repository is Copyright (C) 2015-2022 Espressif Systems. This source code is licensed under the Apache License 2.0 as described in the file LICENSE.

Additional third party copyrighted code is included under the following licenses.

Where source code headers specify Copyright & License information, this information takes precedence over the summaries made here.

Some examples use external components which are not Apache licensed, please check the copyright description in each example source code.

10.1.1 Firmware Components

These third party libraries can be included into the application (firmware) produced by ESP-IDF.

- **Newlib** is licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB.
- **Xtensa header files** are Copyright (C) 2013 Tensilica Inc and are licensed under the MIT License as reproduced in the individual header files.
- Original parts of **FreeRTOS** (components/freertos) are Copyright (C) 2017 Amazon.com, Inc. or its affiliates are licensed under the MIT License, as described in license.txt.
- Original parts of **LWIP** (components/lwip) are Copyright (C) 2001, 2002 Swedish Institute of Computer Science and are licensed under the BSD License as described in COPYING file.
- **wpa_supplicant** Copyright (c) 2003-2005 Jouni Malinen and licensed under the BSD license.
- **FreeBSD net80211** Copyright (c) 2004-2008 Sam Leffler, Erno Consulting and licensed under the BSD license.
- **argtable3** argument parsing library Copyright (C) 1998-2001,2003-2011,2013 Stewart Heitmann and licensed under 3-clause BSD license. argtable3 also includes the following software components. For details, please see argtable3 LICENSE file.
  - C Hash Table library, Copyright (c) 2002, Christopher Clark and licensed under 3-clause BSD license.
  - The Better String library, Copyright (c) 2014, Paul Hsieh and licensed under 3-clause BSD license.
  - TCL library, Copyright the Regents of the University of California, Sun Microsystems, Inc., Scrypts Corporation, ActiveState Corporation and other parties, and licensed under TCL/TK License.
- **linenoise** line editing library Copyright (c) 2010-2014 Salvatore Sanfilippo, Copyright (c) 2010-2013 Pieter Noordhuis, licensed under 2-clause BSD license.
- **FatFS** library, Copyright (C) 2017 ChaN, is licensed under a BSD-style license.
- **cJSON** library, Copyright (c) 2009-2017 Dave Gamble and cJSON contributors, is licensed under MIT license as described in LICENSE file.
- **micro-ecc** library, Copyright (c) 2014 Kenneth MacKay, is licensed under 2-clause BSD license.
• Mbed TLS library, Copyright (C) 2006-2018 ARM Limited, is licensed under Apache License 2.0 as described in LICENSE file.
• SPIFFS library, Copyright (c) 2013-2017 Peter Andersson, is licensed under MIT license as described in LICENSE file.
• SD/MMC driver is derived from OpenBSD SD/MMC driver, Copyright (c) 2006 Uwe Stuehler, and is licensed under BSD license.
• ESP-MQTT MQTT Package (contiki-mqtt) - Copyright (c) 2014, Stephen Robinson, MQTT-ESP - Tuan PM <tuanpm at live dot com> is licensed under Apache License 2.0 as described in LICENSE file.
• BLE Mesh is adapted from Zephyr Project, Copyright (c) 2017-2018 Intel Corporation and licensed under Apache License 2.0
• mynewt-nimble Apache Mynewt NimBLE, Copyright 2015-2018, The Apache Software Foundation, is licensed under Apache License 2.0 as described in LICENSE file.
• TLSF allocator Two Level Segregated Fit memory allocator, Copyright (c) 2006-2016, Matthew Conte, and licensed under the BSD 3-clause license.
• openthread, Copyright (c) The OpenThread Authors, is licensed under BSD License as described in LICENSE file.
• UBSAN runtime — Copyright (c) 2016, Linaro Limited and Jiří Zárevúcky, licensed under the BSD 2-clause license.
• HTTP Parser Based on src/http/ngx_http_parse.c from NGINX copyright Igor Sysoev. Additional changes are licensed under the same terms as NGINX and Joyent, Inc. and other Node contributors. For details please check LICENSE file.
• SEGGER SystemView target-side library, Copyright (c) 1995-2021 SEGGER Microcontroller GmbH, is licensed under BSD 1-clause license.

10.1.2 Documentation

• HTML version of the ESP-IDF Programming Guide uses the Sphinx theme sphinx_idf_theme, which is Copyright (c) 2013-2020 Dave Snider, Read the Docs, Inc. & contributors, and Espressif Systems (Shanghai) CO., LTD. It is based on sphinx_rtd_theme. Both are licensed under MIT license.

10.2 ROM Source Code Copyrights

ESP32, ESP32-S and ESP32-C Series SoCs mask ROM hardware includes binaries compiled from portions of the following third party software:

• Newlib, licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB.
• Xtensa libhal, Copyright (c) Tensilica Inc and licensed under the MIT license (see below).
• TinyBasic Plus, Copyright Mike Field & Scott Lawrence and licensed under the MIT license (see below).
• miniz, by Rich Geldreich - placed into the public domain.
• wpa_supplicant Copyright (c) 2003-2005 Jouni Malinen and licensed under the BSD license.
• TJpgDec Copyright (C) 2011, ChaN, all right reserved. See below for license.

10.3 Xtensa libhal MIT License

Copyright (c) 2003, 2006, 2010 Tensilica Inc.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the “Software”), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.
Chapter 10. Copyrights and Licenses

THE SOFTWARE IS PROVIDED “AS IS”, WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. 10.5 TJpgDec License

TJpgDec - Tiny JPEG Decompressor R0.01 (C)ChaN, 2011 The TJpgDec is a generic JPEG decompressor module for tiny embedded systems. This is a free software that opened for education, research and commercial developments under license policy of following terms.

Copyright (C) 2011, ChaN, all right reserved.

- The TJpgDec module is a free software and there is NO WARRANTY.
- No restriction on use. You can use, modify and redistribute it for personal, non-profit or commercial products UNDER YOUR RESPONSIBILITY.
- Redistributions of source code must retain the above copyright notice.
Chapter 11

About

This is documentation of ESP-IDF, the framework to develop applications for ESP32 chip by Espressif.

The ESP32 is 2.4 GHz Wi-Fi and Bluetooth combo, which integrates one or two Xtensa® 32-bit LX6 CPU, with up to 600 DMIPS processing power.

Fig. 1: Espressif IoT Integrated Development Framework

The ESP-IDF, Espressif IoT Development Framework, provides toolchain, API, components and workflows to develop applications for ESP32 using Windows, Linux and macOS operating systems.
Chapter 12

Switch Between Languages

The ESP-IDF Programming Guide is now available in two languages. Please refer to the English version if there is any discrepancy.

- English
- Chinese

You can easily change from one language to another by clicking the language link you can find at the top of every document that has a translation.

Release v5.1.1


mcpwm_timer_config_t::update_period_on_sync
(C++ member), 1205
mcpwm_timer_config_t::update_period_on_empty
(C++ member), 1205
mcpwm_operator_set_brake_on_fault
(C++ member), 1202
mcpwm_operator_set_timer
(C++ member), 1202
mcpwm_timer_handle_t
(C++ type), 1224
mcpwm_soft_sync_activate
(C++ function), 1217
mcpwm_soft_sync_config_t
(C++ struct), 1218
mcpwm_timer_clock_source_t
(C++ type), 1225
mcpwm_timer_config_t
(C++ struct), 1202
mcpwm_timer_callback_t
(C++ struct), 1202
mcpwm_timer_event_data_t::direction
(C++ function), 1205
mcpwm_timer_event_callbacks_t::on_full
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_empty
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_brake_output
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_brake_offs
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_brake_on
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_fault
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_gen_action_on_tez
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_gen_action_on_tep
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_gen_action_on_tez
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_gen_action_on_tep
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_gen_action_on_tez
(C++ function), 1204
mcpwm_timer_event_callbacks_t::on_gen_action_on_tep
(C++ function), 1204
mcpwm_timer_event_data_t::direction
(C++ function), 1205
mcpwm_timer_event_data_t::count_value
(C++ function), 1205
mesh_event_transfer_t::mesh_rx_pending_t::toSelf (C++ member), 852
mesh_event_transfer_t::mesh_rx_pending_t::toDS (C++ member), 852
mesh_event_transfer_t::mesh_rx_pending_t::toParent (C++ member), 845
mesh_event_transfer_t::mesh_rx_pending_t::broadcast (C++ member), 851
mesh_event_transfer_t::mesh_rx_pending_t::toJson (C++ member), 855
mesh_event_transfer_t::mesh_rx_pending_t::toChild (C++ member), 851
mesh_event_transfer_t::mesh_rx_pending_t::toChild_p2p (C++ member), 851
mesh_event_transfer_t::mesh_rx_pending_t::toParent (C++ member), 851
mesh_event_transfer_t::mesh_rx_pending_t::toParent_p2p (C++ member), 851
mesh_event_transfer_t::mesh_rx_pending_t::toRoot (C++ member), 851
multi_heap_info_t::allocated_blocks (C++ member), 2076
multi_heap_info_t::free_blocks (C++ member), 2076
multi_heap_info_t::largest_free_block (C++ member), 2076
multi_heap_info_t::minimum_free_bytes (C++ member), 2076
multi_heap_info_t::total_allocated_bytes (C++ member), 2076
multi_heap_info_t::total_blocks (C++ member), 2076
multi_heap_info_t::total_free_bytes (C++ member), 2076
multi_heap_malloc (C++ function), 2074
multi_heap_minimum_free_size (C++ function), 2076
multi_heap_realloc (C++ function), 2074
multi_heap_register (C++ function), 2075
multi_heap_set_lock (C++ function), 2075

N
name_uuid (C++ struct), 1736
name_uuid::name (C++ member), 1736
name_uuid::uuid (C++ member), 1736
NAN_MAX_PEERS_RECORD (C macro), 934
nan_peer_record (C++ struct), 933
nan_peer_record::ndp_id (C++ member), 933
nan_peer_record::own_svc_id (C++ member), 933
nan_peer_record::peer_ndi (C++ member), 933
nan_peer_record::peer_nmi (C++ member), 933
nan_peer_record::peer_svc_id (C++ member), 933
nan_peer_record::peer_svc_type (C++ member), 933
NDP_STATUS_ACCEPTED (C macro), 933
NDP_STATUS_REJECTED (C macro), 934
nvs_close (C++ function), 1789
nvs_commit (C++ function), 1789
NVS_DEFAULT_PART_NAME (C macro), 1794
nvs_entry_find (C++ function), 1791
nvs_entry_info (C++ function), 1791
nvs_entry_info_t (C++ struct), 1792
nvs_entry_info_t::key (C++ member), 1792
nvs_entry_info_t::namespace_name (C++ member), 1792
nvs_entry_info_t::type (C++ member), 1792
nvs_entry_next (C++ function), 1791
nvs_erase_all (C++ function), 1789
nvs_erase_key (C++ function), 1788
nvs_flash_deinit (C++ function), 1781
nvs_flash_deinit_partition (C++ function), 1781
nvs_flash_erase (C++ function), 1781
nvs_flash_erase_partition (C++ function), 1782
nvs_flash_erase_partition_ptr (C++ function), 1782
nvs_flash_generate_keys (C++ function), 1782
nvs_flash_init (C++ function), 1780
nvs_flash_init_partition (C++ function), 1781
nvs_flash_init_partition_ptr (C++ function), 1781
nvs_flash_read_security_cfg (C++ function), 1783
nvs_flash_secure_init (C++ function), 1782
nvs_flash_secure_init_partition (C++ function), 1783
nvs_get_blob (C++ function), 1787
nvs_get_i16 (C++ function), 1786
nvs_get_i32 (C++ function), 1786
nvs_get_i64 (C++ function), 1786
nvs_get_i8 (C++ function), 1785
nvs_get_stats (C++ function), 1789
nvs_get_str (C++ function), 1786
nvs_get_u16 (C++ function), 1786
nvs_get_u32 (C++ function), 1786
nvs_get_u64 (C++ function), 1786
nvs_get_u8 (C++ function), 1786
nvs_get_used_entry_count (C++ function), 1790
nvs_handle (C++ type), 1794
nvs_handle_t (C++ type), 1794
nvs_iterator_t (C++ type), 1794
NVS_KEY_NAME_MAX_SIZE (C macro), 1794
NVS_KEY_SIZE (C macro), 1784
NVS_NS_NAME_MAX_SIZE (C macro), 1794
nvs_open (C++ function), 1787
nvs_open_from_partition (C++ function), 1788
nvs_open_mode (C++ type), 1794
nvs_open_mode_t (C++ enum), 1795
nvs_open_mode_t::NVS_READONLY (C++ enumerator), 1795
nvs_open_mode_t::NVS_READWRITE (C++ enumerator), 1795
NVS_PART_NAME_MAX_SIZE (C macro), 1794
nvs_release_iterator (C++ function), 1792
nvs_sec_cfg_t (C++ struct), 1783
nvs_sec_cfg_t::eky (C++ member), 1783
nvs_sec_cfg_t::tky (C++ member), 1783
nvs_set_blob (C++ function), 1788
nvs_set_i16 (C++ function), 1784
nvs_set_i32 (C++ function), 1784
nvs_set_i64 (C++ function), 1785
nvs_set_i8 (C++ function), 1784
nvs_set_str (C++ function), 1785
nvs_set_u16 (C++ function), 1784
nvs_set_u32 (C++ function), 1784
nvs_set_u64 (C++ function), 1785
pcnt_chan_config_t::invert_edge_input
          (C++ member), 1240
pcnt_chan_config_t::invert_level_input
          (C++ member), 1240
pcnt_chan_config_t::io_loop_back (C++ member), 1240
pcnt_chan_config_t::level_gpio_num
          (C++ member), 1240
pcnt_chan_config_t::virt_edge_io_level
          (C++ member), 1240
pcnt_chan_config_t::virt_level_io_level
          (C++ member), 1240
pcnt_channel_edge_action_t (C++ enum), 1241
pcnt_channel_edge_action_t::PCNT_CHANNEL_EDGE_ACTION_UP
          (C++ enumerator), 1242
pcnt_channel_edge_action_t::PCNT_CHANNEL_EDGE_ACTION_DOWN
          (C++ enumerator), 1242
pcnt_channel_edge_action_t::PCNT_CHANNEL_EDGE_ACTION_HOLD
          (C++ enumerator), 1242
pcnt_channel_handle_t (C++ type), 1241
pcnt_channel_level_action_t (C++ enum), 1241
pcnt_channel_level_action_t::PCNT_CHANNEL_LEVEL_ACTION_KEEP
          (C++ enumerator), 1241
pcnt_channel_level_action_t::PCNT_CHANNEL_LEVEL_ACTION_INVERSE
          (C++ enumerator), 1241
pcnt_channel_level_action_t::PCNT_CHANNEL_LEVEL_ACTION_HOLD
          (C++ enumerator), 1241
pcnt_channel_set_edge_action (C++ function), 1238
pcnt_channel_set_edge_action_t (C++ function), 1239
pcnt_del_channel (C++ function), 1238
pcnt_del_unit (C++ function), 1234
pcnt_event_callbacks_t (C++ struct), 1239
pcnt_event_callbacks_t::on_reach (C++ member), 1239
pcnt_glitch_filter_config_t (C++ struct), 1241
pcnt_glitch_filter_config_t::max_glitch_ns
          (C++ member), 1241
pcnt_new_channel (C++ function), 1238
pcnt_new_unit (C++ function), 1234
pcnt_unit_add_watch_point (C++ function), 1237
pcnt_unit_clear_count (C++ function), 1236
pcnt_unit_config_t (C++ struct), 1240
pcnt_unit_config_t::accum_count
          (C++ member), 1240
pcnt_unit_config_t::flags (C++ member), 1240
pcnt_unit_disable (C++ function), 1235
pcnt_unit_enable (C++ function), 1235

O
OPCODE_ADC (C macro), 2218
OPCODE_ALU (C macro), 2218
OPCODE_BRANCH (C macro), 2219
OPCODE_DELAY (C macro), 2218
OPCODE_END (C macro), 2220
OPCODE_HALT (C macro), 2220
OPCODE_I2C (C macro), 2217
OPCODE_ID (C macro), 2220
OPCODE_MACRO (C macro), 2220
OPCODE_RD_REG (C macro), 2217
OPCODE_ST (C macro), 2218
OPCODE_TSENS (C macro), 2220
OPCODE_WR_REG (C macro), 2217
OTA_SIZE_UNKNOWN (C macro), 2148
OTA_WITH_SEQUENTIAL_WRITES (C macro), 2148

P
pcnt_chan_config_t (C++ struct), 1240
pcnt_chan_config_t::edge_gpio_num
          (C++ member), 1240
pcnt_chan_config_t::flags (C++ member), 1240
pcnt_chan_config_t::virt_level_io_level
          (C++ member), 1240
pcnt_chan_config_t::virt_edge_io_level
          (C++ member), 1240
pcnt_chan_config_t::invert_level_input
          (C++ member), 1240
pcnt_chan_config_t::invert_edge_input
          (C++ member), 1240
pcnt_unit_enable (C++ function), 1235
pcnt_unit_disable (C++ function), 1235
pcnt_unit_enable (C++ function), 1235
pcnt_unit_disable (C++ function), 1235
pcnt_unit_get_count (C++ function), 1237
pcnt_unit_handle_t (C++ type), 1241
pcnt_unit_register_event_callbacks (C++ function), 1237
pcnt_unit_remove_watch_point (C++ function), 1238
pcnt_unit_set_glitch_filter (C++ function), 1234
pcnt_unit_start (C++ function), 1235
pcnt_unit_stop (C++ function), 1236
pcnt_unit_zero_cross_mode_t (C++ enum), 1242

pcnt_unit_zero_cross_mode_t::PCNT_UNIT_ZERO_CROSS_POS_NEG (C++ enum), 1242
pcnt_unit_zero_cross_mode_t::PCNT_UNIT_ZERO_CROSS_NEG_ZERO (C++ enum), 1242
pcnt_unit_zero_cross_mode_t::PCNT_UNIT_ZERO_CROSS_NEG_POS (C++ enum), 1242

phy_802_3_t (C++ struct), 965
phy_802_3_t::addr (C++ member), 965
phy_802_3_t::autonego_timeout_ms (C++ member), 965
phy_802_3_t::eth (C++ member), 965
phy_802_3_t::link_status (C++ member), 965
phy_802_3_t::parent (C++ member), 965
phy_802_3_t::reset_gpio_num (C++ member), 965

phy_802_3_t::reset_timeout_ms (C++ member), 965
phy_track_pll_deinit (C++ function), 2494
phy_track_pll_init (C++ function), 2494
protocomm_add_endpoint (C++ function), 1728
protocomm_ble_config (C++ struct), 1736
protocomm_ble_config::ble_bonding (C++ member), 1736
protocomm_ble_config::ble_link_encryption (C++ member), 1736
protocomm_ble_config::ble_sm_sc (C++ member), 1736
protocomm_ble_config::device_name (C++ member), 1736
protocomm_ble_config::manufacturer_data (C++ member), 1736
protocomm_ble_config::manufacturer_data_len (C++ member), 1736

protocomm_ble_config::nu_lookup_count (C++ member), 1736
protocomm_ble_config::nu_lookup (C++ member), 1736
protocomm_ble_config::service_uid (C++ member), 1736
protocomm_ble_config::ble_link_encryption (C++ member), 1737
protocomm_ble_config::ble_bonding (C++ member), 1737
protocomm_ble_config::ble_bonding (C++ member), 1737
protocomm_ble_start (C++ function), 1735
protocomm_ble_stop (C++ function), 1735
protocomm_close_session (C++ function), 1729

pcnt_unit_zero_cross_mode_t::PCNT_UNIT_ZERO_CROSS_NEG_ZERO (C++ function), 1728
protocomm_http_server_config_t (C++ struct), 1734
protocomm_http_server_config_t::port (C++ member), 1734
protocomm_http_server_config_t::stack_size (C++ member), 1734
protocomm_http_server_config_t::task_priority (C++ member), 1734
protocomm_httpd_config_data_t (C++ union), 1734
protocomm_httpd_config_data_t::config (C++ member), 1734
protocomm_httpd_config_data_t::handle (C++ member), 1734
protocomm_httpd_config_data_t::data (C++ member), 1735
protocomm_httpd_config_data_t::ext_handle_provided (C++ member), 1735

protocomm_HTTPD_DEFAULT_CONFIG (C macro), 1735
protocomm_httpd_start (C++ function), 1733
protocomm_httpd_stop (C++ function), 1734
protocomm_new (C++ function), 1728
protocomm_open_session (C++ function), 1729
protocomm_remove_endpoint (C++ function), 1728
protocomm_req_handle (C++ function), 1729
protocomm_req_handler_t (C++ type), 1731
protocomm_security (C++ struct), 1732
protocomm_security1_params (C++ struct), 1731
protocomm_security1_params::data (C++ member), 1731
protocomm_security1_params::len (C++ member), 1731
protocomm_security1_params::t (C++ type), 1732
protocomm_security2_params (C++ struct), 1732
protocomm_security2_params::salt (C++ member), 1732
protocomm_security2_params::salt_len (C++ member), 1732
protocomm_security2_params::verifier (C++ member), 1732
rmt_encoder_t (C++ struct), 1264
rmt_encoder_t::del (C++ member), 1265
rmt_encoder_t::encode (C++ member), 1264
rmt_encoder_t::reset (C++ member), 1265
rmt_new_bytes_encoder (C++ function), 1263
rmt_new_copy_encoder (C++ function), 1264
rmt_new_rx_channel (C++ function), 1260
rmt_new_sync_manager (C++ function), 1257
rmt_new_tx_channel (C++ function), 1255
rmt_receive (C++ function), 1260
rmt_receive_config_t (C++ struct), 1261
rmt_receive_config_t::signal_range_max (C++ member), 1262
rmt_receive_config_t::signal_range_min (C++ member), 1262
rmt_rx_channel_config_t (C++ struct), 1261
rmt_rx_channel_config_t::clk_src (C++ member), 1261
rmt_rx_channel_config_t::flags (C++ member), 1261
rmt_rx_channel_config_t::gpio_num (C++ member), 1261
rmt_rx_channel_config_t::invert_in (C++ member), 1261
rmt_rx_channel_config_t::io_loop_back (C++ member), 1261
rmt_rx_channel_config_t::mem_block_symbols (C++ member), 1261
rmt_rx_channel_config_t::resolution_hz (C++ member), 1261
rmt_rx_channel_config_t::with_dma (C++ member), 1261
rmt_rx_done_callback_t (C++ type), 1267
rmt_rx_done_event_data_t (C++ struct), 1266
rmt_rx_done_event_data_t::num_symbols (C++ member), 1266
rmt_rx_done_event_data_t::received_symbols (C++ member), 1266
rmt_rx_event_callbacks_t (C++ struct), 1261
rmt_rx_event_callbacks_t::on_recv_done (C++ member), 1261
rmt_rx_register_event_callbacks (C++ function), 1260
rmt_symbol_word_t (C++ union), 1267
rmt_symbol_word_t::duration0 (C++ member), 1267
rmt_symbol_word_t::duration1 (C++ member), 1267
rmt_symbol_word_t::level0 (C++ member), 1267
rmt_symbol_word_t::level1 (C++ member), 1267
rmt_symbol_word_t::val (C++ member), 1267
rmt_symbol_word_t::[anonymous] (C++ member), 1267
rmt_sync_manager_config_t (C++ struct), 1259
rmt_sync_manager_config_t::array_size (C++ member), 1259
rmt_sync_manager_config_t::tx_channel_array (C++ member), 1259
rmt_sync_manager_config_t::tx_channel_handle (C++ type), 1266
rmt_sync_reset (C++ function), 1257
rmt_transmit (C++ function), 1256
rmt_transmit_config_t (C++ struct), 1259
rmt_transmit_config_t::eot_level (C++ member), 1259
rmt_transmit_config_t::flags (C++ member), 1259
rmt_transmit_config_t::loop_count (C++ member), 1259
rmt_rx_channel_config_t (C++ struct), 1258
rmt_tx_channel_config_t::clk_src (C++ member), 1258
rmt_tx_channel_config_t::flags (C++ member), 1259
rmt_tx_channel_config_t::gpio_num (C++ member), 1258
rmt_tx_channel_config_t::invert_out (C++ member), 1258
rmt_tx_channel_config_t::io_loop_back (C++ member), 1259
rmt_tx_channel_config_t::io_od_mode (C++ member), 1259
rmt_rx_channel_config_t::mem_block_symbols (C++ member), 1258
rmt_rx_channel_config_t::resolution_hz (C++ member), 1258
rmt_tx_channel_config_t::trans_queue_depth (C++ member), 1258
rmt_tx_channel_config_t::with_dma (C++ member), 1259
rmt_rx_done_callback_t (C++ type), 1266
rmt_rx_done_event_data_t (C++ struct), 1266
rmt_xml_done_event_data_t::num_symbols (C++ member), 1266
rmt_rx_event_callbacks_t (C++ struct), 1258
rmt_rx_event_callbacks_t::on_recv_done (C++ member), 1258
rmt_tx_register_event_callbacks (C++ function), 1256
rmt_tx_wait_all_done (C++ function), 1256
rtc_gpio_deinit (C++ function), 1073
rtc_gpio_force_hold_dis_all (C++ function), 1075
rtc_gpio_force_hold_en_all (C++ function), 1075
rtc_gpio_get_drive_capability (C++ function), 1075
rtc_gpio_get_level (C++ function), 1073
rtc_gpio_hold_dis (C++ function), 1075
rtc_gpio_hold_en (C++ function), 1075
rtc_gpio_init (C++ function), 1073
RTC_GPIO_IS_VALID_GPIO (C macro), 1076
rtc_gpio_is_valid_gpio (C++ function), 1073
Index
