- `idf-env.json` —user install options, such as targets and features, are stored in this file. Targets are selected chip targets for which tools are installed and kept up-to-date. Features determine the Python package set which should be installed. These options will be discussed later.
- `python_env` —not related to the tools; virtual Python environments are installed in the sub-directories. Note that the Python environment directory can be placed elsewhere by setting the `IDF_PYTHON_ENV_PATH` environment variable.
- `espidf.constraints.*.txt` —one constraint file for each ESP-IDF release containing Python package version requirements.

GitHub Assets Mirror

Most of the tools downloaded by the tools installer are GitHub Release Assets, which are files attached to a software release on GitHub.

If GitHub downloads are inaccessible or slow to access, a GitHub assets mirror can be configured.

To use Espressif's download server, set the environment variable `IDF_GITHUB_ASSETS` to `dl.espressif.com/github_assets`, or `dl.espressif.cn/github_assets` for faster download in China. When the install process is downloading a tool from `github.com`, the URL will be rewritten to use this server instead.

Any mirror server can be used provided the URL matches the `github.com` download URL format. For any GitHub asset URL that the install process downloads, it will replace `https://github.com` with `https://${IDF_GITHUB_ASSETS}`.

Note: The Espressif download server currently does not mirror everything from GitHub, but only files attached as Assets to some releases, as well as source archives for some releases.

`idf_tools.py` Script

The tools/idf_tools.py script bundled with ESP-IDF performs several functions:

- `install`: Download the tool into the `${IDF_TOOLS_PATH}/dist` directory and extract it into `${IDF_TOOLS_PATH}/tools/TOOL_NAME/VERSION`.
  The `install` command accepts the list of tools to install in the `TOOL_NAME` or `TOOL_NAME@VERSION` format. If `all` is given, all the tools, including required and optional ones, are installed. If no argument or `required` is given, only the required tools are installed.
- `download`: Similar to `install` but doesn't extract the tools. An optional `--platform` argument may be used to download the tools for the specific platform.

- `export`: Lists the environment variables that need to be set to use the installed tools. For most of the tools, setting the `PATH` environment variable is sufficient, but some tools require extra environment variables.
  The environment variables can be listed in either `shell` or `key-value` formats, which can be set using the `--format` parameter:
  - `export` optional parameters:
    - `--unset`: Creates a statement that unsets specific global variables and restores the environment to its state before calling `export.{sh/fish}`.
    - `--add_paths_extras`: Adds extra ESP-IDF-related paths of `$PATH` to `${IDF_TOOLS_PATH}/esp-idf.json`, which is used to remove global variables when the active ESP-IDF environment is deactivated. For example, while processing the `export.{sh/fish}` script, if new paths are added to the global variable `$PATH`, this option saves these new paths to the `${IDF_TOOLS_PATH}/esp-idf.json` file.
  - `shell`: Produces output suitable for evaluation in the shell. For example, produce the following output on Linux and macOS:

    ```
    export PATH="/home/user/.espressif/tools/tool/v1.0.0/bin:$PATH"
    ```

    Produce the following output on Windows:

    ```
    set "PATH=C:\Users\user\.espressif\tools\v1.0.0\bin;%PATH%"
    ```

    Note: Exporting environment variables in Powershell format is not supported at the moment. `key-value` format may be used instead.

    The output of this command may be used to update the environment variables if the shell supports it. For example

    ```
    eval $($IDF_PATH/tools/idf_tools.py export)
    ```

  - `key-value`: Produces output in the `VARIABLE=VALUE` format that is suitable for parsing by other scripts

    ```
    PATH=/home/user/.espressif/tools/tool/v1.0.0:$PATH
    ```

    Note that the script consuming this output has to perform expansion of `$VAR` or `%VAR%` patterns found in the output.
- `list`: Lists the known versions of the tools, and indicates which ones are installed.
  The following option is available to customize the output.
  - `--outdated`: Lists only outdated versions of tools installed in `IDF_TOOLS_PATH`.
- `check`: For each tool, checks whether the tool is available in the system path and in `IDF_TOOLS_PATH`.
- `install-python-env`: Creates a Python virtual environment in the `${IDF_TOOLS_PATH}/python_env` directory or directly in the directory set by the `IDF_PYTHON_ENV_PATH` environment variable, and install the required Python packages there.
  - An optional `--features` argument allows one to specify a comma-separated list of features to be added or removed.
    1. A feature that begins with − will be removed, and features with + or without any sign will be added. Example syntax for removing feature `XY` is `--features=-XY`, and for adding feature `XY` is `--features=+XY` or `--features=XY`. If both removing and adding options are provided with the same feature, no operation is performed.
    2. For each feature, a requirements file must exist. For example, feature `XY` is a valid feature if `${IDF_PATH}/tools/requirements/requirements.XY.txt` is an existing file with a list of Python packages to be installed.
    3. There is one mandatory `core` feature ensuring the core functionality of ESP-IDF, e.g., build, flash, monitor, debug in console. There can be an arbitrary number of optional features.
    4. The selected list of features is stored in `idf-env.json`.
    5. The requirement files contain a list of the desired Python packages to be installed and the `espidf.constraints.*.txt` file downloaded from https://dl.espressif.com and stored in `${IDF_TOOLS_PATH}`, which contains the package version requirements for a given ESP-IDF version.

Note: Although **it is not recommended**, the download and use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to `no`.

- `check-python-dependencies`: Checks if all required Python packages are installed. Packages from `${IDF_PATH}/tools/requirements/requirements.*.txt` files selected by the feature list of `idf-env.json` are checked with the package versions specified in the `espidf.constraints.*.txt` file.

Note: The constraint file is downloaded with the `install-python-env` command. Similar to the `install-python-env` command, the use of constraint files can be disabled with the `--no-constraints` argument or setting the `IDF_PYTHON_CHECK_CONSTRAINTS` environment variable to `no`.

- `uninstall`: Prints and removes tools that are currently not used by the active ESP-IDF version.
  - `--dry-run`: Prints installed unused tools.
  - `--remove-archives`: Additionally removes all older versions of previously downloaded installation packages.

Install Scripts

Shell-specific user-facing installation scripts are provided in the root directory of ESP-IDF repository to facilitate tools installation. These are:

- `install.bat` for Windows Command Prompt
- `install.ps1` for Powershell
- `install.sh` for Bash
- `install.fish` for Fish

Apart from downloading and installing the tools in `IDF_TOOLS_PATH`, these scripts prepare a Python virtual environment, and install the required packages into that environment.

These scripts accept optionally a comma-separated list of chip targets and `--enable-*` arguments for enabling features. These arguments are passed to the `idf_tools.py` script which stores them in `idf-env.json`. Therefore, chip targets and features can be enabled incrementally.

To install tools for all chip targets, run the scripts without any optional arguments using `idf_tools.py install --targets=all`. Similarly, to install Python packages for core ESP-IDF functionality, run `idf_tools.py install-python-env --features=core`.

It is also possible to install tools for specific chip targets. For example, `install.sh esp32` installs tools only for ESP32. See *Step 3. Set up the Tools* for more examples.

`install.sh --enable-XY` enables feature `XY` (by running `idf_tools.py install-python-env --features=core,XY`).

Export Scripts

Since the installed tools are not permanently added to the user or system `PATH` environment variable, an extra step is required to use them in the command line. The following scripts modify the environment variables in the current shell to make the correct versions of the tools available:

- `export.bat` for Windows Command Prompt
- `export.ps1` for Powershell
- `export.sh` for Bash
- `export.fish` for Fish

Note: To modify the shell environment in Bash, `export.sh` must be "sourced" by using the `. ./export.sh` command. Please ensure to include the leading dot and space.

`export.sh` may be used with shells other than Bash (such as zsh). However, in this case, it is required to set the `IDF_PATH` environment variable before running the script. When used in Bash, the script guesses the `IDF_PATH` value from its own location.

In addition to calling `idf_tools.py`, these scripts list the directories that have been added to the `PATH`.

Other Installation Methods

Depending on the environment, more user-friendly wrappers for `idf_tools.py` are provided:

- *ESP-IDF Tools Installer* can download and install the tools. Internally the installer uses `idf_tools.py`.
- ESP-IDF Eclipse Plugin includes a menu item to set up the tools. Internally the plugin calls `idf_tools.py`.
- VSCode ESP-IDF Extension includes an onboarding flow. This flow helps set up the tools. Although the extension does not rely on `idf_tools.py`, the same installation method is used.

Custom Installation

Although the methods above are recommended for ESP-IDF users, they are not a must for building ESP-IDF applications. ESP-IDF build system expects that all the necessary tools are installed somewhere, and made available in the `PATH`.

Uninstall ESP-IDF

Uninstalling ESP-IDF requires removing both the tools and the environment variables that have been configured during the installation.

- Windows users using the *Windows ESP-IDF Tools Installer* can simply run the uninstall wizard to remove ESP-IDF.
- To remove an installation performed by running the supported *install scripts*, simply delete the *tools installation directory* including the downloaded and installed tools. Any environment variables set by the *export scripts* are not permanent and will not be present after opening a new environment.
- When dealing with a custom installation, in addition to deleting the tools as mentioned above, you may also need to manually revert any changes to environment variables or system paths that were made to accommodate the ESP-IDF tools (e.g., `IDF_PYTHON_ENV_PATH` or `IDF_TOOLS_PATH`). If you manually copied any tools, you would need to track and delete those files manually.
- If you installed any plugins like the ESP-IDF Eclipse Plugin or VSCode ESP-IDF Extension, you should follow the specific uninstallation instructions described in the documentation of those components.

Note: Uninstalling the ESP-IDF tools does not remove any project files or your code. Be mindful of what you are deleting to avoid losing any work. If you are unsure about a step, refer back to the installation instructions.

These instructions assume that the tools were installed following the procedures in this provided document. If you've used a custom installation method, you might need to adapt these instructions accordingly.

4.30 Unit Testing in ESP32-S3

ESP-IDF provides the following methods to test software.

- Target based tests using a central unit test application which runs on the esp32s3. These tests use the Unity unit test framework. They can be integrated into an ESP-IDF component by placing them in the component's `test` subdirectory. This document mainly introduces this target based tests.
- Linux-host based unit tests in which part of the hardware can be abstracted via mocks. Currently, Linux-host based tests are still under development and only a small fraction of IDF components support them. More information on running IDF applications on the host can be found here: *Running Applications on the Host Machine*.

4.30.1 Normal Test Cases

Unit tests are located in the `test` subdirectory of a component. Tests are written in C, and a single C source file can contain multiple test cases. Test files start with the word "test".

Each test file should include the `unity.h` header and the header for the C module to be tested.

Tests are added in a function in the C file as follows:

```
TEST_CASE("test name", "[module name]")
{
        // Add test here
}
```

- The first argument is a descriptive name for the test.
- The second argument is an identifier in square brackets. Identifiers are used to group related test, or tests with specific properties.

Note: There is no need to add a main function with `UNITY_BEGIN()` and `UNITY_END()` in each test case. `unity_platform.c` will run `UNITY_BEGIN()` autonomously, and run the test cases, then call `UNITY_END()`.

The `test` subdirectory should contain a *component CMakeLists.txt*, since they are themselves components (i.e., a test component). ESP-IDF uses the Unity test framework located in the `unity` component. Thus, each test component

should specify the `unity` component as a component requirement using the `REQUIRES` argument. Normally, components *should list their sources manually*; for component tests however, this requirement is relaxed and the use of the `SRC_DIRS` argument in `idf_component_register` is advised.

Overall, the minimal `test` subdirectory `CMakeLists.txt` file should contain the following:

```
idf_component_register(SRC_DIRS "."
                       INCLUDE_DIRS "."
                       REQUIRES unity)
```

See http://www.throwtheswitch.org/unity for more information about writing tests in Unity.

4.30.2 Multi-device Test Cases

The normal test cases will be executed on one DUT (Device Under Test). However, components that require some form of communication (e.g., GPIO, SPI) require another device to communicate with, thus cannot be tested through normal test cases. Multi-device test cases involve writing multiple test functions, and running them on multiple DUTs.

The following is an example of a multi-device test case:

```
void gpio_master_test()
{
    gpio_config_t slave_config = {
            .pin_bit_mask = 1 << MASTER_GPIO_PIN,
            .mode = GPIO_MODE_INPUT,
    };
    gpio_config(&slave_config);
    unity_wait_for_signal("output high level");
    TEST_ASSERT(gpio_get_level(MASTER_GPIO_PIN) == 1);
}

void gpio_slave_test()
{
    gpio_config_t master_config = {
            .pin_bit_mask = 1 << SLAVE_GPIO_PIN,
            .mode = GPIO_MODE_OUTPUT,
    };
    gpio_config(&master_config);
    gpio_set_level(SLAVE_GPIO_PIN, 1);
    unity_send_signal("output high level");
}

TEST_CASE_MULTIPLE_DEVICES("gpio multiple devices test example", "[driver]", gpio_
↪master_test, gpio_slave_test);
```

The macro `TEST_CASE_MULTIPLE_DEVICES` is used to declare a multi-device test case.

- The first argument is test case name.
- The second argument is test case description.
- From the third argument, up to 5 test functions can be defined, each function will be the entry point of tests running on each DUT.

Running test cases from different DUTs could require synchronizing between DUTs. We provide `unity_wait_for_signal` and `unity_send_signal` to support synchronizing with UART. As the scenario in the above example, the slave should get GPIO level after master set level. DUT UART console will prompt and user interaction is required:

DUT1 (master) console:

```
Waiting for signal: [output high level]!
Please press "Enter" key to once any board send this signal.
```

DUT2 (slave) console:

```
Send signal: [output high level]!
```

Once the signal is sent from DUT2, you need to press "Enter" on DUT1, then DUT1 unblocks from `unity_wait_for_signal` and starts to change GPIO level.

4.30.3 Multi-stage Test Cases

The normal test cases are expected to finish without reset (or only need to check if reset happens). Sometimes we expect to run some specific tests after certain kinds of reset. For example, we want to test if the reset reason is correct after a wake up from deep sleep. We need to create a deep-sleep reset first and then check the reset reason. To support this, we can define multi-stage test cases, to group a set of test functions:

```
static void trigger_deepsleep(void)
{
    esp_sleep_enable_timer_wakeup(2000);
    esp_deep_sleep_start();
}

void check_deepsleep_reset_reason()
{
    soc_reset_reason_t reason = esp_rom_get_reset_reason(0);
    TEST_ASSERT(reason == RESET_REASON_CORE_DEEP_SLEEP);
}

TEST_CASE_MULTIPLE_STAGES("reset reason check for deepsleep", "[esp32s3]", trigger_
↪deepsleep, check_deepsleep_reset_reason);
```

Multi-stage test cases present a group of test functions to users. It needs user interactions (select cases and select different stages) to run the case.

4.30.4 Tests For Different Targets

Some tests (especially those related to hardware) cannot run on all targets. Below is a guide how to make your unit tests run on only specified targets.

1. Wrap your test code by `!(TEMPORARY_)DISABLED_FOR_TARGETS()` macros and place them either in the original test file, or separate the code into files grouped by functions, but make sure all these files will be processed by the compiler. E.g.:

   ```
   #if !TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
   TEST_CASE("a test that is not ready for esp32 and esp8266 yet", "[]")
   {
   }
   #endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP32, ESP8266)
   ```

Once you need one of the tests to be compiled on a specified target, just modify the targets in the disabled list. It's more encouraged to use some general conception that can be described in `soc_caps.h` to control the disabling of tests. If this is done but some of the tests are not ready yet, use both of them (and remove `!(TEMPORARY_)DISABLED_FOR_TARGETS()` later). E.g.:

```
#if SOC_SDIO_SLAVE_SUPPORTED
#if !TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
TEST_CASE("a sdio slave tests that is not ready for esp64 yet", "[sdio_slave]")
{
    //available for esp32 now, and will be available for esp64 in the future
}
#endif //!TEMPORARY_DISABLED_FOR_TARGETS(ESP64)
#endif //SOC_SDIO_SLAVE_SUPPORTED
```

2. For test code that you are 100% for sure that will not be supported (e.g., no peripheral at all), use `DISABLED_FOR_TARGETS`; for test code that should be disabled temporarily, or due to lack of runners, etc., use `TEMPORARY_DISABLED_FOR_TARGETS`.

Some old ways of disabling unit tests for targets, that have obvious disadvantages, are deprecated:

- DON'T put the test code under `test/target` folder and use CMakeLists.txt to choose one of the target folder. This is prevented because test code is more likely to be reused than the implementations. If you put something into `test/esp32` just to avoid building it on esp32s2, it's hard to make the code tidy if you want to enable the test again on esp32s3.
- DON'T use `CONFIG_IDF_TARGET_xxx` macros to disable the test items any more. This makes it harder to track disabled tests and enable them again. Also, a black-list style `#if !disabled` is preferred to white-list style `#if CONFIG_IDF_TARGET_xxx`, since you will not silently disable cases when new targets are added in the future. But for test implementations, it's allowed to use `#if CONFIG_IDF_TARGET_xxx` to pick one of the implementation code.
  - Test item: some items that will be performed on some targets, but skipped on other targets. E.g.
    There are three test items SD 1-bit, SD 4-bit and SDSPI. For ESP32-S2, which doesn't have SD host, among the tests only SDSPI is enabled on ESP32-S2.
  - Test implementation: some code will always happen, but in different ways. E.g.
    There is no SDIO PKT_LEN register on ESP8266. If you want to get the length from the slave as a step in the test process, you can have different implementation code protected by `#if CONFIG_IDF_TARGET_` reading in different ways.
    But please avoid using `#else` macro. When new target is added, the test case will fail at building stage, so that the maintainer will be aware of this, and choose one of the implementations explicitly.

4.30.5 Building Unit Test App

Follow the setup instructions in the top-level esp-idf README. Make sure that `IDF_PATH` environment variable is set to point to the path of esp-idf top-level directory.

Change into `tools/unit-test-app` directory to configure and build it:

- `idf.py menuconfig` - configure unit test app.
- `idf.py -T all build` - build unit test app with tests for each component having tests in the `test` subdirectory.
- `idf.py -T "xxx yyy" build` - build unit test app with tests for some space-separated specific components (For instance: `idf.py -T heap build` - build unit tests only for `heap` component directory).
- `idf.py -T all -E "xxx yyy" build` - build unit test app with all unit tests, except for unit tests of some components (For instance: `idf.py -T all -E "ulp mbedtls" build` - build all unit tests excludes `ulp` and `mbedtls` components).

Note: Due to inherent limitations of Windows command prompt, following syntax has to be used in order to build unit-test-app with multiple components: `idf.py -T xxx -T yyy build` or with escaped quotes: `idf.py -T \`"xxx yyy\`" build` in PowerShell or `idf.py -T \^"ssd1306 hts221\^" build` in Windows command prompt.

When the build finishes, it will print instructions for flashing the chip. You can simply run `idf.py flash` to flash all build output.

You can also run `idf.py -T all flash` or `idf.py -T xxx flash` to build and flash. Everything needed will be rebuilt automatically before flashing.

Use menuconfig to set the serial port for flashing. For more information, see tools/unit-test-app/README.md.

4.30.6 Running Unit Tests

Note: We also provide the pytest-based framework pytest-embedded to help make running unit-tests more convenient and efficient. If you need to run tests in CI or run multiple tests in a row we recommend checking out this project. For more information see Pytest-embedded Docs and *pytest in ESP-IDF*.

After flashing reset the ESP32-S3 and it will boot the unit test app.

When unit test app is idle, press "Enter" will make it print test menu with all available tests:

```
Here's the test menu, pick your combo:
(1)     "esp_ota_begin() verifies arguments" [ota]
(2)     "esp_ota_get_next_update_partition logic" [ota]
(3)     "Verify bootloader image in flash" [bootloader_support]
(4)     "Verify unit test app image" [bootloader_support]
(5)     "can use new and delete" [cxx]
(6)     "can call virtual functions" [cxx]
(7)     "can use static initializers for non-POD types" [cxx]
(8)     "can use std::vector" [cxx]
(9)     "static initialization guards work as expected" [cxx]
(10)    "global initializers run in the correct order" [cxx]
(11)    "before scheduler has started, static initializers work correctly" [cxx]
(12)    "adc2 work with wifi" [adc]
(13)    "gpio master/slave test example" [ignore][misc][test_env=UT_T2_1][multi_
↪device]
        (1)     "gpio_master_test"
        (2)     "gpio_slave_test"
(14)    "SPI Master clockdiv calculation routines" [spi]
(15)    "SPI Master test" [spi][ignore]
(16)    "SPI Master test, interaction of multiple devs" [spi][ignore]
(17)    "SPI Master no response when switch from host1 (SPI2) to host2 (SPI3)"␣
↪[spi]
(18)    "SPI Master DMA test, TX and RX in different regions" [spi]
(19)    "SPI Master DMA test: length, start, not aligned" [spi]
(20)    "reset reason check for deepsleep" [esp32s3][test_env=UT_T2_1][multi_stage]
        (1)     "trigger_deepsleep"
        (2)     "check_deepsleep_reset_reason"
```

The normal case will print the case name and description. Master-slave cases will also print the sub-menu (the registered test function names).

Test cases can be run by inputting one of the following:

- Test case name in quotation marks to run a single test case
- Test case index to run a single test case
- Module name in square brackets to run all test cases for a specific module
- An asterisk to run all test cases

`[multi_device]` and `[multi_stage]` tags tell the test runner whether a test case is a multiple devices or multiple stages of test case. These tags are automatically added by `` `TEST_CASE_MULTIPLE_STAGES `` and `TEST_CASE_MULTIPLE_DEVICES` macros.

After you select a multi-device test case, it will print sub-menu:

```
Running gpio master/slave test example...
gpio master/slave test example
        (1)     "gpio_master_test"
        (2)     "gpio_slave_test"
```

You need to input a number to select the test running on the DUT.

Similar to multi-device test cases, multi-stage test cases will also print sub-menu:

```
Running reset reason check for deepsleep...
reset reason check for deepsleep
        (1)     "trigger_deepsleep"
        (2)     "check_deepsleep_reset_reason"
```

First time you execute this case, input `1` to run first stage (trigger deepsleep). After DUT is rebooted and able to run test cases, select this case again and input `2` to run the second stage. The case only passes if the last stage passes and all previous stages trigger reset.

4.30.7 Timing Code with Cache Compensated Timer

Instructions and data stored in external memory (e.g., SPI Flash and SPI RAM) are accessed through the CPU's unified instruction and data cache. When code or data is in cache, access is very fast (i.e., a cache hit).

However, if the instruction or data is not in cache, it needs to be fetched from external memory (i.e., a cache miss). Access to external memory is significantly slower, as the CPU must execute stall cycles whilst waiting for the instruction or data to be retrieved from external memory. This can cause the overall code execution speed to vary depending on the number of cache hits or misses.

Code and data placements can vary between builds, and some arrangements may be more favorable with regards to cache access (i.e., minimizing cache misses). This can technically affect execution speed, however these factors are usually irrelevant as their effect 'average out' over the device's operation.

The effect of the cache on execution speed, however, can be relevant in benchmarking scenarios (especially micro benchmarks). There might be some variability in measured time between runs and between different builds. A technique for eliminating for some of the variability is to place code and data in instruction or data RAM (IRAM/DRAM), respectively. The CPU can access IRAM and DRAM directly, eliminating the cache out of the equation. However, this might not always be viable as the size of IRAM and DRAM is limited.

The cache compensated timer is an alternative to placing the code/data to be benchmarked in IRAM/DRAM. This timer uses the processor's internal event counters in order to determine the amount of time spent on waiting for code/data in case of a cache miss, then subtract that from the recorded wall time.

```
// Start the timer
ccomp_timer_start();

// Function to time
func_code_to_time();

// Stop the timer, and return the elapsed time in microseconds relative to
// ccomp_timer_start
int64_t t = ccomp_timer_stop();
```

One limitation of the cache compensated timer is that the task that benchmarked functions should be pinned to a core. This is due to each core having its own event counters that are independent of each other. For example, if `ccomp_timer_start` gets called on one core, put to sleep by the scheduler, wakes up, and gets rescheduled on the other core, then the corresponding `ccomp_timer_stop` will be invalid.

4.30.8 Mocks

Note: Currently, mocking is only possible with some selected components when running on the Linux host. In the future, we plan to make essential components in IDF mock-able. This will also include mocking when running on the ESP32-S3.

One of the biggest problems regarding unit testing on embedded systems are the strong hardware dependencies. Running unit tests directly on the ESP32-S3 can be especially difficult for higher layer components for the following reasons:

- Decreased test reliability due to lower layer components and/or hardware setup.
- Increased difficulty in testing edge cases due to limitations of lower layer components and/or hardware setup
- Increased difficulty in identifying the root cause due to the large number of dependencies influencing the behavior

When testing a particular component, (i.e., the component under test), mocking allows the dependencies of the component under test to be substituted (i.e., mocked) entirely in software. Through mocking, hardware details are emulated and specified at run time, but only if necessary. To allow mocking, ESP-IDF integrates the CMock mocking framework as a component. With the addition of some CMake functions in the ESP-IDF build system, it is possible to conveniently mock the entirety (or a part) of an IDF component.

Ideally, all components that the component under test is dependent on should be mocked, thus allowing the test environment complete control over all interactions with the component under test. However, if mocking all dependent components becomes too complex or too tedious (e.g., because you need to mock too many function calls) you have the following options:

- Include more "real" IDF code in the tests. This may work but increases the dependency on the "real" code's behavior. Furthermore, once a test fails, you may not know if the failure is in your actual code under test or the "real" IDF code.
- Re-evaluate the design of the code under test and attempt to reduce its dependencies by dividing the code under test into more manageable components. This may seem burdensome but it is quite common that unit tests expose software design weaknesses. Fixing design weaknesses will not only help with unit testing in the short term, but will help future code maintenance as well.

Refer to cmock/CMock/docs/CMock_Summary.md for more details on how CMock works and how to create and use mocks.

Requirements

Mocking with CMock requires `Ruby` on the host machine. Furthermore, since mocking currently only works on the Linux target, the requirements of the latter also need to be fulfilled:

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the CMakeLists.txt of the application's root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

Mock a Component

If a mocked component, called a *component mock*, is already available in ESP-IDF, then it can be used right away as long as it satisfies the required functionality. Refer to *Component Linux/Mock Support Overview* to see which components are mocked already. Then refer to *Adjustments in Unit Test* in order to use the component mock.

It is necessary to create component mocks if they are not yet provided in ESP-IDF. To create a component mock, the component needs to be overwritten in a particular way. Overriding a component entails creating a component with the exact same name as the original component, then letting the build system discover it later than the original component (see *Multiple components with the same name* for more details).

In the component mock, the following parts are specified:

- The headers providing the functions to generate mocks for
- Include paths of the aforementioned headers
- Dependencies of the mock component (this is necessary e.g. if the headers include files from other components)

All these parts have to be specified using the IDF build system function `idf_component_mock`. You can use the IDF build system function `idf_component_get_property` with the tag `COMPONENT_OVERRIDEN_DIR` to access the component directory of the original component and then register the mock component parts using `idf_component_mock`:

```
idf_component_get_property(original_component_dir <original-component-name>␣
↪COMPONENT_OVERRIDEN_DIR)
...
idf_component_mock(INCLUDE_DIRS "${original_component_dir}/include"
    REQUIRES freertos
    MOCK_HEADER_FILES ${original_component_dir}/include/header_containing_
↪functions_to_mock.h)
```

The component mock also requires a separate `mock` directory containing a `mock_config.yaml` file that configures CMock. A simple `mock_config.yaml` could look like this:

```
:cmock:
  :plugins:
    - expect
    - expect_any_args
```

For more details about the CMock configuration yaml file, have a look at cmock/CMock/docs/CMock_Summary.md.

Note that the component mock does not have to mock the original component in its entirety. As long as the test project's dependencies and dependencies of other code to the original components are satisfied by the component mock, partial mocking is adequate. In fact, most of the component mocks in IDF in `tools/mocks` are only partially mocking the original component.

Examples of component mocks can be found under tools/mocks in the IDF directory. General information on how to *override an IDF component* can be found in *Multiple components with the same name*. There are several examples for testing code while mocking dependencies with CMock (non-exhaustive list):

- unit test for the NVS Page class .
- unit test for esp_event .
- unit test for mqtt .

Adjustments in Unit Test

The unit test needs to inform the cmake build system to mock dependent components (i.e., it needs to override the original component with the mock component). This is done by either placing the component mock into the project's `components` directory or adding the mock component's directory using the following line in the project's root `CMakeLists.txt`:

```
list(APPEND EXTRA_COMPONENT_DIRS "<mock_component_dir>")
```

Both methods will override existing components in ESP-IDF with the component mock. The latter is particularly convenient if you use component mocks that are already supplied by IDF.

Users can refer to the `esp_event` host-based unit test and its esp_event/host_test/esp_event_unit_test/CMakeLists.txt as an example of a component mock.

4.31 Running ESP-IDF Applications on Host

Note: Running ESP-IDF applications on host is currently still an experimental feature, thus there is no guarantee for API stability. However, user feedback via the ESP-IDF GitHub repository or the ESP32 forum is highly welcome, and may help influence the future of design of the ESP-IDF host-based applications.

This document provides an overview of the methods to run ESP-IDF applications on Linux, and what type of ESP-IDF applications can typically be run on Linux.

4.31.1 Introduction

Typically, an ESP-IDF application is built (cross-compiled) on a host machine, uploaded (i.e., flashed) to an ESP chip for execution, and monitored by the host machine via a UART/USB port. However, execution of an ESP-IDF application on an ESP chip can be limiting in various development/usage/testing scenarios.

Therefore, it is possible for an ESP-IDF application to be built and executed entirely within the same Linux host machine (henceforth referred to as "running on host"). Running ESP-IDF applications on host has several advantages:

- No need to upload to a target.
- Faster execution on a host machine, compared to running on an ESP chip.
- No requirements for any specific hardware, except the host machine itself.
- Easier automation and setup for software testing.
- Large number of tools for code and runtime analysis, e.g., Valgrind.

A large number of ESP-IDF components depend on chip-specific hardware. These hardware dependencies must be mocked or simulated when running on host. ESP-IDF currently supports the following mocking and simulation approaches:

1. Using the FreeRTOS POSIX/Linux simulator that simulates FreeRTOS scheduling. On top of this simulation, other APIs are also simulated or implemented when running on host.
2. Using CMock to mock all dependencies and run the code in complete isolation.

In principle, it is possible to mix both approaches (POSIX/Linux simulator and mocking using CMock), but this has not been done yet in ESP-IDF. Note that despite the name, the FreeRTOS POSIX/Linux simulator currently also works on macOS. Running ESP-IDF applications on host machines is often used for testing. However, simulating the environment and mocking dependencies does not fully represent the target device. Thus, testing on the target device is still necessary, though with a different focus that usually puts more weight on integration and system testing.

Note: Another possibility to run applications on the host is to use the QEMU simulator. However, QEMU development for ESP-IDF applications is still a work in progress and has not been documented yet.

CMock-Based Approach

This approach uses the CMock framework to solve the problem of missing hardware and software dependencies. CMock-based applications running on the host machine have the added advantage that they usually only compile the necessary code, i.e., the (mostly mocked) dependencies instead of the entire system. For a general introduction to Mocks and how to configure and use them in ESP-IDF, please refer to *Mocks*.

POSIX/Linux Simulator Approach

The FreeRTOS POSIX/Linux simulator is available on ESP-IDF as a preview target already. This simulator allows ESP-IDF components to be implemented on the host, making them accessible to ESP-IDF applications when running on host. Currently, only a limited number of components are ready to be built on Linux. Furthermore, the functionality of each component ported to Linux may also be limited or different compared to the functionality when building that component for a chip target. For more information about whether the desired components are supported on Linux, please refer to *Component Linux/Mock Support Overview*.

Note: The FreeRTOS POSIX/Linux simulator allows configuring the *Amazon SMP FreeRTOS* version. However, the simulation still runs in single-core mode. The main reason allowing Amazon SMP FreeRTOS is to provide API compatibility with ESP-IDF applications written for Amazon SMP FreeRTOS.

4.31.2 Requirements for Using Mocks

- Installed ESP-IDF including all ESP-IDF requirements
- System package requirements (`libbsd`, `libbsd-dev`)
- A recent enough Linux or macOS version and GCC compiler
- All components the application depends on must be either supported on the Linux target (Linux/POSIX simulator) or mock-able

An application that runs on the Linux target has to set the `COMPONENTS` variable to `main` in the CMakeLists.txt of the application's root directory:

```
set(COMPONENTS main)
```

This prevents the automatic inclusion of all components from ESP-IDF to the build process which is otherwise done for convenience.

If any mocks are used, then `Ruby` is required, too.

4.31.3 Build and Run

To build the application on Linux, the target has to be set to `linux` and then it can be built and run:

```
idf.py --preview set-target linux
idf.py build
idf.py monitor
```

4.31.4 Component Linux/Mock Support Overview

Note that any "Yes" here does not necessarily mean a full implementation or mocking. It can also mean a partial implementation or mocking of functionality. Usually, the implementation or mocking is done to a point where enough functionality is provided to build and run a test application.

Component	Mock	Simulation
cmock	No	Yes
driver	Yes	No
esp_common	No	Yes
esp_event	Yes	Yes
esp_http_client	No	Yes
esp_http_server	No	Yes
esp_https_server	No	Yes
esp_hw_support	Yes	Yes
esp_netif	Yes	Yes
esp_netif_stack	No	Yes
esp_partition	Yes	Yes
esp_rom	No	Yes
esp_system	No	Yes
esp_timer	Yes	No
esp_tls	Yes	Yes
fatfs	No	Yes

continues on next page

Table 30 – continued from previous page

Component	Mock	Simulation
freertos	Yes	Yes
hal	No	Yes
heap	No	Yes
http_parser	Yes	Yes
json	No	Yes
linux	No	Yes
log	No	Yes
lwip	Yes	Yes
mbedtls	No	Yes
mqtt	No	Yes
nvs_flash	No	Yes
partition_table	No	Yes
protobuf-c	No	Yes
pthread	No	Yes
soc	No	Yes
spiffs	No	Yes
spi_flash	Yes	No
tcp_transport	Yes	No
unity	No	Yes

4.32 USB OTG Console

On chips with an integrated USB peripheral, it is possible to use USB Communication Device Class (CDC) to implement the serial console, instead of using UART with an external USB-UART bridge chip. ESP32-S3 ROM code contains a USB CDC implementation, which supports for some basic functionality without requiring the application to include the USB stack:

- Bidirectional serial console, which can be used with *IDF Monitor* or another serial monitor
- Flashing using `esptool.py` and `idf.py flash`.
- *Device Firmware Update (DFU)* interface for flashing the device using `dfu-util` and `idf.py dfu`.

Note: At the moment, this "USB Console" feature is incompatible with TinyUSB stack. However, if TinyUSB is used, it can provide its own CDC implementation.

4.32.1 Hardware Requirements

Connect ESP32-S3 to the USB port as follows

GPIO	USB
20	D+ (green)
19	D- (white)
GND	GND (black)
	+5V (red)

Some development boards may offer a USB connector for the internal USB peripheral —in that case, no extra connections are required.

By default, *USB_SERIAL_JTAG* module is connected to the internal PHY of the ESP32-S3, while USB_OTG peripheral can be used only if the external USB PHY is connected. Since CDC console is provided via USB_OTG peripheral, it cannot be used through the internal PHY in this configuration.

You can permanently switch the internal USB PHY to work with USB_OTG peripheral instead of USB_SERIAL_JTAG by burning `USB_PHY_SEL` eFuse. See ESP32-S3 Technical Reference Manual for more details about USB_SERIAL_JTAG and USB_OTG.

Note however that USB_SERIAL_JTAG also provides a CDC console, so enabling the CDC console should not be the primary reason for switching from USB_SERIAL_JTAG to USB_CDC.

4.32.2 Software Configuration

USB console feature can be enabled using `CONFIG_ESP_CONSOLE_USB_CDC` option in menuconfig tool (see *CONFIG_ESP_CONSOLE_UART*).

Once the option is enabled, build the project as usual.

4.32.3 Uploading the Application

Initial Upload

If the ESP32-S3 is not yet flashed with a program that enables a USB console, an initial upload of the program is required. There are 3 alternative options to perform the initial upload.

Once the initial upload is done, the application will start up and a USB CDC port will appear in the system.

Note: The port name may change after the initial upload, so check the port list again before running `idf.py monitor`.

Initial Upload Using the ROM Download Mode, over USB CDC

- Place ESP32-S3 into download mode. To do this, keep GPIO0 low while toggling reset. On many development boards, the "Boot" button is connected to GPIO0, and you can press "Reset" button while holding "Boot".
- A serial port will appear in the system. On most operating systems (Windows 8 and later, Linux, macOS) driver installation is not required. Find the port name using Device Manager (Windows) or by listing `/dev/ttyACM*` devices on Linux or `/dev/cu*` devices on macOS.
- Run `idf.py flash -p PORT` to upload the application, with `PORT` determined in the previous step.

Initial Upload Using the ROM Download Mode, over USB DFU

- Place ESP32-S3 into download mode. To do this, keep GPIO0 low while toggling reset. On many development boards, the "Boot" button is connected to GPIO0, and you can press "Reset" button while holding "Boot".
- Run `idf.py dfu-flash`.

See *Flashing the DFU Image* for details about DFU flashing.

Initial Upload Using UART On development boards with a USB-UART bridge, upload the application over UART: `idf.py flash -p PORT` where `PORT` is the name of the serial port provided by the USB-UART bridge.

Subsequent Usage

Once the application is uploaded for the first time, you can run `idf.py flash` and `idf.py monitor` as usual.

4.32.4 Limitations

There are several limitations to the USB console feature. These may or may not be significant, depending on the type of application being developed, and the development workflow. Most of these limitations stem from the fact that USB CDC is implemented in software, so the console working over USB CDC is more fragile and complex than a console working over UART.

1. If the application crashes, panic handler output may not be sent over USB CDC in some cases. If the memory used by the CDC driver is corrupted, or there is some other system-level issue, CDC may not work for sending panic handler messages over USB. This does work in many situations, but is not guaranteed to work as reliably as the UART output does. Similarly, if the application enters a boot loop before the USB CDC driver has a chance to start up, there will be no console output.
2. If the application accidentally reconfigures the USB peripheral pins, or disables the USB peripheral, USB CDC device will disappear from the system. After fixing the issue in the application, you will need to follow the *Initial Upload* process to flash the application again.
3. If the application enters light sleep (including automatic light sleep) or deep sleep mode, USB CDC device will disappear from the system.
4. USB CDC driver reserves some amount of RAM and increases application code size. Keep this in mind if trying to optimize application memory usage.
5. By default, the low-level `esp_rom_printf` feature and `ESP_EARLY_LOG` are disabled when USB CDC is used. These can be enabled using *CONFIG_ESP_CONSOLE_USB_CDC_SUPPORT_ETS_PRINTF* option. With this option enabled, `esp_rom_printf` can be used, at the expense of increased IRAM usage. Keep in mind that the cost of `esp_rom_printf` and `ESP_EARLY_LOG` over USB CDC is significantly higher than over UART. This makes these logging mechanisms much less suitable for "printf debugging", especially in the interrupt handlers.
6. If you are developing an application which uses the USB peripheral with the TinyUSB stack, this USB Console feature can not be used. This is mainly due to the following reasons:
   - This feature relies on a different USB CDC software stack in ESP32-S3 ROM.
   - USB descriptors used by the ROM CDC stack may be different from the descriptors used by TinyUSB.
   - When developing applications which use USB peripheral, it is very likely that USB functionality will not work or will not fully work at some moments during development. This can be due to misconfigured USB descriptors, errors in the USB stack usage, or other reasons. In this case, using the UART console for flashing and monitoring provides a much better development experience.
7. When debugging the application using JTAG, USB CDC may stop working if the CPU is stopped on a breakpoint. USB CDC operation relies on interrupts from the USB peripheral being serviced periodically. If the host computer does not receive valid responses from the USB device side for some time, it may decide to disconnect the device. The actual time depends on the OS and the driver, and ranges from a few hundred milliseconds to a few seconds.

4.33 USB Serial/JTAG Controller Console

Generally, ESP chips implement a serial port using UART and can be connected to a serial console emulator on a host/PC via an external USB-UART bridge chip. However, on ESP chips that contain a USB Serial/JTAG Controller, the CDC-ACM portion of the controller implements a serial port that is connected directly to a host/PC, thus does not require an external USB-UART bridge chip.

ESP32-S3 contains a USB Serial/JTAG Controller providing the following functions:

- Bidirectional serial console, which can be used with *IDF Monitor* or another serial monitor.
- Flashing using `esptool.py` and `idf.py flash`.
- JTAG debugging, performed simultaneously with serial operations using tools like OpenOCD.

Note: The USB Serial/JTAG Controller is a fixed-function USB device that is implemented entirely in hardware, meaning that it cannot be reconfigured to perform any function other than a serial port and JTAG debugging functionality. This is in contrast to the USB OTG controllers in some ESP chips that can be configured to perform the

function of multiple types of USB devices.

4.33.1 Hardware Requirements

Connect ESP32-S3 to the USB port as follows:

GPIO	USB
20	D+ (green)
19	D- (white)
GND	GND (black)
5V (or externally supplied)	+5V (red)

Some development boards may offer a USB connector for the USB Serial/JTAG Controller. In that case, no extra connections are required.

4.33.2 Software Configuration

The USB Serial/JTAG Controller can be used as the serial port by selecting `CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG` in the *CONFIG_ESP_CONSOLE_UART* option. Once selected, building and flashing the project can occur as usual.

Alternatively, you can access the output through the `usb_serial_jtag` port but make sure `CONFIG_ESP_CONSOLE_SECONDARY_USB_SERIAL_JTAG` is selected in the *CONFIG_ESP_CONSOLE_SECONDARY*.

Warning: Besides output, if you also want to input or use REPL with the console, please select `CONFIG_ESP_CONSOLE_USB_SERIAL_JTAG`.

4.33.3 Uploading the Application

The USB Serial/JTAG Controller is able to put the ESP32-S3 into download mode automatically. Simply flash as usual, but specify the USB Serial/JTAG Controller port on your system: `idf.py flash -p PORT`, where `PORT` is the name of the proper port.

Note: The USB Serial/JTAG Controller's serial port usually appears:

- as `/dev/ttyACM*` on Linux
- as `/dev/cu*` on Mac
- as a `COM*` port in the Windows Device Manager

4.33.4 Limitations

There are several limitations to the USB Serial/JTAG console feature. The significance of these limitations depends on the type of application being developed, and the development workflow.

USB Pin Reconfiguration

If the application accidentally reconfigures the USB peripheral pins or disables the USB Serial/JTAG Controller, the device disappears from the system. After fixing the issue in the application, you need to manually put the ESP32-S3 into download mode by pulling low GPIO0 and resetting the chip.

If the application enters Deep-sleep mode, the USB Serial/JTAG device disappears from the system.

Data Buffering

For data transmitted from ESP32-S3 to PC Terminal (e.g., stdout, logs), the ESP32-S3 first writes to a small internal buffer. After this buffer becomes full (for example, if no PC Terminal is connected), the ESP32-S3 does a one-time wait of 50 ms for the PC Terminal to request the data. This can appear as a very brief pause in your application.

For data transmitted from the PC Terminal to ESP32-S3 (e.g., console commands), many PC Terminals wait for the ESP32-S3 to ingest the bytes before allowing you to send more data. This is in contrast to using a USB-to-Serial (UART) bridge chip, which always ingests the bytes and sends them to a (possibly not listening) ESP32-S3.

Note: In rare cases it's possible that data sent from the ESP32-S3 to the host gets 'stuck' in host memory. Sending more data will get it 'unstuck', but if the application does not send more data, depending on the driver, this data needs to be flushed to the host manually. The non-blocking (default) driver and the VFS implementation will flush automatically after a newline. The blocking (interrupt-based) driver will automatically flush when its transmit buffer becomes empty.

Sleep Mode Considerations

The USB Serial/JTAG controller and its associated USB PHY are driven by particular clocks (e.g., APB and USB PHY clock) and belong to a particular power domain (e.g., digital power domain). Thus, any change to the clock and power domains associated with the USB Serial/JTAG controller, such as entering different sleep modes, can affect the controller's operation.

Deep Sleep When entering deep sleep, both the USB Serial/JTAG controller and the USB PHY are powered off, leading to the USB PHY's D+ line no longer being pulled up. As a result:

- When entering deep sleep, the USB Serial/JTAG device appears disconnected from the host/PC (even if the USB cable is still physically connected).
- When exiting deep sleep, the USB Serial/JTAG device reconnects to the host/PC.

Light Sleep When entering light sleep, the APB and USB PHY clock are gated. Thus, the USB Serial/JTAG controller is no longer able to receive or respond to any USB transactions from the connected host (including periodic CDC Data IN transactions). As a result:

- when entering light sleep, the USB Serial/JTAG device is unresponsive to the host/PC's USB CDC driver. The host/PC may then report the USB Serial/JTAG device as disconnected or erroneous (even if the USB cable is still physically connected).
- when exiting light sleep, it is possible that the host/PC does not re-enumerate (i.e., reconnect) the USB Serial/JTAG device given that the USB PHY's D+ line remains pulled up state during light sleep. Users may need to physically disconnect and then reconnect the USB cable.

Automatic and Manual Sleep Entry If users enter sleep manually (via `esp_light_sleep_start()` or `esp_deep_sleep_start()`), users should be cognizant of the fact that USB Serial/JTAG controller does not work during sleep. ESP-IDF **does not add any safety check to reject entry to sleep** even if the USB Serial/JTAG controller is connected. In the case where sleep is entered while the USB Serial/JTAG controller is connected, the connection can be re-established by unplugging and re-plugging the USB cable.

If users enter sleep automatically (via `esp_pm_configure()`), enabling the *CONFIG_USJ_NO_AUTO_LS_ON_CONNECTION* option allows the ESP32-S3 to automatically detect whether the USB Serial/JTAG controller is currently connected to a host, and prevent automatic entry to sleep as long as the connection persists. However, note that this option increases power consumption.

4.34 Wi-Fi Driver

4.34.1 ESP32-S3 Wi-Fi Feature List

The following features are supported:

- 4 virtual Wi-Fi interfaces, which are STA, AP, Sniffer and reserved.
- Station-only mode, AP-only mode, station/AP-coexistence mode
- IEEE 802.11b, IEEE 802.11g, IEEE 802.11n, and APIs to configure the protocol mode
- WPA/WPA2/WPA3/WPA2-Enterprise/WPA3-Enterprise/WAPI/WPS and DPP
- AMSDU, AMPDU, HT40, QoS, and other key features
- Modem-sleep
- The Espressif-specific ESP-NOW protocol and Long Range mode, which supports up to **1 km** of data traffic
- Up to 20 MBit/s TCP throughput and 30 MBit/s UDP throughput over the air
- Sniffer
- Both fast scan and all-channel scan
- Multiple antennas
- Channel state information

4.34.2 How To Write a Wi-Fi Application

Preparation

Generally, the most effective way to begin your own Wi-Fi application is to select an example which is similar to your own application, and port the useful part into your project. It is not a MUST, but it is strongly recommended that you take some time to read this article first, especially if you want to program a robust Wi-Fi application.

This article is supplementary to the Wi-Fi APIs/Examples. It describes the principles of using the Wi-Fi APIs, the limitations of the current Wi-Fi API implementation, and the most common pitfalls in using Wi-Fi. This article also reveals some design details of the Wi-Fi driver. We recommend you to select an example .

Setting Wi-Fi Compile-time Options

Refer to *Wi-Fi Menuconfig*.

Init Wi-Fi

Refer to *ESP32-S3 Wi-Fi station General Scenario* and *ESP32-S3 Wi-Fi AP General Scenario*.

Start/Connect Wi-Fi

Refer to *ESP32-S3 Wi-Fi station General Scenario* and *ESP32-S3 Wi-Fi AP General Scenario*.

Event-Handling

Generally, it is easy to write code in "sunny-day" scenarios, such as *WIFI_EVENT_STA_START* and *WIFI_EVENT_STA_CONNECTED*. The hard part is to write routines in "rainy-day" scenarios, such as *WIFI_EVENT_STA_DISCONNECTED*. Good handling of "rainy-day" scenarios is fundamental to robust Wi-Fi applications. Refer to *ESP32-S3 Wi-Fi Event Description*, *ESP32-S3 Wi-Fi station General Scenario*, and *ESP32-S3 Wi-Fi AP General Scenario*. See also the *overview of the Event Loop Library in ESP-IDF*.

Write Error-Recovery Routines Correctly at All Times

Just like the handling of "rainy-day" scenarios, a good error-recovery routine is also fundamental to robust Wi-Fi applications. Refer to *ESP32-S3 Wi-Fi API Error Code*.

4.34.3 ESP32-S3 Wi-Fi API Error Code

All of the ESP32-S3 Wi-Fi APIs have well-defined return values, namely, the error code. The error code can be categorized into:

- No errors, e.g., *ESP_OK* means that the API returns successfully.
- Recoverable errors, such as *ESP_ERR_NO_MEM*.
- Non-recoverable, non-critical errors.
- Non-recoverable, critical errors.

Whether the error is critical or not depends on the API and the application scenario, and it is defined by the API user.

The primary principle to write a robust application with Wi-Fi API is to always check the error code and write the error-handling code. Generally, the error-handling code can be used:

- For recoverable errors, in which case you can write a recoverable-error code. For example, when *esp_wifi_start()* returns *ESP_ERR_NO_MEM*, the recoverable-error code vTaskDelay can be called in order to get a microseconds' delay for another try.
- For non-recoverable, yet non-critical errors, in which case printing the error code is a good method for error handling.
- For non-recoverable and also critical errors, in which case "assert" may be a good method for error handling. For example, if *esp_wifi_set_mode()* returns ESP_ERR_WIFI_NOT_INIT, it means that the Wi-Fi driver is not initialized by *esp_wifi_init()* successfully. You can detect this kind of error very quickly in the application development phase.

In esp_common/include/esp_err.h, ESP_ERROR_CHECK checks the return values. It is a rather commonplace error-handling code and can be used as the default error-handling code in the application development phase. However, it is strongly recommended that API users write their own error-handling code.

4.34.4 ESP32-S3 Wi-Fi API Parameter Initialization

When initializing struct parameters for the API, one of two approaches should be followed:

- Explicitly set all fields of the parameter.
- Use get API to get current configuration first, then set application specific fields.

Initializing or getting the entire structure is very important, because most of the time the value 0 indicates that the default value is used. More fields may be added to the struct in the future and initializing these to zero ensures the application will still work correctly after ESP-IDF is updated to a new release.

4.34.5 ESP32-S3 Wi-Fi Programming Model

The ESP32-S3 Wi-Fi programming model is depicted as follows:

The Wi-Fi driver can be considered a black box that knows nothing about high-layer code, such as the TCP/IP stack, application task, and event task. The application task (code) generally calls *Wi-Fi driver APIs* to initialize Wi-Fi and handles Wi-Fi events when necessary. Wi-Fi driver receives API calls, handles them, and posts events to the application.

Wi-Fi event handling is based on the *esp_event library*. Events are sent by the Wi-Fi driver to the *default event loop*. Application may handle these events in callbacks registered using *esp_event_handler_register()*. Wi-Fi events are also handled by *esp_netif component* to provide a set of default behaviors. For example, when Wi-Fi station connects to an AP, esp_netif will automatically start the DHCP client by default.

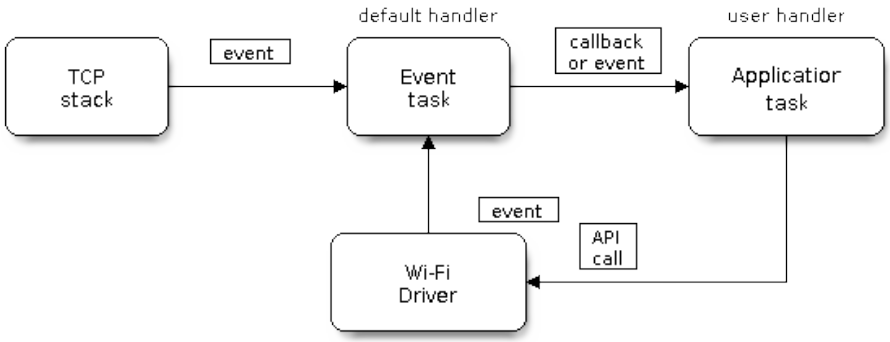

Fig. 80: Wi-Fi Programming Model

4.34.6 ESP32-S3 Wi-Fi Event Description

WIFI_EVENT_WIFI_READY

The Wi-Fi driver will never generate this event, which, as a result, can be ignored by the application event callback. This event may be removed in future releases.

WIFI_EVENT_SCAN_DONE

The scan-done event is triggered by `esp_wifi_scan_start()` and will arise in the following scenarios:

- The scan is completed, e.g., the target AP is found successfully, or all channels have been scanned.
- The scan is stopped by `esp_wifi_scan_stop()`.
- The `esp_wifi_scan_start()` is called before the scan is completed. A new scan will override the current scan and a scan-done event will be generated.

The scan-done event will not arise in the following scenarios:

- It is a blocked scan.
- The scan is caused by `esp_wifi_connect()`.

Upon receiving this event, the event task does nothing. The application event callback needs to call `esp_wifi_scan_get_ap_num()` and `esp_wifi_scan_get_ap_records()` to fetch the scanned AP list and trigger the Wi-Fi driver to free the internal memory which is allocated during the scan **(do not forget to do this!)**. Refer to *ESP32-S3 Wi-Fi Scan* for a more detailed description.

WIFI_EVENT_STA_START

If `esp_wifi_start()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will initialize the LwIP network interface (netif). Generally, the application event callback needs to call `esp_wifi_connect()` to connect to the configured AP.

WIFI_EVENT_STA_STOP

If `esp_wifi_stop()` returns `ESP_OK` and the current Wi-Fi mode is station or station/AP, then this event will arise. Upon receiving this event, the event task will release the station's IP address, stop the DHCP client, remove TCP/UDP-related connections, and clear the LwIP station netif, etc. The application event callback generally does not need to do anything.

WIFI_EVENT_STA_CONNECTED

If `esp_wifi_connect()` returns `ESP_OK` and the station successfully connects to the target AP, the connection event will arise. Upon receiving this event, the event task starts the DHCP client and begins the DHCP process of getting the IP address. Then, the Wi-Fi driver is ready for sending and receiving data. This moment is good for beginning the application work, provided that the application does not depend on LwIP, namely the IP address. However, if the application is LwIP-based, then you need to wait until the *got ip* event comes in.

WIFI_EVENT_STA_DISCONNECTED

This event can be generated in the following scenarios:

- When `esp_wifi_disconnect()` or `esp_wifi_stop()` is called and the station is already connected to the AP.
- When `esp_wifi_connect()` is called, but the Wi-Fi driver fails to set up a connection with the AP due to certain reasons, e.g., the scan fails to find the target AP or the authentication times out. If there are more than one AP with the same SSID, the disconnected event will be raised after the station fails to connect all of the found APs.
- When the Wi-Fi connection is disrupted because of specific reasons, e.g., the station continuously loses N beacons, the AP kicks off the station, or the AP's authentication mode is changed.

Upon receiving this event, the default behaviors of the event task are:

- Shutting down the station's LwIP netif.
- Notifying the LwIP task to clear the UDP/TCP connections which cause the wrong status to all sockets. For socket-based applications, the application callback can choose to close all sockets and re-create them, if necessary, upon receiving this event.

The most common event handle code for this event in application is to call `esp_wifi_connect()` to reconnect the Wi-Fi. However, if the event is raised because `esp_wifi_disconnect()` is called, the application should not call `esp_wifi_connect()` to reconnect. It is the application's responsibility to distinguish whether the event is caused by `esp_wifi_disconnect()` or other reasons. Sometimes a better reconnection strategy is required. Refer to *Wi-Fi Reconnect* and *Scan When Wi-Fi Is Connecting*.

Another thing that deserves attention is that the default behavior of LwIP is to abort all TCP socket connections on receiving the disconnect. In most cases, it is not a problem. However, for some special applications, this may not be what they want. Consider the following scenarios:

- The application creates a TCP connection to maintain the application-level keep-alive data that is sent out every 60 seconds.
- Due to certain reasons, the Wi-Fi connection is cut off, and the *WIFI_EVENT_STA_DISCONNECTED* is raised. According to the current implementation, all TCP connections will be removed and the keep-alive socket will be in a wrong status. However, since the application designer believes that the network layer should **ignore** this error at the Wi-Fi layer, the application does not close the socket.
- Five seconds later, the Wi-Fi connection is restored because `esp_wifi_connect()` is called in the application event callback function. **Moreover, the station connects to the same AP and gets the same IPV4 address as before**.
- Sixty seconds later, when the application sends out data with the keep-alive socket, the socket returns an error and the application closes the socket and re-creates it when necessary.

In above scenarios, ideally, the application sockets and the network layer should not be affected, since the Wi-Fi connection only fails temporarily and recovers very quickly. The application can enable "Keep TCP connections when IP changed" via LwIP menuconfig.

IP_EVENT_STA_GOT_IP

This event arises when the DHCP client successfully gets the IPV4 address from the DHCP server, or when the IPV4 address is changed. The event means that everything is ready and the application can begin its tasks (e.g., creating sockets).

The IPV4 may be changed because of the following reasons:

- The DHCP client fails to renew/rebind the IPV4 address, and the station's IPV4 is reset to 0.
- The DHCP client rebinds to a different address.
- The static-configured IPV4 address is changed.

Whether the IPV4 address is changed or not is indicated by the field `ip_change` of `ip_event_got_ip_t`.

The socket is based on the IPV4 address, which means that, if the IPV4 changes, all sockets relating to this IPV4 will become abnormal. Upon receiving this event, the application needs to close all sockets and recreate the application when the IPV4 changes to a valid one.

IP_EVENT_GOT_IP6

This event arises when the IPV6 SLAAC support auto-configures an address for the ESP32-S3, or when this address changes. The event means that everything is ready and the application can begin its tasks, e.g., creating sockets.

IP_EVENT_STA_LOST_IP

This event arises when the IPV4 address becomes invalid.

IP_EVENT_STA_LOST_IP does not arise immediately after the Wi-Fi disconnects. Instead, it starts an IPV4 address lost timer. If the IPV4 address is got before ip lost timer expires, IP_EVENT_STA_LOST_IP does not happen. Otherwise, the event arises when the IPV4 address lost timer expires.

Generally, the application can ignore this event, because it is just a debug event to inform that the IPV4 address is lost.

WIFI_EVENT_AP_START

Similar to *WIFI_EVENT_STA_START*.

WIFI_EVENT_AP_STOP

Similar to *WIFI_EVENT_STA_STOP*.

WIFI_EVENT_AP_STACONNECTED

Every time a station is connected to ESP32-S3 AP, the *WIFI_EVENT_AP_STACONNECTED* will arise. Upon receiving this event, the event task will do nothing, and the application callback can also ignore it. However, you may want to do something, for example, to get the info of the connected STA.

WIFI_EVENT_AP_STADISCONNECTED

This event can happen in the following scenarios:

- The application calls *`esp_wifi_disconnect()`*, or *`esp_wifi_deauth_sta()`*, to manually disconnect the station.
- The Wi-Fi driver kicks off the station, e.g., because the AP has not received any packets in the past five minutes. The time can be modified by *`esp_wifi_set_inactive_time()`*.
- The station kicks off the AP.

When this event happens, the event task will do nothing, but the application event callback needs to do something, e.g., close the socket which is related to this station.

WIFI_EVENT_AP_PROBEREQRECVED

This event is disabled by default. The application can enable it via API `esp_wifi_set_event_mask()`. When this event is enabled, it will be raised each time the AP receives a probe request.

WIFI_EVENT_STA_BEACON_TIMEOUT

If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens, the *WIFI_EVENT_STA_BEACON_TIMEOUT* will arise. The application can set inactive time via API `esp_wifi_set_inactive_time()`.

WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START

The *WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START* will arise at the start of connectionless module *Interval*. See *connectionless module power save*.

4.34.7 ESP32-S3 Wi-Fi Station General Scenario

Below is a "big scenario" which describes some small scenarios in station mode:

1. Wi-Fi/LwIP Init Phase

- s1.1: The main task calls `esp_netif_init()` to create an LwIP core task and initialize LwIP-related work.
- s1.2: The main task calls `esp_event_loop_create()` to create a system Event task and initialize an application event's callback function. In the scenario above, the application event's callback function does nothing but relaying the event to the application task.
- s1.3: The main task calls `esp_netif_create_default_wifi_ap()` or `esp_netif_create_default_wifi_sta()` to create default network interface instance binding station or AP with TCP/IP stack.
- s1.4: The main task calls `esp_wifi_init()` to create the Wi-Fi driver task and initialize the Wi-Fi driver.
- s1.5: The main task calls OS API to create the application task.

Step 1.1 ~ 1.5 is a recommended sequence that initializes a Wi-Fi-/LwIP-based application. However, it is **NOT** a must-follow sequence, which means that you can create the application task in step 1.1 and put all other initialization in the application task. Moreover, you may not want to create the application task in the initialization phase if the application task depends on the sockets. Rather, you can defer the task creation until the IP is obtained.

2. Wi-Fi Configuration Phase

Once the Wi-Fi driver is initialized, you can start configuring the Wi-Fi driver. In this scenario, the mode is station, so you may need to call `esp_wifi_set_mode()` (WIFI_MODE_STA) to configure the Wi-Fi mode as station. You can call other *esp_wifi_set_xxx* APIs to configure more settings, such as the protocol mode, the country code, and the bandwidth. Refer to *ESP32-S3 Wi-Fi Configuration*.

Generally, the Wi-Fi driver should be configured before the Wi-Fi connection is set up. But this is **NOT** mandatory, which means that you can configure the Wi-Fi connection anytime, provided that the Wi-Fi driver is initialized successfully. However, if the configuration does not need to change after the Wi-Fi connection is set up, you should configure the Wi-Fi driver at this stage, because the configuration APIs (such as `esp_wifi_set_protocol()`) will cause the Wi-Fi to reconnect, which may not be desirable.

If the Wi-Fi NVS flash is enabled by menuconfig, all Wi-Fi configuration in this phase, or later phases, will be stored into flash. When the board powers on/reboots, you do not need to configure the Wi-Fi driver from scratch. You only need to call `esp_wifi_get_xxx` APIs to fetch the configuration stored in flash previously. You can also configure the Wi-Fi driver if the previous configuration is not what you want.

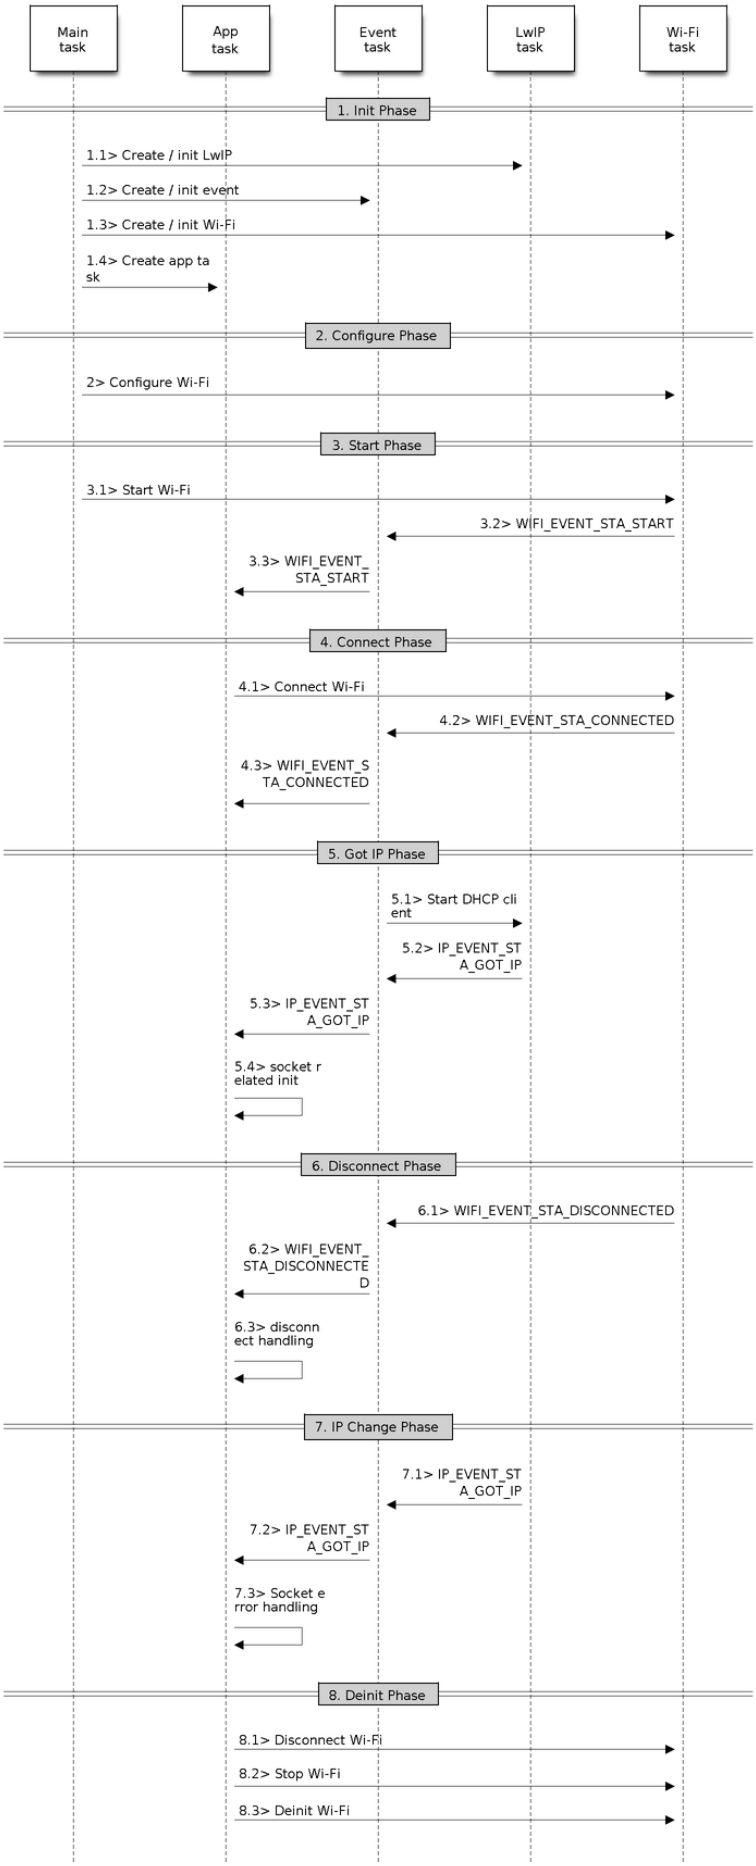

Fig. 81: Sample Wi-Fi Event Scenarios in Station Mode

3. Wi-Fi Start Phase

- s3.1: Call `esp_wifi_start()` to start the Wi-Fi driver.
- s3.2: The Wi-Fi driver posts *WIFI_EVENT_STA_START* to the event task; then, the event task will do some common things and will call the application event callback function.
- s3.3: The application event callback function relays the *WIFI_EVENT_STA_START* to the application task. We recommend that you call `esp_wifi_connect()`. However, you can also call `esp_wifi_connect()` in other phrases after the *WIFI_EVENT_STA_START* arises.

4. Wi-Fi Connect Phase

- s4.1: Once `esp_wifi_connect()` is called, the Wi-Fi driver will start the internal scan/connection process.
- s4.2: If the internal scan/connection process is successful, the *WIFI_EVENT_STA_CONNECTED* will be generated. In the event task, it starts the DHCP client, which will finally trigger the DHCP process.
- s4.3: In the above-mentioned scenario, the application event callback will relay the event to the application task. Generally, the application needs to do nothing, and you can do whatever you want, e.g., print a log.

In step 4.2, the Wi-Fi connection may fail because, for example, the password is wrong, or the AP is not found. In a case like this, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason for such a failure will be provided. For handling events that disrupt Wi-Fi connection, please refer to phase 6.

5. Wi-Fi 'Got IP' Phase

- s5.1: Once the DHCP client is initialized in step 4.2, the *got IP* phase will begin.
- s5.2: If the IP address is successfully received from the DHCP server, then *IP_EVENT_STA_GOT_IP* will arise and the event task will perform common handling.
- s5.3: In the application event callback, *IP_EVENT_STA_GOT_IP* is relayed to the application task. For LwIP-based applications, this event is very special and means that everything is ready for the application to begin its tasks, e.g., creating the TCP/UDP socket. A very common mistake is to initialize the socket before *IP_EVENT_STA_GOT_IP* is received. **DO NOT start the socket-related work before the IP is received.**

6. Wi-Fi Disconnect Phase

- s6.1: When the Wi-Fi connection is disrupted, e.g., the AP is powered off or the RSSI is poor, *WIFI_EVENT_STA_DISCONNECTED* will arise. This event may also arise in phase 3. Here, the event task will notify the LwIP task to clear/remove all UDP/TCP connections. Then, all application sockets will be in a wrong status. In other words, no socket can work properly when this event happens.
- s6.2: In the scenario described above, the application event callback function relays *WIFI_EVENT_STA_DISCONNECTED* to the application task. The recommended actions are: 1) call `esp_wifi_connect()` to reconnect the Wi-Fi, 2) close all sockets, and 3) re-create them if necessary. For details, please refer to *WIFI_EVENT_STA_DISCONNECTED*.

7. Wi-Fi IP Change Phase

- s7.1: If the IP address is changed, the *IP_EVENT_STA_GOT_IP* will arise with "ip_change" set to true.
- s7.2: **This event is important to the application. When it occurs, the timing is good for closing all created sockets and recreating them.**

8. Wi-Fi Deinit Phase

- s8.1: Call `esp_wifi_disconnect()` to disconnect the Wi-Fi connectivity.
- s8.2: Call `esp_wifi_stop()` to stop the Wi-Fi driver.
- s8.3: Call `esp_wifi_deinit()` to unload the Wi-Fi driver.

4.34.8 ESP32-S3 Wi-Fi AP General Scenario

Below is a "big scenario" which describes some small scenarios in AP mode:

4.34.9 ESP32-S3 Wi-Fi Scan

Currently, the *esp_wifi_scan_start()* API is supported only in station or station/AP mode.

Scan Type

Mode	Description
Active Scan	Scan by sending a probe request. The default scan is an active scan.
Passive Scan	No probe request is sent out. Just switch to the specific channel and wait for a beacon. Application can enable it via the scan_type field of *wifi_scan_config_t*.
Foreground Scan	This scan is applicable when there is no Wi-Fi connection in station mode. Foreground or background scanning is controlled by the Wi-Fi driver and cannot be configured by the application.
Background Scan	This scan is applicable when there is a Wi-Fi connection in station mode or in station/AP mode. Whether it is a foreground scan or background scan depends on the Wi-Fi driver and cannot be configured by the application.
All-Channel Scan	It scans all of the channels. If the channel field of *wifi_scan_config_t* is set to 0, it is an all-channel scan.
Specific Channel Scan	It scans specific channels only. If the channel field of *wifi_scan_config_t* set to 1-14, it is a specific-channel scan.

The scan modes in above table can be combined arbitrarily, so there are in total 8 different scans:

- All-Channel Background Active Scan
- All-Channel Background Passive Scan
- All-Channel Foreground Active Scan
- All-Channel Foreground Passive Scan
- Specific-Channel Background Active Scan
- Specific-Channel Background Passive Scan
- Specific-Channel Foreground Active Scan
- Specific-Channel Foreground Passive Scan

Scan Configuration

The scan type and other per-scan attributes are configured by *esp_wifi_scan_start()*. The table below provides a detailed description of *wifi_scan_config_t*.

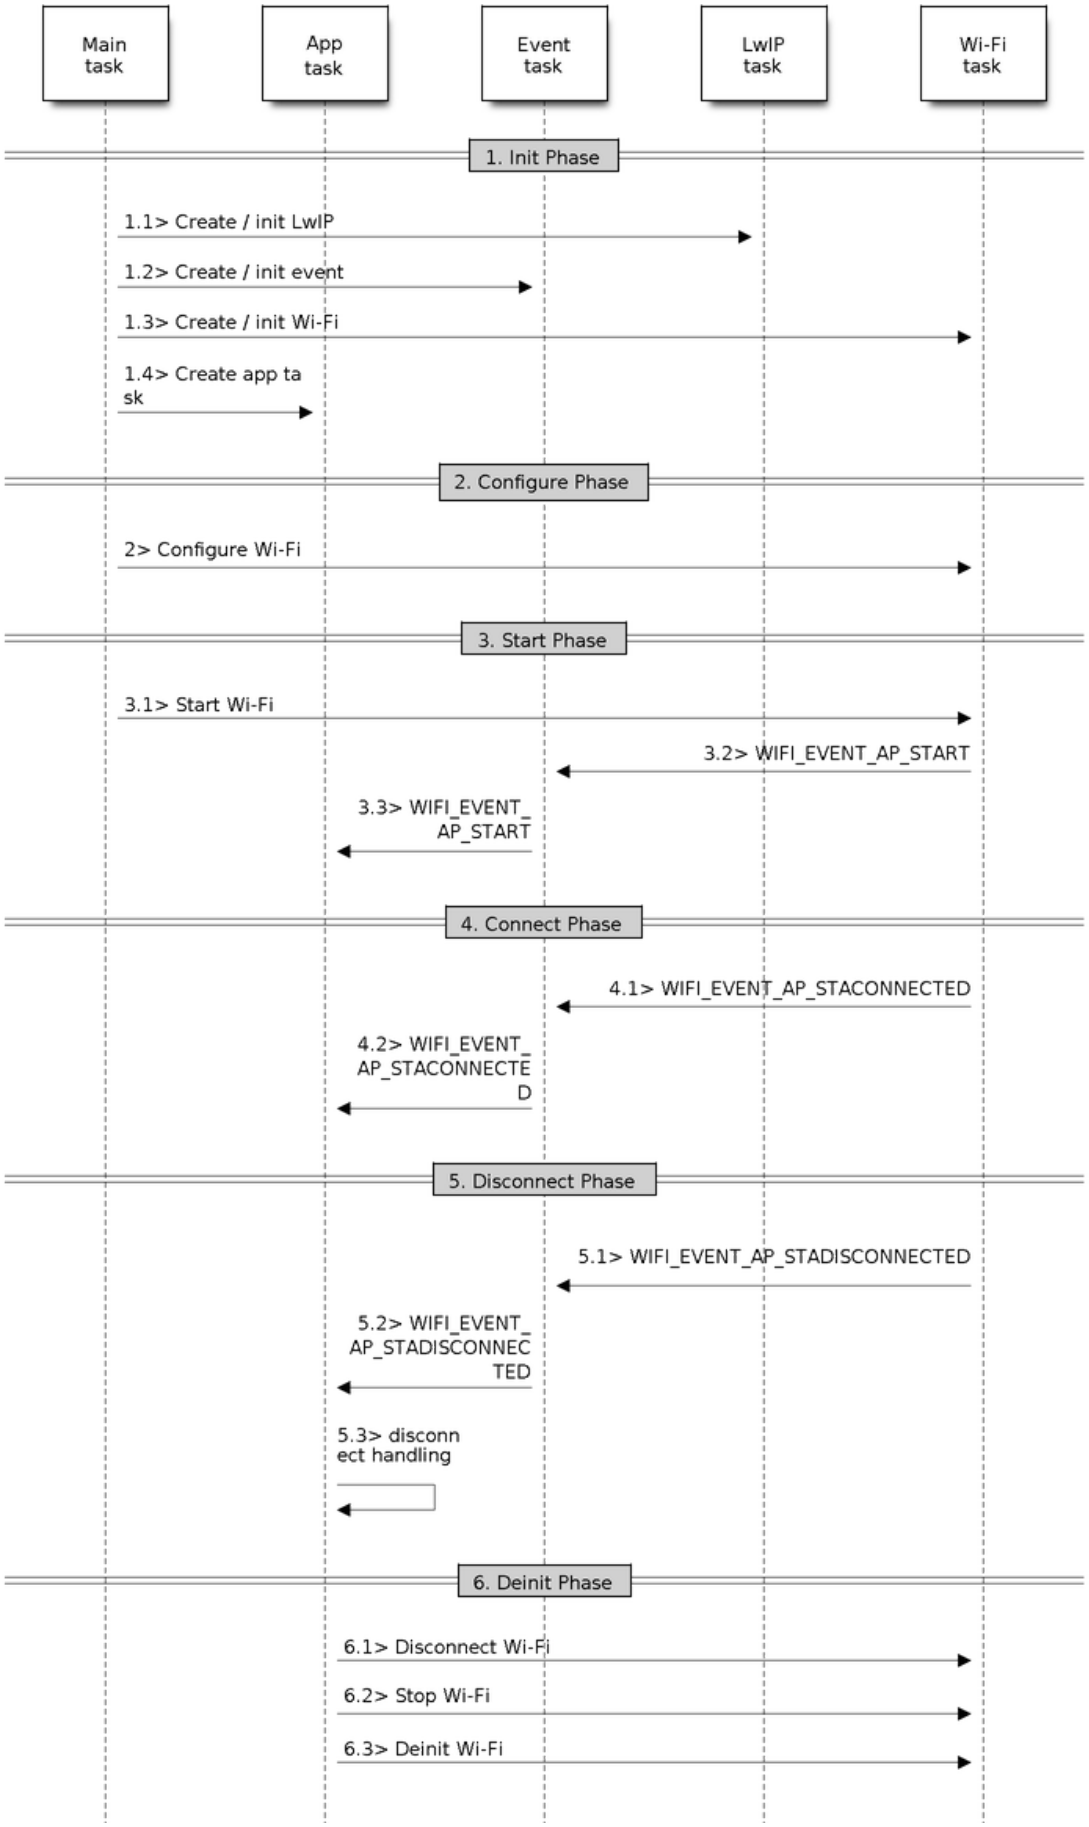

Fig. 82: Sample Wi-Fi Event Scenarios in AP Mode

Field	Description
ssid	If the SSID is not NULL, it is only the AP with the same SSID that can be scanned.
bssid	If the BSSID is not NULL, it is only the AP with the same BSSID that can be scanned.
channel	If "channel" is 0, there will be an all-channel scan; otherwise, there will be a specific-channel scan.
show_hidden	If "show_hidden" is 0, the scan ignores the AP with a hidden SSID; otherwise, the scan considers the hidden AP a normal one.
scan_type	If "scan_type" is WIFI_SCAN_TYPE_ACTIVE, the scan is "active" ; otherwise, it is a "passive" one.
scan_time	This field is used to control how long the scan dwells on each channel. For passive scans, scan_time.passive designates the dwell time for each channel. For active scans, dwell times for each channel are listed in the table below. Here, min is short for scan time.active.min and max is short for scan_time.active.max. • min=0, max=0: scan dwells on each channel for 120 ms. • min>0, max=0: scan dwells on each channel for 120 ms. • min=0, max>0: scan dwells on each channel for `max` ms. • min>0, max>0: the minimum time the scan dwells on each channel is `min` ms. If no AP is found during this time frame, the scan switches to the next channel. Otherwise, the scan dwells on the channel for `max` ms. If you want to improve the performance of the scan, you can try to modify these two parameters.

There are also some global scan attributes which are configured by API `esp_wifi_set_config()`, refer to *Station Basic Configuration*

Scan All APs on All Channels (Foreground)

Scenario:

The scenario above describes an all-channel, foreground scan. The foreground scan can only occur in station mode where the station does not connect to any AP. Whether it is a foreground or background scan is totally determined by the Wi-Fi driver, and cannot be configured by the application.

Detailed scenario description:

Scan Configuration Phase

- s1.1: Call `esp_wifi_set_country()` to set the country info if the default country info is not what you want. Refer to *Wi-Fi Country Code*.
- s1.2: Call `esp_wifi_scan_start()` to configure the scan. To do so, you can refer to *Scan Configuration*. Since this is an all-channel scan, just set the SSID/BSSID/channel to 0.

Wi-Fi Driver's Internal Scan Phase

- s2.1: The Wi-Fi driver switches to channel 1. In this case, the scan type is WIFI_SCAN_TYPE_ACTIVE, and a probe request is broadcasted. Otherwise, the Wi-Fi will wait for a beacon from the APs. The Wi-Fi driver will stay in channel 1 for some time. The dwell time is configured in min/max time, with the default value being 120 ms.
- s2.2: The Wi-Fi driver switches to channel 2 and performs the same operation as in step 2.1.
- s2.3: The Wi-Fi driver scans the last channel N, where N is determined by the country code which is configured in step 1.1.

Scan-Done Event Handling Phase

- s3.1: When all channels are scanned, *WIFI_EVENT_SCAN_DONE* will arise.

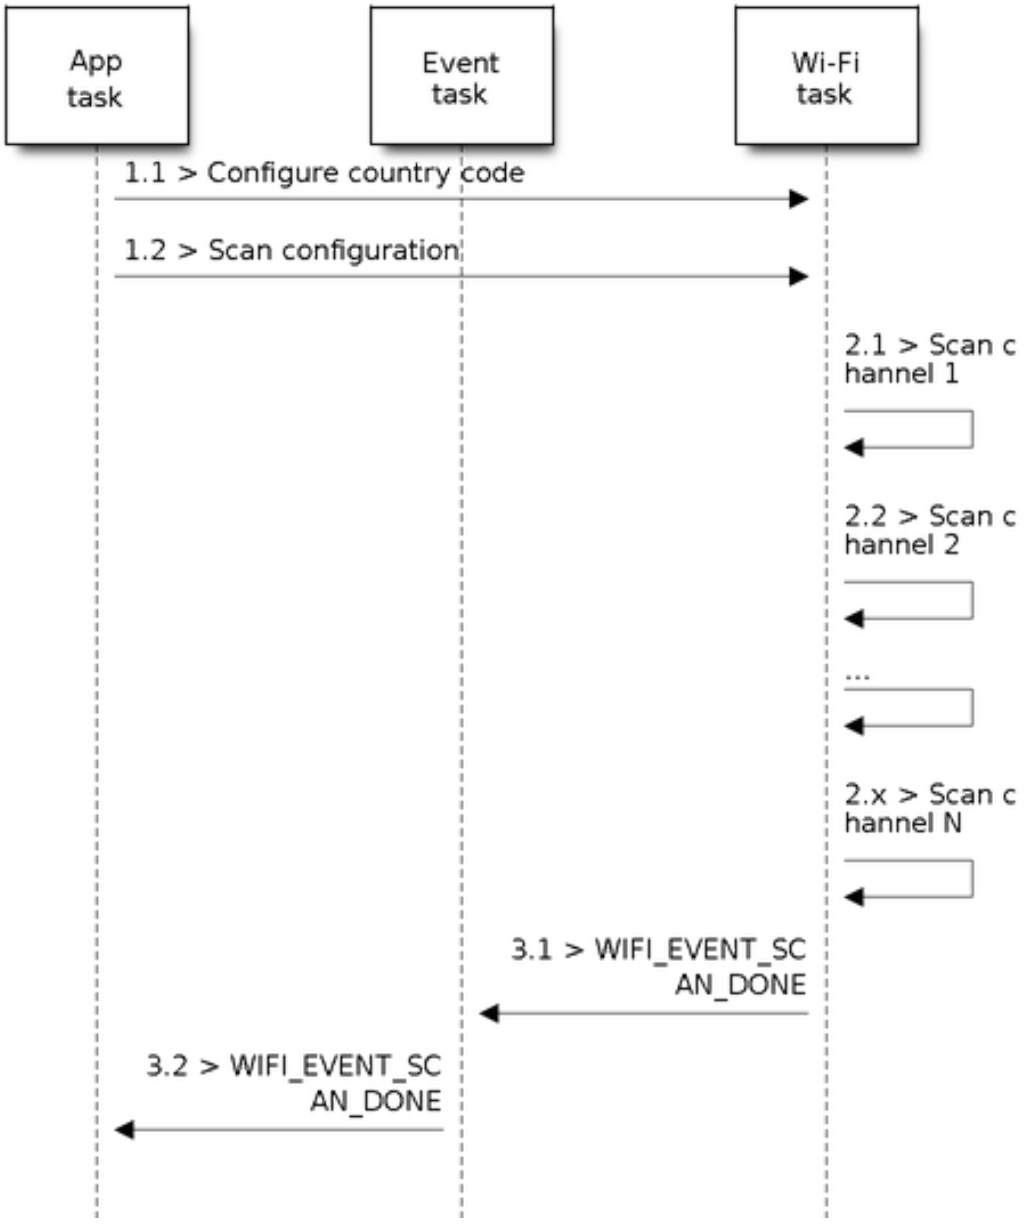

Fig. 83: Foreground Scan of all Wi-Fi Channels

- s3.2: The application's event callback function notifies the application task that *WIFI_EVENT_SCAN_DONE* is received. `esp_wifi_scan_get_ap_num()` is called to get the number of APs that have been found in this scan. Then, it allocates enough entries and calls `esp_wifi_scan_get_ap_records()` to get the AP records. Please note that the AP records in the Wi-Fi driver will be freed once `esp_wifi_scan_get_ap_records()` is called. Do not call `esp_wifi_scan_get_ap_records()` twice for a single scan-done event. If `esp_wifi_scan_get_ap_records()` is not called when the scan-done event occurs, the AP records allocated by the Wi-Fi driver will not be freed. So, make sure you call `esp_wifi_scan_get_ap_records()`, yet only once.

Scan All APs on All Channels (Background)

Scenario:

The scenario above is an all-channel background scan. Compared to *Scan All APs on All Channels (Foreground)* , the difference in the all-channel background scan is that the Wi-Fi driver will scan the back-to-home channel for 30 ms before it switches to the next channel to give the Wi-Fi connection a chance to transmit/receive data.

Scan for Specific AP on All Channels

Scenario:

This scan is similar to *Scan All APs on All Channels (Foreground)*. The differences are:

- s1.1: In step 1.2, the target AP will be configured to SSID/BSSID.
- s2.1 ~ s2.N: Each time the Wi-Fi driver scans an AP, it will check whether it is a target AP or not. If the scan is `WIFI_FAST_SCAN` scan and the target AP is found, then the scan-done event will arise and scanning will end; otherwise, the scan will continue. Please note that the first scanned channel may not be channel 1, because the Wi-Fi driver optimizes the scanning sequence.

It is a possible situation that there are multiple APs that match the target AP info, e.g., two APs with the SSID of "ap" are scanned. In this case, if the scan is `WIFI_FAST_SCAN`, then only the first scanned "ap" will be found. If the scan is `WIFI_ALL_CHANNEL_SCAN`, both "ap" will be found and the station will connect the "ap" according to the configured strategy. Refer to *Station Basic Configuration*.

You can scan a specific AP, or all of them, in any given channel. These two scenarios are very similar.

Scan in Wi-Fi Connect

When `esp_wifi_connect()` is called, the Wi-Fi driver will try to scan the configured AP first. The scan in "Wi-Fi Connect" is the same as *Scan for Specific AP On All Channels*, except that no scan-done event will be generated when the scan is completed. If the target AP is found, the Wi-Fi driver will start the Wi-Fi connection; otherwise, *WIFI_EVENT_STA_DISCONNECTED* will be generated. Refer to *Scan for Specific AP On All Channels*.

Scan in Blocked Mode

If the block parameter of `esp_wifi_scan_start()` is true, then the scan is a blocked one, and the application task will be blocked until the scan is done. The blocked scan is similar to an unblocked one, except that no scan-done event will arise when the blocked scan is completed.

Parallel Scan

Two application tasks may call `esp_wifi_scan_start()` at the same time, or the same application task calls `esp_wifi_scan_start()` before it gets a scan-done event. Both scenarios can happen. **However, the Wi-Fi driver does not support multiple concurrent scans adequately. As a result, concurrent scans should be avoided.** Support for concurrent scan will be enhanced in future releases, as the ESP32-S3's Wi-Fi functionality improves continuously.

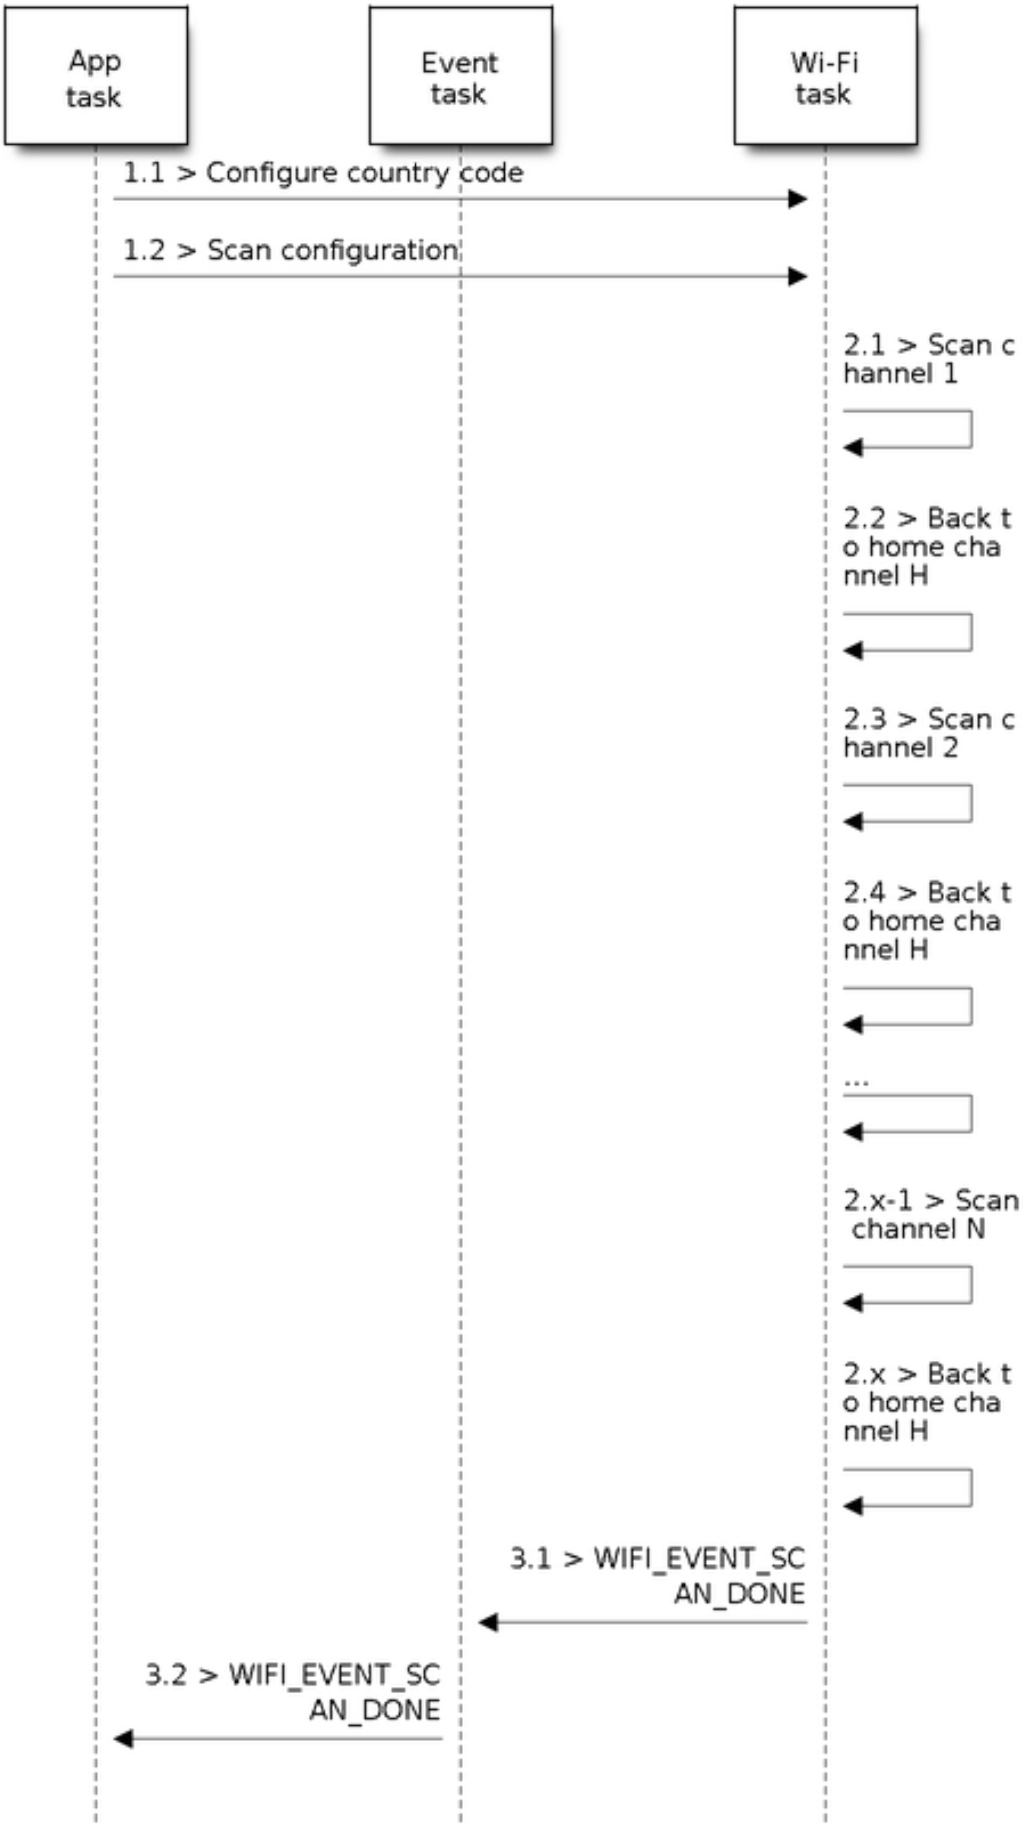

Fig. 84: Background Scan of all Wi-Fi Channels

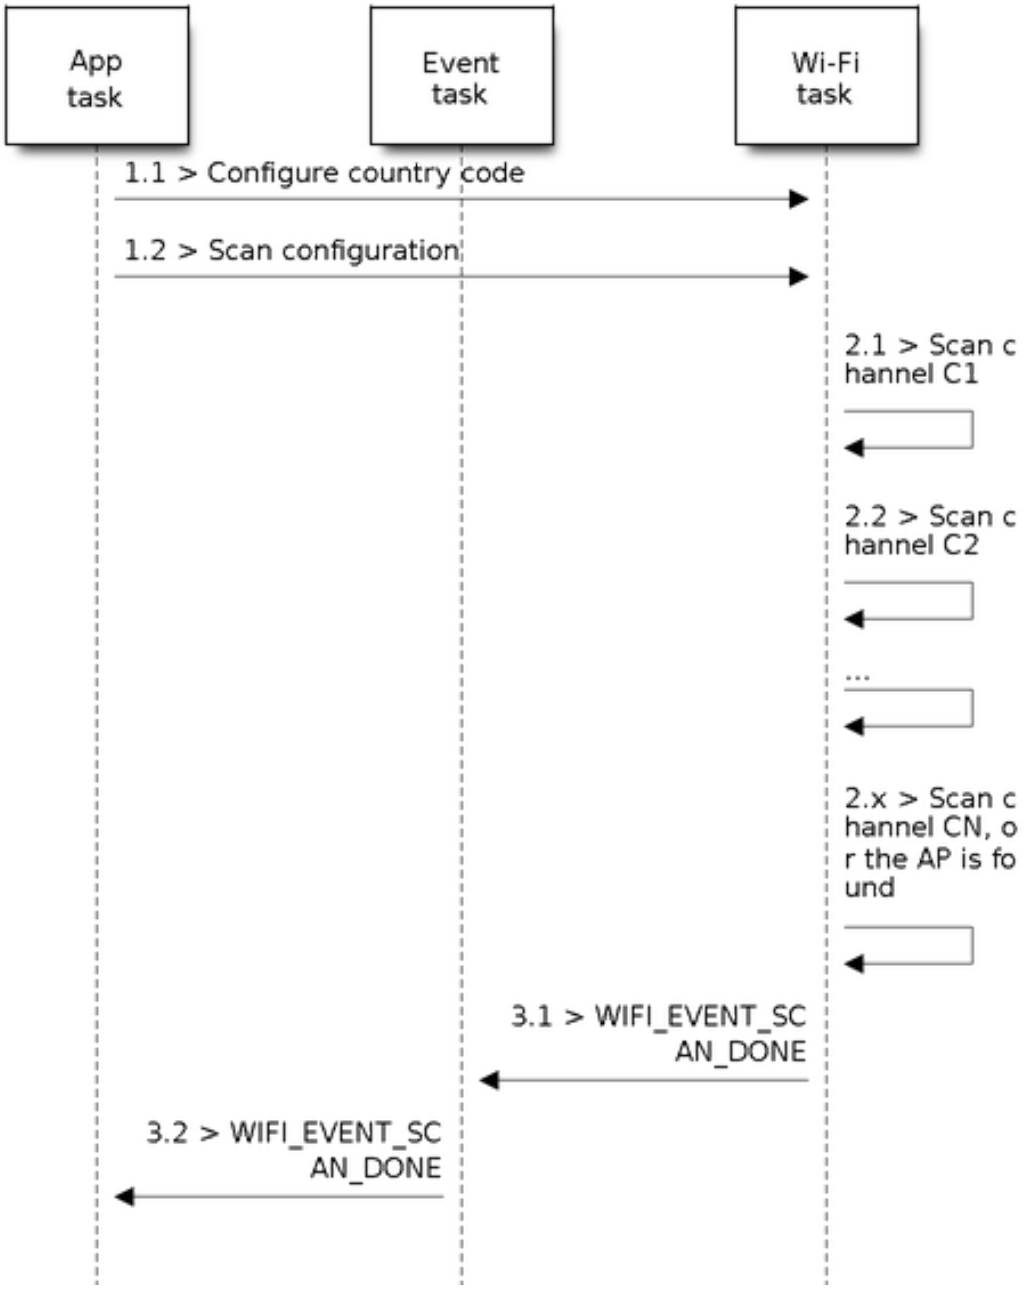

Fig. 85: Scan of specific Wi-Fi Channels

Scan When Wi-Fi Is Connecting

The `esp_wifi_scan_start()` fails immediately if the Wi-Fi is connecting, because the connecting has higher priority than the scan. If scan fails because of connecting, the recommended strategy is to delay for some time and retry scan again. The scan will succeed once the connecting is completed.

However, the retry/delay strategy may not work all the time. Considering the following scenarios:

- The station is connecting a non-existing AP or it connects the existing AP with a wrong password, it always raises the event *WIFI_EVENT_STA_DISCONNECTED*.
- The application calls `esp_wifi_connect()` to reconnect on receiving the disconnect event.
- Another application task, e.g., the console task, calls `esp_wifi_scan_start()` to do scan, the scan always fails immediately because the station keeps connecting.
- When scan fails, the application simply delays for some time and retries the scan.

In the above scenarios, the scan will never succeed because the connecting is in process. So if the application supports similar scenario, it needs to implement a better reconnection strategy. For example:

- The application can choose to define a maximum continuous reconnection counter and stop reconnecting once the counter reaches the maximum.
- The application can choose to reconnect immediately in the first N continuous reconnection, then give a delay sometime and reconnect again.

The application can define its own reconnection strategy to avoid the scan starve to death. Refer to <*Wi-Fi Reconnect*>.

4.34.10 ESP32-S3 Wi-Fi Station Connecting Scenario

This scenario depicts the case if only one target AP is found in the scan phase. For scenarios where more than one AP with the same SSID is found, refer to *ESP32-S3 Wi-Fi Station Connecting When Multiple APs Are Found*.

Generally, the application can ignore the connecting process. Below is a brief introduction to the process for those who are really interested.

Scenario:

Scan Phase

- s1.1: The Wi-Fi driver begins scanning in "Wi-Fi Connect". Refer to *Scan in Wi-Fi Connect* for more details.
- s1.2: If the scan fails to find the target AP, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code could either be `WIFI_REASON_NO_AP_FOUND` or `WIFI_REASON_NO_AP_FOUND_W_COMPATIBLE_SECURITY` or `WIFI_REASON_NO_AP_FOUND_IN_AUTHMODE_THRESHOLD` or `WIFI_REASON_NO_AP_FOUND_IN_RSSI_THRES` depending of the Station's configuration. Refer to *Wi-Fi Reason Code*.

Auth Phase

- s2.1: The authentication request packet is sent and the auth timer is enabled.
- s2.2: If the authentication response packet is not received before the authentication timer times out, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_AUTH_EXPIRE`. Refer to *Wi-Fi Reason Code*.
- s2.3: The auth-response packet is received and the auth-timer is stopped.
- s2.4: The AP rejects authentication in the response and *WIFI_EVENT_STA_DISCONNECTED* arises, while the reason code is `WIFI_REASON_AUTH_FAIL` or the reasons specified by the AP. Refer to *Wi-Fi Reason Code*.

Association Phase

- s3.1: The association request is sent and the association timer is enabled.

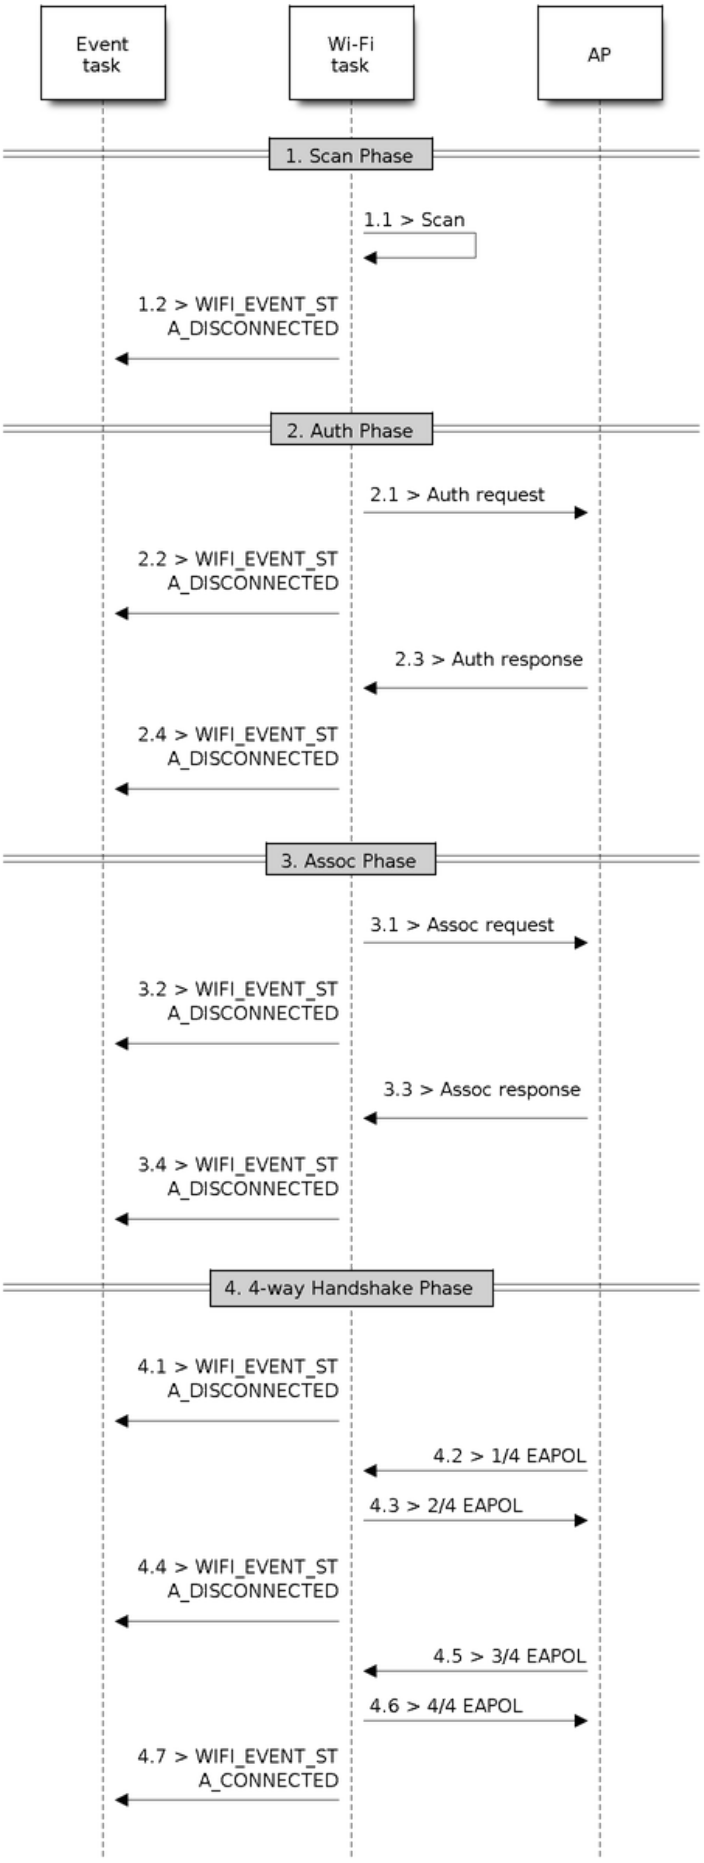

Fig. 86: Wi-Fi Station Connecting Process

- s3.2: If the association response is not received before the association timer times out, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_DISASSOC_DUE_TO_INACTIVITY`. Refer to *Wi-Fi Reason Code*.
- s3.3: The association response is received and the association timer is stopped.
- s3.4: The AP rejects the association in the response and *WIFI_EVENT_STA_DISCONNECTED* arises, while the reason code is the one specified in the association response. Refer to *Wi-Fi Reason Code*.

Four-way Handshake Phase

- s4.1: The handshake timer is enabled, and the 1/4 EAPOL is not received before the handshake timer expires. *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to *Wi-Fi Reason Code*.
- s4.2: The 1/4 EAPOL is received.
- s4.3: The station replies 2/4 EAPOL.
- s4.4: If the 3/4 EAPOL is not received before the handshake timer expires, *WIFI_EVENT_STA_DISCONNECTED* will arise and the reason code will be `WIFI_REASON_HANDSHAKE_TIMEOUT`. Refer to *Wi-Fi Reason Code*.
- s4.5: The 3/4 EAPOL is received.
- s4.6: The station replies 4/4 EAPOL.
- s4.7: The station raises *WIFI_EVENT_STA_CONNECTED*.

Wi-Fi Reason Code

The table below shows the reason-code defined in ESP32-S3. The first column is the macro name defined in esp_wifi/include/esp_wifi_types.h. The common prefix `WIFI_REASON` is removed, which means that `UNSPECIFIED` actually stands for `WIFI_REASON_UNSPECIFIED` and so on. The second column is the value of the reason. This reason value is same as defined in section 9.4.1.7 of IEEE 802.11-2020. (For more information, refer to the standard mentioned above.) The last column describes the reason. Reason-codes starting from 200 are Espressif defined reason-codes and are not part of IEEE 802.11-2020.

Also note that REASON_NO_AP_FOUND_XXX codes are mentioned in increasing order of importance. So if a single AP has a combination of the above reasons for failure, the more important one will be reported. Additionally, if there are multiple APs that satisfy the identifying criteria and connecting to all of them fails for different reasons mentioned above, then the reason code reported is for the AP that failed connection due to the least important reason code, as it was the one closest to a successful connection.

Following reason codes are renamed to their shorter form to wrap the table in page width.

- TRANSMISSION_LINK_ESTABLISHMENT_FAILED : TX_LINK_EST_FAILED
- NO_AP_FOUND_W_COMPATIBLE_SECURITY : NO_AP_FOUND_SECURITY
- NO_AP_FOUND_IN_AUTHMODE_THRESHOLD : NO_AP_FOUND_AUTHMODE
- NO_AP_FOUND_IN_RSSI_THRESHOLD : NO_AP_FOUND_RSSI

Reason code	Value	Description
UNSPECIFIED	1	Generally, it means an internal failure, e.g., the memory runs out, the internal TX fails, or the reason is received from the remote side.

Table 31 – continued from previous page

Reason code	Value	Description
AUTH_EXPIRE	2	The previous authentication is no longer valid. For the ESP station, this reason is reported when: • auth is timed out. • the reason is received from the AP. For the ESP AP, this reason is reported when: • the AP has not received any packets from the station in the past five minutes. • the AP is stopped by calling `esp_wifi_stop()`. • the station is de-authed by calling `esp_wifi_deauth_sta()`.
AUTH_LEAVE	3	De-authenticated, because the sending station is leaving (or has left). For the ESP station, this reason is reported when: • it is received from the AP.
DISASSOC_DUE_TO_INACTIVITY	4	Disassociated due to inactivity. For the ESP station, this reason is reported when: • assoc is timed out. • it is received from the AP.
ASSOC_TOOMANY	5	Disassociated, because the AP is unable to handle all currently associated STAs at the same time. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the stations associated with the AP reach the maximum number that the AP can support.
CLASS2_FRAME_FROM_NONAUTH_STA	6	Class 2 frame received from a non-authenticated STA. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP receives a packet with data from a non-authenticated station.
CLASS3_FRAME_FROM_NONASSOC_STA	7	Class 3 frame received from a non-associated STA. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP receives a packet with data from a non-associated station.
ASSOC_LEAVE	8	Disassociated, because the sending station is leaving (or has left) BSS. For the ESP station, this reason is reported when: • it is received from the AP. • the station is disconnected by `esp_wifi_disconnect()` and other APIs.
ASSOC_NOT_AUTHED	9	station requesting (re)association is not authenticated by the responding STA. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP receives packets with data from an associated, yet not authenticated, station.

Table 31 – continued from previous page

Reason code	Value	Description
DISASSOC_PWRCAP_BAD	10	Disassociated, because the information in the Power Capability element is unacceptable. For the ESP station, this reason is reported when: • it is received from the AP.
DISASSOC_SUPCHAN_BAD	11	Disassociated, because the information in the Supported Channels element is unacceptable. For the ESP station, this reason is reported when: • it is received from the AP.
BSS_TRANSITION_DISASSOC	12	Disassociated, because it wants us to move to another AP, sent as a part of BTM procedure. Please note that when station is sending BTM request and moving to another AP, ROAMING reason code will be reported instead of this. For the ESP station, this reason is reported when: • it is received from the AP.
IE_INVALID	13	Invalid element, i.e., an element whose content does not meet the specifications of the Standard in frame formats clause. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • the AP parses a wrong WPA or RSN IE.
MIC_FAILURE	14	Message integrity code (MIC) failure. For the ESP station, this reason is reported when: • it is received from the AP.
4WAY_HANDSHAKE_TIMEOUT	15	Four-way handshake times out. For legacy reasons, in ESP this reason code is replaced with `WIFI_REASON_HANDSHAKE_TIMEOUT`. For the ESP station, this reason is reported when: • the handshake times out. • it is received from the AP.
GROUP_KEY_UPDATE_TIMEOUT	16	Group key handshake times out. For the ESP station, this reason is reported when: • it is received from the AP.
IE_IN_4WAY_DIFFERS	17	The element in the four-way handshake is different from the (Re-)Association Request/Probe and Response/Beacon frame. For the ESP station, this reason is reported when: • it is received from the AP. • the station finds that the four-way handshake IE differs from the IE in the (Re-)Association Request/Probe and Response/Beacon frame.
GROUP_CIPHER_INVALID	18	Invalid group cipher. For the ESP station, this reason is reported when: • it is received from the AP.
PAIRWISE_CIPHER_INVALID	19	Invalid pairwise cipher. For the ESP station, this reason is reported when: • it is received from the AP.
AKMP_INVALID	20	Invalid AKMP. For the ESP station, this reason is reported when: - it is received from the AP.

continues on next page

Table 31 – continued from previous page

Reason code	Value	Description
UNSUPP_RSN_IE_VERSION	21	Unsupported RSNE version. For the ESP station, this reason is reported when: • it is received from the AP.
INVALID_RSN_IE_CAP	22	Invalid RSNE capabilities. For the ESP station, this reason is reported when: • it is received from the AP.
802_1X_AUTH_FAILED	23	IEEE 802.1X. authentication failed. For the ESP station, this reason is reported when: • it is received from the AP. For the ESP AP, this reason is reported when: • IEEE 802.1X. authentication fails.
CIPHER_SUITE_REJECTED	24	Cipher suite rejected due to security policies. For the ESP station, this reason is reported when: • it is received from the AP.
TDLS_PEER_UNREACHABLE	25	TDLS direct-link teardown due to TDLS peer STA unreachable via the TDLS direct link.
TDLS_UNSPECIFIED	26	TDLS direct-link teardown for unspecified reason.
SSP_REQUESTED_DISASSOC	27	Disassociated because session terminated by SSP request.
NO_SSP_ROAMING_AGREEMENT	28	Disassociated because of lack of SSP roaming agreement.
BAD_CIPHER_OR_AKM	29	Requested service rejected because of SSP cipher suite or AKM requirement.
NOT_AUTHORIZED_THIS_LOCATION	30	Requested service not authorized in this location.
SERVICE_CHANGE_PRECLUDES_TS	31	TS deleted because QoS AP lacks sufficient bandwidth for this QoS STA due to a change in BSS service characteristics or operational mode (e.g., an HT BSS change from 40 MHz channel to 20 MHz channel).
UNSPECIFIED_QOS	32	Disassociated for unspecified, QoS-related reason.
NOT_ENOUGH_BANDWIDTH	33	Disassociated because QoS AP lacks sufficient bandwidth for this QoS STA.
MISSING_ACKS	34	Disassociated because excessive number of frames need to be acknowledged, but are not acknowledged due to AP transmissions and/or poor channel conditions.
EXCEEDED_TXOP	35	Disassociated because STA is transmitting outside the limits of its TXOPs.
STA_LEAVING	36	Requesting STA is leaving the BSS (or resetting).
END_BA	37	Requesting STA is no longer using the stream or session.
UNKNOWN_BA	38	Requesting STA received frames using a mechanism for which a setup has not been completed.
TIMEOUT	39	Requested from peer STA due to timeout
Reserved	40 ~ 45	Reserved as per IEEE80211-2020 specifications.
PEER_INITIATED	46	In a Disassociation frame: Disassociated because authorized access limit reached.
AP_INITIATED	47	In a Disassociation frame: Disassociated due to external service requirements.
INVALID_FT_ACTION_FRAME_COUNT	48	Invalid FT Action frame count.
INVALID_PMKID	49	Invalid pairwise master key identifier (PMKID).

continues on next page

Table 31 – continued from previous page

Reason code	Value	Description
INVALID_MDE	50	Invalid MDE.
INVALID_FTE	51	Invalid FTE
TX_LINK_EST_FAILED	67	TRANSMISSION_LINK_ESTABLISHMENT_FAILED will be reported when Transmission link establishment in alternative channel failed.
ALTERNATIVE_CHANNEL_OCCUPIED	68	The alternative channel is occupied.
BEACON_TIMEOUT	200	Espressif-specific Wi-Fi reason code: when the station loses N beacons continuously, it will disrupt the connection and report this reason.
NO_AP_FOUND	201	Espressif-specific Wi-Fi reason code: when the station fails to scan the target AP, this reason code will be reported. In case of security mismatch or station's configuration mismatch, new reason codes NO_AP_FOUND_XXX will be reported.
AUTH_FAIL	202	Espressif-specific Wi-Fi reason code: the authentication fails, but not because of a timeout.
ASSOC_FAIL	203	Espressif-specific Wi-Fi reason code: the association fails, but not because of DISASSOC_DUE_TO_INACTIVITY or ASSOC_TOOMANY.
HANDSHAKE_TIMEOUT	204	Espressif-specific Wi-Fi reason code: the handshake fails for the same reason as that in WIFI_REASON_4WAY_HANDSHAKE_TIMEOUT.
CONNECTION_FAIL	205	Espressif-specific Wi-Fi reason code: the connection to the AP has failed.
AP_TSF_RESET	206	Espressif-specific Wi-Fi reason code: the disconnection happened due to AP's TSF reset.
ROAMING	207	Espressif-specific Wi-Fi reason code: the station is roaming to another AP, this reason code is just for info, station will automatically move to another AP.
ASSOC_COMEBACK_TIME_TOO_LONG	208	Espressif-specific Wi-Fi reason code: This reason code will be reported when Assoc comeback time in association response is too high.
SA_QUERY_TIMEOUT	209	Espressif-specific Wi-Fi reason code: This reason code will be reported when AP did not reply of SA query sent by ESP station.

continues on next page

Table 31 – continued from previous page

Reason code	Value	Description
NO_AP_FOUND_SECURITY	210	Espressif-specific Wi-Fi reason code: NO_AP_FOUND_W_COMPATIBLE_SECURITY will be reported if an AP that fits identifying criteria (e.g. ssid) is found but the connection is rejected due to incompatible security configuration. These situations could be: • The Access Point is offering WEP security, but our station's password is not WEP-compliant. • The station is configured in Open mode; however, the Access Point is broadcasting in secure mode. • The Access Point uses Enterprise security, but we haven't set up the corresponding enterprise configuration, and vice versa. • SAE-PK is configured in the station configuration, but the Access Point does not support SAE-PK. • SAE-H2E is configured in the station configuration; however, the AP only supports WPA3-PSK or WPA3-WPA2-PSK. • The station is configured in secure mode (Password or Enterprise mode); however, an Open AP is found during the scan. • SAE HnP is configured in the station configuration; however, the AP supports H2E only. • H2E is disabled in the station configuration; however, the AP is WPA3-EXT-PSK, which requires H2E support. • The Access Point requires PMF, but the station is not configured for PMF capable/required. • The station configuration requires PMF, but the AP is not configured for PMF capable/required. • The Access Point is using unsupported group management/pairwise ciphers. • OWE is not enabled in the station configuration, but the discovered AP is using OWE only mode. • The Access Point is broadcasting an invalid RSNXE in its beacons. • The Access Point is in Independent BSS mode.
NO_AP_FOUND_AUTHMODE	211	Espressif-specific Wi-Fi reason code: NO_AP_FOUND_IN_AUTHMODE_THRESHOLD will be reported if an AP that fit identifying criteria (e.g. ssid) is found but the authmode threhsold set in the wifi_config_t is not met.
NO_AP_FOUND_RSSI	212	Espressif-specific Wi-Fi reason code: NO_AP_FOUND_IN_RSSI_THRESHOLD will be reported if an AP that fits identifying criteria (e.g. ssid) is found but the RSSI threhsold set in the wifi_config_t is not met.

Wi-Fi Reason code related to wrong password

The table below shows the Wi-Fi reason-code may related to wrong password.

Reason code	Value	Description
4WAY_HANDSHAKE_TIMEOUT	15	Four-way handshake times out. Setting wrong password when STA connecting to an encrypted AP.
NO_AP_FOUND	201	This may related to wrong password in the two scenarios: • Setting password when STA connecting to an unencrypted AP. • Does not set password when STA connecting to an encrypted AP.
HANDSHAKE_TIMEOUT	204	Four-way handshake fails.

Wi-Fi Reason code related to low RSSI

The table below shows the Wi-Fi reason-code may related to low RSSI.

Reason code	Value	Description
NO_AP_FOUND_IN_RSSI_THRESHOLD	201	The station fails to scan the target AP due to low RSSI
HANDSHAKE_TIMEOUT	204	Four-way handshake fails.

4.34.11 ESP32-S3 Wi-Fi Station Connecting When Multiple APs Are Found

This scenario is similar as *ESP32-S3 Wi-Fi Station Connecting Scenario*. The difference is that the station will not raise the event *WIFI_EVENT_STA_DISCONNECTED* unless it fails to connect all of the found APs.

4.34.12 Wi-Fi Reconnect

The station may disconnect due to many reasons, e.g., the connected AP is restarted. It is the application's responsibility to reconnect. The recommended reconnection strategy is to call `esp_wifi_connect()` on receiving event *WIFI_EVENT_STA_DISCONNECTED*.

Sometimes the application needs more complex reconnection strategy:

- If the disconnect event is raised because the `esp_wifi_disconnect()` is called, the application may not want to do the reconnection.
- If the `esp_wifi_scan_start()` may be called at anytime, a better reconnection strategy is necessary. Refer to *Scan When Wi-Fi Is Connecting*.

Another thing that need to be considered is that the reconnection may not connect the same AP if there are more than one APs with the same SSID. The reconnection always select current best APs to connect.

4.34.13 Wi-Fi Beacon Timeout

The beacon timeout mechanism is used by ESP32-S3 station to detect whether the AP is alive or not. If the station does not receive the beacon of the connected AP within the inactive time, the beacon timeout happens. The application can set inactive time via API `esp_wifi_set_inactive_time()`.

After the beacon times out, the station sends 5 probe requests to the AP. If still no probe response or beacon is received from AP, the station disconnects from the AP and raises the event *WIFI_EVENT_STA_DISCONNECTED*.

It should be considered that the timer used for beacon timeout will be reset during the scanning process. It means that the scan process will affect the triggering of the event *WIFI_EVENT_STA_BEACON_TIMEOUT*.

4.34.14 ESP32-S3 Wi-Fi Configuration

All configurations will be stored into flash when the Wi-Fi NVS is enabled; otherwise, refer to *Wi-Fi NVS Flash*.

Wi-Fi Mode

Call `esp_wifi_set_mode()` to set the Wi-Fi mode.

Mode	Description
WIFI_MODE_NULL	NULL mode: in this mode, the internal data struct is not allocated to the station and the AP, while both the station and AP interfaces are not initialized for RX/TX Wi-Fi data. Generally, this mode is used for Sniffer, or when you only want to stop both the station and the AP without calling *esp_wifi_deinit()* to unload the whole Wi-Fi driver.
WIFI_MODE_STA	Station mode: in this mode, *esp_wifi_start()* will init the internal station data, while the station's interface is ready for the RX and TX Wi-Fi data. After *esp_wifi_connect()*, the station will connect to the target AP.
WIFI_MODE_AP	AP mode: in this mode, *esp_wifi_start()* will init the internal AP data, while the AP's interface is ready for RX/TX Wi-Fi data. Then, the Wi-Fi driver starts broad-casting beacons, and the AP is ready to get connected to other stations.
WIFI_MODE_APSTA	Station/AP coexistence mode: in this mode, *esp_wifi_start()* will simultaneously initialize both the station and the AP. This is done in station mode and AP mode. Please note that the channel of the external AP, which the ESP station is connected to, has higher priority over the ESP AP channel.

Station Basic Configuration

API *esp_wifi_set_config()* can be used to configure the station. And the configuration will be stored in NVS. The table below describes the fields in detail.

Field	Description
ssid	This is the SSID of the target AP, to which the station wants to connect.
password	Password of the target AP.
scan_method	For WIFI_FAST_SCAN scan, the scan ends when the first matched AP is found. For WIFI_ALL_CHANNEL_SCAN, the scan finds all matched APs on all channels. The default scan is WIFI_FAST_SCAN.
bssid_set	If bssid_set is 0, the station connects to the AP whose SSID is the same as the field "ssid", while the field "bssid" is ignored. In all other cases, the station connects to the AP whose SSID is the same as the "ssid" field, while its BSSID is the same the "bssid" field .
bssid	This is valid only when bssid_set is 1; see field "bssid_set".
channel	If the channel is 0, the station scans the channel 1 ~ N to search for the target AP; otherwise, the station starts by scanning the channel whose value is the same as that of the "channel" field, and then scans the channel 1 ~ N but skip the specific channel to find the target AP. For example, if the channel is 3, the scan order will be 3, 1, 2, 4,..., N. If you do not know which channel the target AP is running on, set it to 0.
sort_method	This field is only for WIFI_ALL_CHANNEL_SCAN. If the sort_method is WIFI_CONNECT_AP_BY_SIGNAL, all matched APs are sorted by signal, and the AP with the best signal will be connected firstly. For example, the station wants to connect an AP whose SSID is "apxx". If the scan finds two APs whose SSID equals to "apxx", and the first AP's signal is -90 dBm while the second AP's signal is -30 dBm, the station connects the second AP firstly, and it would not connect the first one unless it fails to connect the second one. If the sort_method is WIFI_CONNECT_AP_BY_SECURITY, all matched APs are sorted by security. For example, the station wants to connect an AP whose SSID is "apxx". If the scan finds two APs whose SSID is "apxx", and the security of the first found AP is open while the second one is WPA2, the station connects to the second AP firstly, and it would not connect the first one unless it fails to connect the second one.
threshold	The threshold is used to filter the found AP. If the RSSI or security mode is less than the configured threshold, the AP will be discarded. If the RSSI is set to 0, it means the default threshold is used, and the default RSSI threshold is -127 dBm. If the authmode threshold is set to 0, it means the default threshold is used, and the default authmode threshold is open.

Attention: WEP/WPA security modes are deprecated in IEEE 802.11-2016 specifications and are recommended not to be used. These modes can be rejected using authmode threshold by setting threshold as WPA2 by threshold.authmode as `WIFI_AUTH_WPA2_PSK`.

AP Basic Configuration

API *`esp_wifi_set_config()`* can be used to configure the AP. And the configuration will be stored in NVS. The table below describes the fields in detail.

Field	Description
ssid	SSID of AP; if the ssid[0] is 0xFF and ssid[1] is 0xFF, the AP defaults the SSID to `ESP_aabbcc`, where "aabbcc" is the last three bytes of the AP MAC.
password	Password of AP; if the auth mode is `WIFI_AUTH_OPEN`, this field will be ignored.
ssid_len	Length of SSID; if ssid_len is 0, check the SSID until there is a termination character. If ssid_len > 32, change it to 32; otherwise, set the SSID length according to ssid_len.
channel	Channel of AP; if the channel is out of range, the Wi-Fi driver defaults to channel 1. So, please make sure the channel is within the required range. For more details, refer to *Wi-Fi Country Code*.
authmode	Auth mode of ESP AP; currently, ESP AP does not support AUTH_WEP. If the authmode is an invalid value, AP defaults the value to `WIFI_AUTH_OPEN`.
ssid_hidden	If ssid_hidden is 1, AP does not broadcast the SSID; otherwise, it does broadcast the SSID.
max_connection	The max number of stations allowed to connect in, the default value is 10. ESP Wi-Fi supports up to 15 (`ESP_WIFI_MAX_CONN_NUM`) Wi-Fi connections. Please note that ESP AP and ESP-NOW share the same encryption hardware keys, so the max_connection parameter will be affected by the *CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM*. The total number of encryption hardware keys is 17, if *CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM* <= 2, the max_connection can be set up to 15, otherwise the max_connection can be set up to (17 - *CONFIG_ESP_WIFI_ESPNOW_MAX_ENCRYPT_NUM*).
beacon_interval	Beacon interval; the value is 100 ~ 60000 ms, with default value being 100 ms. If the value is out of range, AP defaults it to 100 ms.

Wi-Fi Protocol Mode

Currently, the ESP-IDF supports the following protocol modes:

Protocol Mode	Description
802.11b	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B)` to set the station/AP to 802.11b-only mode.
802.11bg	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G)` to set the station/AP to 802.11bg mode.
802.11g	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G)` and esp_wifi_config_11b_rate(ifx, true) to set the station/AP to 802.11g mode.
802.11bgn	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N)` to set the station/ AP to BGN mode.
802.11gn	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_` and esp_wifi_config_11b_rate(ifx, true) to set the station/AP to 802.11gn mode.
802.11 BGNLR	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_11B|WIFI_PROTOCOL_11G|WIFI_PROTOCOL_11N|WIFI_PROTOCOL_LR)` to set the station/AP to BGN and the LR mode.
802.11 LR	Call `esp_wifi_set_protocol(ifx, WIFI_PROTOCOL_LR)` to set the station/AP only to the LR mode. **This mode is an Espressif-patented mode which can achieve a one-kilometer line of sight range. Please make sure both the station and the AP are connected to an ESP device.**

Long Range (LR)

Long Range (LR) mode is an Espressif-patented Wi-Fi mode which can achieve a one-kilometer line of sight range. Compared to the traditional 802.11b mode, it has better reception sensitivity, stronger anti-interference ability, and longer transmission distance.

LR Compatibility Since LR is Espressif-unique Wi-Fi mode, only ESP32 chip series devices (except ESP32-C2) can transmit and receive the LR data. In other words, the ESP32 chip series devices (except ESP32-C2) should NOT transmit the data in LR data rate if the connected device does not support LR. The application can achieve this by configuring a suitable Wi-Fi mode. If the negotiated mode supports LR, the ESP32 chip series devices (except ESP32-C2) may transmit data in LR rate. Otherwise, ESP32 chip series devices (except ESP32-C2) will transmit all data in the traditional Wi-Fi data rate.

The following table depicts the Wi-Fi mode negotiation:

APSTA	BGN	BG	B	BGNLR	BGLR	BLR	LR
BGN	BGN	BG	B	BGN	BG	B	•
BG	BG	BG	B	BG	BG	B	•
B	B	B	B	B	B	B	•
BGNLR	•	•	•	BGNLR	BGLR	BLR	LR
BGLR	•	•	•	BGLR	BGLR	BLR	LR
BLR	•	•	•	BLR	BLR	BLR	LR
LR	•	•	•	LR	LR	LR	LR

In the above table, the row is the Wi-Fi mode of AP and the column is the Wi-Fi mode of station. The "-" indicates Wi-Fi mode of the AP and station are not compatible.

According to the table, the following conclusions can be drawn:

- For LR-enabled AP of ESP32-S3, it is incompatible with traditional 802.11 mode, because the beacon is sent in LR mode.
- For LR-enabled station of ESP32-S3 whose mode is NOT LR-only mode, it is compatible with traditional 802.11 mode.
- If both station and AP are ESP32 series chips devices (except ESP32-C2) and both of them have enabled LR mode, the negotiated mode supports LR.

If the negotiated Wi-Fi mode supports both traditional 802.11 mode and LR mode, it is the Wi-Fi driver's responsibility to automatically select the best data rate in different Wi-Fi modes and the application can ignore it.

LR Impacts to Traditional Wi-Fi Device The data transmission in LR rate has no impacts on the traditional Wi-Fi device because:

- The CCA and backoff process in LR mode are consistent with 802.11 specification.
- The traditional Wi-Fi device can detect the LR signal via CCA and do backoff.

In other words, the transmission impact in LR mode is similar to that in 802.11b mode.

LR Transmission Distance The reception sensitivity gain of LR is about 4 dB larger than that of the traditional 802.11b mode. Theoretically, the transmission distance is about 2 to 2.5 times the distance of 11B.

LR Throughput The LR rate has very limited throughput, because the raw PHY data rate LR is 1/2 Mbps and 1/4 Mbps.

When to Use LR The general conditions for using LR are:

- Both the AP and station are Espressif devices.
- Long distance Wi-Fi connection and data transmission is required.
- Data throughput requirements are very small, such as remote device control.

Wi-Fi Country Code

Call *esp_wifi_set_country()* to set the country info. The table below describes the fields in detail. Please consult local 2.4 GHz RF operating regulations before configuring these fields.

Field	Description
cc[3]	Country code string. This attribute identifies the country or noncountry entity in which the station/AP is operating. If it is a country, the first two octets of this string is the two-character country info as described in the document ISO/IEC3166-1. The third octet is one of the following: • an ASCII space character, which means the regulations under which the station/AP is operating encompass all environments for the current frequency band in the country. • an ASCII 'O' character, which means the regulations under which the station/AP is operating are for an outdoor environment only. • an ASCII 'I' character, which means the regulations under which the station/AP is operating are for an indoor environment only. • an ASCII 'X' character, which means the station/AP is operating under a non-country entity. The first two octets of the noncountry entity is two ASCII 'XX' characters. • the binary representation of the Operating Class table number currently in use. Refer to Annex E of IEEE Std 802.11-2020.
schan	Start channel. It is the minimum channel number of the regulations under which the station/AP can operate.
nchan	Total number of channels as per the regulations. For example, if the schan=1, nchan=13, then the station/AP can send data from channel 1 to 13.
policy	Country policy. This field controls which country info will be used if the configured country info is in conflict with the connected AP's. For more details on related policies, see the following section.

The default country info is:

```
wifi_country_t config = {
    .cc = "01",
    .schan = 1,
    .nchan = 11,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

If the Wi-Fi Mode is station/AP coexist mode, they share the same configured country info. Sometimes, the country info of AP, to which the station is connected, is different from the country info of configured. For example, the configured station has country info:

```
wifi_country_t config = {
    .cc = "JP",
    .schan = 1,
    .nchan = 14,
    .policy = WIFI_COUNTRY_POLICY_AUTO,
};
```

but the connected AP has country info:

```
wifi_country_t config = {
    .cc = "CN",
    .schan = 1,
    .nchan = 13,
};
```

then country info of connected AP's is used.

The following table depicts which country info is used in different Wi-Fi modes and different country policies, and it also describes the impact on active scan.

Wi-Fi Mode	Policy	Description
Station	WIFI_COUNTRY_POLICY_AUTO	If the connected AP has country IE in its beacon, the country info equals to the country info in beacon. Otherwise, use the default country info. For scan: Use active scan from 1 to 11 and use passive scan from 12 to 14. Always keep in mind that if an AP with hidden SSID and station is set to a passive scan channel, the passive scan will not find it. In other words, if the application hopes to find the AP with hidden SSID in every channel, the policy of country info should be configured to WIFI_COUNTRY_POLICY_MANUAL.
Station	WIFI_COUNTRY_POLICY_MANUAL	Always use the configured country info. For scan: Use active scan from schan to schan+nchan-1.
AP	WIFI_COUNTRY_POLICY_AUTO	Always use the configured country info.
AP	WIFI_COUNTRY_POLICY_MANUAL	Always use the configured country info.
Station/AP-coexistence	WIFI_COUNTRY_POLICY_AUTO	Station: Same as station mode with policy WIFI_COUNTRY_POLICY_AUTO. AP: If the station does not connect to any external AP, the AP uses the configured country info. If the station connects to an external AP, the AP has the same country info as the station.
Station/AP-coexistence	WIFI_COUNTRY_POLICY_MANUAL	Station: Same as station mode with policy WIFI_COUNTRY_POLICY_MANUAL. AP: Same as AP mode with policy WIFI_COUNTRY_POLICY_MANUAL.

Home Channel In AP mode, the home channel is defined as the AP channel. In station mode, home channel is defined as the channel of AP which the station is connected to. In station/AP-coexistence mode, the home channel of AP and station must be the same, and if they are different, the station's home channel is always in priority. For example, assume that the AP is on channel 6, and the station connects to an AP whose channel is 9. Since the station's home channel has higher priority, the AP needs to switch its channel from 6 to 9 to make sure that it has the same home channel as the station. While switching channel, the ESP32-S3 in AP mode will notify the connected stations about the channel migration using a Channel Switch Announcement (CSA). Station that supports channel switching will transit without disconnecting and reconnecting to the AP.

Wi-Fi Vendor IE Configuration

By default, all Wi-Fi management frames are processed by the Wi-Fi driver, and the application can ignore them. However, some applications may have to handle the beacon, probe request, probe response, and other management frames. For example, if you insert some vendor-specific IE into the management frames, it is only the management frames which contain this vendor-specific IE that will be processed. In ESP32-S3, `esp_wifi_set_vendor_ie()` and `esp_wifi_set_vendor_ie_cb()` are responsible for this kind of tasks.

4.34.15 Wi-Fi Easy Connect™ (DPP)

Wi-Fi Easy Connect™ (or Device Provisioning Protocol) is a secure and standardized provisioning protocol for configuring Wi-Fi devices. More information can be found in *esp_dpp*.

WPA2-Enterprise

WPA2-Enterprise is the secure authentication mechanism for enterprise wireless networks. It uses RADIUS server for authentication of network users before connecting to the Access Point. The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, and PEAP. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both. When ESP32-S3 in station mode tries to connect an AP in enterprise mode, it sends authentication request to AP which is sent to RADIUS server by AP for authenticating the station. Based on different EAP methods, the parameters can be set in configuration which can be opened using `idf.py menuconfig`. WPA2_Enterprise is supported by ESP32-S3 only in station mode.

For establishing a secure connection, AP and station negotiate and agree on the best possible cipher suite to be used. ESP32-S3 supports 802.1X/EAP (WPA) method of AKM and Advanced encryption standard with Counter Mode Cipher Block Chaining Message Authentication protocol (AES-CCM) cipher suite. It also supports the cipher suites supported by mbedtls if *USE_MBEDTLS_CRYPTO* flag is set.

ESP32-S3 currently supports the following EAP methods:

- EAP-TLS: This is a certificate-based method and only requires SSID and EAP-IDF.
- PEAP: This is a Protected EAP method. Username and Password are mandatory.
- **EAP-TTLS: This is a credential-based method. Only server authentication is mandatory while user authenticatio**
  - PAP: Password Authentication Protocol.
  - CHAP: Challenge Handshake Authentication Protocol.
  - MSCHAP and MSCHAP-V2.
- EAP-FAST: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, USE_MBEDTLS_CRYPTO flag should be disabled to use this feature.

Detailed information on creating certificates and how to run wpa2_enterprise example on ESP32-S3 can be found in wifi/wifi_enterprise.

4.34.16 Wireless Network Management

Wireless Network Management allows client devices to exchange information about the network topology, including information related to RF environment. This makes each client network-aware, facilitating overall improvement in the performance of the wireless network. It is part of 802.11v specification. It also enables the client to support Network assisted Roaming. - Network assisted Roaming: Enables WLAN to send messages to associated clients, resulting clients to associate with APs with better link metrics. This is useful for both load balancing and in directing poorly connected clients.

Current implementation of 802.11v includes support for BSS transition management frames.

4.34.17 Radio Resource Measurement

Radio Resource Measurement (802.11k) is intended to improve the way traffic is distributed within a network. In a WLAN, each device normally connects to the access point (AP) that provides the strongest signal. Depending on the number and geographic locations of the subscribers, this arrangement can sometimes lead to excessive demand on one AP and underutilization of others, resulting in degradation of overall network performance. In a network conforming to 802.11k, if the AP having the strongest signal is loaded to its full capacity, a wireless device can be moved to one of the underutilized APs. Even though the signal may be weaker, the overall throughput is greater because more efficient use is made of the network resources.

Current implementation of 802.11k includes support for beacon measurement report, link measurement report, and neighbor request.

Refer ESP-IDF example examples/wifi/roaming/README.md to set up and use these APIs. Example code only demonstrates how these APIs can be used, and the application should define its own algorithm and cases as required.

4.34.18 Fast BSS Transition

Fast BSS transition (802.11R FT), is a standard to permit continuous connectivity aboard wireless devices in motion, with fast and secure client transitions from one Basic Service Set (abbreviated BSS, and also known as a base station or more colloquially, an access point) to another performed in a nearly seamless manner **avoiding 802.11i 4 way handshake**. 802.11R specifies transitions between access points by redefining the security key negotiation protocol, allowing both the negotiation and requests for wireless resources to occur in parallel. The key derived from the server to be cached in the wireless network, so that a reasonable number of future connections can be based on the cached key, avoiding the 802.1X process.

ESP32-S3 station supports FT for WPA2-PSK networks. Do note that ESP32-S3 station only support FT over the air protocol only.

A config option *CONFIG_ESP_WIFI_11R_SUPPORT* and configuration parameter `ft_enabled` in `wifi_sta_config_t` is provided to enable 802.11R support for station. Refer ESP-IDF example examples/wifi/roaming/README.md for further details.

Attention: Distance measurement using RTT is not accurate, and factors such as RF interference, multi-path travel, antenna orientation, and lack of calibration increase these inaccuracies. For better results, it is suggested to perform FTM between two ESP32 chip series devices as station and AP.

Refer to ESP-IDF example examples/wifi/ftm/README.md for steps on how to set up and perform FTM.

4.34.19 Wi-Fi Location

Wi-Fi Location will improve the accuracy of a device's location data beyond the Access Point, which will enable creation of new and feature-rich applications and services such as geo-fencing, network management, and navigation. One of the protocols used to determine the device location with respect to the Access Point is Fine Timing Measurement which calculates Time-of-Flight of a Wi-Fi frame.

Fine Timing Measurement (FTM)

FTM is used to measure Wi-Fi Round Trip Time (Wi-Fi RTT) which is the time a Wi-Fi signal takes to travel from a device to another device and back again. Using Wi-Fi RTT, the distance between the devices can be calculated with a simple formula of *RTT * c / 2*, where c is the speed of light.

FTM uses timestamps given by Wi-Fi interface hardware at the time of arrival or departure of frames exchanged between a pair of devices. One entity called FTM Initiator (mostly a station device) discovers the FTM Responder (can be a station or an Access Point) and negotiates to start an FTM procedure. The procedure uses multiple Action frames sent in bursts and its ACK's to gather the timestamps data. FTM Initiator gathers the data in the end to calculate an average Round-Trip-Time.

ESP32-S3 supports FTM in below configuration:

- ESP32-S3 as FTM Initiator in station mode.
- ESP32-S3 as FTM Responder in AP mode.

4.34.20 ESP32-S3 Wi-Fi Power-saving Mode

This subsection will briefly introduce the concepts and usage related to Wi-Fi Power Saving Mode, for a more detailed introduction please refer to the *Low Power Mode User Guide*

Station Sleep

Currently, ESP32-S3 Wi-Fi supports the Modem-sleep mode which refers to the legacy power-saving mode in the IEEE 802.11 protocol. Modem-sleep mode works in station-only mode and the station must connect to the AP first.

If the Modem-sleep mode is enabled, station will switch between active and sleep state periodically. In sleep state, RF, PHY and BB are turned off in order to reduce power consumption. Station can keep connection with AP in modem-sleep mode.

Modem-sleep mode includes minimum and maximum power-saving modes. In minimum power-saving mode, station wakes up every DTIM to receive beacon. Broadcast data will not be lost because it is transmitted after DTIM. However, it cannot save much more power if DTIM is short for DTIM is determined by AP.

In maximum power-saving mode, station wakes up in every listen interval to receive beacon. This listen interval can be set to be longer than the AP DTIM period. Broadcast data may be lost because station may be in sleep state at DTIM time. If listen interval is longer, more power is saved, but broadcast data is more easy to lose. Listen interval can be configured by calling API *esp_wifi_set_config()* before connecting to AP.

Call `esp_wifi_set_ps(WIFI_PS_MIN_MODEM)` to enable Modem-sleep minimum power-saving mode or `esp_wifi_set_ps(WIFI_PS_MAX_MODEM)` to enable Modem-sleep maximum power-saving mode after calling *esp_wifi_init()*. When station connects to AP, Modem-sleep will start. When station disconnects from AP, Modem-sleep will stop.

Call `esp_wifi_set_ps(WIFI_PS_NONE)` to disable Modem-sleep mode entirely. Disabling it increases power consumption, but minimizes the delay in receiving Wi-Fi data in real time. When Modem-sleep mode is enabled, the delay in receiving Wi-Fi data may be the same as the DTIM cycle (minimum power-saving mode) or the listening interval (maximum power-saving mode).

Note that in coexist mode, Wi-Fi will remain active only during Wi-Fi time slice, and sleep during non Wi-Fi time slice even if `esp_wifi_set_ps(WIFI_PS_NONE)` is called. Please refer to *coexist policy*.

The default Modem-sleep mode is WIFI_PS_MIN_MODEM.

AP Sleep

Currently, ESP32-S3 AP does not support all of the power-saving feature defined in Wi-Fi specification. To be specific, the AP only caches unicast data for the stations connect to this AP, but does not cache the multicast data for the stations. If stations connected to the ESP32-S3 AP are power-saving enabled, they may experience multicast packet loss.

In the future, all power-saving features will be supported on ESP32-S3 AP.

Disconnected State Sleep

Disconnected state is the duration without Wi-Fi connection between *esp_wifi_start()* to *esp_wifi_stop()*.

Currently, ESP32-S3 Wi-Fi supports sleep mode in disconnected state if running at station mode. This feature could be configured by Menuconfig choice *CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE*.

If *CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE* is enabled, RF, PHY and BB would be turned off in disconnected state when IDLE. The current would be same with current at modem-sleep.

The choice *CONFIG_ESP_WIFI_STA_DISCONNECTED_PM_ENABLE* would be selected by default, while it would be selected forcefully in Menuconfig at coexistence mode.

Connectionless Modules Power-saving

Connectionless modules are those Wi-Fi modules not relying on Wi-Fi connection, e.g ESP-NOW, DPP, FTM. These modules start from *esp_wifi_start()*, working until *esp_wifi_stop()*.

Currently, if ESP-NOW works at station mode, its supported to sleep at both connected state and disconnected state.

Connectionless Modules TX For each connectionless module, its supported to TX at any sleeping time without any extra configuration.

Meanwhile, *esp_wifi_80211_tx()* is supported at sleep as well.

Connectionless Modules RX For each connectionless module, two parameters shall be configured to RX at sleep, which are *Window* and *Interval*.

At the start of *Interval* time, RF, PHY, BB would be turned on and kept for *Window* time. Connectionless Module could RX in the duration.

Interval

- There is only one *Interval*. Its configured by `esp_wifi_set_connectionless_interval()`. The unit is milliseconds.
- The default value of *Interval* is *ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE*.
- Event *WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START* would be posted at the start of *Interval*. Since *Window* also starts at that moment, its recommended to TX in that event.
- At connected state, the start of *Interval* would be aligned with TBTT. To improve the packet reception success rate in connectionless modules, the sender and receiver can be connected to the same AP, and packets can be transmitted within the event *WIFI_EVENT_CONNECTIONLESS_MODULE_WAKE_INTERVAL_START*. This synchronization helps align the connectionless modules transmission window.

Window

- Each connectionless module has its own *Window* after start. Connectionless Modules Power-saving would work with the max one among them.
- *Window* is configured by `module_name_set_wake_window()`. The unit is milliseconds.
- The default value of *Window* is the maximum.

Table 32: RF, PHY and BB usage under different circumstances

		Interval	
		`ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE`	1 - maximum
Window	0	not used	
	1 - maximum	default mode	used periodically (Window < Interval) / used all time (Window ≥ Interval)

Default Mode If *Interval* is `ESP_WIFI_CONNECTIONLESS_INTERVAL_DEFAULT_MODE` with non-zero *Window*, Connectionless Modules Power-saving would work in default mode.

In default mode, RF, PHY, BB would be kept on if no coexistence with non-Wi-Fi protocol.

With coexistence, RF, PHY, BB resources are allocated by coexistence module to Wi-Fi connectionless module and non-Wi-Fi module, using time-division method. In default mode, Wi-Fi connectionless module is allowed to use RF, BB, PHY periodically under a stable performance.

Its recommended to configure Connectionless Modules Power-saving to default mode if there is Wi-Fi connectionless module coexists with non-Wi-Fi module.

4.34.21 ESP32-S3 Wi-Fi Throughput

The table below shows the best throughput results gained in Espressif's lab and in a shielded box.

Type/Throughput	Air In Lab	Shield-box	Test Tool	IDF Version (commit ID)
Raw 802.11 Packet RX	N/A	**130 MBit/s**	Internal tool	NA
Raw 802.11 Packet TX	N/A	**130 MBit/s**	Internal tool	NA
UDP RX	30 MBit/s	88 MBit/s	iperf example	15575346
UDP TX	30 MBit/s	98 MBit/s	iperf example	15575346
TCP RX	20 MBit/s	73 MBit/s	iperf example	15575346
TCP TX	20 MBit/s	83 MBit/s	iperf example	15575346

When the throughput is tested by iperf example, the sdkconfig is examples/wifi/iperf/sdkconfig.defaults.esp32s3.

4.34.22 Wi-Fi 80211 Packet Send

The *esp_wifi_80211_tx()* API can be used to:

- Send the beacon, probe request, probe response, and action frame.
- Send the non-QoS data frame.

It cannot be used for sending encrypted or QoS frames.

Preconditions of Using `esp_wifi_80211_tx()`

- The Wi-Fi mode is station, or AP, or station/AP.
- Either `esp_wifi_set_promiscuous(true)`, or *esp_wifi_start()*, or both of these APIs return *ESP_OK*. This is because Wi-Fi hardware must be initialized before *esp_wifi_80211_tx()* is called. In ESP32-S3, both `esp_wifi_set_promiscuous(true)` and *esp_wifi_start()* can trigger the initialization of Wi-Fi hardware.
- The parameters of *esp_wifi_80211_tx()* are hereby correctly provided.

Data Rate

- The default data rate is 1 Mbps.
- Can set any rate through *esp_wifi_config_80211_tx_rate()* API.
- Can set any bandwidth through *esp_wifi_set_bandwidth()* API.

Side-Effects to Avoid in Different Scenarios

Theoretically, if the side-effects the API imposes on the Wi-Fi driver or other stations/APs are not considered, a raw 802.11 packet can be sent over the air with any destination MAC, any source MAC, any BSSID, or any other types of packet. However, robust or useful applications should avoid such side-effects. The table below provides some tips and recommendations on how to avoid the side-effects of *esp_wifi_80211_tx()* in different scenarios.

Scenario	Description
No Wi-Fi connection	In this scenario, no Wi-Fi connection is set up, so there are no side-effects on the Wi-Fi driver. If `en_sys_seq==true`, the Wi-Fi driver is responsible for the sequence control. If `en_sys_seq==false`, the application needs to ensure that the buffer has the correct sequence. Theoretically, the MAC address can be any address. However, this may impact other stations/APs with the same MAC/BSSID. Side-effect example#1 The application calls *esp_wifi_80211_tx()* to send a beacon with BSSID == mac_x in AP mode, but the mac_x is not the MAC of the AP interface. Moreover, there is another AP, e.g., "other-AP" , whose BSSID is mac_x. If this happens, an "unexpected behavior"may occur, because the stations which connect to the "other-AP"cannot figure out whether the beacon is from the "other-AP" or the *esp_wifi_80211_tx()*. To avoid the above-mentioned side-effects, it is recommended that: • If *esp_wifi_80211_tx()* is called in station mode, the first MAC should be a multicast MAC or the exact target-device' s MAC, while the second MAC should be that of the station interface. • If *esp_wifi_80211_tx()* is called in AP mode, the first MAC should be a multicast MAC or the exact target-device' s MAC, while the second MAC should be that of the AP interface. The recommendations above are only for avoiding side-effects and can be ignored when there are good reasons.
Have Wi-Fi connection	When the Wi-Fi connection is already set up, and the sequence is controlled by the application, the latter may impact the sequence control of the Wi-Fi connection as a whole. So, the `en_sys_seq` need to be true, otherwise `ESP_ERR_INVALID_ARG` is returned. The MAC-address recommendations in the "No Wi-Fi connection" scenario also apply to this scenario. If the Wi-Fi mode is station mode, the MAC address1 is the MAC of AP to which the station is connected, and the MAC address2 is the MAC of station interface, it is said that the packet is sent from the station to AP. Otherwise, if the Wi-Fi is in AP mode, the MAC address1 is the MAC of the station that connects to this AP, and the MAC address2 is the MAC of AP interface, it is said that the packet is sent from the AP to station. To avoid conflicting with Wi-Fi connections, the following checks are applied: • If the packet type is data and is sent from the station to AP, the ToDS bit in IEEE 80211 frame control should be 1 and the FromDS bit should be 0. Otherwise, the packet will be discarded by Wi-Fi driver. • If the packet type is data and is sent from the AP to station, the ToDS bit in IEEE 80211 frame control should be 0 and the FromDS bit should be 1. Otherwise, the packet will be discarded by Wi-Fi driver. • If the packet is sent from station to AP or from AP to station, the Power Management, More Data, and Re-Transmission bits should be 0. Otherwise, the packet will be discarded by Wi-Fi driver. `ESP_ERR_INVALID_ARG` is returned if any check fails.

4.34.23 Wi-Fi Sniffer Mode

The Wi-Fi sniffer mode can be enabled by *esp_wifi_set_promiscuous()*. If the sniffer mode is enabled, the following packets **can** be dumped to the application:

- 802.11 Management frame.
- 802.11 Data frame, including MPDU, AMPDU, and AMSDU.
- 802.11 MIMO frame, for MIMO frame, the sniffer only dumps the length of the frame.
- 802.11 Control frame.
- 802.11 CRC error frame.

The following packets will **NOT** be dumped to the application:

- Other 802.11 error frames.

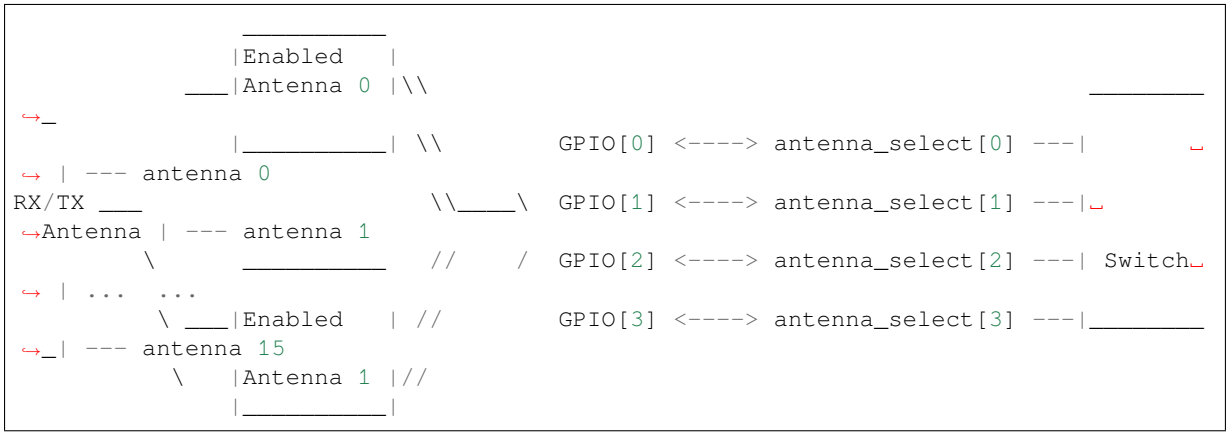
For frames that the sniffer **can** dump, the application can additionally decide which specific type of packets can be filtered to the application by using *esp_wifi_set_promiscuous_filter()* and *esp_wifi_set_promiscuous_ctrl_filter()*. By default, it will filter all 802.11 data and management frames to the application. If you want to filter the 802.11 control frames, the filter parameter in *esp_wifi_set_promiscuous_filter()* should include *WIFI_PROMIS_FILTER_MASK_CTRL* type, and if you want to differentiate control frames further, then call *esp_wifi_set_promiscuous_ctrl_filter()*.

The Wi-Fi sniffer mode can be enabled in the Wi-Fi mode of *WIFI_MODE_NULL*, *WIFI_MODE_STA*, *WIFI_MODE_AP*, or *WIFI_MODE_APSTA*. In other words, the sniffer mode is active when the station is connected to the AP, or when the AP has a Wi-Fi connection. Please note that the sniffer has a **great impact** on the throughput of the station or AP Wi-Fi connection. Generally, the sniffer should be enabled **only if** the station/AP Wi-Fi connection does not experience heavy traffic.

Another noteworthy issue about the sniffer is the callback *wifi_promiscuous_cb_t*. The callback will be called directly in the Wi-Fi driver task, so if the application has a lot of work to do for each filtered packet, the recommendation is to post an event to the application task in the callback and defer the real work to the application task.

4.34.24 Wi-Fi Multiple Antennas

The Wi-Fi multiple antennas selecting can be depicted as following picture:



ESP32-S3 supports up to sixteen antennas through external antenna switch. The antenna switch can be controlled by up to four address pins - antenna_select[0:3]. Different input value of antenna_select[0:3] means selecting different antenna. For example, the value '0b1011' means the antenna 11 is selected. The default value of antenna_select[3:0] is '0b0000', which means the antenna 0 is selected by default.

Up to four GPIOs are connected to the four active high antenna_select pins. ESP32-S3 can select the antenna by control the GPIO[0:3]. The API *esp_wifi_set_ant_gpio()* is used to configure which GPIOs are connected to antenna_selects. If GPIO[x] is connected to antenna_select[x], then gpio_config->gpio_cfg[x].gpio_select should be set to 1 and gpio_config->gpio_cfg[x].gpio_num should be provided.

For the specific implementation of the antenna switch, there may be illegal values in *antenna_select[0:3]*. It means that ESP32-S3 may support less than sixteen antennas through the switch. For example, ESP32-WROOM-DA which uses RTC6603SP as the antenna switch, supports two antennas. Two GPIOs are connected to two active high antenna selection inputs. The value '0b01' means the antenna 0 is selected, the value '0b10' means the antenna 1 is selected. Values '0b00' and '0b11' are illegal.

Although up to sixteen antennas are supported, only one or two antennas can be simultaneously enabled for RX/TX. The API *esp_wifi_set_ant()* is used to configure which antennas are enabled.

The enabled antennas selecting algorithm is also configured by *esp_wifi_set_ant()*. The RX/TX antenna mode can be *WIFI_ANT_MODE_ANT0*, *WIFI_ANT_MODE_ANT1*, or *WIFI_ANT_MODE_AUTO*. If the antenna mode is *WIFI_ANT_MODE_ANT0*, the enabled antenna 0 is selected for RX/TX data. If the antenna mode is *WIFI_ANT_MODE_ANT1*, the enabled antenna 1 is selected for RX/TX data. Otherwise, Wi-Fi automatically selects the enabled antenna that has better signal.

If the RX antenna mode is *WIFI_ANT_MODE_AUTO*, the default antenna mode also needs to be set, because the RX antenna switching only happens when some conditions are met. For example, the RX antenna starts to switch if the RSSI is lower than -65 dBm or another antenna has better signal. RX uses the default antenna if the conditions are not met. If the default antenna mode is *WIFI_ANT_MODE_ANT1*, the enabled antenna 1 is used as the default RX antenna, otherwise the enabled antenna 0 is used.

Some limitations need to be considered:

- The TX antenna can be set to *WIFI_ANT_MODE_AUTO* only if the RX antenna mode is *WIFI_ANT_MODE_AUTO*, because TX antenna selecting algorithm is based on RX antenna in *WIFI_ANT_MODE_AUTO* type.
- When the TX antenna mode or RX antenna mode is configured to *WIFI_ANT_MODE_AUTO* the switching mode will easily trigger the switching phase, as long as there is deterioration of the RF signal. So in situations where the RF signal is not stable, the antenna switching will occur frequently, resulting in an RF performance that may not meet expectations.
- Currently, Bluetooth® does not support the multiple antennas feature, so please do not use multiple antennas related APIs.

Following is the recommended scenarios to use the multiple antennas:

- The applications can always choose to select a specified antenna or implement their own antenna selecting algorithm, e.g., selecting the antenna mode based on the information collected by the application. Refer to ESP-IDF example examples/wifi/antenna/README.md for the antenna selecting algorithm design.
- Both RX/TX antenna modes are configured to WIFI_ANT_MODE_ANT0 or WIFI_ANT_MODE_ANT1.

Wi-Fi Multiple Antennas Configuration

Generally, following steps can be taken to configure the multiple antennas:

- Configure which GPIOs are connected to the antenna_selects. For example, if four antennas are supported and GPIO20/GPIO21 are connected to antenna_select[0]/antenna_select[1], the configurations look like:

```
wifi_ant_gpio_config_t ant_gpio_config = {
    .gpio_cfg[0] = { .gpio_select = 1, .gpio_num = 20 },
    .gpio_cfg[1] = { .gpio_select = 1, .gpio_num = 21 }
};
```

- Configure which antennas are enabled and how RX/TX use the enabled antennas. For example, if antenna1 and antenna3 are enabled, the RX needs to select the better antenna automatically and uses antenna1 as its default antenna, the TX always selects the antenna3. The configuration looks like:

```
wifi_ant_config_t config = {
    .rx_ant_mode = WIFI_ANT_MODE_AUTO,
    .rx_ant_default = WIFI_ANT_ANT0,
    .tx_ant_mode = WIFI_ANT_MODE_ANT1,
    .enabled_ant0 = 1,
    .enabled_ant1 = 3
};
```

4.34.25 Wi-Fi Channel State Information

Channel state information (CSI) refers to the channel information of a Wi-Fi connection. In ESP32-S3, this information consists of channel frequency responses of sub-carriers and is estimated when packets are received from the transmitter. Each channel frequency response of sub-carrier is recorded by two bytes of signed characters. The first one is imaginary part and the second one is real part. There are up to three fields of channel frequency responses according to the type of received packet. They are legacy long training field (LLTF), high throughput LTF (HT-LTF), and space time block code HT-LTF (STBC-HT-LTF). For different types of packets which are received on channels with different state, the sub-carrier index and total bytes of signed characters of CSI are shown in the following table.

channel	secondary channel	none			below					above				
packet information	signal mode	non HT	HT		non HT	HT				non HT	HT			
	channel bandwidth	20 MHz	20 MHz		20 MHz	20 MHz		40 MHz		20 MHz	20 MHz		40 MHz	
	STBC	non STBC	non STBC	STBC	non STBC	non STBC	STBC	non STBC	STBC	non STBC	non STBC	STBC	non STBC	STBC
sub-carrier index	LLTF	0~31, -32~-1	0~31, -32~-1	0~31, -32~-1	0~63	0~63	0~63	0~63	0~63	-64~-1	-64~-1	-64~-1	-64~-1	-64~-1
	HT-LTF	•	0~31, -32~-1	0~31, -32~-1	•	0~63	0~62	0~63, -64~-1	0~60, -60~-1	•	-64~-1	-62~-1	0~63, -64~-1	0~60, -60~-1
	STBC-HT-LTF	•	•	0~31, -32~-1	•	•	0~62	•	0~60, -60~-1	•	•	-62~-1	•	0~60, -60~-1
total bytes		128	256	384	128	256	380	384	612	128	256	376	384	612

All of the information in the table can be found in the structure wifi_csi_info_t.

- Secondary channel refers to secondary_channel field of rx_ctrl field.
- Signal mode of packet refers to sig_mode field of rx_ctrl field.
- Channel bandwidth refers to cwb field of rx_ctrl field.
- STBC refers to stbc field of rx_ctrl field.
- Total bytes refers to len field.
- The CSI data corresponding to each Long Training Field (LTF) type is stored in a buffer starting from the buf field. Each item is stored as two bytes: imaginary part followed by real part. The order of each item is the same as the sub-carrier in the table. The order of LTF is: LLTF, HT-LTF, STBC-HT-LTF. However, all 3 LTFs may not be present, depending on the channel and packet information (see above).
- If first_word_invalid field of `wifi_csi_info_t` is true, it means that the first four bytes of CSI data is invalid due to a hardware limitation in ESP32-S3.
- More information like RSSI, noise floor of RF, receiving time and antenna is in the rx_ctrl field.

When imaginary part and real part data of sub-carrier are used, please refer to the table below.

PHY standard	Sub-carrier range	Pilot sub-carrier	Sub-carrier (total/data)
802.11a/g	-26 to +26	-21, -7, +7, +21	52 total, 48 usable
802.11n, 20 MHz	-28 to +28	-21, -7, +7, +21	56 total, 52 usable
802.11n, 40 MHz	-57 to +57	-53, -25, -11, +11, +25, +53	114 total, 108 usable

Note:

- For STBC packet, CSI is provided for every space-time stream without CSD (cyclic shift delay). As each cyclic shift on the additional chains shall be -200 ns, only the CSD angle of first space-time stream is recorded in sub-carrier 0 of HT-LTF and STBC-HT-LTF for there is no channel frequency response in sub-carrier 0. CSD[10:0] is 11 bits, ranging from -pi to pi.
- If LLTF, HT-LTF, or STBC-HT-LTF is not enabled by calling API `esp_wifi_set_csi_config()`, the total bytes of CSI data will be fewer than that in the table. For example, if LLTF and HT-LTF is not enabled

and STBC-HT-LTF is enabled, when a packet is received with the condition above/HT/40MHz/STBC, the total bytes of CSI data is 244 ((61 + 60) * 2 + 2 = 244. The result is aligned to four bytes, and the last two bytes are invalid).

4.34.26 Wi-Fi Channel State Information Configure

To use Wi-Fi CSI, the following steps need to be done.

- Select Wi-Fi CSI in menuconfig. Go to `Menuconfig > Components config > Wi-Fi > Wi-Fi CSI (Channel State Information)`.
- Set CSI receiving callback function by calling API *`esp_wifi_set_csi_rx_cb()`*.
- Configure CSI by calling API *`esp_wifi_set_csi_config()`*.
- Enable CSI by calling API *`esp_wifi_set_csi()`*.

The CSI receiving callback function runs from Wi-Fi task. So, do not do lengthy operations in the callback function. Instead, post necessary data to a queue and handle it from a lower priority task. Because station does not receive any packet when it is disconnected and only receives packets from AP when it is connected, it is suggested to enable sniffer mode to receive more CSI data by calling *`esp_wifi_set_promiscuous()`*.

4.34.27 Wi-Fi HT20/40

ESP32-S3 supports Wi-Fi bandwidth HT20 or HT40 and does not support HT20/40 coexist. *`esp_wifi_set_bandwidth()`* can be used to change the default bandwidth of station or AP. The default bandwidth for ESP32-S3 station and AP is HT40.

In station mode, the actual bandwidth is firstly negotiated during the Wi-Fi connection. It is HT40 only if both the station and the connected AP support HT40, otherwise it is HT20. If the bandwidth of connected AP is changes, the actual bandwidth is negotiated again without Wi-Fi disconnecting.

Similarly, in AP mode, the actual bandwidth is negotiated between AP and the stations that connect to the AP. It is HT40 if the AP and one of the stations support HT40, otherwise it is HT20.

In station/AP coexist mode, the station/AP can configure HT20/40 seperately. If both station and AP are negotiated to HT40, the HT40 channel should be the channel of station because the station always has higher priority than AP in ESP32-S3. For example, the configured bandwidth of AP is HT40, the configured primary channel is 6, and the configured secondary channel is 10. The station is connected to an router whose primary channel is 6 and secondary channel is 2, then the actual channel of AP is changed to primary 6 and secondary 2 automatically.

Theoretically, the HT40 can gain better throughput because the maximum raw physicial (PHY) data rate for HT40 is 150 Mbps while it is 72 Mbps for HT20. However, if the device is used in some special environment, e.g., there are too many other Wi-Fi devices around the ESP32-S3 device, the performance of HT40 may be degraded. So if the applications need to support same or similar scenarios, it is recommended that the bandwidth is always configured to HT20.

4.34.28 Wi-Fi QoS

ESP32-S3 supports all the mandatory features required in WFA Wi-Fi QoS Certification.

Four ACs (Access Category) are defined in Wi-Fi specification, and each AC has its own priority to access the Wi-Fi channel. Moreover, a map rule is defined to map the QoS priority of other protocol, e.g., 802.11D or TCP/IP precedence is mapped to Wi-Fi AC.

The table below describes how the IP Precedences are mapped to Wi-Fi ACs in ESP32-S3. It also indicates whether the AMPDU is supported for this AC. The table is sorted from high to low priority. That is to say, the AC_VO has the highest priority.

IP Precedence	Wi-Fi AC	Support AMPDU?
6, 7	AC_VO (Voice)	No
4, 5	AC_VI (Video)	Yes
3, 0	AC_BE (Best Effort)	Yes
1, 2	AC_BK (Background)	Yes

The application can make use of the QoS feature by configuring the IP precedence via socket option IP_TOS. Here is an example to make the socket to use VI queue:

```
const int ip_precedence_vi = 4;
const int ip_precedence_offset = 5;
int priority = (ip_precedence_vi << ip_precedence_offset);
setsockopt(socket_id, IPPROTO_IP, IP_TOS, &priority, sizeof(priority));
```

Theoretically, the higher priority AC has better performance than the lower priority AC. However, it is not always true. Here are some suggestions about how to use the Wi-Fi QoS:

- Some really important application traffic can be put into the AC_VO queue. But avoid using the AC_VO queue for heavy traffic, as it may impact the management frames which also use this queue. Eventually, it is worth noting that the AC_VO queue does not support AMPDU, and its performance with heavy traffic is no better than other queues.
- Avoid using more than two precedences supported by different AMPDUs, e.g., when socket A uses precedence 0, socket B uses precedence 1, and socket C uses precedence 2. This can be a bad design because it may need much more memory. To be specific, the Wi-Fi driver may generate a Block Ack session for each precedence and it needs more memory if the Block Ack session is set up.

4.34.29 Wi-Fi AMSDU

ESP32-S3 supports receiving and transmitting AMSDU. AMSDU TX is disabled by default, since enable AMSDU TX need more memory. Select *CONFIG_ESP_WIFI_AMSDU_TX_ENABLED* to enable AMSDU Tx feature, it depends on *CONFIG_SPIRAM*.

4.34.30 Wi-Fi Fragment

ESP32-S3 supports Wi-Fi receiving and transmitting fragment.

4.34.31 WPS Enrollee

ESP32-S3 supports WPS enrollee feature in Wi-Fi mode `WIFI_MODE_STA` or `WIFI_MODE_APSTA`. Currently, ESP32-S3 supports WPS enrollee type PBC and PIN.

4.34.32 Wi-Fi Buffer Usage

This section is only about the dynamic buffer configuration.

Why Buffer Configuration Is Important

In order to get a high-performance system, consider the memory usage/configuration carefully for the following reasons:

- the available memory in ESP32-S3 is limited.
- currently, the default type of buffer in LwIP and Wi-Fi drivers is "dynamic", **which means that both the LwIP and Wi-Fi share memory with the application**. Programmers should always keep this in mind; otherwise, they will face a memory issue, such as "running out of heap memory".

- it is very dangerous to run out of heap memory, as this will cause ESP32-S3 an "undefined behavior". Thus, enough heap memory should be reserved for the application, so that it never runs out of it.
- the Wi-Fi throughput heavily depends on memory-related configurations, such as the TCP window size and Wi-Fi RX/TX dynamic buffer number.
- the peak heap memory that the ESP32-S3 LwIP/Wi-Fi may consume depends on a number of factors, such as the maximum TCP/UDP connections that the application may have.
- the total memory that the application requires is also an important factor when considering memory configuration.

Due to these reasons, there is not a good-for-all application configuration. Rather, it is recommended to consider memory configurations separately for every different application.

Dynamic vs. Static Buffer

The default type of buffer in Wi-Fi drivers is "dynamic". Most of the time the dynamic buffer can significantly save memory. However, it makes the application programming a little more difficult, because in this case the application needs to consider memory usage in Wi-Fi.

lwIP also allocates buffers at the TCP/IP layer, and this buffer allocation is also dynamic. See *lwIP documentation section about memory use and performance*.

Peak Wi-Fi Dynamic Buffer

The Wi-Fi driver supports several types of buffer (refer to *Wi-Fi Buffer Configure*). However, this section is about the usage of the dynamic Wi-Fi buffer only. The peak heap memory that Wi-Fi consumes is the **theoretically-maximum memory** that the Wi-Fi driver consumes. Generally, the peak memory depends on:

- b_{rx} the number of dynamic RX buffers that are configured
- b_{tx} the number of dynamic TX buffers that are configured
- m_{rx} the maximum packet size that the Wi-Fi driver can receive
- m_{tx} the maximum packet size that the Wi-Fi driver can send

So, the peak memory that the Wi-Fi driver consumes (p) can be calculated with the following formula:

$$p = (b_{rx} * m_{rx}) + (b_{tx} * m_{tx})$$

Generally, the dynamic TX long buffers and dynamic TX long long buffers can be ignored, because they are management frames which only have a small impact on the system.

4.34.33 How to Improve Wi-Fi Performance

The performance of ESP32-S3 Wi-Fi is affected by many parameters, and there are mutual constraints between each parameter. A proper configuration cannot only improve performance, but also increase available memory for applications and improve stability.

This section briefly explains the operating mode of the Wi-Fi/LwIP protocol stack and the role of each parameter. It also gives several recommended configuration ranks to help choose the appropriate rank according to the usage scenario.

Protocol Stack Operation Mode

The ESP32-S3 protocol stack is divided into four layers: Application, LwIP, Wi-Fi, and Hardware.

- During receiving, hardware puts the received packet into DMA buffer, and then transfers it into the RX buffer of Wi-Fi and LwIP in turn for related protocol processing, and finally to the application layer. The Wi-Fi RX buffer and the LwIP RX buffer shares the same buffer by default. In other words, the Wi-Fi forwards the packet to LwIP by reference by default.

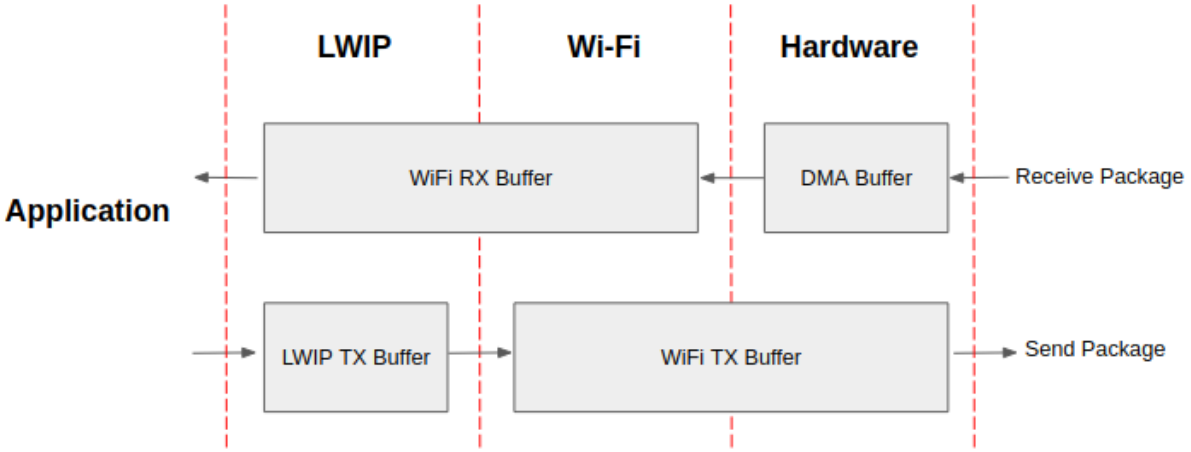


Fig. 87: ESP32-S3 datapath

- During sending, the application copies the messages to be sent into the TX buffer of the LwIP layer for TCP/IP encapsulation. The messages will then be passed to the TX buffer of the Wi-Fi layer for MAC encapsulation and wait to be sent.

Parameters

Increasing the size or number of the buffers mentioned above properly can improve Wi-Fi performance. Meanwhile, it will reduce available memory to the application. The following is an introduction to the parameters that users need to configure:

RX direction:

- ***CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM*** This parameter indicates the number of DMA buffer at the hardware layer. Increasing this parameter will increase the sender's one-time receiving throughput, thereby improving the Wi-Fi protocol stack ability to handle burst traffic.
- ***CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM*** This parameter indicates the number of RX buffer in the Wi-Fi layer. Increasing this parameter will improve the performance of packet reception. This parameter needs to match the RX buffer size of the LwIP layer.
- ***CONFIG_ESP_WIFI_RX_BA_WIN*** This parameter indicates the size of the AMPDU BA Window at the receiving end. This parameter should be configured to the smaller value between twice of *CONFIG_ESP_WIFI_STATIC_RX_BUFFER_NUM* and *CONFIG_ESP_WIFI_DYNAMIC_RX_BUFFER_NUM*.
- ***CONFIG_LWIP_TCP_WND_DEFAULT*** This parameter represents the RX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_RX_BUFFER_NUM (KB) to reach a high and stable performance. Meanwhile, in case of multiple streams, this value needs to be reduced proportionally.

TX direction:

- ***CONFIG_ESP_WIFI_TX_BUFFER*** This parameter indicates the type of TX buffer, it is recommended to configure it as a dynamic buffer, which can make full use of memory.
- ***CONFIG_ESP_WIFI_DYNAMIC_TX_BUFFER_NUM*** This parameter indicates the number of TX buffer on the Wi-Fi layer. Increasing this parameter will improve the performance of packet sending. The parameter value needs to match the TX buffer size of the LwIP layer.
- ***CONFIG_LWIP_TCP_SND_BUF_DEFAULT*** This parameter represents the TX buffer size of the LwIP layer for each TCP stream. Its value should be configured to the value of WIFI_DYNAMIC_TX_BUFFER_NUM (KB) to reach a high and stable performance. In case of multiple streams, this value needs to be reduced proportionally.

Throughput optimization by placing code in IRAM:

CACHE:

- *CONFIG_ESP32S3_INSTRUCTION_CACHE_SIZE* Configure the size of the instruction Cache.
- *CONFIG_ESP32S3_INSTRUCTION_CACHE_LINE_SIZE* Configure the size of the instruction Cache bus.
- *CONFIG_ESP32S3_ICACHE_ASSOCIATED_WAYS* Configure the associated ways of the instruction Cache.
- *CONFIG_ESP32S3_DATA_CACHE_SIZE* Configure the size of the Data Cache.
- *CONFIG_ESP32S3_DATA_CACHE_LINE_SIZE* Configure the line size of the Data Cache.
- *CONFIG_ESP32S3_DCACHE_ASSOCIATED_WAYS* Configure the associated ways of the Data Cache.

Note: The buffer size mentioned above is fixed as 1.6 KB.

How to Configure Parameters

The memory of ESP32-S3 is shared by protocol stack and applications.

Here, several configuration ranks are given. In most cases, the user should select a suitable rank for parameter configuration according to the size of the memory occupied by the application.

The parameters not mentioned in the following table should be set to the default.

Rank	Iperf	Default	Minimum
Available memory (KB)	133.9	183.9	273.6
WIFI_STATIC_RX_BUFFER_NUM	24	8	3
WIFI_DYNAMIC_RX_BUFFER_NUM	64	32	6
WIFI_DYNAMIC_TX_BUFFER_NUM	64	32	6
WIFI_RX_BA_WIN	32	16	6
TCP_SND_BUF_DEFAULT (KB)	64	32	6
TCP_WND_DEFAULT (KB)	64	32	6
WIFI_IRAM_OPT	ENABLE	ENABLE	ENABLE
WIFI_RX_IRAM_OPT	ENABLE	ENABLE	ENABLE
LWIP_IRAM_OPTIMIZATION	ENABLE	ENABLE	DISABLE
INSTRUCTION_CACHE	32	32	16
INSTRUCTION_CACHE_LINE	32	32	32
INSTRUCTION_CACHE_WAYS	8	8	4
TCP TX throughput (Mbit/s)	83.93	64.28	23.17
TCP RX throughput (Mbit/s)	73.98	60.39	18.11
UDP TX throughput (Mbit/s)	98.69	96.28	48.78
UDP RX throughput (Mbit/s)	88.58	86.57	59.45

Note: The test was performed with a single stream in a shielded box using an ASUS RT-N66U router. ESP32-S3's CPU is dual core with 240 MHz. ESP32-S3's flash is in QIO mode with 80 MHz.

Ranks:

- **Iperf rank** ESP32-S3 extreme performance rank used to test extreme performance.
- **Default rank** ESP32-S3's default configuration rank, the available memory, and performance are in balance.

- **Minimum rank** This is the minimum configuration rank of ESP32-S3. The protocol stack only uses the necessary memory for running. It is suitable for scenarios where there is no requirement for performance and the application requires lots of space.

Using PSRAM

PSRAM is generally used when the application takes up a lot of memory. In this mode, the *CONFIG_ESP_WIFI_TX_BUFFER* is forced to be static. *CONFIG_ESP_WIFI_STATIC_TX_BUFFER_NUM* indicates the number of DMA buffers at the hardware layer, and increasing this parameter can improve performance. The following are the recommended ranks for using PSRAM:

PSRAM with 4 lines:

Rank	Iperf	Default	Memory saving	Minimum
Available memory (KB)	50.3	158.7	198.2	228.9
WIFI_STATIC_RX_BUFFER_NUM	8	8	6	4
WIFI_DYNAMIC_RX_BUFFER_NUM	64	64	32	32
WIFI_STATIC_TX_BUFFER_NUM	32	32	6	4
WIFI_RX_BA_WIN	32	16	12	Disable
TCP_SND_BUF_DEFAULT (KB)	65	32	32	32
TCP_WND_DEFAULT (KB)	65	32	32	32
WIFI_IRAM_OPT	ENABLE	ENABLE	ENABLE	DISABLE
WIFI_RX_IRAM_OPT	ENABLE	ENABLE	DISABLE	DISABLE
LWIP_IRAM_OPTIMIZATION	ENABLE	DISABLE	DISABLE	DISABLE
LWIP_UDP_RECVMBOX_SIZE	16	16	16	16
INSTRUCTION_CACHE	32	16	16	16
INSTRUCTION_CACHE_LINE	32	16	16	16
INSTRUCTION_CACHE_WAYS	8	8	8	8
DATA_CACHE	64	16	16	16
DATA_CACHE_LINE	32	32	32	32
DATA_CACHE_WAYS	8	8	8	8
TCP TX throughput (Mbit/s)	93.1	62.5	41.3	42.7
TCP RX throughput (Mbit/s)	88.9	46.5	46.2	37.9
UDP TX throughput (Mbit/s)	106.4	106.2	60.7	50
UDP RX throughput (Mbit/s)	99.8	92.6	94.3	53.3

PSRAM with 8 lines:

Rank	Iperf	Default	Memory saving	Minimum
Available memory (KB)	49.1	151.3	215.3	243.6
WIFI_STATIC_RX_BUFFER_NUM	24	8	6	4
WIFI_DYNAMIC_RX_BUFFER_NUM	64	64	32	32
WIFI_STATIC_TX_BUFFER_NUM	32	32	6	4

UDP RX throughput (Mbit/s)	104.6	104.8	104	55.7

4.34.34 Wi-Fi Menuconfig

Wi-Fi Buffer Configure

If you are going to modify the default number or type of buffer, it would be helpful to also have an overview of how the buffer is allocated/freed in the data path. The following diagram shows this process in the TX direction:

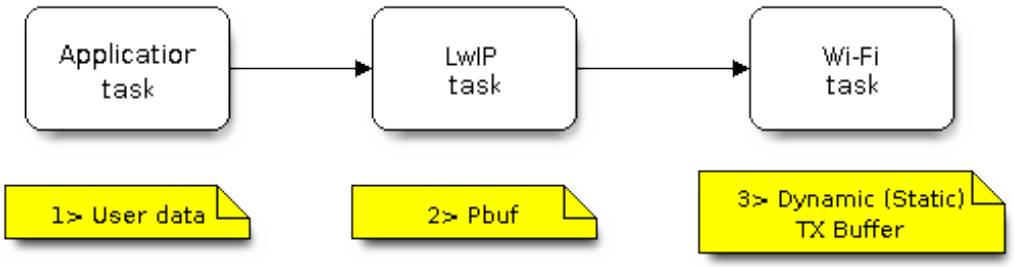

Fig. 88: TX Buffer Allocation

Description:

- The application allocates the data which needs to be sent out.

- The application calls TCPIP-/Socket-related APIs to send the user data. These APIs will allocate a PBUF used in LwIP, and make a copy of the user data.
- When LwIP calls a Wi-Fi API to send the PBUF, the Wi-Fi API will allocate a "Dynamic Tx Buffer" or "Static Tx Buffer", make a copy of the LwIP PBUF, and finally send the data.

The following diagram shows how buffer is allocated/freed in the RX direction:

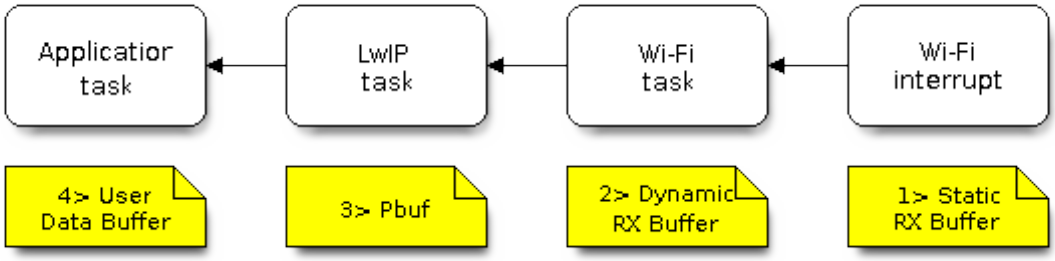

Fig. 89: RX Buffer Allocation

Description:

- The Wi-Fi hardware receives a packet over the air and puts the packet content to the "Static Rx Buffer", which is also called "RX DMA Buffer".
- The Wi-Fi driver allocates a "Dynamic Rx Buffer", makes a copy of the "Static Rx Buffer", and returns the "Static Rx Buffer" to hardware.
- The Wi-Fi driver delivers the packet to the upper-layer (LwIP), and allocates a PBUF for holding the "Dynamic Rx Buffer".
- The application receives data from LwIP.

The diagram shows the configuration of the Wi-Fi internal buffer.

Buffer Type	Alloc Type	Default	Configurable	Description
Static RX Buffer (Hardware RX Buffer)	Static	10 * 1600 Bytes	Yes	This is a kind of DMA memory. It is initialized in `esp_wifi_init()` and freed in `esp_wifi_deinit()`. The 'Static Rx Buffer' forms the hardware receiving list. Upon receiving a frame over the air, hardware writes the frame into the buffer and raises an interrupt to the CPU. Then, the Wi-Fi driver reads the content from the buffer and returns the buffer back to the list. If needs be, the application can reduce the memory statically allocated by Wi-Fi. It can reduce this value from 10 to 6 to save 6400 Bytes of memory. It is not recommended to reduce the configuration to a value less than 6 unless the AMPDU feature is disabled.
Dynamic RX Buffer	Dynamic	32	Yes	The buffer length is variable and it depends on the received frames' length. When the Wi-Fi driver receives a frame from the 'Hardware Rx Buffer', the 'Dynamic Rx Buffer' needs to be allocated from the heap. The number of the Dynamic Rx Buffer, configured in the menuconfig, is used to limit the total un-freed Dynamic Rx Buffer number.
Dynamic TX Buffer	Dynamic	32	Yes	This is a kind of DMA memory. It is allocated to the heap. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a 'Dynamic TX Buffer' and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffers are mutually exclusive.
Static TX Buffer	Static	16 * 1600Bytes	Yes	This is a kind of DMA memory. It is initialized in `esp_wifi_init()` and freed in `esp_wifi_deinit()`. When the upper-layer (LwIP) sends packets to the Wi-Fi driver, it firstly allocates a 'Static TX Buffer' and makes a copy of the upper-layer buffer. The Dynamic and Static TX Buffer are mutually exclusive. The TX buffer must be a DMA buffer. For this reason, if PSRAM is enabled, the TX buffer must be static.
Management Short Buffer	Dynamic	8	NO	Wi-Fi driver's internal buffer.
Management Long Buffer	Dynamic	32	NO	Wi-Fi driver's internal buffer.
Management Long Long Buffer	Dynamic	32	NO	Wi-Fi driver's internal buffer.

Wi-Fi NVS Flash

If the Wi-Fi NVS flash is enabled, all Wi-Fi configurations set via the Wi-Fi APIs will be stored into flash, and the Wi-Fi driver will start up with these configurations the next time it powers on/reboots. However, the application can choose to disable the Wi-Fi NVS flash if it does not need to store the configurations into persistent memory, or has its own persistent storage, or simply due to debugging reasons, etc.

Wi-Fi Aggregate MAC Protocol Data Unit (AMPDU)

ESP32-S3 supports both receiving and transmitting AMPDU, and the AMPDU can greatly improve the Wi-Fi throughput.

Generally, the AMPDU should be enabled. Disabling AMPDU is usually for debugging purposes.

4.34.35 Troubleshooting

Please refer to a separate document with *Espressif Wireshark User Guide*.

Espressif Wireshark User Guide

1. Overview

1.1 What Is Wireshark? Wireshark (originally named "Ethereal") is a network packet analyzer that captures network packets and displays the packet data as detailed as possible. It uses WinPcap as its interface to directly capture network traffic going through a network interface controller (NIC).

You could think of a network packet analyzer as a measuring device used to examine what is going on inside a network cable, just like a voltmeter is used by an electrician to examine what is going on inside an electric cable.

In the past, such tools were either very expensive, proprietary, or both. However, with the advent of Wireshark, all that has changed.

Wireshark is released under the terms of the GNU General Public License, which means you can use the software and the source code free of charge. It also allows you to modify and customize the source code.

Wireshark is, perhaps, one of the best open source packet analyzers available today.

1.2 Some Intended Purposes Here are some examples of how Wireshark is typically used:

- Network administrators use it to troubleshoot network problems.
- Network security engineers use it to examine security problems.
- Developers use it to debug protocol implementations.
- People use it to learn more about network protocol internals.

Beside these examples, Wireshark can be used for many other purposes.

1.3 Features The main features of Wireshark are as follows:

- Available for UNIX and Windows
- Captures live packet data from a network interface
- Displays packets along with detailed protocol information
- Opens/saves the captured packet data
- Imports/exports packets into a number of file formats, supported by other capture programs
- Advanced packet filtering
- Searches for packets based on multiple criteria

- Colorizes packets according to display filters
- Calculates statistics
- ... and a lot more!

1.4 Wireshark Can or Cannot Do

- **Live capture from different network media**.
  Wireshark can capture traffic from different network media, including wireless LAN.
- **Import files from many other capture programs**.
  Wireshark can import data from a large number of file formats, supported by other capture programs.
- **Export files for many other capture programs**.
  Wireshark can export data into a large number of file formats, supported by other capture programs.
- **Numerous protocol dissectors**.
  Wireshark can dissect, or decode, a large number of protocols.
- **Wireshark is not an intrusion detection system**.
  It will not warn you if there are any suspicious activities on your network. However, if strange things happen, Wireshark might help you figure out what is really going on.
- **Wireshark does not manipulate processes on the network, it can only perform "measurements" within it**.
  Wireshark does not send packets on the network or influence it in any other way, except for resolving names (converting numerical address values into a human readable format), but even that can be disabled.

1. Where to Get Wireshark You can get Wireshark from the official website: https://www.wireshark.org/download.html

Wireshark can run on various operating systems. Please download the correct version according to the operating system you are using.

3. Step-by-step Guide **This demonstration uses Wireshark 2.2.6 on Linux.**

a) Start Wireshark

On Linux, you can run the shell script provided below. It starts Wireshark, then configures NIC and the channel for packet capture.

```
ifconfig $1 down
iwconfig $1 mode monitor
iwconfig $1 channel $2
ifconfig $1 up
Wireshark&
```

In the above script, the parameter `$1` represents NIC and `$2` represents channel. For example, `wlan0` in `./xxx.sh wlan0 6`, specifies the NIC for packet capture, and `6` identifies the channel of an AP or Soft-AP.

b) Run the Shell Script to Open Wireshark and Display Capture Interface

c) Select the Interface to Start Packet Capture

As the red markup shows in the picture above, many interfaces are available. The first one is a local NIC and the second one is a wireless NIC.

Please select the NIC according to your requirements. This document will use the wireless NIC to demonstrate packet capture.

Double click *wlan0* to start packet capture.

d) Set up Filters

Since all packets in the channel will be captured, and many of them are not needed, you have to set up filters to get the packets that you need.

Please find the picture below with the red markup, indicating where the filters should be set up.

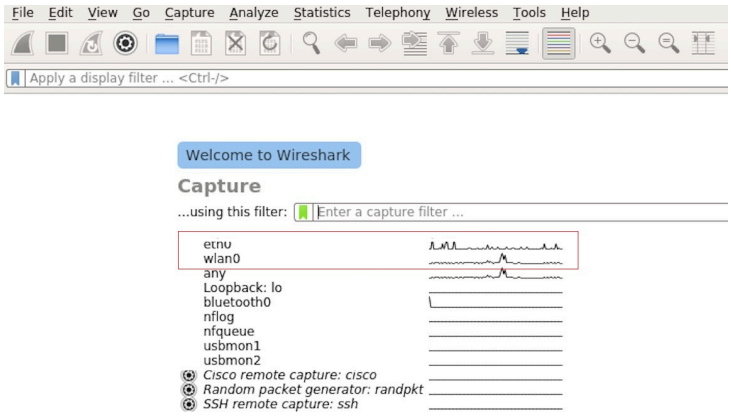

Fig. 90: Wireshark Capture Interface

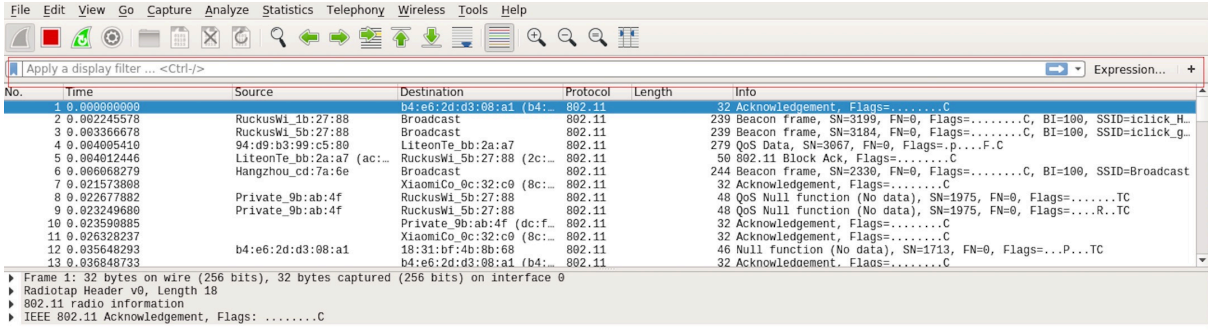

Fig. 91: Setting up Filters in Wireshark

Click *Filter*, the top left blue button in the picture below. The *display filter* dialogue box will appear.

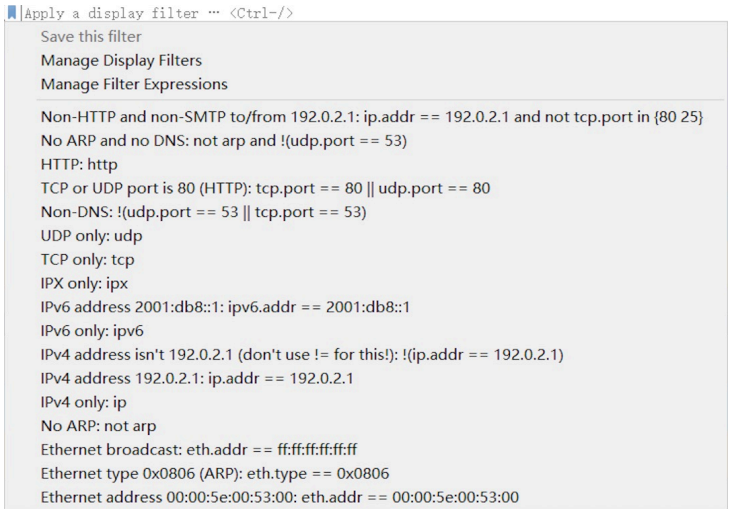

Fig. 92: *Display Filter* Dialogue Box

Click the *Expression* button to bring up the *Filter Expression* dialogue box and set the filter according to your requirements.

The quickest way: enter the filters directly in the toolbar.

Click on this area to enter or modify the filters. If you enter a wrong or unfinished filter, the built-in syntax check turns the background red. As soon as the correct expression is entered, the background becomes green.

The previously entered filters are automatically saved. You can access them anytime by opening the drop down list.

For example, as shown in the picture below, enter two MAC addresses as the filters and click *Apply* (the blue arrow). In this case, only the packet data transmitted between these two MAC addresses will be captured.

e) Packet List

You can click any packet in the packet list and check the detailed information about it in the box below the list. For example, if you click the first packet, its details will appear in that box.

f) Stop/Start Packet Capture

As shown in the picture below, click the red button to stop capturing the current packet.

Click the top left blue button to start or resume packet capture.

g) Save the Current Packet

On Linux, go to *File -> Export Packet Dissections -> As Plain Text File* to save the packet.

Please note that *All packets*, *Displayed* and *All expanded* must be selected.

By default, Wireshark saves the captured packet in a libpcap file. You can also save the file in other formats, e.g., txt, to analyze it in other tools.

4.35 Wi-Fi Security

4.35.1 ESP32-S3 Wi-Fi Security Features

- Support for Protected Management Frames (PMF)
- Support for WPA3-Personal

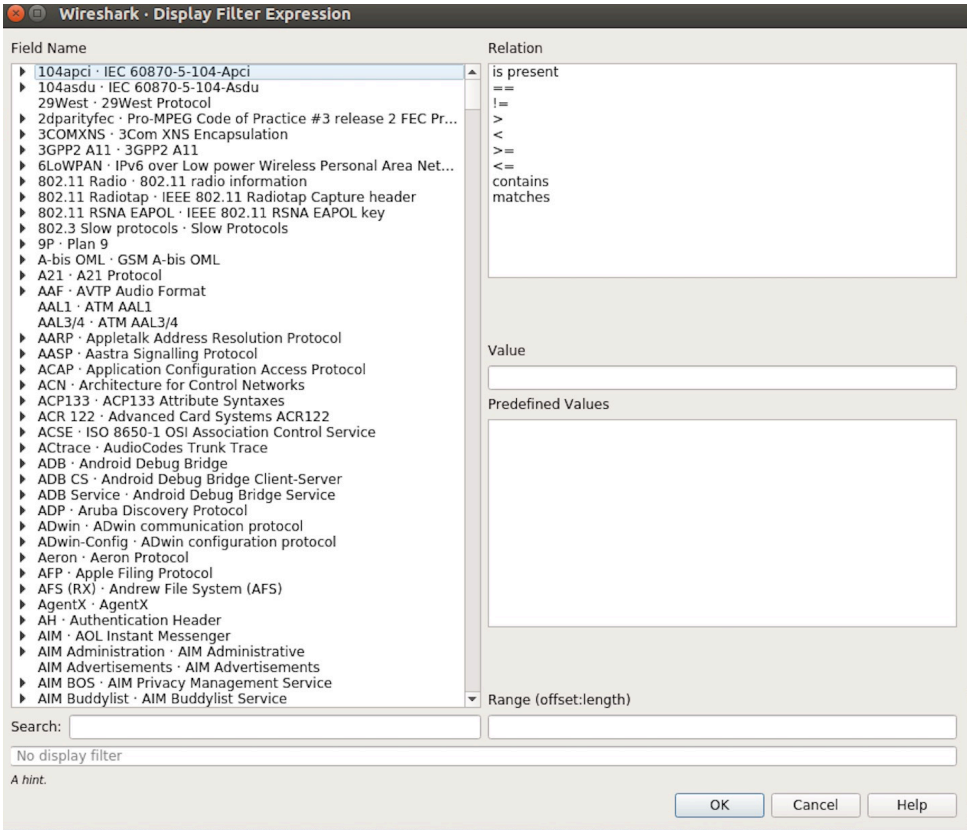

Fig. 93: *Filter Expression* Dialogue Box

Fig. 94: Filter Toolbar

Fig. 95: Example of MAC Addresses applied in the Filter Toolbar

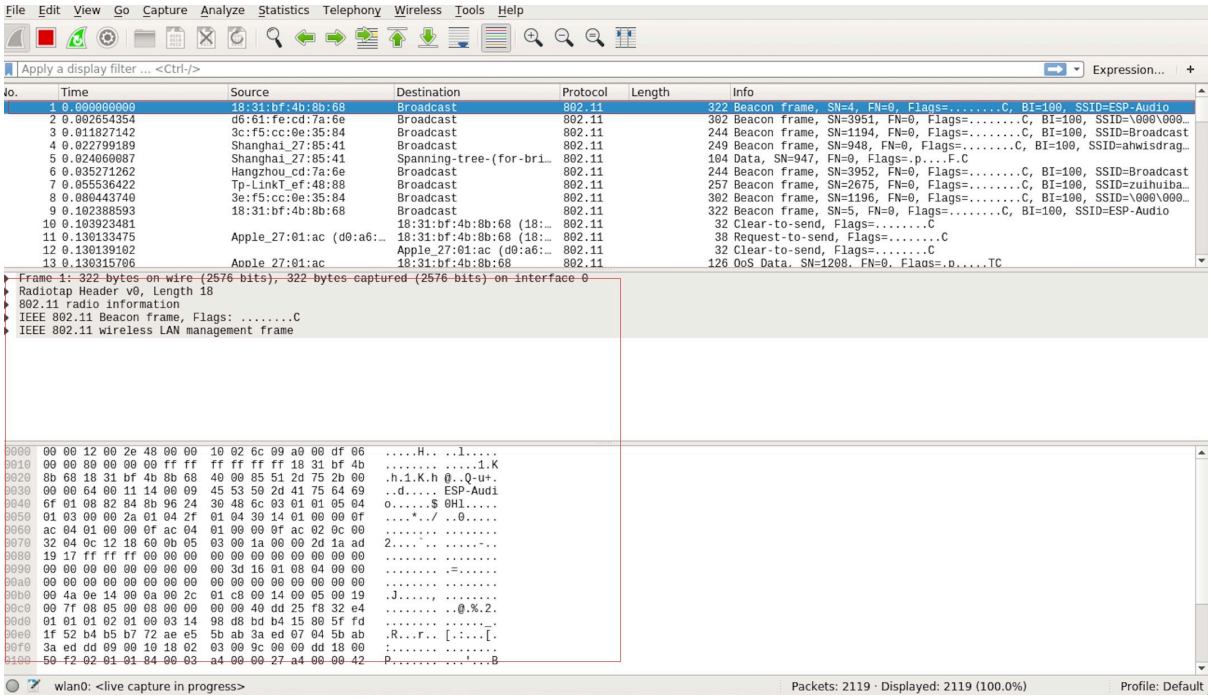

Fig. 96: Example of Packet List Details

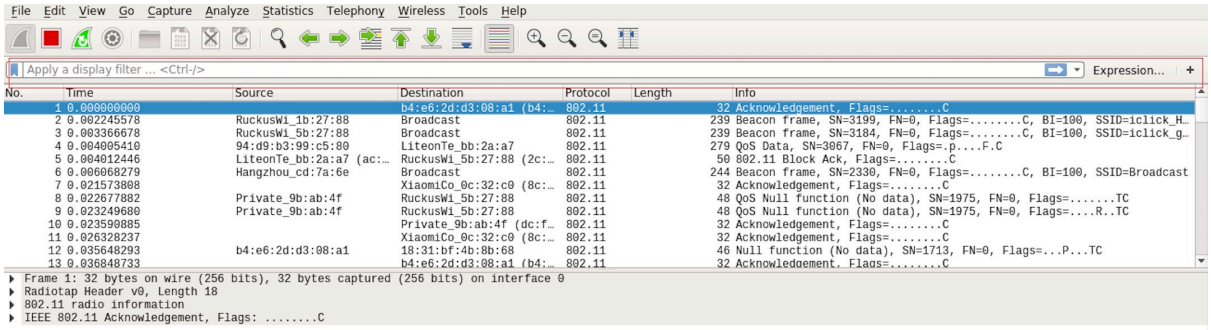

Fig. 97: Stopping Packet Capture

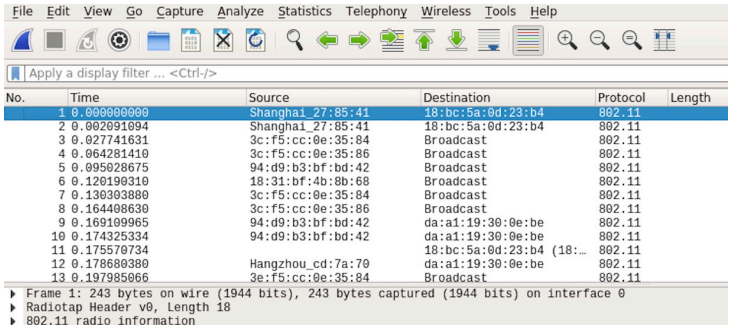

Fig. 98: Starting or Resuming the Packets Capture

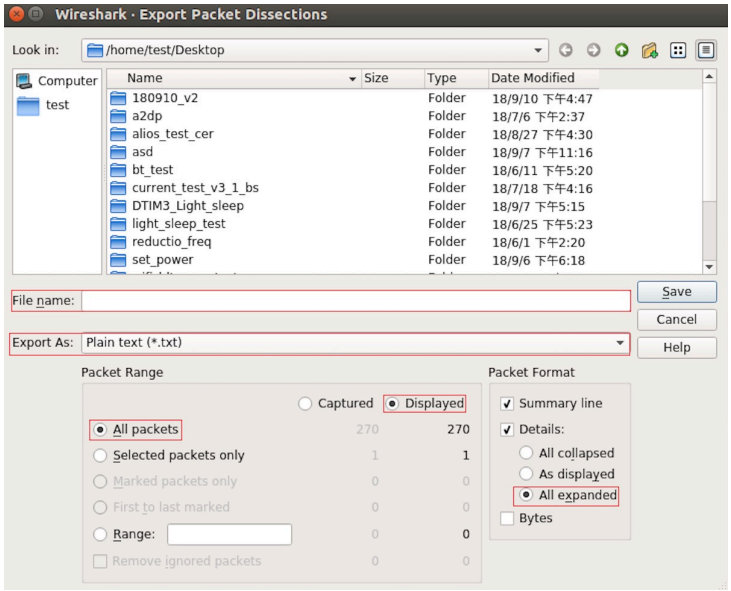

Fig. 99: Saving Captured Packets

- Support for Opportunistic Wireless Encryption (OWE)

In addition to traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), ESP32-S3 Wi-Fi supports state-of-the-art security protocols, namely Protected Management Frames (PMF), Wi-Fi Protected Access 3 and Enhanced Open™ based on Opportunistic Wireless Encryption. WPA3 provides better privacy and robustness against known attacks on traditional modes. Enhanced Open™ enhances the security and privacy of users connecting to open (public) Wireless Networks without authentication.

4.35.2 Protected Management Frames (PMF)

Introduction

In Wi-Fi, management frames such as beacons, probes, authentication/deauthentication, and association/disassociation are used by non-AP stations to scan and connect to an AP. Unlike data frames, these frames are sent unencrypted.

An attacker can use eavesdropping and packet injection to send spoofed authentication/deauthentication or association/disassociation frames at the right time, leading to attacks such as Denial-of-Service (DOS) and man-in-the-middle.

PMF provides protection against these attacks by encrypting unicast management frames and providing integrity checks for broadcast management frames. These include deauthentication, disassociation, and robust management frames. It also provides a Secure Association (SA) teardown mechanism to prevent spoofed association/authentication frames from disconnecting already connected clients.

There are three types of PMF configuration modes on both the station and AP sides:

- PMF Optional
- PMF Required
- PMF Disabled

API & Usage

ESP32-S3 supports PMF in both the station and SoftAP mode. For both, the default mode is PMF Optional. For even higher security, PMF Required mode can be enabled by setting the `required` flag in `pmf_cfg` while using the *`esp_wifi_set_config()`* API. This results in the device only connecting to a PMF-enabled device and

rejecting others. PMF Optional can be disabled using *esp_wifi_disable_pmf_config()* API. If SoftAP is started in WPA3 or WPA2/WPA3 mixed mode, trying to disable PMF results in an error.

Attention: `capable` flag in `pmf_cfg` is deprecated and set to `true` internally. This is to take the additional security benefit of PMF whenever possible.

4.35.3 Wi-Fi Enterprise

Introduction

Enterprise security is the secure authentication mechanism for enterprise wireless networks. It uses the RADIUS server for authentication of network users before connecting to the Access Point (AP). The authentication process is based on 802.1X policy and comes with different Extended Authentication Protocol (EAP) methods such as TLS, TTLS, PEAP, and EAP-FAST. RADIUS server authenticates the users based on their credentials (username and password), digital certificates, or both.

Note: ESP32-S3 supports Wi-Fi Enterprise only in station mode.

ESP32-S3 supports **WPA2-Enterprise** and **WPA3-Enterprise**. WPA3-Enterprise builds upon the foundation of WPA2-Enterprise with the additional requirement of using Protected Management Frames (PMF) and server certificate validation on all WPA3 connections. **WPA3-Enterprise also offers an additional secure mode using 192-bit minimum-strength security protocols and cryptographic tools to better protect sensitive data.** The 192-bit security mode offered by WPA3-Enterprise ensures the right combination of cryptographic tools is used and sets a consistent baseline of security within a WPA3 network. WPA3-Enterprise 192-bit mode is only supported by modules having *SOC_WIFI_GCMP_SUPPORT* support. Enable *CONFIG_ESP_WIFI_SUITE_B_192* flag to support WPA3-Enterprise with 192-bit mode.

ESP32-S3 supports the following EAP methods:

- EAP-TLS: This is a certificate-based method and only requires SSID and EAP-IDF.
- PEAP: This is a Protected EAP method. Usernames and passwords are mandatory.
- **EAP-TTLS: This is a credential-based method. Only server authentication is mandatory while user authentication**
  - PAP: Password Authentication Protocol.
  - CHAP: Challenge Handshake Authentication Protocol.
  - MSCHAP and MSCHAP-V2.
- EAP-FAST: This is an authentication method based on Protected Access Credentials (PAC) which also uses identity and password. Currently, *CONFIG_ESP_WIFI_MBEDTLS_TLS_CLIENT* flag should be disabled to use this feature.

Example wifi/wifi_enterprise demonstrates all the supported Wi-Fi Enterprise methods except EAP-FAST. Please refer wifi/wifi_eap_fast for the EAP-FAST example. EAP method can be selected from the Example Configuration menu in `idf.py menuconfig`. Refer to examples/wifi/wifi_enterprise/README.md for information on how to generate certificates and run the example.

4.35.4 WPA3-Personal

Introduction

Wi-Fi Protected Access-3 (WPA3) is a set of enhancements to Wi-Fi access security intended to replace the current WPA2 standard. It includes new features and capabilities that offer significantly better protection against different types of attacks. It improves upon WPA2-Personal in the following ways:

- WPA3 uses Simultaneous Authentication of Equals (SAE), which is a password-authenticated key agreement method based on Diffie-Hellman key exchange. Unlike WPA2, the technology is resistant to offline-dictionary

attacks, where the attacker attempts to determine a shared password based on a captured 4-way handshake without any further network interaction.
- Disallows outdated protocols such as TKIP, which is susceptible to simple attacks like MIC key recovery attacks.
- Mandates Protected Management Frames (PMF), which provides protection for unicast and multicast robust management frames which include Disassoc and Deauth frames. This means that the attacker cannot disrupt an established WPA3 session by sending forged Assoc frames to the AP or Deauth/Disassoc frames to the station.
- Provides forward secrecy, which means the captured data cannot be decrypted even if the password is compromised after data transmission.

ESP32-S3 station also supports following additional Wi-Fi CERTIFIED WPA3™ features:

- **Transition Disable** : WPA3 defines transition modes for client devices so that they can connect to a network even when some of the APs in that network do not support the strongest security mode. Client device implementations typically configure network profiles in a transition mode by default. However, such a client device could be subject to an active downgrade attack in which the attacker causes the client device to use a lower security mode in order to exploit a vulnerability with that mode. WPA3 has introduced the Transition Disable feature to mitigate such attacks, by enabling client devices to change from a transition mode to an "only" mode when connecting to a network, once that network indicates it fully supports the higher security mode. Enable `transition_disable` in *`wifi_sta_config_t`* to enable this feature for ESP32-S3 station.
- **SAE PUBLIC-KEY (PK)** : As the password at small public networks is shared with multiple users, it may be relatively easy for an attacker to find out the password, which is sufficient to launch an evil twin attack. Such attacks are prevented by an extension to WPA3-Personal called SAE-PK. The SAE-PK authentication exchange is very similar to the regular SAE exchange, with the addition of a digital signature sent by the AP to the client device. The client device validates the public key asserted by the AP based on the password fingerprint and verifies the signature using the public key. So even if the attacker knows the password, it does not know the private key to generate a valid signature, and therefore the client device is protected against an evil twin attack. Enable *CONFIG_ESP_WIFI_ENABLE_SAE_PK* and `sae_pk_mode` in *`wifi_sta_config_t`* to add support of SAE PK for ESP32-S3 station.
- **SAE PWE Methods**: ESP32-S3 station as well as SoftAP supports SAE Password Element derivation method *Hunting And Pecking* and *Hash to Element (H2E)*. H2E is computationally efficient as it uses fewer iterations than Hunt and Peck, and also it mitigates side-channel attacks. These can be configured using the parameter `sae_pwe_h2e` from *`wifi_sta_config_t`* and *`wifi_ap_config_t`* for station and SoftAP respectively. Hunt and peck, H2E both can be enabled by using *`WPA3_SAE_PWE_BOTH`* configuration.

Please refer to the Security section of Wi-Fi Alliance's official website for further details.

Setting up WPA3 Personal with ESP32-S3

A configuration option *CONFIG_ESP_WIFI_ENABLE_WPA3_SAE* is provided to enable/disable WPA3 for the station. By default, it is kept enabled. If disabled, ESP32-S3 will not be able to establish a WPA3 connection. Also under the Wi-Fi component, a configuration option *CONFIG_ESP_WIFI_SOFTAP_SAE_SUPPORT* is provided to enable/disable WPA3 for SoftAP. Additionally, since PMF is mandated by WPA3 protocol, PMF Optional is set by default for station and SoftAP. PMF Required can be configured using Wi-Fi configuration. For WPA3 SoftAP, PMF Required is mandatory and will be configured and stored in NVS implicitly if not specified by the user.

Refer to *Protected Management Frames (PMF)* on how to set this mode.

After configuring all required settings for the WPA3-Personal station, application developers need not worry about the underlying security mode of the AP. WPA3-Personal is now the highest supported protocol in terms of security, so it is automatically selected for the connection whenever available. For example, if an AP is configured to be in WPA3 Transition Mode, where it advertises as both WPA2 and WPA3 capable, the station chooses WPA3 for the connection with the above settings.

After configuring all required setting for WPA3-Personal SoftAP, application developers have to set `WIFI_AUTH_WPA3_PSK` for *authmode* in *`wifi_ap_config_t`* to start AP in WPA3 security. SoftAP can be also configured to use `WIFI_AUTH_WPA2_WPA3_PSK` mixed mode.

Note that binary size will be increased by about 6.5 kilobytes after enabling *CONFIG_ESP_WIFI_SOFTAP_SAE_SUPPORT*.

4.35.5 Wi-Fi Enhanced Open™

Introduction

Enhanced Open™ is used for providing security and privacy to users connecting to open (public) wireless networks, particularly in scenarios where user authentication is not desired or distribution of credentials impractical. Each user is provided with unique individual encryption keys that protect data exchange between a user device and the Wi-Fi network. Protected Management Frames further protect management traffic between the access point and the user device. Enhanced Open™ is based on the Opportunistic Wireless Encryption (OWE) standard. OWE Transition Mode enables a seamless transition from Open unencrypted WLANs to OWE WLANs without adversely impacting the end-user experience.

Note: ESP32-S3 supports Wi-Fi Enhanced Open™ only in station mode.

Setting up OWE with ESP32-S3

A configuration option *CONFIG_ESP_WIFI_ENABLE_WPA3_OWE_STA* and configuration parameter `owe_enabled` in `wifi_sta_config_t` is provided to enable OWE support for the station. To use OWE transition mode, along with the configuration provided above, *authmode* from `wifi_scan_threshold_t` should be set to `WIFI_AUTH_OPEN`.

4.36 Low Power Mode User Guide

The document has not been translated into English yet. In the meantime, please refer to the Chinese version.

Chapter 5

Security Guides

5.1 Overview

5.1.1 Security

This guide provides an overview of the overall security features available in various Espressif solutions. It is highly recommended to consider this guide while designing the products with the Espressif platform and the ESP-IDF software stack from the **security** perspective.

Goals

High level security goals are as follows:

1. Preventing untrustworthy code from being executed
2. Protecting the identity and integrity of the code stored in the off-chip flash memory
3. Securing device identity
4. Secure storage for confidential data
5. Authenticated and encrypted communication from the device

Platform Security

Secure Boot The Secure Boot feature ensures that only authenticated software can execute on the device. The Secure Boot process forms a chain of trust by verifying all **mutable** software entities involved in the *Application Startup Flow*. Signature verification happens during both boot-up as well as in OTA updates.

Please refer to *Secure Boot V2* for detailed documentation about this feature.

Important: It is highly recommended that Secure Boot be enabled on all production devices.

Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Always keep the signing key private. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using `espsecure.py`. Both processes are vulnerable to timing or other side-channel attacks.

- Ensure that all security eFuses have been correctly programmed, including disabling of the debug interfaces, non-required boot mediums (e.g., UART DL mode), etc.

Flash Encryption The Flash Encryption feature helps to encrypt the contents on the off-chip flash memory and thus provides the **confidentiality** aspect to the software or data stored in the flash memory.

Please refer to *Flash Encryption* for detailed information about this feature.

If ESP32-S3 is connected to an external SPI RAM, the contents written to or read from the SPI RAM will also be encrypted and decrypted respectively (via the MMU's flash cache, provided that FLash Encryption is enabled). This provides an additional safety layer for the data stored in SPI RAM, hence configurations like `CONFIG_MBEDTLS_EXTERNAL_MEM_ALLOC` can be safely enabled in this case.

Flash Encryption Best Practices

- It is recommended to use flash Encryption release mode for the production use-cases.
- It is recommended to have a unique flash encryption key per device.
- Enable *Secure Boot* as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

Device Identity The Digital Signature peripheral in ESP32-S3 produces hardware-accelerated RSA digital signatures with the assistance of HMAC, without the RSA private key being accessible by software. This allows the private key to be kept secured on the device without anyone other than the device hardware being able to access it.

DS peripheral can help to establish the **Secure Device Identity** to the remote endpoint, e.g., in the case of TLS mutual authentication based on the RSA cipher scheme.

Please refer to the *Digital Signature (DS)* for detailed documentation.

Memory Protection ESP32-S3 supports the **Memory Protection** scheme, either through architecture or special peripheral like PMS, which provides an ability to enforce and monitor permission attributes to memory and, in some cases, peripherals. ESP-IDF application startup code configures the permissions attributes like Read/Write access on data memories and Read/Execute access on instruction memories using the relevant peripheral. If there is any attempt made that breaks these permission attributes, e.g., a write operation to instruction memory region, then a violation interrupt is raised, and it results in system panic.

This feature depends on the config option *CONFIG_ESP_SYSTEM_MEMPROT_FEATURE* and it is kept enabled by default. Please note that the API for this feature is **private** and used exclusively by ESP-IDF code only.

Note: This feature can help to prevent the possibility of remote code injection due to the existing vulnerabilities in the software.

Debug Interfaces

JTAG

- JTAG interface stays disabled if any of the security features are enabled. Please refer to *JTAG with Flash Encryption or Secure Boot* for more information.
- JTAG interface can also be disabled in the absence of any other security features using *eFuse API*.
- ESP32-S3 supports soft disabling the JTAG interface and it can be re-enabled by programming a secret key through HMAC. (*HMAC for Enabling JTAG*)

UART Download Mode In ESP32-S3, Secure UART Download mode gets activated if any of the security features are enabled.

- Secure UART Download mode can also be enabled by calling `esp_efuse_enable_rom_secure_download_mode()`.
- This mode does not allow any arbitrary code to execute if downloaded through the UART download mode.
- It also limits the available commands in Download mode to update SPI config, e.g., changing baud rate, basic flash write, and the command to return a summary of currently enabled security features (`get_security_info`).
- To disable Download Mode entirely, select the *CONFIG_SECURE_UART_ROM_DL_MODE* to the recommended option `Permanently disable ROM Download Mode` or call `esp_efuse_disable_rom_download_mode()` at runtime.

Important: In Secure UART Download mode, `esptool.py` can only work with the argument `--no-stub`.

Network Security

Wi-Fi In addition to the traditional security methods (WEP/WPA-TKIP/WPA2-CCMP), Wi-Fi driver in ESP-IDF also supports additional state-of-the-art security protocols. Please refer to the *Wi-Fi Security* for detailed documentation.

TLS (Transport Layer Security) It is recommended to use TLS (Transport Layer Security) in all external communications (e.g., cloud communication, OTA updates) from the ESP device. ESP-IDF supports *Mbed TLS* as the official TLS stack.

TLS is default integrated in *ESP HTTP Client*, *HTTPS Server* and several other components that ship with ESP-IDF.

Note: It is recommended to use the ESP-IDF protocol components in their default configuration, which has been ensured to be secure. Disabling of HTTPS and similar security-critical configurations should be avoided.

ESP-TLS Abstraction ESP-IDF provides an abstraction layer for the most-used TLS functionalities. Hence, it is recommended that an application uses the API exposed by *ESP-TLS*.

TLS Server Verification section highlights diverse ways in which the identity of server could be established on the device side.

ESP Certificate Bundle The *ESP x509 Certificate Bundle* API provides an easy way to include a bundle of custom x509 root certificates for TLS server verification. The certificate bundle is the easiest way to verify the identity of almost all standard TLS servers.

Important: It is highly recommended to verify the identity of the server based on X.509 certificates to avoid establishing communication with the **fake** server.

Product Security

Secure Provisioning Secure Provisioning refers to a process of secure on-boarding of the ESP device on to the Wi-Fi network. This mechanism also allows provision of additional custom configuration data during the initial provisioning phase from the provisioning entity, e.g., Smartphone.

ESP-IDF provides various security schemes to establish a secure session between ESP and the provisioning entity, they are highlighted at *Security Schemes*.

Please refer to the *Wi-Fi Provisioning* documentation for details and the example code for this feature.

Note: Espressif provides Android and iOS Phone Apps along with their sources, so that it could be easy to further customize them as per the product requirement.

Secure OTA (Over-the-air) Updates

- OTA Updates must happen over secure transport, e.g., HTTPS.
- ESP-IDF provides a simplified abstraction layer *ESP HTTPS OTA* for this.
- If *Secure Boot* is enabled, then the server should host the signed application image.
- If *Flash Encryption* is enabled, then no additional steps are required on the server side, encryption shall be taken care on the device itself during flash write.
- OTA update *Rollback Process* can help to switch the application as `active` only after its functionality has been verified.

Anti-Rollback Protection Anti-rollback protection feature ensures that device only executes the application that meets the security version criteria as stored in its eFuse. So even though the application is trusted and signed by legitimate key, it may contain some revoked security feature or credential. Hence, device must reject any such application.

ESP-IDF allows this feature for the application only and it is managed through 2nd stage bootloader. The security version is stored in the device eFuse and it is compared against the application image header during both bootup and over-the-air updates.

Please see more information to enable this feature in the *Anti-rollback* guide.

Encrypted Firmware Distribution Encrypted firmware distribution during over-the-air updates ensures that the application stays encrypted **in transit** from the server to the the device. This can act as an additional layer of protection on top of the TLS communication during OTA updates and protect the identity of the application.

Please see working example for this documented in *OTA Upgrades with Pre-Encrypted Firmware* section.

Secure Storage Secure storage refers to the application-specific data that can be stored in a secure manner on the device, i.e., off-chip flash memory. This is typically a read-write flash partition and holds device specific configuration data, e.g., Wi-Fi credentials.

ESP-IDF provides the **NVS (Non-volatile Storage)** management component which allows encrypted data partitions. This feature is tied with the platform *Flash Encryption* feature described earlier.

Please refer to the *NVS Encryption* for detailed documentation on the working and instructions to enable this feature.

Important: By default, ESP-IDF components writes the device specific data into the default NVS partition, including Wi-Fi credentials too, and it is recommended to protect this data using **NVS Encryption** feature.

Secure Device Control ESP-IDF provides capability to control an ESP device over `Wi-Fi + HTTP` or `BLE` in a secure manner using ESP Local Control component.

Please refer to the *ESP Local Control* for detailed documentation about this feature.

Security Policy

The ESP-IDF GitHub repository has attached Security Policy Brief.

Advisories

- Espressif publishes critical Security Advisories, which includes security advisories regarding both hardware and software.
- The specific advisories of the ESP-IDF software components are published through the GitHub repository.

Software Updates Critical security issues in the ESP-IDF components, and third-party libraries are fixed as and when we find them or when they are reported to us. Gradually, we make the fixes available in all applicable release branches in ESP-IDF.

Applicable security issues and CVEs for the ESP-IDF components, third-party libraries are mentioned in the ESP-IDF release notes.

Important: We recommend periodically updating to the latest bugfix version of the ESP-IDF release to have all critical security fixes available.

5.2 Features

5.2.1 Flash Encryption

This is a quick start guide to ESP32-S3's flash encryption feature. Using application code as an example, it demonstrates how to test and verify flash encryption operations during development and production.

Introduction

Flash encryption is intended for encrypting the contents of the ESP32-S3's off-chip flash memory. Once this feature is enabled, firmware is flashed as plaintext, and then the data is encrypted in place on the first boot. As a result, physical readout of flash will not be sufficient to recover most flash contents.

Important: For production use, flash encryption should be enabled in the "Release" mode only.

Important: Enabling flash encryption limits the options for further updates of ESP32-S3. Before using this feature, read the document and make sure to understand the implications.

Encrypted Partitions

With flash encryption enabled, the following types of data are encrypted by default:

- *Second Stage Bootloader* (Firmware Bootloader)
- Partition Table
- *NVS Key Partition*
- Otadata
- All `app` type partitions

Other types of data can be encrypted conditionally:

- Any partition marked with the `encrypted` flag in the partition table. For details, see *Encrypted Partition Flag*.
- Secure Boot bootloader digest if Secure Boot is enabled (see below).

Relevant eFuses

The flash encryption operation is controlled by various eFuses available on ESP32-S3. The list of eFuses and their descriptions is given in the table below. The names in eFuse column are also used by espefuse.py tool. For usage in the eFuse API, modify the name by adding `ESP_EFUSE_`, for example: esp_efuse_read_field_bit(ESP_EFUSE_DISABLE_DL_ENCRYPT).

Table 1: eFuses Used in Flash Encryption

eFuse	Description	Bit Depth
`BLOCK_KEYN`	AES key storage. N is between 0 and 5.	One 256 bit key block for XTS_AES_128, Two 256 bit key blocks for XTS_AES_256 (512 bit total)
`KEY_PURPOSE_N`	Controls the purpose of eFuse block `BLOCK_KEYN`, where N is between 0 and 5. Possible values: `2` for `XTS_AES_256_KEY_1`, `3` for `XTS_AES_256_KEY_2`, and `4` for `XTS_AES_128_KEY`. Final AES key is derived based on the value of one or two of these purpose eFuses. For a detailed description of the possible combinations, see *ESP32-S3 Technical Reference Manual* > *External Memory Encryption and Decryption (XTS_AES)* [PDF].	4
`DIS_DOWNLOAD_MANUAL_ENCRYPT`	If set, disables flash encryption when in download boot modes.	1
`SPI_BOOT_CRYPT_CNT`	Enables encryption and decryption, when an SPI boot mode is set. Feature is enabled if 1 or 3 bits are set in the eFuse, disabled otherwise.	3

Note:

- R/W access control is available for all the eFuse bits listed in the table above.
- The default value of these bits is 0 afer manufacturing.

Read and write access to eFuse bits is controlled by appropriate fields in the registers `WR_DIS` and `RD_DIS`. For more information on ESP32-S3 eFuses, see *eFuse manager*. To change protection bits of eFuse field using espefuse.py, use these two commands: read_protect_efuse and write_protect_efuse. Example `espefuse.py write_protect_efuse DISABLE_DL_ENCRYPT`.

Flash Encryption Process

Assuming that the eFuse values are in their default states and the firmware bootloader is compiled to support flash encryption, the flash encryption process executes as shown below:

1. On the first power-on reset, all data in flash is un-encrypted (plaintext). The ROM bootloader loads the firmware bootloader.
2. Firmware bootloader reads the `SPI_BOOT_CRYPT_CNT` eFuse value (`0b000`). Since the value is `0` (even number of bits set), it configures and enables the flash encryption block. For more information on the flash encryption block, see *ESP32-S3 Technical Reference Manual* > *eFuse Controller (eFuse)* > *Auto Encryption Block* [PDF].

3. Firmware bootloader first checks if a valid key is already present in the eFuse (e.g., burned using espefuse tool) then the process of key generation is skipped and the same key is used for flash encryption process. Otherwise, Firmware bootloader uses RNG (random) module to generate an 256 bit or 512 bit key, depending on the value of *Size of generated XTS-AES key*, and then writes it into respectively one or two *BLOCK_KEYN* eFuses. The software also updates the `KEY_PURPOSE_N` for the blocks where the keys were stored. The key cannot be accessed via software as the write and read protection bits for one or two *BLOCK_KEYN* eFuses are set. `KEY_PURPOSE_N` field is write-protected as well. The flash encryption operations happen entirely by hardware, and the key cannot be accessed via software.
4. Flash encryption block encrypts the flash contents - the firmware bootloader, applications and partitions marked as `encrypted`. Encrypting in-place can take time, up to a minute for large partitions.
5. Firmware bootloader sets the first available bit in `SPI_BOOT_CRYPT_CNT` (0b001) to mark the flash contents as encrypted. Odd number of bits is set.
6. For *Development Mode*, the firmware bootloader allows the UART bootloader to re-flash encrypted binaries. Also, the `SPI_BOOT_CRYPT_CNT` eFuse bits are NOT write-protected. In addition, the firmware bootloader by default sets the following eFuse bits:

    - `DIS_DOWNLOAD_ICACHE`
    - `DIS_DOWNLOAD_DCACHE`
    - `HARD_DIS_JTAG`
    - `DIS_LEGACY_SPI_BOOT`

7. For *Release Mode*, the firmware bootloader sets all the eFuse bits set under development mode as well as `DIS_DOWNLOAD_MANUAL_ENCRYPT`. It also write-protects the `SPI_BOOT_CRYPT_CNT` eFuse bits. To modify this behavior, see *Enabling UART Bootloader Encryption/Decryption*.
8. The device is then rebooted to start executing the encrypted image. The firmware bootloader calls the flash decryption block to decrypt the flash contents and then loads the decrypted contents into IRAM.

During the development stage, there is a frequent need to program different plaintext flash images and test the flash encryption process. This requires that Firmware Download mode is able to load new plaintext images as many times as it might be needed. However, during manufacturing or production stages, Firmware Download mode should not be allowed to access flash contents for security reasons.

Hence, two different flash encryption configurations were created: for development and for production. For details on these configurations, see Section *Flash Encryption Configuration*.

Flash Encryption Configuration

The following flash encryption modes are available:

- *Development Mode* - recommended for use only during development. In this mode, it is still possible to flash new plaintext firmware to the device, and the bootloader will transparently encrypt this firmware using the key stored in hardware. This allows, indirectly, to read out the plaintext of the firmware in flash.
- *Release Mode* - recommended for manufacturing and production. In this mode, flashing plaintext firmware to the device without knowing the encryption key is no longer possible.

This section provides information on the mentioned flash encryption modes and step by step instructions on how to use them.

Development Mode During development, you can encrypt flash using either an ESP32-S3 generated key or external host-generated key.

Using ESP32-S3 Generated Key Development mode allows you to download multiple plaintext images using Firmware Download mode.

To test flash encryption process, take the following steps:

1. Ensure that you have an ESP32-S3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

See how to check *ESP32-S3 Flash Encryption Status*.

2. In *Project Configuration Menu*, do the following:

   - *Enable flash encryption on boot*.
   - *Select encryption mode* (**Development mode** by default).
   - *Select UART ROM download mode* (**enabled** by default).
   - Set *Size of generated XTS-AES key*.
   - *Select the appropriate bootloader log verbosity*.
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-S3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

A sample output of the first ESP32-S3 boot after enabling flash encryption is given below:

```

Example to check Flash Encryption status
This is esp32s3 chip with 2 CPU core(s), WiFi/BLE, silicon revision 0, 2MB␣
↪external flash
FLASH_CRYPT_CNT eFuse value is 1
Flash encryption feature is enabled in DEVELOPMENT mode
```

At this stage, if you need to update and re-flash binaries, see *Re-flashing Updated Partitions*.

Using Host Generated Key It is possible to pre-generate a flash encryption key on the host computer and burn it into the eFuse. This allows you to pre-encrypt data on the host and flash already encrypted data without needing a plaintext flash update. This feature can be used in both *Development Mode* and *Release Mode*. Without a pre-generated key, data is flashed in plaintext and then ESP32-S3 encrypts the data in-place.

Note: This option is not recommended for production, unless a separate key is generated for each individual device.

To use a host generated key, take the following steps:

1. Ensure that you have an ESP32-S3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-S3 Flash Encryption Status*.

2. Generate a random key by running:

   If *Size of generated XTS-AES key* is AES-128 (256-bit key):

   ```
   espsecure.py generate_flash_encryption_key my_flash_encryption_key.bin
   ```

   else if *Size of generated XTS-AES key* is AES-256 (512-bit key):

   ```
   espsecure.py generate_flash_encryption_key --keylen 512 my_flash_
   ↪encryption_key.bin
   ```

3. **Before the first encrypted boot**, burn the key into your device's eFuse using the command below. This action can be done **only once**.

   ```
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin␣
   ↪KEYPURPOSE
   ```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`. And `KEYPURPOSE` is either `AES_256_KEY_1`, `XTS_AES_256_KEY_2`, `XTS_AES_128_KEY`. See ESP32-S3 Technical Reference Manual for a description of the key purposes.

   For AES-128 (256-bit key) - `XTS_AES_128_KEY`:

   ```
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin XTS_
   ↪AES_128_KEY
   ```

   For AES-256 (512-bit key) - `XTS_AES_256_KEY_1` and `XTS_AES_256_KEY_2`. `espefuse.py` supports burning both these two key purposes together with a 512 bit key to two separate key blocks via the virtual key purpose `XTS_AES_256_KEY`. When this is used `espefuse.py` will burn the first 256 bit of the key to the specified `BLOCK` and burn the corresponding block key purpose to `XTS_AES_256_KEY_1`. The last 256 bit of the key will be burned to the first free key block after `BLOCK` and the corresponding block key purpose to `XTS_AES_256_KEY_2`

   ```
   espefuse.py  --port PORT  burn_key BLOCK my_flash_encryption_key.bin XTS_
   ↪AES_256_KEY
   ```

   If you wish to specify exactly which two blocks are used then it is possible to divide key into two 256 bit keys, and manually burn each half with `XTS_AES_256_KEY_1` and `XTS_AES_256_KEY_2` as key purposes:

   ```
   split -b 32 my_flash_encryption_key.bin my_flash_encryption_key.bin.
   espefuse.py  --port PORT  burn_key BLOCK my_flash_encryption_key.bin.aa␣
   ↪XTS_AES_256_KEY_1
   espefuse.py  --port PORT  burn_key BLOCK+1 my_flash_encryption_key.bin.ab␣
   ↪XTS_AES_256_KEY_2
   ```

   If the key is not burned and the device is started after enabling flash encryption, the ESP32-S3 will generate a random key that software cannot access or modify.

4. In *Project Configuration Menu*, do the following:
   - *Enable flash encryption on boot*
   - *Select encryption mode* (**Development mode** by default)
   - *Select the appropriate bootloader log verbosity*
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

5. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-S3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

If using Development Mode, then the easiest way to update and re-flash binaries is *Re-flashing Updated Partitions*.

If using Release Mode, then it is possible to pre-encrypt the binaries on the host and then flash them as ciphertext. See *Manually Encrypting Files*.

Re-flashing Updated Partitions If you update your application code (done in plaintext) and want to re-flash it, you will need to encrypt it before flashing. To encrypt the application and flash it in one step, run:

```
idf.py encrypted-app-flash monitor
```

If all partitions needs to be updated in encrypted format, run:

```
idf.py encrypted-flash monitor
```

Release Mode In Release mode, UART bootloader cannot perform flash encryption operations. New plaintext images can ONLY be downloaded using the over-the-air (OTA) scheme which will encrypt the plaintext image before writing to flash.

To use this mode, take the following steps:

1. Ensure that you have an ESP32-S3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-S3 Flash Encryption Status*.

2. In *Project Configuration Menu*, do the following:

   - *Enable flash encryption on boot*.
   - *Select Release mode*. (Note that once Release mode is selected, the `EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT` eFuse bit will be burned to disable flash encryption hardware in ROM Download Mode.)
   - *Select UART ROM download mode (Permanently switch to Secure mode (recommended))*. This is the default option, and is recommended. It is also possible to change this configuration setting to permanently disable UART ROM download mode, if this mode is not needed.
   - *Select the appropriate bootloader log verbosity*.
   - Save the configuration and exit.

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

3. Run the command given below to build and flash the complete images.

```
idf.py flash monitor
```

Note: This command does not include any user files which should be written to the partitions on the flash memory. Please write them manually before running this command otherwise the files should be encrypted separately before writing.

This command will write to flash memory unencrypted images: the firmware bootloader, the partition table and applications. Once the flashing is complete, ESP32-S3 will reset. On the next boot, the firmware bootloader encrypts: the firmware bootloader, application partitions and partitions marked as `encrypted` then resets. Encrypting in-place can take time, up to a minute for large partitions. After that, the application is decrypted at runtime and executed.

Once the flash encryption is enabled in Release mode, the bootloader will write-protect the `SPI_BOOT_CRYPT_CNT` eFuse.

For subsequent plaintext field updates, use *OTA scheme*.

Note: If you have pre-generated the flash encryption key and stored a copy, and the UART download mode is not permanently disabled via *CONFIG_SECURE_UART_ROM_DL_MODE* , then it is possible to update the flash locally by pre-encrypting the files and then flashing the ciphertext. See *Manually Encrypting Files*.

Best Practices When using Flash Encryption in production:

- Do not reuse the same flash encryption key between multiple devices. This means that an attacker who copies encrypted data from one device cannot transfer it to a second device.
- The UART ROM Download Mode should be disabled entirely if it is not needed, or permanently set to "Secure Download Mode" otherwise. Secure Download Mode permanently limits the available commands to updating SPI config, changing baud rate, basic flash write, and returning a summary of the currently enabled security features with the *get_security_info* command. The default behaviour is to set Secure Download Mode on first boot in Release mode. To disable Download Mode entirely, select *CONFIG_SECURE_UART_ROM_DL_MODE* to "Permanently disable ROM Download Mode (recommended)" or call `esp_efuse_disable_rom_download_mode()` at runtime.
- Enable *Secure Boot* as an extra layer of protection, and to prevent an attacker from selectively corrupting any part of the flash before boot.

Enable Flash Encryption Externally

In the process mentioned above, flash encryption related eFuses which ultimately enable flash encryption are programmed through the firmware bootloader. Alternatively, all the eFuses can be programmed with the help of `espefuse` tool. Please refer *Enable Flash Encryption Externally* for more details.

Possible Failures

Once flash encryption is enabled, the `SPI_BOOT_CRYPT_CNT` eFuse value will have an odd number of bits set. It means that all the partitions marked with the encryption flag are expected to contain encrypted ciphertext. Below are the three typical failure cases if the ESP32-S3 is erroneously loaded with plaintext data:

1. If the bootloader partition is re-flashed with a **plaintext firmware bootloader image**, the ROM bootloader will fail to load the firmware bootloader resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
```

(continues on next page)

(continued from previous page)

```
invalid header: 0xb414f76b
invalid header: 0xb414f76b
invalid header: 0xb414f76b
```

Note: The value of invalid header will be different for every application.

Note: This error also appears if the flash contents are erased or corrupted.

2. If the firmware bootloader is encrypted, but the partition table is re-flashed with a **plaintext partition table image**, the bootloader will fail to read the partition table resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00

E (80) flash_parts: partition 0 invalid magic number 0x94f6
E (86) boot: Failed to verify partition table
E (91) boot: load partition table error!
```

3. If the bootloader and partition table are encrypted, but the application is re-flashed with a **plaintext application image**, the bootloader will fail to load the application resulting in the following failure:

```
rst:0x3 (SW_RESET),boot:0x13 (SPI_FAST_FLASH_BOOT)
configsip: 0, SPIWP:0xee
clk_drv:0x00,q_drv:0x00,d_drv:0x00,cs0_drv:0x00,hd_drv:0x00,wp_drv:0x00

E (138) boot: No bootable app partitions in the partition table
```

ESP32-S3 Flash Encryption Status

1. Ensure that you have an ESP32-S3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

To check if flash encryption on your ESP32-S3 device is enabled, do one of the following:

- flash the application example security/flash_encryption onto your device. This application prints the `SPI_BOOT_CRYPT_CNT` eFuse value and if flash encryption is enabled or disabled.
- *Find the serial port name* under which your ESP32-S3 device is connected, replace `PORT` with your port name in the following command, and run it:

```
espefuse.py -p PORT summary
```

Reading and Writing Data in Encrypted Flash

ESP32-S3 application code can check if flash encryption is currently enabled by calling *`esp_flash_encryption_enabled()`*. Also, a device can identify the flash encryption mode by calling *`esp_get_flash_encryption_mode()`*.

Once flash encryption is enabled, be more careful with accessing flash contents from code.

Scope of Flash Encryption Whenever the `SPI_BOOT_CRYPT_CNT` eFuse is set to a value with an odd number of bits, all flash content accessed via the MMU's flash cache is transparently decrypted. It includes:

- Executable application code in flash (IROM).
- All read-only data stored in flash (DROM).
- Any data accessed via *`spi_flash_mmap()`*.
- The firmware bootloader image when it is read by the ROM bootloader.

Important: The MMU flash cache unconditionally decrypts all existing data. Data which is stored unencrypted in flash memory will also be "transparently decrypted" via the flash cache and will appear to software as random garbage.

Reading from Encrypted Flash To read data without using a flash cache MMU mapping, you can use the partition read function *`esp_partition_read()`*. This function will only decrypt data when it is read from an encrypted partition. Data read from unencrypted partitions will not be decrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also use the following SPI flash API functions:

- *`esp_flash_read()`* to read raw (encrypted) data which will not be decrypted
- *`esp_flash_read_encrypted()`* to read and decrypt data

Data stored using the Non-Volatile Storage (NVS) API is always stored and read decrypted from the perspective of flash encryption. It is up to the library to provide encryption feature if required. Refer to *NVS Encryption* for more details.

Writing to Encrypted Flash It is recommended to use the partition write function `esp_partition_write()`. This function will only encrypt data when it is written to an encrypted partition. Data written to unencrypted partitions will not be encrypted. In this way, software can access encrypted and non-encrypted flash in the same way.

You can also pre-encrypt and write data using the function `esp_flash_write_encrypted()`

Also, the following ROM function exist but not supported in esp-idf applications:

- `esp_rom_spiflash_write_encrypted` pre-encrypts and writes data to flash
- `SPIWrite` writes unencrypted data to flash

Since data is encrypted in blocks, the minimum write size for encrypted data is 16 bytes and the alignment is also 16 bytes.

Updating Encrypted Flash

OTA Updates OTA updates to encrypted partitions will automatically write encrypted data if the function `esp_partition_write()` is used.

Before building the application image for OTA updating of an already encrypted device, enable the option *Enable flash encryption on boot* in project configuration menu.

For general information about ESP-IDF OTA updates, please refer to *OTA*

Updating Encrypted Flash via Serial Flashing an encrypted device via serial bootloader requires that the serial bootloader download interface has not been permanently disabled via eFuse.

In Development Mode, the recommended method is *Re-flashing Updated Partitions*.

In Release Mode, if a copy of the same key stored in eFuse is available on the host then it is possible to pre-encrypt files on the host and then flash them. See *Manually Encrypting Files*.

Disabling Flash Encryption

If flash encryption was enabled accidentally, flashing of plaintext data will soft-brick the ESP32-S3. The device will reboot continuously, printing the error `flash read err, 1000` or `invalid header: 0xXXXXXX`.

For flash encryption in Development mode, encryption can be disabled by burning the `SPI_BOOT_CRYPT_CNT` eFuse. It can only be done one time per chip by taking the following steps:

1. In *Project Configuration Menu*, disable *Enable flash encryption on boot*, then save and exit.
2. Open project configuration menu again and **double-check** that you have disabled this option! If this option is left enabled, the bootloader will immediately re-enable encryption when it boots.
3. With flash encryption disabled, build and flash the new bootloader and application by running `idf.py flash`.
4. Use `espefuse.py` (in `components/esptool_py/esptool`) to disable the `SPI_BOOT_CRYPT_CNT` by running:

```
espefuse.py burn_efuse SPI_BOOT_CRYPT_CNT
```

Reset the ESP32-S3. Flash encryption will be disabled, and the bootloader will boot as usual.

Key Points About Flash Encryption

- Flash memory contents is encrypted using XTS-AES-128 or XTS-AES-256. The flash encryption key is 256 bits and 512 bits respectively and stored in one or two `BLOCK_KEYN` eFuses internal to the chip and, by default, is protected from software access.

- Flash access is transparent via the flash cache mapping feature of ESP32-S3 - any flash regions which are mapped to the address space will be transparently decrypted when read.
  Some data partitions might need to remain unencrypted for ease of access or might require the use of flash-friendly update algorithms which are ineffective if the data is encrypted. NVS partitions for non-volatile storage cannot be encrypted since the NVS library is not directly compatible with flash encryption. For details, refer to *NVS Encryption*.
- If flash encryption might be used in future, the programmer must keep it in mind and take certain precautions when writing code that *uses encrypted flash*.
- If secure boot is enabled, re-flashing the bootloader of an encrypted device requires a "Re-flashable" secure boot digest (see *Flash Encryption and Secure Boot*).

Enabling flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

Important: Do not interrupt power to the ESP32-S3 while the first boot encryption pass is running. If power is interrupted, the flash contents will be corrupted and will require flashing with unencrypted data again. In this case, re-flashing will not count towards the flashing limit.

Limitations of Flash Encryption

Flash encryption protects firmware against unauthorised readout and modification. It is important to understand the limitations of the flash encryption feature:

- Flash encryption is only as strong as the key. For this reason, we recommend keys are generated on the device during first boot (default behaviour). If generating keys off-device, ensure proper procedure is followed and do not share the same key between all production devices.
- Not all data is stored encrypted. If storing data on flash, check if the method you are using (library, API, etc.) supports flash encryption.
- Flash encryption does not prevent an attacker from understanding the high-level layout of the flash. This is because the same AES key is used for every pair of adjacent 16 byte AES blocks. When these adjacent 16 byte blocks contain identical content (such as empty or padding areas), these blocks will encrypt to produce matching pairs of encrypted blocks. This may allow an attacker to make high-level comparisons between encrypted devices (i.e., to tell if two devices are probably running the same firmware version).
- Flash encryption alone may not prevent an attacker from modifying the firmware of the device. To prevent unauthorised firmware from running on the device, use flash encryption in combination with *Secure Boot*.

Flash Encryption and Secure Boot

It is recommended to use flash encryption in combination with Secure Boot. However, if Secure Boot is enabled, additional restrictions apply to device re-flashing:

- *OTA Updates* are not restricted, provided that the new app is signed correctly with the Secure Boot signing key.

Advanced Features

The following section covers advanced features of flash encryption.

Encrypted Partition Flag Some partitions are encrypted by default. Other partitions can be marked in the partition table description as requiring encryption by adding the flag `encrypted` to the partitions' flag field. As a result, data in these marked partitions will be treated as encrypted in the same manner as an app partition.

```
# Name,   Type, SubType, Offset,  Size, Flags
nvs,      data, nvs,     0x9000,  0x6000
phy_init, data, phy,     0xf000,  0x1000
factory,  app,  factory, 0x10000, 1M
secret_data, 0x40, 0x01, 0x20000, 256K, encrypted
```

For details on partition table description, see *partition table*.

Further information about encryption of partitions:

- Default partition tables do not include any encrypted data partitions.
- With flash encryption enabled, the `app` partition is always treated as encrypted and does not require marking.
- If flash encryption is not enabled, the flag "encrypted" has no effect.
- You can also consider protecting `phy_init` data from physical access, readout, or modification, by marking the optional `phy` partition with the flag `encrypted`.
- The `nvs` partition cannot be encrypted, because the NVS library is not directly compatible with flash encryption.

Enabling UART Bootloader Encryption/Decryption On the first boot, the flash encryption process burns by default the following eFuses:

- `DIS_DOWNLOAD_MANUAL_ENCRYPT` which disables flash encryption operation when running in UART bootloader boot mode.
- `DIS_DOWNLOAD_ICACHE` and `DIS_DOWNLOAD_DCACHE` which disables the entire MMU flash cache when running in UART bootloader mode.
- `HARD_DIS_JTAG` and `DIS_USB_JTAG` which disables JTAG.
- `DIS_DIRECT_BOOT` (old name `DIS_LEGACY_SPI_BOOT`) which disables direct boot mode

However, before the first boot you can choose to keep any of these features enabled by burning only selected eFuses and write-protect the rest of eFuses with unset value 0. For example:

```
espefuse.py --port PORT burn_efuse DIS_DOWNLOAD_MANUAL_ENCRYPT
espefuse.py --port PORT write_protect_efuse DIS_DOWNLOAD_MANUAL_ENCRYPT
```

Note: Set all appropriate bits before write-protecting!

Write protection of all the three eFuses is controlled by one bit. It means that write-protecting one eFuse bit will inevitably write-protect all unset eFuse bits.

Write protecting these eFuses to keep them unset is not currently very useful, as `esptool.py` does not support reading encrypted flash.

JTAG Debugging By default, when Flash Encryption is enabled (in either Development or Release mode) then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables flash encryption.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with Flash Encryption.

Manually Encrypting Files Manually encrypting or decrypting files requires the flash encryption key to be pre-burned in eFuse (see *Using Host Generated Key*) and a copy to be kept on the host. If the flash encryption is configured in Development Mode then it is not necessary to keep a copy of the key or follow these steps, the simpler *Re-flashing Updated Partitions* steps can be used.

The key file should be a single raw binary file (example: `key.bin`).

For example, these are the steps to encrypt the file `build/my-app.bin` to flash at offset 0x10000. Run espsecure.py as follows:

```
espsecure.py encrypt_flash_data --aes_xts --keyfile /path/to/key.bin --address␣
↪0x10000 --output my-app-ciphertext.bin build/my-app.bin
```

The file `my-app-ciphertext.bin` can then be flashed to offset 0x10000 using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds.

Note: If the flashed ciphertext file is not recognized by the ESP32-S3 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset.

The command `espsecure.py decrypt_flash_data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

External RAM

When Flash Encryption is enabled any data read from and written to external SPI RAM through the cache will also be encrypted/decrypted. This happens the same way and with the same key as for Flash Encryption. If Flash Encryption is enabled then encryption for external SPI RAM is also always enabled, it is not possible to separately control this functionality.

Technical Details

The following sections provide some reference information about the operation of flash encryption.

Flash Encryption Algorithm

- ESP32-S3 use the XTS-AES block cipher mode with 256 bit or 512 bit key size for flash encryption.
- XTS-AES is a block cipher mode specifically designed for disc encryption and addresses the weaknesses other potential modes (e.g., AES-CTR) have for this use case. A detailed description of the XTS-AES algorithm can be found in IEEE Std 1619-2007.
- The flash encryption key is stored in one or two `BLOCK_KEYN` eFuses and, by default, is protected from further writes or software readout.
- To see the full flash encryption algorithm implemented in Python, refer to the *_flash_encryption_operation()* function in the `espsecure.py` source code.

5.2.2 Secure Boot V2

Important: This document is about Secure Boot V2, supported on ESP32-S3

Secure Boot V2 uses RSA-PSS based app and bootloader (*Second Stage Bootloader*) verification. This document can also be used as a reference for signing apps using the RSA-PSS scheme without signing the bootloader.

Background

Secure Boot protects a device from running any unauthorized (i.e., unsigned) code by checking that each piece of software that is being booted is signed. On an ESP32-S3, these pieces of software include the second stage bootloader and each application binary. Note that the first stage bootloader does not require signing as it is ROM code thus cannot be changed.

A RSA based Secure Boot verification scheme (Secure Boot V2) is implemented on ESP32-S3 .

The Secure Boot process on the ESP32-S3 involves the following steps:

1. When the first stage bootloader loads the second stage bootloader, the second stage bootloader's RSA-PSS signature is verified. If the verification is successful, the second stage bootloader is executed.
2. When the second stage bootloader loads a particular application image, the application's RSA-PSS signature is verified. If the verification is successful, the application image is executed.

Advantages

- The RSA-PSS public key is stored on the device. The corresponding RSA-PSS private key is kept at a secret place and is never accessed by the device.
- Up to three public keys can be generated and stored in the chip during manufacturing.
- ESP32-S3 provides the facility to permanently revoke individual public keys. This can be configured conservatively or aggressively.
- Conservatively - The old key is revoked after the bootloader and application have successfully migrated to a new key. Aggressively - The key is revoked as soon as verification with this key fails.
- Same image format and signature verification method is applied for applications and software bootloader.
- No secrets are stored on the device. Therefore, it is immune to passive side-channel attacks (timing or power analysis, etc.)

Secure Boot V2 Process

This is an overview of the Secure Boot V2 Process. Instructions how to enable Secure Boot are supplied in section *How To Enable Secure Boot V2*.

Secure Boot V2 verifies the bootloader image and application binary images using a dedicated *signature block*. Each image has a separately generated signature block which is appended to the end of the image.

Up to 3 signature blocks can be appended to the bootloader or application image in ESP32-S3.

Each signature block contains a signature of the preceding image as well as the corresponding RSA-3072 public key. For more details about the format, refer to *Signature Block Format*. A digest of the RSA-3072 public key is stored in the eFuse.

The application image is not only verified on every boot but also on each over the air (OTA) update. If the currently selected OTA app image cannot be verified, the bootloader will fall back and look for another correctly signed application image.

The Secure Boot V2 process follows these steps:

1. On startup, the ROM code checks the Secure Boot V2 bit in the eFuse. If Secure Boot is disabled, a normal boot will be executed. If Secure Boot is enabled, the boot will proceed according to the following steps.
2. The ROM code verifies the bootloader's signature block (*Verifying a Signature Block*). If this fails, the boot process will be aborted.
3. The ROM code verifies the bootloader image using the raw image data, its corresponding signature block(s), and the eFuse (*Verifying an Image*). If this fails, the boot process will be aborted.
4. The ROM code executes the bootloader.
5. The bootloader verifies the application image's signature block (*Verifying a Signature Block*). If this fails, the boot process will be aborted.
6. The bootloader verifies the application image using the raw image data, its corresponding signature blocks and the eFuse (*Verifying an Image*). If this fails, the boot process will be aborted. If the verification fails but another application image is found, the bootloader will then try to verify that other image using steps 5 to 7. This repeats until a valid image is found or no other images are found.
7. The bootloader executes the verified application image.

Signature Block Format

The signature block starts on a 4 KB aligned boundary and has a flash sector of its own. The signature is calculated over all bytes in the image including the padding bytes (*Secure Padding*).

The content of each signature block is shown in the following table:

Table 2: Content of a RSA Signature Block

Offset	Size (bytes)	Description
0	1	Magic byte
1	1	Version number byte (currently 0x02), 0x01 is for Secure Boot V1.
2	2	Padding bytes, Reserved. Should be zero.
4	32	SHA-256 hash of only the image content, not including the signature block.
36	384	RSA Public Modulus used for signature verification. (value 'n' in RFC8017).
420	4	RSA Public Exponent used for signature verification (value 'e' in RFC8017).
424	384	Pre-calculated R, derived from 'n'.
808	4	Pre-calculated M', derived from 'n'
812	384	RSA-PSS Signature result (section 8.1.1 of RFC8017) of image content, computed using following PSS parameters: SHA256 hash, MGF1 function, salt length 32 bytes, default trailer field (0xBC).
1196	4	CRC32 of the preceding 1196 bytes.
1200	16	Zero padding to length 1216 bytes.

Note: R and M' are used for hardware-assisted Montgomery Multiplication.

The remainder of the signature sector is erased flash (0xFF) which allows writing other signature blocks after previous signature block.

Secure Padding

In Secure Boot V2 scheme, the application image is padded to the flash MMU page size boundary to ensure that only verified contents are mapped in the internal address space. This is known as secure padding. Signature of the image is calculated after padding and then signature block (4KB) gets appended to the image.

- Default flash MMU page size is 64KB
- Secure padding is applied through the option `--secure-pad-v2` in the `elf2image` conversion using `esptool.py`

Following table explains the Secure Boot V2 signed image with secure padding and signature block appended:

Table 3: Contents of a signed application

Offset	Size (KB)	Description
0	580	Unsigned application size (as an example)
580	60	Secure padding (aligned to next 64KB boundary)
640	4	Signature block

Note: Please note that the application image always starts on the next flash MMU page size boundary (default 64KB) and hence the space left over after the signature block shown above can be utilized to store any other data partitions (e.g., `nvs`).

Verifying a Signature Block

A signature block is "valid" if the first byte is 0xe7 and a valid CRC32 is stored at offset 1196. Otherwise it is invalid.

Verifying an Image

An image is "verified" if the public key stored in any signature block is valid for this device, and if the stored signature is valid for the image data read from flash.

1. Compare the SHA-256 hash digest of the public key embedded in the bootloader's signature block with the digest(s) saved in the eFuses. If public key's hash does not match any of the hashes from the eFuses, the verification fails.
2. Generate the application image digest and match it with the image digest in the signature block. If the digests do not match, the verification fails.
3. Use the public key to verify the signature of the bootloader image, using RSA-PSS (section 8.1.2 of RFC8017) with the image digest calculated in step (2) for comparison.

Bootloader Size

Enabling Secure boot and/or flash encryption will increase the size of bootloader, which might require updating partition table offset. See *Bootloader Size*.

In the case when *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* is disabled, the bootloader is sector padded (4KB) using the `--pad-to-size` option in `elf2image` command of `esptool`.

eFuse Usage

- SECURE_BOOT_EN - Enables Secure Boot protection on boot.
- KEY_PURPOSE_X - Set the purpose of the key block on ESP32-S3 by programming SECURE_BOOT_DIGESTX (X = 0, 1, 2) into KEY_PURPOSE_X (X = 0, 1, 2, 3, 4, 5). Example: If KEY_PURPOSE_2 is set to SECURE_BOOT_DIGEST1, then BLOCK_KEY2 will have the Secure Boot V2 public key digest. The write-protection bit must be set (this field does not have a read-protection bit).
- BLOCK_KEYX - The block contains the data corresponding to its purpose programmed in KEY_PURPOSE_X. Stores the SHA-256 digest of the public key. SHA-256 hash of public key modulus, exponent, pre-calculated R & M' values (represented as 776 bytes –offsets 36 to 812 - as per the *Signature Block Format*) is written to an eFuse key block. The write-protection bit must be set, but the read-protection bit must not.
- KEY_REVOKEX - The revocation bits corresponding to each of the 3 key block. Ex. Setting KEY_REVOKE2 revokes the key block whose key purpose is SECURE_BOOT_DIGEST2.
- SECURE_BOOT_AGGRESSIVE_REVOKE - Enables aggressive revocation of keys. The key is revoked as soon as verification with this key fails.

To ensure no trusted keys can be added later by an attacker, each unused key digest slot should be revoked (KEY_REVOKEX). It will be checked during app startup in `esp_secure_boot_init_checks()` and fixed unless *CONFIG_SECURE_BOOT_ALLOW_UNUSED_DIGEST_SLOTS* is enabled.

The key(s) must be readable in order to give software access to it. If the key(s) is read-protected then the software reads the key(s) as all zeros and the signature verification process will fail, and the boot process will be aborted.

How To Enable Secure Boot V2

1. Open the *Project Configuration Menu*, in "Security features" set "Enable hardware Secure Boot in bootloader" to enable Secure Boot.
2. The "Secure Boot V2" option will be selected and the "App Signing Scheme" would be set to RSA by default.
3. Specify the path to Secure Boot signing key, relative to the project directory.

4. Select the desired UART ROM download mode in "UART ROM download mode". By default, it is set to "Permanently switch to Secure mode" which is generally recommended. For production devices, the most secure option is to set it to "Permanently disabled".
5. Set other menuconfig options (as desired). Then exit menuconfig and save your configuration.
6. The first time you run `idf.py build`, if the signing key is not found then an error message will be printed with a command to generate a signing key via `espsecure.py generate_signing_key`.

Important: A signing key generated this way will use the best random number source available to the OS and its Python installation (*/dev/urandom* on OSX/Linux and *CryptGenRandom()* on Windows). If this random number source is weak, then the private key will be weak.

Important: For production environments, we recommend generating the key pair using openssl or another industry standard encryption program. See *Generating Secure Boot Signing Key* for more details.

---

7. Run `idf.py bootloader` to build a Secure Boot enabled bootloader. The build output will include a prompt for a flashing command, using `esptool.py write_flash`.
8. When you are ready to flash the bootloader, run the specified command (you have to enter it yourself, this step is not performed by the build system) and then wait for flashing to complete.
9. Run `idf.py flash` to build and flash the partition table and the just-built app image. The app image will be signed using the signing key you generated in step 6.

Note: `idf.py flash` does not flash the bootloader if Secure Boot is enabled.

---

10. Reset the ESP32-S3 and it will boot the software bootloader you flashed. The software bootloader will enable Secure Boot on the chip, and then it verifies the app image signature and boots the app. You should watch the serial console output from the ESP32-S3 to verify that Secure Boot is enabled and no errors have occurred due to the build configuration.

Note: Secure boot will not be enabled until after a valid partition table and app image have been flashed. This is to prevent accidents before the system is fully configured.

Note: If the ESP32-S3 is reset or powered down during the first boot, it will start the process again on the next boot.

---

11. On subsequent boots, the Secure Boot hardware will verify the software bootloader has not changed and the software bootloader will verify the signed app image (using the validated public key portion of its appended signature block).

Restrictions After Secure Boot Is Enabled

- Any updated bootloader or app will need to be signed with a key matching the digest already stored in eFuse.
- Please note that enabling Secure Boot or flash encryption disables the USB-OTG USB stack in the ROM, disallowing updates via the serial emulation or Device Firmware Update (DFU) on that port.

Burning read-protected keys After Secure Boot is enabled, no further eFuses can be read-protected, because this might allow an attacker to read-protect the efuse block holding the public key digest, causing an immediate denial of service and possibly allowing an additional fault injection attack to bypass the signature protection.

If *Flash Encryption* is enabled by the 2nd stage bootloader, it ensures that the flash encryption key generated on the first boot shall already be read-protected.

In case you need to read-protect a key after Secure Boot has been enabled on the device, for example,

- the flash encryption key
- HMAC keys

you need to enable the config *CONFIG_SECURE_BOOT_V2_ALLOW_EFUSE_RD_DIS* at the same time when you enable Secure Boot to prevent disabling the ability to read-protect further efuses.

It is highly recommended that all such keys must been burned before enabling secure boot.

In case you need to enable *CONFIG_SECURE_BOOT_V2_ALLOW_EFUSE_RD_DIS*, make sure that you burn the efuse ESP_EFUSE_WR_DIS_RD_DIS, using `esp_efuse_write_field_bit()` API from `esp_efuse.h`, once all the read-protected efuse keys have been programmed.

Generating Secure Boot Signing Key

The build system will prompt you with a command to generate a new signing key via `espsecure.py generate_signing_key`.

The `--version 2` parameter will generate the RSA 3072 private key for Secure Boot V2. Additionally `--scheme rsa3072` can be passed as well to generate RSA 3072 private key

The strength of the signing key is proportional to (a) the random number source of the system, and (b) the correctness of the algorithm used. For production devices, we recommend generating signing keys from a system with a quality entropy source, and using the best available RSA-PSS key generation utilities.

For example, to generate a signing key using the openssl command line:

For RSA 3072

```
` openssl genrsa -out my_secure_boot_signing_key.pem 3072 `
```

Remember that the strength of the Secure Boot system depends on keeping the signing key private.

Remote Signing of Images

Signing Using `espsecure.py` For production builds, it can be good practice to use a remote signing server rather than have the signing key on the build machine (which is the default esp-idf Secure Boot configuration). The espsecure.py command line program can be used to sign app images & partition table data for Secure Boot, on a remote system.

To use remote signing, disable the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* and build the firmware. The private signing key does not need to be present on the build system.

After the app image and partition table are built, the build system will print signing steps using espsecure.py:

```
espsecure.py sign_data BINARY_FILE --version 2 --keyfile PRIVATE_SIGNING_KEY
```

The above command appends the image signature to the existing binary. You can use the *--output* argument to write the signed binary to a separate file:

```
espsecure.py sign_data --version 2 --keyfile PRIVATE_SIGNING_KEY --output SIGNED_
↪BINARY_FILE BINARY_FILE
```

Signing Using Pre-calculated Signatures If you have valid pre-calculated signatures generated for an image and their corresponding public keys, you can use these signatures to generate a signature sector and append it to the image. Note that the pre-calculated signature should be calculated over all bytes in the image including the secure-padding bytes.

In such cases, the firmware image should be built by disabling the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES*. This image will be secure-padded and to generate a signed binary use the following command:

```
espsecure.py sign_data --version 2 --pub-key PUBLIC_SIGNING_KEY --signature␣
↪SIGNATURE_FILE --output SIGNED_BINARY_FILE BINARY_FILE
```

The above command verifies the signature, generates a signature block (refer to *Signature Block Format*) and appends it to the binary file.

Signing Using an External Hardware Security Module (HSM) For security reasons, you might also use an external Hardware Security Module (HSM) to store your private signing key, which cannot be accessed directly but has an interface to generate the signature of a binary file and its corresponding public key.

In such cases, disable the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* and build the firmware. This secure-padded image then can be used to supply the external HSM for generating a signature. Refer to Signing using an External HSM to generate a signed image.

Note: For all the above three remote signing workflows, the signed binary is written to the filename provided to the `--output` argument and the option `--append_signatures` allows us to append multiple signatures (up to 3) the image.

Secure Boot Best Practices

- Generate the signing key on a system with a quality source of entropy.
- Keep the signing key private at all times. A leak of this key will compromise the Secure Boot system.
- Do not allow any third party to observe any aspects of the key generation or signing process using espsecure.py. Both processes are vulnerable to timing or other side-channel attacks.
- Enable all Secure Boot options in the Secure Boot Configuration. These include flash encryption, disabling of JTAG, disabling BASIC ROM interpreter, and disabling the UART bootloader encrypted flash access.
- Use Secure Boot in combination with *Flash Encryption* to prevent local readout of the flash contents.

Key Management

- Between 1 and 3 RSA-3072 public key pairs (Keys #0, #1, #2) should be computed independently and stored separately.
- The KEY_DIGEST eFuses should be write protected after being programmed.
- The unused KEY_DIGEST slots must have their corresponding KEY_REVOKE eFuse burned to permanently disable them. This must happen before the device leaves the factory.
- The eFuses can either be written by the software bootloader during during first boot after enabling "Secure Boot V2" from menuconfig or can be done using *espefuse.py* which communicates with the serial bootloader program in ROM.
- The KEY_DIGESTs should be numbered sequentially beginning at key digest #0. (i.e., if key digest #1 is used, key digest #0 should be used. If key digest #2 is used, key digest #0 & #1 must be used.)
- The software bootloader (non OTA upgradeable) is signed using at least one, possibly all three, private keys and flashed in the factory.
- Apps should only be signed with a single private key (the others being stored securely elsewhere), however they may be signed with multiple private keys if some are being revoked (see Key Revocation, below).

Multiple Keys

- The bootloader should be signed with all the private key(s) that are needed for the life of the device, before it is flashed.
- The build system can sign with at most one private key, user has to run manual commands to append more signatures if necessary.
- **You can use the append functionality of `espsecure.py`, this command would also printed at the end of the Secure B**

  espsecure.py sign_data -k secure_boot_signing_key2.pem -v 2 --append_signatures -o signed_bootloader.bin build/bootloader/bootloader.bin

- While signing with multiple private keys, it is recommended that the private keys be signed independently, if possible on different servers and stored separately.
- **You can check the signatures attached to a binary using -** espsecure.py signature_info_v2 datafile.bin

Key Revocation

- Keys are processed in a linear order. (key #0, key #1, key #2).
- Applications should be signed with only one key at a time, to minimize the exposure of unused private keys.
- The bootloader can be signed with multiple keys from the factory.

Conservative Approach: Assuming a trusted private key (N-1) has been compromised, to update to new key pair (N).

1. Server sends an OTA update with an application signed with the new private key (#N).
2. The new OTA update is written to an unused OTA app partition.
3. The new application's signature block is validated. The public keys are checked against the digests programmed in the eFuse & the application is verified using the verified public key.
4. The active partition is set to the new OTA application's partition.
5. Device resets, loads the bootloader (verified with key #N-1 and #N) which then boots new app (verified with key #N).
6. The new app verifies bootloader and application with key #N (as a final check) and then runs code to revoke key #N-1 (sets KEY_REVOKE eFuse bit).
7. The API *esp_ota_revoke_secure_boot_public_key()* can be used to revoke the key #N-1.

- A similar approach can also be used to physically re-flash with a new key. For physical re-flashing, the bootloader content can also be changed at the same time.

Aggressive Approach: ROM code has an additional feature of revoking a public key digest if the signature verification fails.

To enable this feature, you need to burn SECURE_BOOT_AGGRESSIVE_REVOKE efuse or enable *CONFIG_SECURE_BOOT_ENABLE_AGGRESSIVE_KEY_REVOKE*

Key revocation is not applicable unless secure boot is successfully enabled. Also, a key is not revoked in case of invalid signature block or invalid image digest, it is only revoked in case the signature verification fails, i.e., revoke key only if failure in step 3 of *Verifying an Image*

Once a key is revoked, it can never be used for verfying a signature of an image. This feature provides strong resistance against physical attacks on the device. However, this could also brick the device permanently if all the keys are revoked because of signature verification failure.

Technical Details

The following sections contain low-level reference descriptions of various Secure Boot elements:

Manual Commands Secure boot is integrated into the esp-idf build system, so `idf.py build` will sign an app image and `idf.py bootloader` will produce a signed bootloader if secure signed binaries on build is enabled.

However, it is possible to use the `espsecure.py` tool to make standalone signatures and digests.

To sign a binary image:

```
espsecure.py sign_data --version 2 --keyfile ./my_signing_key.pem --output ./image_
↪signed.bin image-unsigned.bin
```

Keyfile is the PEM file containing an RSA-3072 private signing key.

Secure Boot & Flash Encryption

If Secure Boot is used without *Flash Encryption*, it is possible to launch "time-of-check to time-of-use" attack, where flash contents are swapped after the image is verified and running. Therefore, it is recommended to use both the features together.

Signed App Verification Without Hardware Secure Boot

The Secure Boot V2 signature of apps can be checked on OTA update, without enabling the hardware Secure Boot option. This option uses the same app signature scheme as Secure Boot V2, but unlike hardware Secure Boot it does not prevent an attacker who can write to flash from bypassing the signature protection.

This may be desirable in cases where the delay of Secure Boot verification on startup is unacceptable, and/or where the threat model does not include physical access or attackers writing to bootloader or app partitions in flash.

In this mode, the public key which is present in the signature block of the currently running app will be used to verify the signature of a newly updated app. (The signature on the running app is not verified during the update process, it is assumed to be valid.) In this way the system creates a chain of trust from the running app to the newly updated app.

For this reason, it is essential that the initial app flashed to the device is also signed. A check is run on app startup and the app will abort if no signatures are found. This is to try and prevent a situation where no update is possible. The app should have only one valid signature block in the first position. Note again that, unlike hardware Secure Boot V2, the signature of the running app is not verified on boot. The system only verifies a signature block in the first position and ignores any other appended signatures.

Although multiple trusted keys are supported when using hardware Secure Boot, only the first public key in the signature block is used to verify updates if signature checking without Secure Boot is configured. If multiple trusted public keys are required, it is necessary to enable the full Secure Boot feature instead.

Note: In general, it is recommended to use full hardware Secure Boot unless certain that this option is sufficient for application security needs.

How To Enable Signed App Verification

1. Open *Project Configuration Menu* -> Security features
2. Ensure *App Signing Scheme* is *RSA*
3. Enable *CONFIG_SECURE_SIGNED_APPS_NO_SECURE_BOOT*
4. By default, "Sign binaries during build" will be enabled on selecting "Require signed app images" option, which will sign binary files as a part of build process. The file named in "Secure boot private signing key" will be used to sign the image.
5. If you disable "Sign binaries during build" option then all app binaries must be manually signed by following instructions in *Remote Signing of Images*.

Warning: It is very important that all apps flashed have been signed, either during the build or after the build.

Advanced Features

JTAG Debugging By default, when Secure Boot is enabled then JTAG debugging is disabled via eFuse. The bootloader does this on first boot, at the same time it enables Secure Boot.

See *JTAG with Flash Encryption or Secure Boot* for more information about using JTAG Debugging with either Secure Boot or signed app verification enabled.

5.3 Workflows

5.3.1 Host-Based Security Workflows

Introduction

It is recommended to have an uninterrupted power supply while enabling security features on ESP32 SoCs. Power failures during the secure manufacturing process could cause issues that are hard to debug and, in some cases, may cause permanent boot-up failures.

This guide highlights an approach where security features are enabled with the assistance of an external host machine. Security workflows are broken down into various stages and key material is generated on the host machine; thus, allowing greater recovery chances in case of power or other failures. It also offers better timings for secure manufacturing, e.g., in the case of encryption of firmware on the host machine vs. on the device.

Goals

1. Simplify the traditional workflow with stepwise instructions.
2. Design a more flexible workflow as compared to the traditional firmware-based workflow.
3. Improve reliability by dividing the workflow into small operations.
4. Eliminate dependency on *Second Stage Bootloader* (firmware bootloader).

Pre-requisite

- `esptool`: Please make sure the `esptool` has been installed. It can be installed by running:

```
pip install esptool
```

Scope

- *Enable Flash Encryption and Secure Boot V2 Externally*
- *Enable Flash Encryption Externally*
- *Enable Secure Boot V2 Externally*

Security Workflows

Enable Flash Encryption and Secure Boot V2 Externally

Important: It is recommended to enable both Flash Encryption and Secure Boot V2 for a production use case.

When enabling the Flash Encryption and Secure Boot V2 externally we need to enable them in the following order:

1. Enable the Flash Encryption feature by following the steps listed in *Enable Flash Encryption Externally*.
2. Enable the Secure Boot V2 feature by following the steps listed in *Enable Secure Boot V2 Externally*.

The reason for this order is as follows:

To enable the Secure Boot (SB) V2, it is necessary to keep the SB V2 key readable. To protect the key's readability, the write protection for `RD_DIS` (`ESP_EFUSE_WR_DIS_RD_DIS`) is applied. However, this action poses a challenge when attempting to enable Flash Encryption, as the Flash Encryption (FE) key needs to remain unreadable. This conflict arises because the `RD_DIS` is already write-protected, making it impossible to read protect the FE key.

Enable Flash Encryption Externally In this case, all the eFuses related to flash encryption are written with help of the espefuse tool. More details about flash encryption can be found in the *Flash Encryption Guide*

1. Ensure that you have an ESP32-S3 device with default flash encryption eFuse settings as shown in *Relevant eFuses*.

   See how to check *ESP32-S3 Flash Encryption Status*.

   In this case, the flash on the chip must be erased and flash encryption must not be enabled. The chip can be erased by running:

   ```
   esptool.py --port PORT erase_flash
   ```

2. Generate a flash encryption key.

   A random flash encryption key can be generated by running:

   If *Size of generated AES-XTS key* is AES-128 (256-bit key):

   ```
   espsecure.py generate_flash_encryption_key my_flash_encryption_key.bin
   ```

   else if *Size of generated AES-XTS key* is AES-256 (512-bit key):

   ```
   espsecure.py generate_flash_encryption_key --keylen 512 my_flash_
   ↪encryption_key.bin
   ```

3. Burn the flash encryption key into eFuse.

   This action **cannot be reverted**. It can be done by running:

   ```
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin␣
   ↪KEYPURPOSE
   ```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`. And `KEYPURPOSE` is either `XTS_AES_256_KEY_1`, `XTS_AES_256_KEY_2`, `XTS_AES_128_KEY`. See ESP32-S3 Technical Reference Manual for a description of the key purposes.

   For AES-128 (256-bit key) - `XTS_AES_128_KEY`:

   ```
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin XTS_
   ↪AES_128_KEY
   ```

   For AES-256 (512-bit key) - `XTS_AES_256_KEY_1` and `XTS_AES_256_KEY_2`. `espefuse.py` supports burning both these two key purposes together with a 512-bit key to two separate key blocks via the virtual key purpose `XTS_AES_256_KEY`. When this is used `espefuse.py` will burn the first 256 bits of the key to the specified `BLOCK` and burn the corresponding block key purpose to `XTS_AES_256_KEY_1`. The last 256 bits of the key will be burned to the first free key block after `BLOCK` and the corresponding block key purpose to `XTS_AES_256_KEY_2`

   ```
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin XTS_
   ↪AES_256_KEY
   ```

   If you wish to specify exactly which two blocks are used then it is possible to divide the key into two 256-bit keys, and manually burn each half with `XTS_AES_256_KEY_1` and `XTS_AES_256_KEY_2` as key purposes:

   ```
   split -b 32 my_flash_encryption_key.bin my_flash_encryption_key.bin
   espefuse.py --port PORT burn_key BLOCK my_flash_encryption_key.bin.aa XTS_
   ↪AES_256_KEY_1
   espefuse.py --port PORT burn_key BLOCK+1 my_flash_encryption_key.bin.ab␣
   ↪XTS_AES_256_KEY_2
   ```

Warning: For the ESP32-S3 BLOCK9 (BLOCK_KEY5) can not be used by XTS_AES keys.

4. Burn the `SPI_BOOT_CRYPT_CNT` eFuse.

   If you only want to enable flash encryption in **Development** mode and want to keep the ability to disable it in the future, Update the SPI_BOOT_CRYPT_CNT value in the below command from 7 to 0x1 (not recommended for production).

```
espefuse.py --port PORT --chip esp32s3 burn_efuse SPI_BOOT_CRYPT_CNT 7
```

Note: At this point, the flash encryption on the device has been enabled. You may test the flash encryption process as given in step 5. Please note that the security-related eFuses have not been burned at this point. It is recommended that they should be burned in production use cases as explained in step 6.

5. Encrypt and flash the binaries.

   The bootloader and the application binaries for the project must be built with Flash Encryption Release mode with default configurations.

   Flash encryption Release mode can be set in the menuconfig as follows:

   - *Enable flash encryption on boot*
   - *Select Release mode* (Note that once Release mode is selected, the `EFUSE_DIS_DOWNLOAD_MANUAL_ENCRYPT` eFuse bit will be burned to disable flash encryption hardware in ROM Download Mode.)
   - *Select UART ROM download mode (Permanently switch to Secure mode (recommended))*. This is the default option and is recommended. It is also possible to change this configuration setting to permanently disable UART ROM download mode, if this mode is not needed.
   - *Select the appropriate bootloader log verbosity*
   - Save the configuration and exit.

   The binaries can be encrypted on the host machine by running:

```
espsecure.py encrypt_flash_data --aes_xts --keyfile my_flash_encryption_
↪key.bin --address 0x0 --output bootloader-enc.bin build/my-app.bin

espsecure.py encrypt_flash_data --aes_xts --keyfile my_flash_encryption_
↪key.bin --address 0x8000 --output partition-table-enc.bin build/
↪partition_table/partition-table.bin

espsecure.py encrypt_flash_data --aes_xts --keyfile my_flash_encryption_
↪key.bin --address 0x10000 --output my-app-enc.bin build/my-app.bin
```

   The above files can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds. In the above command the offsets are used for a sample firmware, the actual offset for your firmware can be obtained by checking the partition table entry or by running *idf.py partition-table*. When the application contains the following partition: `otadata`, `nvs_encryption_keys` they need to be encrypted as well. Please refer to *Encrypted Partitions* for more details about encrypted partitions.

   Note: If the flashed ciphertext file is not recognized by the ESP32-S3 when it boots, check that the keys match and that the command line arguments match exactly, including the correct offset. It is important to provide the correct offset as the ciphertext changes when the offset changes.

   The command `espsecure.py decrypt_flash_data` can be used with the same options (and different input/output files), to decrypt ciphertext flash contents or a previously encrypted file.

6. Burn flash encryption-related security eFuses as listed below:

   A) Burn security eFuses:

   Important: For production use cases, it is highly recommended to burn all the eFuses listed below.

   - `DIS_DOWNLOAD_ICACHE`: Disable UART cache
   - `DIS_DOWNLOAD_DCACHE`: Disable UART cache.
   - `HARD_DIS_JTAG`: Hard disable JTAG peripheral
   - `DIS_DIRECT_BOOT`: Disable direct boot (legacy SPI boot mode)
   - `DIS_USB_JTAG`: Disable USB switch to JTAG
   - `DIS_DOWNLOAD_MANUAL_ENCRYPT`: Disable UART bootloader encryption access

   The respective eFuses can be burned by running:

   ```
   espefuse.py burn_efuse --port PORT EFUSE_NAME 0x1
   ```

   Note: Please update the EFUSE_NAME with the eFuse that you need to burn. Multiple eFuses can be burned at the same time by appending them to the above command (e.g., EFUSE_NAME VAL EFUSE_NAME2 VAL2). More documentation about *espefuse.py* can be found here.

   B) Write protect security eFuses:

   After burning the respective eFuses we need to write_protect the security configurations

   ```
   espefuse.py --port PORT write_protect_efuse DIS_ICACHE
   ```

   Note: The write protection of above eFuse also write protects multiple other eFuses, Please refer to the ESP32-S3 eFuse table for more details.

   C) Enable Security Download mode:

   Warning: Please burn the following bit at the very end. After this bit is burned, the espefuse tool can no longer be used to burn additional eFuses.

   - `ENABLE_SECURITY_DOWNLOAD`: Enable Secure ROM download mode

   The eFuse can be burned by running:

   ```
   espefuse.py --port PORT burn_efuse ENABLE_SECURITY_DOWNLOAD
   ```

Important:

7. Delete flash encryption key on host:
   Once the flash encryption has been enabled for the device, the key **must be deleted immediately**. This ensures that the host cannot produce encrypted binaries for the same device going forward. This step is important to reduce the vulnerability of the flash encryption key.

Flash Encryption Guidelines

- It is recommended to generate a unique flash encryption key for each device for production use-cases.
- It is recommended to ensure that the RNG used by host machine to generate the flash encryption key has good entropy.
- See *Limitations of Flash Encryption* for more details.

Enable Secure Boot V2 Externally In this workflow, we shall use `espsecure` tool to generate signing keys and use the `espefuse` tool to burn the relevant eFuses. The details about the Secure Boot V2 process can be found at *Secure Boot V2 Guide*

1. Generate Secure Boot V2 Signing Private Key.

   The Secure Boot V2 signing key for the RSA3072 scheme can be generated by running:

   ```
   espsecure.py generate_signing_key --version 2 --scheme rsa3072 secure_
   ↪boot_signing_key.pem
   ```

   A total of 3 keys can be used for Secure Boot V2 at once. These should be computed independently and stored separately. The same command with different key file names can be used to generate multiple Secure Boot V2 signing keys. It is recommended to use multiple keys in order to reduce dependency on a single key.

2. Generate Public Key Digest.

   The public key digest for the private key generated in the previous step can be generated by running:

   ```
   espsecure.py digest_sbv2_public_key --keyfile secure_boot_signing_key.pem␣
   ↪--output digest.bin
   ```

   In case of multiple digests, each digest should be kept in a separate file.

3. Burn the key digest in eFuse.

   The public key digest can be burned in the eFuse by running:

   ```
   espefuse.py --port PORT --chip esp32s3 burn_key digest.bin BLOCK SECURE_
   ↪BOOT_DIGEST0
   ```

   where `BLOCK` is a free keyblock between `BLOCK_KEY0` and `BLOCK_KEY5`.

   In case of multiple digests, the other digests can be burned sequentially by changing the key purpose to `SECURE_BOOT_DIGEST1` and `SECURE_BOOT_DIGEST2` respectively.

4. Enable Secure Boot V2.

   Secure Boot V2 eFuse can be enabled by running:

   ```
   espefuse.py --port PORT --chip esp32s3 burn_efuse SECURE_BOOT_EN
   ```

   Note: At this stage the secure boot V2 has been enabled for the ESP32-S3. The ROM bootloader shall now verify the authenticity of the *Second Stage Bootloader* on every bootup. You may test the secure boot process by executing Steps 5 & 6. Please note that security-related eFuses have not been burned at this point. For production use cases, all security-related eFuses must be burned as given in step 7.

5. Build the binaries.

   By default, the ROM bootloader would only verify the *Second Stage Bootloader* (firmware bootloader). The firmware bootloader would verify the app partition only when the *CONFIG_SECURE_BOOT* option is enabled (and *CONFIG_SECURE_BOOT_VERSION* is set to `SECURE_BOOT_V2_ENABLED`) while building the bootloader.

a) Open the *Project Configuration Menu*, in "Security features" set "Enable hardware Secure Boot in bootloader" to enable Secure Boot.

The "Secure Boot V2" option will be selected and the "App Signing Scheme" will be set to RSA by default.

b) Disable the option *CONFIG_SECURE_BOOT_BUILD_SIGNED_BINARIES* for the project in the *Project Configuration Menu*. This shall make sure that all the generated binaries are secure padded and unsigned. This step is done to avoid generating signed binaries as we are going to manually sign the binaries using `espsecure` tool.

After the above configurations, the bootloader and application binaries can be built with `idf.py build` command.

6. Sign and Flash the binaries.

   The Secure Boot V2 workflow only verifies the `bootloader` and `application` binaries, hence only those binaries need to be signed. The other binaries (e.g., `partition-table.bin`) can be flashed as they are generated in the build stage.

   The `bootloader.bin` and `app.bin` binaries can be signed by running:

```
espsecure.py sign_data --version 2 --keyfile secure_boot_signing_key.pem -
↪-output bootloader-signed.bin build/bootloader/bootloader.bin

espsecure.py sign_data --version 2 --keyfile secure_boot_signing_key.pem -
↪-output my-app-signed.bin build/my-app.bin
```

   If multiple keys secure boot keys are to be used then the same signed binary can be appended with a signature block signed with the new key as follows:

```
espsecure.py sign_data --keyfile secure_boot_signing_key2.pem --version 2␣
↪--append_signatures -o bootloader-signed2.bin bootloader-signed.bin

espsecure.py sign_data --keyfile secure_boot_signing_key2.pem --version 2␣
↪--append_signatures -o my-app-signed2.bin my-app-signed.bin
```

   The same process can be repeated for the third key. Note that the names of the input and output files must not be the same.

   The signatures attached to a binary can be checked by running:

```
espsecure.py signature_info_v2 bootloader-signed.bin
```

   The above files along with other binaries (e.g., partition table) can then be flashed to their respective offset using `esptool.py`. To see all of the command line options recommended for `esptool.py`, see the output printed when `idf.py build` succeeds. The flash offset for your firmware can be obtained by checking the partition table entry or by running `idf.py partition-table`.

7. Burn relevant eFuses.

   A) Burn security eFuses:

   Important: For production use cases, it is highly recommended to burn all the eFuses listed below.

   - `HARD_DIS_JTAG`: Hard disable JTAG peripheral
   - `SOFT_DIS_JTAG`: Disable software access to JTAG peripheral
   - `DIS_DIRECT_BOOT`: Disable direct boot (legacy SPI boot mode)
   - `DIS_USB_JTAG`: Disable USB switch to JTAG
   - `SECURE_BOOT_AGGRESSIVE_REVOKE`: Aggressive revocation of key digests, see *Aggressive Approach:* for more details.

The respective eFuses can be burned by running:

```
espefuse.py burn_efuse --port PORT EFUSE_NAME 0x1
```

Note: Please update the EFUSE_NAME with the eFuse that you need to burn. Multiple eFuses can be burned at the same time by appending them to the above command (e.g., EFUSE_NAME VAL EFUSE_NAME2 VAL2). More documentation about *espefuse.py* can be found here

B) Secure Boot V2-related eFuses:

i) Disable the ability for read protection:

The secure boot digest burned in the eFuse must be kept readable otherwise secure boot operation would result in a failure. To prevent the accidental enabling of read protection for this key block we need to burn the following eFuse:

```
espefuse.py -p $ESPPORT write_protect_efuse RD_DIS
```

Important: After this eFuse has been burned, read protection cannot be enabled for any key. E.g., if flash encryption which requires read protection for its key is not enabled at this point then it cannot be enabled afterwards. Please ensure that no eFuse keys are going to need read protection after this.

ii) Revoke key digests:

The unused digest slots need to be revoked when we are burning the secure boot key. The respective slots can be revoked by running

```
espefuse.py --port PORT --chip esp32s3 burn_efuse EFUSE_REVOKE_BIT
```

The `EFUSE_REVOKE_BIT` in the above command can be `SECURE_BOOT_KEY_REVOKE0` or `SECURE_BOOT_KEY_REVOKE1` or `SECURE_BOOT_KEY_REVOKE2`. Please note that only the unused key digests must be revoked. Once revoked, the respective digest cannot be used again.

C) Enable Security Download mode:

Warning: Please burn the following bit at the very end. After this bit is burned, the espefuse tool can no longer be used to burn additional eFuses.

- `ENABLE_SECURITY_DOWNLOAD`: Enable Secure ROM download mode

The eFuse can be burned by running:

```
espefuse.py --port PORT burn_efuse ENABLE_SECURITY_DOWNLOAD
```

Secure Boot V2 Guidelines

- It is recommended to store the secure boot key in a highly secure place. A physical or a cloud HSM may be used for secure storage of the secure boot private key. Please take a look at *Remote Signing of Images* for more details.
- It is recommended to use all the available digest slots to reduce dependency on a single private key.

Chapter 6

Migration Guides

6.1 ESP-IDF 5.x Migration Guide

6.1.1 Migration from 4.4 to 5.0

Bluetooth Low Energy

Bluedroid

The following Bluedroid macros, types, and functions have been renamed:

- bt/host/bluedroid/api/include/api/esp_gap_ble_api.h
  - In *esp_gap_ble_cb_event_t*:
    - ESP_GAP_BLE_SET_PREFERED_DEFAULT_PHY_COMPLETE_EVT renamed to ESP_GAP_BLE_SET_PREFERRED_DEFAULT_PHY_COMPLETE_EVT
    - ESP_GAP_BLE_SET_PREFERED_PHY_COMPLETE_EVT renamed to ESP_GAP_BLE_SET_PREFERRED_PHY_COMPLETE_EVT
    - ESP_GAP_BLE_CHANNEL_SELETE_ALGORITHM_EVT renamed to ESP_GAP_BLE_CHANNEL_SELECT_ALGORITHM_EVT
  - esp_ble_wl_opration_t renamed to *esp_ble_wl_operation_t*
  - esp_ble_gap_cb_param_t.pkt_data_lenth_cmpl renamed to pkt_data_length_cmpl
  - esp_ble_gap_cb_param_t.update_whitelist_cmpl.wl_opration renamed to wl_operation
  - esp_ble_gap_set_prefered_default_phy renamed to *esp_ble_gap_set_preferred_default_phy()*
  - esp_ble_gap_set_prefered_phy renamed to *esp_ble_gap_set_preferred_phy()*
- bt/host/bluedroid/api/include/api/esp_gatt_defs.h
  - In *esp_gatt_status_t*:
    - ESP_GATT_ENCRYPED_MITM renamed to ESP_GATT_ENCRYPTED_MITM
    - ESP_GATT_ENCRYPED_NO_MITM renamed to ESP_GATT_ENCRYPTED_NO_MITM

Nimble

The following Nimble APIs have been removed:

- bt/host/nimble/esp-hci/include/esp_nimble_hci.h
  - Remove `esp_err_t esp_nimble_hci_and_controller_init(void)`
    - Controller initialization, enable and HCI initialization calls have been moved to *nimble_port_init*. This function can be deleted directly.
  - Remove `esp_err_t esp_nimble_hci_and_controller_deinit(void)`
    - Controller deinitialization, disable and HCI deinitialization calls have been moved to *nimble_port_deinit*. This function can be deleted directly.

ESP-BLE-MESH

The following ESP-BLE-MESH macro has been renamed:

- bt/esp_ble_mesh/api/esp_ble_mesh_defs.h
  - In *esp_ble_mesh_prov_cb_event_t*:
    - `ESP_BLE_MESH_PROVISIONER_DRIECT_ERASE_SETTINGS_COMP_EVT` renamed to `ESP_BLE_MESH_PROVISIONER_DIRECT_ERASE_SETTINGS_COMP_EVT`

Build System

Migrating from GNU Make Build System ESP-IDF v5.0 no longer supports GNU make-based projects. Please follow the *build system* guide for migration.

Update Fragment File Grammar The former grammar, supported in ESP-IDF v3.x, was dropped in ESP-IDF v5.0. Here are a few notes on how to migrate properly:

1. Indentation is now enforced: improperly indented fragment files generate a runtime parse exception. Although the former version did not enforce this, the previous documentation and examples demonstrated properly indented grammar.
2. Migrate the old condition entry to the `if...elif...else` structure for conditionals. You can refer to the *Configuration-Dependent Placements* for detailed grammar.
3. Mapping fragments now requires a name like other fragment types.

Specify Component Requirements Explicitly In previous versions of ESP-IDF, some components were always added as public requirements (dependencies) to every component in the build, in addition to the *common component requirements*:

- `driver`
- `efuse`
- `esp_timer`
- `lwip`
- `vfs`
- `esp_wifi`
- `esp_event`
- `esp_netif`
- `esp_eth`
- `esp_phy`

This means that it was possible to include header files of those components without specifying them as requirements in `idf_component_register`. This behavior was caused by transitive dependencies of various common components.

In ESP-IDF v5.0, this behavior is fixed and these components are no longer added as public requirements by default.

Every component depending on one of the components which isn't part of common requirements has to declare this dependency explicitly. This can be done by adding `REQUIRES <component_name>` or `PRIV_REQUIRES`

<component_name> in idf_component_register call inside component's CMakeLists.txt. See *Component Requirements* for more information on specifying requirements.

Setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS Variables ESP-IDF v5.0 includes a number of improvements to support building projects with space characters in their paths. To make that possible, there are some changes related to setting COMPONENT_DIRS and EXTRA_COMPONENT_DIRS variables in project CMakeLists.txt files.

Adding non-existent directories to COMPONENT_DIRS or EXTRA_COMPONENT_DIRS is no longer supported and will result in an error.

Using string concatenation to define COMPONENT_DIRS or EXTRA_COMPONENT_DIRS variables is now deprecated. These variables should be defined as CMake lists, instead. For example, use:

```
set(EXTRA_COMPONENT_DIRS path1 path2)
list(APPEND EXTRA_COMPONENT_DIRS path3)
```

instead of:

```
set(EXTRA_COMPONENT_DIRS "path1 path2")
set(EXTRA_COMPONENT_DIRS "${EXTRA_COMPONENT_DIRS} path3")
```

Defining these variables as CMake lists is compatible with previous ESP-IDF versions.

Update Usage of target_link_libraries with project_elf ESP-IDF v5.0 fixes CMake variable propagation issues for components. This issue caused compiler flags and definitions that were supposed to apply to one component to be applied to every component in the project.

As a side effect of this, user projects from ESP-IDF v5.0 onwards must use target_link_libraries with project_elf explicitly and custom CMake projects must specify PRIVATE, PUBLIC, or INTERFACE arguments. This is a breaking change and is not backward compatible with previous ESP-IDF versions.

For example:

```
target_link_libraries(${project_elf} PRIVATE "-Wl,--wrap=esp_panic_handler")
```

instead of:

```
target_link_libraries(${project_elf} "-Wl,--wrap=esp_panic_handler")
```

Update CMake Version In ESP-IDF v5.0 minimal CMake version was increased to 3.16 and versions lower than 3.16 are not supported anymore. Run tools/idf_tools.py install cmake to install a suitable version if your OS version doesn't have one.

This affects ESP-IDF users who use system-provided CMake and custom CMake.

Reorder the Applying of the Target-Specific Config Files ESP-IDF v5.0 reorders the applying order of target-specific config files and other files listed in SDKCONFIG_DEFAULTS. Now, target-specific files will be applied right after the file brings it in, before all latter files in SDKCONFIG_DEFAULTS.

For example:

```
If ``SDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig_devkit1"``, and there is a␣
↪file ``sdkconfig.defaults.esp32`` in the same folder, then the files will be␣
↪applied in the following order: (1) sdkconfig.defaults (2) sdkconfig.defaults.
↪esp32 (3) sdkconfig_devkit1.
```

If you have a key with different values in the target-specific files of the former item (e.g., sdkconfig.defaults.esp32 above) and the latter item (e.g., sdkconfig_devkit1 above), please note the latter will override the target-specific file of the former.

If you do want to have some target-specific config values, please put it into the target-specific file of the latter item (e.g., `sdkconfig_devkit1.esp32`).

GCC

GCC Version The previous GCC version was GCC 8.4.0. This has now been upgraded to GCC 11.2.0 on all targets. Users that need to port their code from GCC 8.4.0 to 11.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 9
- Porting to GCC 10
- Porting to GCC 11

Warnings The upgrade to GCC 11.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user's code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter, and ways to suppress them.

> **Warning:** Users are advised to check that a warning is indeed a false positive before attempting to suppress them it.

`-Wstringop-overflow`, `-Wstringop-overread`, `-Wstringop-truncation`, and `-Warray-bounds` Users that use memory/string copy/compare functions will run into one of the `-Wstringop` warnings if the compiler cannot properly determine the size of the memory/string. The examples below demonstrate code that triggers these warnings and how to suppress them.

```
#pragma GCC diagnostic push
#pragma GCC diagnostic ignored "-Wstringop-overflow"
#pragma GCC diagnostic ignored "-Warray-bounds"
    memset(RTC_SLOW_MEM, 0, CONFIG_ULP_COPROC_RESERVE_MEM); // <<-- This line␣
↪leads to warnings
#pragma GCC diagnostic pop
```

```
#pragma GCC diagnostic push
#if     __GNUC__ >= 11
#pragma GCC diagnostic ignored "-Wstringop-overread" // <<-- This key had been␣
↪introduced since GCC 11
#endif
#pragma GCC diagnostic ignored "-Warray-bounds"
            memcpy(backup_write_data, (void *)EFUSE_PGM_DATA0_REG, sizeof(backup_
↪write_data)); // <<-- This line leads to warnings
#pragma GCC diagnostic pop
```

`-Waddress-of-packed-member` GCC will issue this warning when accessing an unaligned member of a packed `struct` due to the incurred penalty of unaligned memory access. However, all ESP chips (on both Xtensa and RISC-V architectures) allow for unaligned memory access and incur no extra penalty. Thus, this warning can be ignored in most cases.

```
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c: In function
↪'btc_to_bta_gatt_id':
components/bt/host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c:105:21: warning:␣
↪taking address of packed member of 'struct <anonymous>' may result in an␣
↪unaligned pointer value [-Waddress-of-packed-member]
  105 |     btc_to_bta_uuid(&p_dest->uuid, &p_src->uuid);
      |                     ^~~~~~~~~~~~
```

If the warning occurs in multiple places across multiple source files, users can suppress the warning at the CMake level as demonstrated below.

```
set_source_files_properties(
    "host/bluedroid/bta/gatt/bta_gattc_act.c"
    "host/bluedroid/bta/gatt/bta_gattc_cache.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatt_util.c"
    "host/bluedroid/btc/profile/std/gatt/btc_gatts.c"
    PROPERTIES COMPILE_FLAGS -Wno-address-of-packed-member)
```

However, if there are only one or two instances, users can suppress the warning directly in the source code itself as demonstrated below.

```
#pragma GCC diagnostic push
#if     __GNUC__ >= 9
#pragma GCC diagnostic ignored "-Waddress-of-packed-member" <<-- This key had been␣
↪introduced since GCC 9
#endif
    uint32_t* reg_ptr = (uint32_t*)src;
#pragma GCC diagnostic pop
```

`llabs()` for 64-bit Integers The function `abs()` from stdlib.h takes `int` argument. Please use `llabs()` for types that are intended to be 64-bit. It is particularly important for `time_t`.

Espressif Toolchain Changes

`int32_t` and `uint32_t` for Xtensa Compiler The types `int32_t` and `uint32_t` have been changed from the previous `int` and `unsigned int` to `long` and `unsigned long` respectively for the Xtensa compiler. This change now matches upstream GCC which `long` integers for `int32_t` and `uint32_t` on Xtensa, RISC-V, and other architectures.

	2021r2 and older, GCC 8	2022r1, GCC 11
Xtensa	(unsigned) int	(unsigned) long
riscv32	(unsigned) long	(unsigned) long

The change mostly affects code that formats strings using types provided by `<inttypes.h>`. When using these fixed-width types (e.g., `uint32_t`), users will need to replace placeholders such as `%i` and `%x` with `PRIi32` and `PRIx32` respectively. Types *not* defined in `<inttypes.h>` (e.g., `int`) do *not* need this special formatting.

In other cases, it should be noted that enums have the `int` type.

In common, `int32_t` and `int`, as well as `uint32_t` and `unsigned int`, are different types.

If users do not make the aforementioned updates to format strings in their applications, the following error will be reported during compilation:

```
/Users/name/esp/esp-rainmaker/components/esp-insights/components/esp_diagnostics/
↪include/esp_diagnostics.h:238:29: error: format '%u' expects argument of type
↪'unsigned int', but argument 3 has type 'uint32_t' {aka 'long unsigned int'} [-
↪Werror=format=]
238 |     esp_diag_log_event(tag, "EV (%u) %s: " format, esp_log_timestamp(), tag,
↪##__VA_ARGS__); \
    |                              ^~~~~~~~~~~~~~         ~~~~~~~~~~~~~~~~~~~
    |                                                     |
    |                                                     uint32_t {aka long␣
↪unsigned int}
                                                uint32_t {aka long unsigned int}
```

Removing `CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` Build Option `CONFIG_COMPILER_DISABLE_GCC8_WARNINGS` option was introduced to allow building of legacy code dating from the rigid GCC 5 toolchain. However, enough time has passed to allow for the warnings to be fixed, thus this option has been removed.

For now in GCC 11, users are advised to review their code and fix the compiler warnings where possible.

Networking

Wi-Fi

Callback Function Type `esp_now_recv_cb_t` Previously, the first parameter of `esp_now_recv_cb_t` was of type `const uint8_t *mac_addr`, which only included the address of ESP-NOW peer device.

This now changes. The first parameter is of type `esp_now_recv_info_t`, which has members `src_addr`, `des_addr` and `rx_ctrl`. Therefore, the following updates are required:

- Redefine ESP-NOW receive callback function.
- `src_addr` can be used to replace original `mac_addr`.
- `des_addr` is the destination MAC address of ESP-NOW packet, which can be unicast or broadcast address. With `des_addr`, the user can distinguish unicast and broadcast ESP-NOW packets where broadcast ESP-NOW packets can be non-encrypted even when encryption policy is configured for the ESP-NOW.
- `rx_ctrl` is Rx control info of the ESP-NOW packet, which provides more information about the packet.

Please refer to the ESP-NOW example: wifi/espnow/main/espnow_example_main.c

Ethernet

`esp_eth_ioctl()` API Previously, the *`esp_eth_ioctl()`* API had the following issues:

- The third parameter (which is of type `void *`) would accept an `int`/`bool` type arguments (i.e., not pointers) as input in some cases. However, these cases were not documented properly.
- To pass `int`/`bool` type argument as the third parameter, the argument had to be "unnaturally" casted to a `void *` type, to prevent a compiler warning as demonstrated in the code snippet below. This casting could lead to misuse of the *`esp_eth_ioctl()`* function.

```
esp_eth_ioctl(eth_handle, ETH_CMD_S_FLOW_CTRL, (void *)true);
```

Therefore, the usage of *`esp_eth_ioctl()`* is now unified. Arguments to the third parameter must be passed as pointers to a specific data type to/from where data is stored/read by *`esp_eth_ioctl()`*. The code snippets below demonstrate the usage of *`esp_eth_ioctl()`*.

Usage example to set Ethernet configuration:

```
eth_duplex_t new_duplex_mode = ETH_DUPLEX_HALF;
esp_eth_ioctl(eth_handle, ETH_CMD_S_DUPLEX_MODE, &new_duplex_mode);
```

Usage example to get Ethernet configuration:

```
eth_duplex_t duplex_mode;
esp_eth_ioctl(eth_handle, ETH_CMD_G_DUPLEX_MODE, &duplex_mode);
```

KSZ8041/81 and LAN8720 Driver Update The KSZ8041/81 and LAN8720 drivers are updated to support more devices (i.e., generations) from their associated product families. The drivers can recognize particular chip numbers and their potential support by the driver.

As a result, the specific "chip number" functions calls are replaced by generic ones as follows:

- Removed `esp_eth_phy_new_ksz8041()` and `esp_eth_phy_new_ksz8081()`, and use *`esp_eth_phy_new_ksz80xx()`* instead
- Removed `esp_eth_phy_new_lan8720()`, and use *`esp_eth_phy_new_lan87xx()`* instead

ESP NETIF Glue Event Handlers `esp_eth_set_default_handlers()` and `esp_eth_clear_default_handlers()` functions are removed. Registration of the default IP layer handlers for Ethernet is now handled automatically. If you have already followed the suggestion to fully initialize the Ethernet driver and network interface before registering their Ethernet/IP event handlers, then no action is required (except for deleting the affected functions). Otherwise, you may start the Ethernet driver right after they register the user event handler.

PHY Address Auto-detect The Ethernet PHY address auto-detect function `esp_eth_detect_phy_addr()` is renamed to *`esp_eth_phy_802_3_detect_phy_addr()`* and its header declaration is moved to esp_eth/include/esp_eth_phy_802_3.h.

SPI-Ethernet Module Initialization The SPI-Ethernet Module initialization is now simplified. Previously, you had to manually allocate an SPI device using *`spi_bus_add_device()`* before instantiating the SPI-Ethernet MAC.

Now, you no longer need to call *`spi_bus_add_device()`* as SPI devices are allocated internally. As a result, the `eth_dm9051_config_t`, `eth_w5500_config_t`, and `eth_ksz8851snl_config_t` configuration structures are updated to include members for SPI device configuration (e.g., to allow fine tuning of SPI timing which may be dependent on PCB design). Likewise, the `ETH_DM9051_DEFAULT_CONFIG`, `ETH_W5500_DEFAULT_CONFIG`, and `ETH_KSZ8851SNL_DEFAULT_CONFIG` configuration initialization macros are updated to accept new input parameters. Refer to *Ethernet API Reference Guide* for an example of SPI-Ethernet Module initialization.

TCP/IP Adapter The TCP/IP Adapter was a network interface abstraction component used in ESP-IDF prior to v4.1. This section outlines migration from `tcpip_adapter` API to its successor *ESP-NETIF*.

Updating Network Connection Code

Network Stack Initialization

- You may simply replace `tcpip_adapter_init()` with `esp_netif_init()`. However, please should note that the `esp_netif_init()` function now returns standard error codes. See *ESP-NETIF* for more details.
- The `esp_netif_deinit()` function is provided to de-initialize the network stack.
- You should also replace `#include "tcpip_adapter.h"` with `#include "esp_netif.h"`.

Network Interface Creation Previously, the TCP/IP Adapter defined the following network interfaces statically:

- WiFi Station
- WiFi Access Point
- Ethernet

This now changes. Network interface instance should be explicitly constructed, so that the *ESP-NETIF* can connect to the TCP/IP stack. For example, after the TCP/IP stack and the event loop are initialized, the initialization code for WiFi must explicitly call `esp_netif_create_default_wifi_sta();` or `esp_netif_create_default_wifi_ap();`.

Please refer to the example initialization code for these three interfaces:

- WiFi Station: wifi/getting_started/station/main/station_example_main.c
- WiFi Access Point: wifi/getting_started/softAP/main/softap_example_main.c
- Ethernet: ethernet/basic/main/ethernet_example_main.c

Other `tcpip_adapter` API Replacement All the `tcpip_adapter` functions have their `esp-netif` counter-part. Please refer to the `esp_netif.h` grouped into these sections:

- Setters/Getters
- DHCP
- DNS
- IP address

The TCP/IP Adapter API `tcpip_adapter_get_sta_list()` that was used to acquire a list of associated Wi-Fi stations to the Software Access Point (softAP) has been moved to the Wi-Fi component and renamed to `esp_wifi_ap_get_sta_list_with_ip()`, which is a special case of the ESP-NETIF API *`esp_netif_dhcps_get_clients_by_mac()`* that could be used more generally to provide a list of clients connected to a DHCP server no matter which network interface the server is running on.

Default Event Handlers Event handlers are moved from `tcpip_adapter` to appropriate driver code. There is no change from application code perspective, as all events should be handled in the same way. Please note that for IP-related event handlers, application code usually receives IP addresses in the form of an `esp-netif` specific struct instead of the LwIP structs. However, both structs are binary compatible.

This is the preferred way to print the address:

```
ESP_LOGI(TAG, "got ip:" IPSTR, IP2STR(&event->ip_info.ip));
```

Instead of

```
ESP_LOGI(TAG, "got ip:%s", ip4addr_ntoa(&event->ip_info.ip));
```

Since `ip4addr_ntoa()` is a LwIP API, the esp-netif provides `esp_ip4addr_ntoa()` as a replacement. However, the above method using `IP2STR()` is generally preferred.

IP Addresses You are advised to use `esp-netif` defined IP structures. Please note that with default compatibility enabled, the LwIP structs still work.

- esp-netif IP address definitions

Peripherals

Peripheral Clock Gating As usual, peripheral clock gating is still handled by driver itself, users do not need to take care of the peripheral module clock gating.

However, for advanced users who implement their own drivers based on `hal` and `soc` components, the previous clock gating include path has been changed from `driver/periph_ctrl.h` to `esp_private/periph_ctrl.h`.

RTC Subsystem Control RTC control APIs have been moved from `driver/rtc_cntl.h` to `esp_private/rtc_ctrl.h`.

ADC

ADC Oneshot & Continuous Mode Drivers The ADC oneshot mode driver has been redesigned.

- The new driver is in `esp_adc` component and the include path is `esp_adc/adc_oneshot.h`.
- The legacy driver is still available in the previous include path `driver/adc.h`.

The ADC continuous mode driver has been moved from `driver` component to `esp_adc` component.

- The include path has been changed from `driver/adc.h` to `esp_adc/adc_continuous.h`.

Attempting to use the legacy include path `driver/adc.h` of either driver triggers the build warning below by default. However, the warning can be suppressed by enabling the *CONFIG_ADC_SUPPRESS_DEPRECATE_WARN* Kconfig option.

```
legacy adc driver is deprecated, please migrate to use esp_adc/adc_oneshot.h and␣
↪esp_adc/adc_continuous.h for oneshot mode and continuous mode drivers␣
↪respectively
```

ADC Calibration Driver The ADC calibration driver has been redesigned.

- The new driver is in `esp_adc` component and the include path is `esp_adc/adc_cali.h` and `esp_adc/adc_cali_scheme.h`.

Legacy driver is still available by including `esp_adc_cal.h`. However, if users still would like to use the include path of the legacy driver, users should add `esp_adc` component to the list of component requirements in CMakeLists.txt.

Attempting to use the legacy include path `esp_adc_cal.h` triggers the build warning below by default. However, the warning can be suppressed by enabling the *CONFIG_ADC_CALI_SUPPRESS_DEPRECATE_WARN* Kconfig option.

```
legacy adc calibration driver is deprecated, please migrate to use esp_adc/adc_
↪cali.h and esp_adc/adc_cali_scheme.h
```

API Changes

- The ADC power management APIs `adc_power_acquire` and `adc_power_release` have made private and moved to `esp_private/adc_share_hw_ctrl.h`.
  - The two APIs were previously made public due to a HW errata workaround.
  - Now, ADC power management is completely handled internally by drivers.
  - Users who still require this API can include `esp_private/adc_share_hw_ctrl.h` to continue using these functions.
- `driver/adc2_wifi_private.h` has been moved to `esp_private/adc_share_hw_ctrl.h`.
- Enums `ADC_UNIT_BOTH`, `ADC_UNIT_ALTER`, and `ADC_UNIT_MAX` in `adc_unit_t` have been removed.
- The following enumerations have been removed as some of their enumeration values are not supported on all chips. This would lead to the driver triggering a runtime error if an unsupported value is used.
  - Enum `ADC_CHANNEL_MAX`
  - Enum `ADC_ATTEN_MAX`

  - Enum `ADC_CONV_UNIT_MAX`
- API `hall_sensor_read` on ESP32 has been removed. Hall sensor is no longer supported on ESP32.
- API `adc_set_i2s_data_source` and `adc_i2s_mode_init` have been deprecated. Related enum `adc_i2s_source_t` has been deprecated. Please migrate to use `esp_adc/adc_continuous.h`.
- API `adc_digi_filter_reset`, `adc_digi_filter_set_config`, `adc_digi_filter_get_config` and `adc_digi_filter_enable` have been removed. These APIs behaviours are not guaranteed. Enum `adc_digi_filter_idx_t`, `adc_digi_filter_mode_t` and structure `adc_digi_iir_filter_t` have been removed as well.
- API `esp_adc_cal_characterize` has been deprecated, please migrate to `adc_cali_create_scheme_curve_fitting` or `adc_cali_create_scheme_line_fitting` instead.
- API `esp_adc_cal_raw_to_voltage` has been deprecated, please migrate to `adc_cali_raw_to_voltage` instead.
- API `esp_adc_cal_get_voltage` has been deprecated, please migrate to `adc_oneshot_get_calibrated_result` instead.

GPIO

- The previous Kconfig option *RTCIO_SUPPORT_RTC_GPIO_DESC* has been removed, thus the `rtc_gpio_desc` array is unavailable. Please use `rtc_io_desc` array instead.
- The user callback of a GPIO interrupt should no longer read the GPIO interrupt status register to get the GPIO's pin number of triggering the interrupt. You should use the callback argument to determine the GPIO's pin number instead.
  - Previously, when a GPIO interrupt occurs, the GPIO's interrupt status register is cleared after calling the user callbacks. Thus, it was possible for users to read the GPIO's interrupt status register inside the callback to determine which GPIO was used to trigger the interrupt.
  - However, clearing the interrupt status register after calling the user callbacks can potentially cause edge-triggered interrupts to be lost. For example, if an edge-triggered interrupt is triggered/retriggered while the user callbacks are being called, that interrupt will be cleared without its registered user callback being handled.
  - Now, the GPIO's interrupt status register is cleared **before** invoking the user callbacks. Thus, users can no longer read the GPIO interrupt status register to determine which pin has triggered the interrupt. Instead, users should use the callback argument to pass the pin number.

Sigma-Delta Modulator The Sigma-Delta Modulator driver has been redesigned into *SDM*.

- The new driver implements a factory pattern, where the SDM channels are managed in a pool internally, thus users do not have to fix a SDM channel to a GPIO manually.
- All SDM channels can be allocated dynamically.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/sigmadelta.h`. However, by default, including `driver/sigmadelta.h` triggers the build warning below. The warning can be suppressed by Kconfig option *CONFIG_SDM_SUPPRESS_DEPRECATE_WARN*.

```
The legacy sigma-delta driver is deprecated, please use driver/sdm.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- SDM channel representation has changed from `sigmadelta_channel_t` to *`sdm_channel_handle_t`*, which is an opaque pointer.
- SDM channel configurations are stored in *`sdm_config_t`* now, instead the previous `sigmadelta_config_t`.
- In the legacy driver, users do not have to set the clock source for SDM channel. But in the new driver, users need to set a proper one in the *`sdm_config_t::clk_src`*. The available clock sources are listed in the *`soc_periph_sdm_clk_src_t`*.

- In the legacy driver, users need to set a `prescale` for the channel, which reflects the frequency in which the modulator outputs a pulse. In the new driver, users should use *`sdm_config_t::sample_rate_hz`* to set the over sample rate.
- In the legacy driver, users set `duty` to decide the output analog value, it is now renamed to a more appropriate name `density`.

Breaking Changes in Usage

- Channel configuration was done by channel allocation, in *`sdm_new_channel()`*. In the new driver, only the `density` can be changed at runtime, by *`sdm_channel_set_pulse_density()`*. Other parameters like `gpio number` and `prescale` are only allowed to set during channel allocation.
- Before further channel operations, users should **enable** the channel in advance, by calling *`sdm_channel_enable()`*. This function helps to manage some system level services, like **Power Management**.

Timer Group Driver Timer Group driver has been redesigned into *GPTimer*, which aims to unify and simplify the usage of general purpose timer.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/timer.h`. However, by default, including `driver/timer.h` triggers the build warning below. The warning can be suppressed by the Kconfig option *CONFIG_GPTIMER_SUPPRESS_DEPRECATE_WARN*.

```
legacy timer group driver is deprecated, please migrate to driver/gptimer.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- `timer_group_t` and `timer_idx_t` which used to identify the hardware timer are removed from user's code. In the new driver, a timer is represented by *`gptimer_handle_t`*.
- Definition of timer clock source is moved to *`gptimer_clock_source_t`*, the previous `timer_src_clk_t` is not used.
- Definition of timer count direction is moved to *`gptimer_count_direction_t`*, the previous `timer_count_dir_t` is not used.
- Only level interrupt is supported, `timer_intr_t` and `timer_intr_mode_t` are not used.
- Auto-reload is enabled by set the *`gptimer_alarm_config_t::auto_reload_on_alarm`* flag. `timer_autoreload_t` is not used.

Breaking Changes in Usage

- Timer initialization is done by creating a timer instance from *`gptimer_new_timer()`*. Basic configurations like clock source, resolution and direction should be set in *`gptimer_config_t`*. Note that, specific configurations of alarm events are not needed during the installation stage of the driver.
- Alarm event is configured by *`gptimer_set_alarm_action()`*, with parameters set in the *`gptimer_alarm_config_t`*.
- Setting and getting count value are done by *`gptimer_get_raw_count()`* and *`gptimer_set_raw_count()`*. The driver does not help convert the raw value into UTC time-stamp. Instead, the conversion should be done from user's side as the timer resolution is also known to the user.
- The driver will install the interrupt service as well if *`gptimer_event_callbacks_t::on_alarm`* is set to a valid callback function. In the callback, users do not have to deal with the low level registers (like "clear interrupt status", "re-enable alarm event" and so on). So functions like `timer_group_get_intr_status_in_isr` and `timer_group_get_auto_reload_in_isr` are not used anymore.
- To update the alarm configurations when alarm event happens, one can call *`gptimer_set_alarm_action()`* in the interrupt callback, then the alarm will be re-enabled again.
- Alarm will always be re-enabled by the driver if *`gptimer_alarm_config_t::auto_reload_on_alarm`* is set to true.

UART

Removed/Deprecated items	Replacement	Remarks
`uart_isr_register()`	None	UART interrupt handling is implemented by driver itself.
`uart_isr_free()`	None	UART interrupt handling is implemented by driver itself.
`use_ref_tick` in *`uart_config_t`*	*`uart_config_t::source_clk`*	Select the clock source.
`uart_enable_pattern_det_intr()`	*`uart_enable_pattern_det_baud_intr()`*	Enable pattern detection interrupt.

I2C

Removed/Deprecated items	Replacement	Remarks
`i2c_isr_register()`	None	I2C interrupt handling is implemented by driver itself.
`i2c_isr_register()`	None	I2C interrupt handling is implemented by driver itself.
`i2c_opmode_t`	None	It is not used anywhere in ESP-IDF.

SPI

Removed/Deprecated items	Replacement	Remarks
`spi_cal_clock()`	*`spi_get_actual_clock()`*	Get SPI real working frequency.

- The internal header file `spi_common_internal.h` has been moved to `esp_private/spi_common_internal.h`.

SDMMC

Removed/Deprecated items	Replacement	Remarks
`sdmmc_host_pullup_en()`	set `SDMMC_SLOT_FLAG_INTERNAL_PULLUP` flag in *`sdmmc_slot_config_t::flags`*	Enable internal pull up.

LEDC

Removed/Deprecated items	Replacement	Remarks
`bit_num` in *`ledc_timer_config_t`*	*`ledc_timer_config_t::duty_resolution`*	Set resolution of the duty cycle.

Pulse Counter Driver Pulse counter driver has been redesigned (see *PCNT*), which aims to unify and simplify the usage of PCNT peripheral.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/pcnt.h`. However, including `driver/pcnt.h` triggers the build warning below by default. The warning can be suppressed by the Kconfig option *CONFIG_PCNT_SUPPRESS_DEPRECATE_WARN*.

```
legacy pcnt driver is deprecated, please migrate to use driver/pulse_cnt.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- `pcnt_port_t`, `pcnt_unit_t` and `pcnt_channel_t` which used to identify the hardware unit and channel are removed from user's code. In the new driver, PCNT unit is represented by *`pcnt_unit_handle_t`*, likewise, PCNT channel is represented by *`pcnt_channel_handle_t`*. Both of them are opaque pointers.

- pcnt_evt_type_t is not used any more, they have been replaced by a universal **Watch Point Event**. In the event callback *pcnt_watch_cb_t*, it is still possible to distinguish different watch points from *pcnt_watch_event_data_t*.
- pcnt_count_mode_t is replaced by *pcnt_channel_edge_action_t*, and pcnt_ctrl_mode_t is replaced by *pcnt_channel_level_action_t*.

Breaking Changes in Usage

- Previously, the PCNT unit configuration and channel configuration were combined into a single function: pcnt_unit_config. They are now split into the two factory APIs: *pcnt_new_unit()* and *pcnt_new_channel()* respectively.
  - Only the count range is necessary for initializing a PCNT unit. GPIO number assignment has been moved to *pcnt_new_channel()*.
  - High/Low control mode and positive/negative edge count mode are set by stand-alone functions: *pcnt_channel_set_edge_action()* and *pcnt_channel_set_level_action()*.
- pcnt_get_counter_value is replaced by *pcnt_unit_get_count()*.
- pcnt_counter_pause is replaced by *pcnt_unit_stop()*.
- pcnt_counter_resume is replaced by *pcnt_unit_start()*.
- pcnt_counter_clear is replaced by *pcnt_unit_clear_count()*.
- pcnt_intr_enable and pcnt_intr_disable are removed. In the new driver, the interrupt is enabled by registering event callbacks *pcnt_unit_register_event_callbacks()*.
- pcnt_event_enable and pcnt_event_disable are removed. In the new driver, the PCNT events are enabled/disabled by adding/removing watch points *pcnt_unit_add_watch_point()*, *pcnt_unit_remove_watch_point()*.
- pcnt_set_event_value is removed. In the new driver, event value is also set when adding watch point by *pcnt_unit_add_watch_point()*.
- pcnt_get_event_value and pcnt_get_event_status are removed. In the new driver, these information are provided by event callback *pcnt_watch_cb_t* in the *pcnt_watch_event_data_t*.
- pcnt_isr_register and pcnt_isr_unregister are removed. Register of the ISR handler from user's code is no longer permitted. Users should register event callbacks instead by calling *pcnt_unit_register_event_callbacks()*.
- pcnt_set_pin is removed and the new driver no longer allows the switching of the GPIO at runtime. If users want to change to other GPIOs, please delete the existing PCNT channel by *pcnt_del_channel()* and reinstall with the new GPIO number by *pcnt_new_channel()*.
- pcnt_filter_enable, pcnt_filter_disable and pcnt_set_filter_value are replaced by *pcnt_unit_set_glitch_filter()*. Meanwhile, pcnt_get_filter_value has been removed.
- pcnt_set_mode is replaced by *pcnt_channel_set_edge_action()* and *pcnt_channel_set_level_action()*.
- pcnt_isr_service_install, pcnt_isr_service_uninstall, pcnt_isr_handler_add and pcnt_isr_handler_remove are replaced by *pcnt_unit_register_event_callbacks()*. The default ISR handler is lazy installed in the new driver.

Temperature Sensor Driver The temperature sensor driver has been redesigned and it is recommended to use the new driver. However, the old driver is still available but cannot be used with the new driver simultaneously.

The new driver can be included via driver/temperature_sensor.h. The old driver is still available in the previous include path driver/temp_sensor.h. However, including driver/temp_sensor.h triggers the build warning below by default. The warning can be suppressed by enabling the menuconfig option *CONFIG_TEMP_SENSOR_SUPPRESS_DEPRECATE_WARN*.

```
legacy temperature sensor driver is deprecated, please migrate to driver/
↪temperature_sensor.h
```

Configuration contents has been changed. In the old version, users need to configure clk_div and dac_offset. While in the new version, users only need to choose tsens_range.

The process of using temperature sensor has been changed. In the old version, users can use `config->start->read_celsius` to get value. In the new version, users should install the temperature sensor driver firstly, by `temperature_sensor_install` and uninstall it when finished. For more information, please refer to *Temperature Sensor* .

RMT Driver RMT driver has been redesigned (see *RMT transceiver*), which aims to unify and extend the usage of RMT peripheral.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/rmt.h`. However, including `driver/rmt.h` triggers the build warning below by default. The warning can be suppressed by the Kconfig option *CONFIG_RMT_SUPPRESS_DEPRECATE_WARN*.

```
The legacy RMT driver is deprecated, please use driver/rmt_tx.h and/or driver/rmt_
↪rx.h
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts

- `rmt_channel_t` which used to identify the hardware channel are removed from user space. In the new driver, RMT channel is represented by *`rmt_channel_handle_t`*. The channel is dynamically allocated by the driver, instead of designated by user.
- `rmt_item32_t` is replaced by *`rmt_symbol_word_t`*, which avoids a nested union inside a struct.
- `rmt_mem_t` is removed, as we do not allow users to access RMT memory block (a.k.an RMTMEM) directly. Direct access to RMTMEM does not make sense but make mistakes, especially when the RMT channel also connected with a DMA channel.
- `rmt_mem_owner_t` is removed, as the ownership is controlled by driver, not by user anymore.
- `rmt_source_clk_t` is replaced by *`rmt_clock_source_t`*, and note they are not binary compatible.
- `rmt_data_mode_t` is removed, the RMT memory access mode is configured to always use Non-FIFO and DMA mode.
- `rmt_mode_t` is removed, as the driver has stand alone install functions for TX and RX channels.
- `rmt_idle_level_t` is removed, setting IDLE level for TX channel is available in *`rmt_transmit_config_t::eot_level`*.
- `rmt_carrier_level_t` is removed, setting carrier polarity is available in *`rmt_carrier_config_t::polarity_active_low`*.
- `rmt_channel_status_t` and `rmt_channel_status_result_t` are removed, they are not used anywhere.
- Transmitting by RMT channel does not expect user to prepare the RMT symbols, instead, user needs to provide an RMT Encoder to tell the driver how to convert user data into RMT symbols.

Breaking Changes in Usage

- Channel installation has been separated for TX and RX channels into *`rmt_new_tx_channel()`* and *`rmt_new_rx_channel()`*.
- `rmt_set_clk_div` and `rmt_get_clk_div` are removed. Channel clock configuration can only be done during channel installation.
- `rmt_set_rx_idle_thresh` and `rmt_get_rx_idle_thresh` are removed. In the new driver, the RX channel IDLE threshold is redesigned into a new concept *`rmt_receive_config_t::signal_range_max_ns`*.
- `rmt_set_mem_block_num` and `rmt_get_mem_block_num` are removed. In the new driver, the memory block number is determined by *`rmt_tx_channel_config_t::mem_block_symbols`* and *`rmt_rx_channel_config_t::mem_block_symbols`*.
- `rmt_set_tx_carrier` is removed, the new driver uses *`rmt_apply_carrier()`* to set carrier behavior.
- `rmt_set_mem_pd` and `rmt_get_mem_pd` are removed. The memory power is managed by the driver automatically.
- `rmt_memory_rw_rst`, `rmt_tx_memory_reset` and `rmt_rx_memory_reset` are removed. Memory reset is managed by the driver automatically.

- `rmt_tx_start` and `rmt_rx_start` are merged into a single function *`rmt_enable()`*, for both TX and RX channels.
- `rmt_tx_stop` and `rmt_rx_stop` are merged into a single function *`rmt_disable()`*, for both TX and RX channels.
- `rmt_set_memory_owner` and `rmt_get_memory_owner` are removed. RMT memory owner guard is added automatically by the driver.
- `rmt_set_tx_loop_mode` and `rmt_get_tx_loop_mode` are removed. In the new driver, the loop mode is configured in *`rmt_transmit_config_t::loop_count`*.
- `rmt_set_source_clk` and `rmt_get_source_clk` are removed. Configuring clock source is only possible during channel installation by *`rmt_tx_channel_config_t::clk_src`* and *`rmt_rx_channel_config_t::clk_src`*.
- `rmt_set_rx_filter` is removed. In the new driver, the filter threshold is redesigned into a new concept *`rmt_receive_config_t::signal_range_min_ns`*.
- `rmt_set_idle_level` and `rmt_get_idle_level` are removed. Setting IDLE level for TX channel is available in *`rmt_transmit_config_t::eot_level`*.
- `rmt_set_rx_intr_en`, `rmt_set_err_intr_en`, `rmt_set_tx_intr_en`, `rmt_set_tx_thr_intr_en` and `rmt_set_rx_thr_intr_en` are removed. The new driver does not allow user to turn on/off interrupt from user space. Instead, it provides callback functions.
- `rmt_set_gpio` and `rmt_set_pin` are removed. The new driver does not support to switch GPIO dynamically at runtime.
- `rmt_config` is removed. In the new driver, basic configuration is done during the channel installation stage.
- `rmt_isr_register` and `rmt_isr_deregister` are removed, the interrupt is allocated by the driver itself.
- `rmt_driver_install` is replaced by *`rmt_new_tx_channel()`* and *`rmt_new_rx_channel()`*.
- `rmt_driver_uninstall` is replaced by *`rmt_del_channel()`*.
- `rmt_fill_tx_items`, `rmt_write_items` and `rmt_write_sample` are removed. In the new driver, user needs to provide an encoder to "translate" the user data into RMT symbols.
- `rmt_get_counter_clock` is removed, as the channel clock resolution is configured by user from *`rmt_tx_channel_config_t::resolution_hz`*.
- `rmt_wait_tx_done` is replaced by *`rmt_tx_wait_all_done()`*.
- `rmt_translator_init`, `rmt_translator_set_context` and `rmt_translator_get_context` are removed. In the new driver, the translator has been replaced by the RMT encoder.
- `rmt_get_ringbuf_handle` is removed. The new driver does not use Ringbuffer to save RMT symbols. Instead, the incoming data are saved to the user provided buffer directly. The user buffer can even be mounted to DMA link internally.
- `rmt_register_tx_end_callback` is replaced by *`rmt_tx_register_event_callbacks()`*, where user can register *`rmt_tx_event_callbacks_t::on_trans_done`* event callback.
- `rmt_set_intr_enable_mask` and `rmt_clr_intr_enable_mask` are removed, as the interrupt is handled by the driver, user does not need to take care of it.
- `rmt_add_channel_to_group` and `rmt_remove_channel_from_group` are replaced by RMT sync manager. Please refer to *`rmt_new_sync_manager()`*.
- `rmt_set_tx_loop_count` is removed. The loop count in the new driver is configured in *`rmt_transmit_config_t::loop_count`*.
- `rmt_enable_tx_loop_autostop` is removed. In the new driver, TX loop auto stop is always enabled if available, it is not configurable anymore.

LCD

- The LCD panel initialization flow is slightly changed. Now the *`esp_lcd_panel_init()`* will not turn on the display automatically. User needs to call *`esp_lcd_panel_disp_on_off()`* to manually turn on the display. Note, this is different from turning on backlight. With this breaking change, user can flash a predefined pattern to the screen before turning on the screen. This can help avoid random noise on the screen after a power on reset.
- *`esp_lcd_panel_disp_off()`* is deprecated, please use *`esp_lcd_panel_disp_on_off()`* instead.
- `dc_as_cmd_phase` is removed. The SPI LCD driver currently does not support a 9-bit SPI LCD. Please always use a dedicated GPIO to control the LCD D/C line.

- The way to register RGB panel event callbacks has been moved from the *esp_lcd_rgb_panel_config_t* into a separate API *esp_lcd_rgb_panel_register_event_callbacks()*. However, the event callback signature is not changed.
- Previous `relax_on_idle` flag in *esp_lcd_rgb_panel_config_t* has been renamed into *esp_lcd_rgb_panel_config_t::refresh_on_demand*, which expresses the same meaning but with a clear name.
- If the RGB LCD is created with the `refresh_on_demand` flag enabled, the driver will not start a refresh in the *esp_lcd_panel_draw_bitmap()*. Now users have to call *esp_lcd_rgb_panel_refresh()* to refresh the screen by themselves.
- `esp_lcd_color_space_t` is deprecated, please use *lcd_color_space_t* to describe the color space, and use *lcd_rgb_element_order_t* to describe the data order of RGB color.

MCPWM MCPWM driver was redesigned (see *MCPWM*), meanwhile, the legacy driver is deprecated.

The new driver's aim is to make each MCPWM submodule independent to each other, and give the freedom of resource connection back to users.

Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/mcpwm.h`. However, using legacy driver triggers the build warning below by default. This warning can be suppressed by the Kconfig option *CONFIG_MCPWM_SUPPRESS_DEPRECATE_WARN*.

```
legacy MCPWM driver is deprecated, please migrate to the new driver (include␣
↪driver/mcpwm_prelude.h)
```

The major breaking changes in concept and usage are listed as follows:

Breaking Changes in Concepts The new MCPWM driver is object-oriented, where most of the MCPWM submodule has a driver object associated with it. The driver object is created by factory function like *mcpwm_new_timer()*. IO control function always needs an object handle, in the first place.

The legacy driver has an inappropriate assumption, that is the MCPWM operator should be connected to different MCPWM timer. In fact, the hardware does not have such limitation. In the new driver, a MCPWM timer can be connected to multiple operators, so that the operators can achieve the best synchronization performance.

The legacy driver presets the way to generate a PWM waveform into a so called `mcpwm_duty_type_t`. However, the duty cycle modes listed there are far from sufficient. Likewise, legacy driver has several preset `mcpwm_deadtime_type_t`, which also does not cover all the use cases. What is more, user usually gets confused by the name of the duty cycle mode and dead-time mode. In the new driver, there are no such limitation, but user has to construct the generator behavior from scratch.

In the legacy driver, the ways to synchronize the MCPWM timer by GPIO, software and other timer module are not unified. It increased learning costs for users. In the new driver, the synchronization APIs are unified.

The legacy driver has mixed the concepts of "Fault detector" and "Fault handler". Which make the APIs very confusing to users. In the new driver, the fault object just represents a failure source, and we introduced a new concept -- **brake** to express the concept of "Fault handler". What is more, the new driver supports software fault.

The legacy drive only provides callback functions for the capture submodule. The new driver provides more useful callbacks for various MCPWM submodules, like timer stop, compare match, fault enter, brake, etc.

- `mcpwm_io_signals_t` and `mcpwm_pin_config_t` are not used. GPIO configuration has been moved into submodule's configuration structure.
- `mcpwm_timer_t`, `mcpwm_generator_t` are not used. Timer and generator are represented by *mcpwm_timer_handle_t* and *mcpwm_gen_handle_t*.
- `mcpwm_fault_signal_t` and `mcpwm_sync_signal_t` are not used. Fault and sync source are represented by *mcpwm_fault_handle_t* and *mcpwm_sync_handle_t*.
- `mcpwm_capture_signal_t` is not used. A capture channel is represented by *mcpwm_cap_channel_handle_t*.

Breaking Changes in Usage

- mcpwm_gpio_init and mcpwm_set_pin: GPIO configurations are moved to submodule's own configuration. e.g., set the PWM GPIO in *mcpwm_generator_config_t::gen_gpio_num*.
- mcpwm_init: To get an expected PWM waveform, users need to allocated at least one MCPWM timer and MCPWM operator, then connect them by calling *mcpwm_operator_connect_timer()*. After that, users should set the generator's actions on various events by calling e.g., *mcpwm_generator_set_actions_on_timer_event()*, *mcpwm_generator_set_actions_on_compare_event()*.
- mcpwm_group_set_resolution: in the new driver, the group resolution is fixed to the maximum, usually it is 80 MHz.
- mcpwm_timer_set_resolution: MCPWM Timer resolution is set in *mcpwm_timer_config_t::resolution_hz*.
- mcpwm_set_frequency: PWM frequency is determined by *mcpwm_timer_config_t::resolution_hz*, *mcpwm_timer_config_t::count_mode* and *mcpwm_timer_config_t::period_ticks*.
- mcpwm_set_duty: To set the PWM duty cycle, users should call *mcpwm_comparator_set_compare_value()* to change comparator's threshold.
- mcpwm_set_duty_type: There is no preset duty cycle types. The duty cycle type is configured by setting different generator actions. e.g., *mcpwm_generator_set_actions_on_timer_event()*.
- mcpwm_set_signal_high and mcpwm_set_signal_low are replaced by *mcpwm_generator_set_force_level()*. In the new driver, it is implemented by setting force action for the generator, instead of changing the duty cycle to 0% or 100% at the background.
- mcpwm_start and mcpwm_stop are replaced by *mcpwm_timer_start_stop()*. You have more modes to start and stop the MCPWM timer, see *mcpwm_timer_start_stop_cmd_t*.
- mcpwm_carrier_init is replaced by *mcpwm_operator_apply_carrier()*.
- mcpwm_carrier_enable and mcpwm_carrier_disable: Enabling and disabling carrier submodule is done automatically by checking whether the carrier configuration structure *mcpwm_carrier_config_t* is NULL.
- mcpwm_carrier_set_period is replaced by *mcpwm_carrier_config_t::frequency_hz*.
- mcpwm_carrier_set_duty_cycle is replaced by *mcpwm_carrier_config_t::duty_cycle*.
- mcpwm_carrier_oneshot_mode_enable is replaced by *mcpwm_carrier_config_t::first_pulse_durat*
- mcpwm_carrier_oneshot_mode_disable is removed. Disabling the first pulse (a.k.a the one-shot pulse) in the carrier is never supported by the hardware.
- mcpwm_carrier_output_invert is replaced by *mcpwm_carrier_config_t::invert_before_modulate* and *mcpwm_carrier_config_t::invert_after_modulate*.
- mcpwm_deadtime_enable and mcpwm_deadtime_disable are replaced by *mcpwm_generator_set_dead_time()*.
- mcpwm_fault_init is replaced by *mcpwm_new_gpio_fault()*.
- mcpwm_fault_set_oneshot_mode, mcpwm_fault_set_cyc_mode are replaced by *mcpwm_operator_set_brake_on_fault()* and *mcpwm_generator_set_actions_on_brake_event()*.
- mcpwm_capture_enable is removed. It is duplicated to mcpwm_capture_enable_channel().
- mcpwm_capture_disable is removed. It is duplicated to mcpwm_capture_capture_disable_channel().
- mcpwm_capture_enable_channel and mcpwm_capture_disable_channel are replaced by *mcpwm_capture_channel_enable()* and *mcpwm_capture_channel_disable()*.
- mcpwm_capture_signal_get_value and mcpwm_capture_signal_get_edge: Capture timer count value and capture edge are provided in the capture event callback, via *mcpwm_capture_event_data_t*. Capture data are only valuable when capture event happens. Providing single API to fetch capture data is meaningless.
- mcpwm_sync_enable is removed. It is duplicated to mcpwm_sync_configure().
- mcpwm_sync_configure is replaced by *mcpwm_timer_set_phase_on_sync()*.
- mcpwm_sync_disable is equivalent to setting *mcpwm_timer_sync_phase_config_t::sync_src* to NULL.
- mcpwm_set_timer_sync_output is replaced by *mcpwm_new_timer_sync_src()*.
- mcpwm_timer_trigger_soft_sync is replaced by *mcpwm_soft_sync_activate()*.
- mcpwm_sync_invert_gpio_synchro is equivalent to setting *mcpwm_gpio_sync_src_config_t::active_ne*
- mcpwm_isr_register is removed. You can register various event callbacks instead. For example, to register capture event callback, users can use *mcpwm_capture_channel_register_event_callbacks()*.

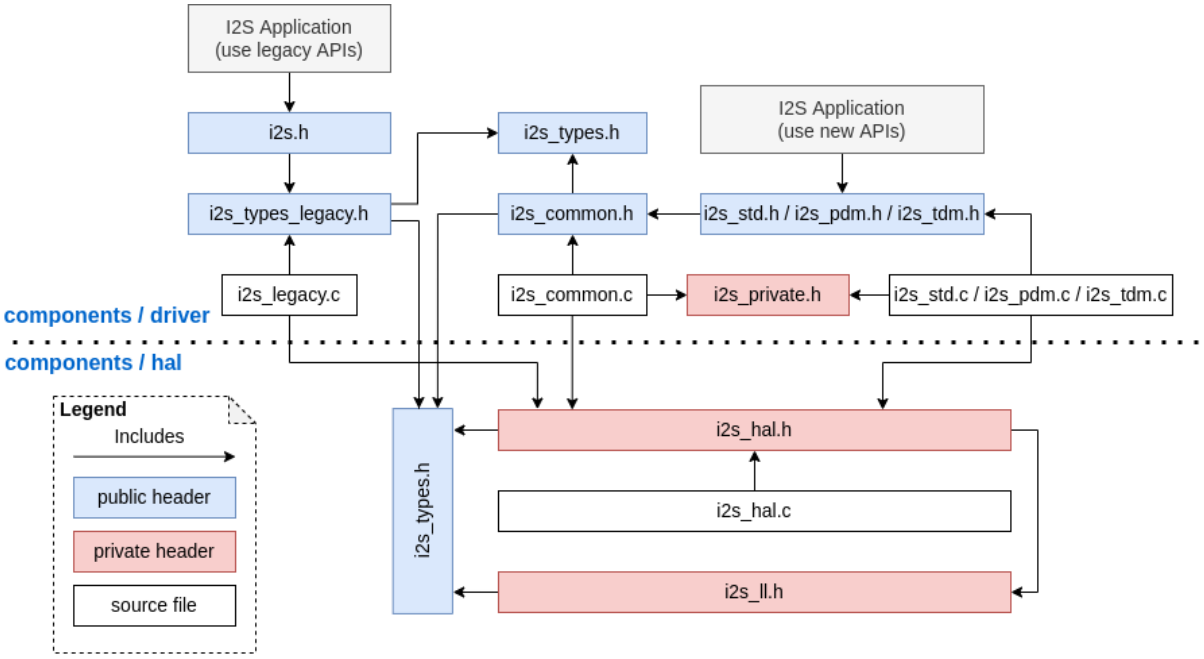
Dedicated GPIO Driver

- All of the dedicated GPIO related Low Level (LL) functions in `cpu_ll.h` have been moved to `dedic_gpio_cpu_ll.h` and renamed.

I2S Driver The I2S driver has been redesigned (see *I2S Driver*), which aims to rectify the shortcomings of the driver that were exposed when supporting all the new features of ESP32-C3 & ESP32-S3. The new driver's APIs are available by including corresponding I2S mode's header files driver/i2s/include/driver/i2s_std.h, driver/i2s/include/driver/i2s_pdm.h, or driver/i2s/include/driver/i2s_tdm.h.

Meanwhile, the old driver's APIs in driver/deprecated/driver/i2s.h are still supported for backward compatibility. But there will be warnings if users keep using the old APIs in their projects, these warnings can be suppressed by the Kconfig option *CONFIG_I2S_SUPPRESS_DEPRECATE_WARN*.

Here is the general overview of the current I2S files:



Breaking changes in Concepts

Independent TX/RX channels The minimum control unit in new I2S driver are now individual TX/RX channels instead of an entire I2S controller (that consistes of multiple channels).

- The TX and RX channels of the same I2S controller can be controlled separately, meaning that they are configured such that they can be started or stopped separately.
- The `i2s_chan_handle_t` handle type is used to uniquely identify I2S channels. All the APIs require the channel handle and users need to maintain the channel handles by themselves.
- On the ESP32-C3 and ESP32-S3, TX and RX channels in the same controller can be configured to different clocks or modes.
- However, on the ESP32 and ESP32-S2, the TX and RX channels of the same controller still share some hardware resources. Thus, configurations may cause one channel to affect another channel in the same controller.
- The channels can be registered to an available I2S controller automatically by setting `i2s_port_t::I2S_NUM_AUTO` as I2S port ID which causes the driver to search for the available TX/RX channels. However, the driver also supports registering channels to a specific port.
- In order to distinguish between TX/RX channels and sound channels, the term "channel" in the context of the I2S driver only refers to TX/RX channels. Meanwhile, sound channels are referred to as "slots".

I2S Mode Categorization I2S communication modes are categorized into the following three modes. Note that:

- **Standard mode**: Standard mode always has two slots, it can support Philips, MSB, and PCM (short frame sync) formats. Please refer to driver/i2s/include/driver/i2s_std.h for more details.
- **PDM mode**: PDM mode only supports two slots with 16-bit data width, but the configurations of PDM TX and PDM RX are slightly different. For PDM TX, the sample rate can be set by `i2s_pdm_tx_clk_config_t::sample_rate`, and its clock frequency depends on the up-sampling configuration. For PDM RX, the sample rate can be set by `i2s_pdm_rx_clk_config_t::sample_rate`, and its clock frequency depends on the down-sampling configuration. Please refer to driver/i2s/include/driver/i2s_pdm.h for details.
- **TDM mode**: TDM mode can support up to 16 slots. It can work in Philips, MSB, PCM (short frame sync), and PCM (long frame sync) formats. Please refer to driver/i2s/include/driver/i2s_tdm.h for details.

When allocating a new channel in a specific mode, users should initialize that channel by its corresponding function. It is strongly recommended to use the helper macros to generate the default configurations in case the default values are changed in the future.

Independent Slot and Clock Configuration The slot configurations and clock configurations can be configured separately.

- Call *`i2s_channel_init_std_mode()`*, *`i2s_channel_init_pdm_rx_mode()`*, *`i2s_channel_init_pdm_tx_mode()`*, or *`i2s_channel_init_tdm_mode()`* to initialize the slot/clock/gpio_pin configurations.
- Calling *`i2s_channel_reconfig_std_slot()`*, *`i2s_channel_reconfig_pdm_rx_slot()`*, *`i2s_channel_reconfig_pdm_tx_slot()`*, or *`i2s_channel_reconfig_tdm_slot()`* can change the slot configurations after initialization.
- Calling *`i2s_channel_reconfig_std_clock()`*, *`i2s_channel_reconfig_pdm_rx_clock()`*, *`i2s_channel_reconfig_pdm_tx_clock()`*, or *`i2s_channel_reconfig_tdm_clock()`* can change the clock configurations after initialization.
- Calling *`i2s_channel_reconfig_std_gpio()`*, *`i2s_channel_reconfig_pdm_rx_gpio()`*, *`i2s_channel_reconfig_pdm_tx_gpio()`*, or *`i2s_channel_reconfig_tdm_gpio()`* can change the GPIO configurations after initialization.

Misc

- States and state-machine are adopted in the new I2S driver to avoid APIs called in wrong state.
- ADC and DAC modes are removed. They are only supported in their own drivers and the legacy I2S driver.

Breaking Changes in Usage To use the new I2S driver, please follow these steps:

1. Call *`i2s_new_channel()`* to acquire channel handles. We should specify the work role and I2S port in this step. Besides, the TX or RX channel handle will be generated by the driver. Inputting both two TX and RX channel handles is not necessary but at least one handle is needed. In the case of inputting both two handles, the driver will work at the duplex mode. Both TX and RX channels will be avaliable on a same port, and they will share the MCLK, BCLK and WS signal. But if only one of the TX or RX channel handle is inputted, this channel will only work in the simplex mode.
2. Call `i2s_channel_init_std_mode()`, `i2s_channel_init_pdm_rx_mode()`, `i2s_channel_init_pdm_tx_mode()` or `i2s_channel_init_tdm_mode()` to initialize the channel to the specified mode. Corresponding slot, clock and GPIO configurations are needed in this step.
3. (Optional) Call *`i2s_channel_register_event_callback()`* to register the ISR event callback functions. I2S events now can be received by the callback function synchronously, instead of from the event queue asynchronously.
4. Call *`i2s_channel_enable()`* to start the hardware of I2S channel. In the new driver, I2S does not start automatically after installed, and users are supposed to know clearly whether the channel has started or not.
5. Read or write data by *`i2s_channel_read()`* or *`i2s_channel_write()`*. Certainly, only the RX channel handle is suppoesd to be inputted in *`i2s_channel_read()`* and the TX channel handle in *`i2s_channel_write()`*.
6. (Optional) The slot, clock and GPIO configurations can be changed by corresponding 'reconfig' functions, but *`i2s_channel_disable()`* must be called before updating the configurations.

7. Call *i2s_channel_disable()* to stop the hardware of I2S channel.
8. Call *i2s_del_channel()* to delete and release the resources of the channel if it is not needed any more, but the channel must be disabled before deleting it.

TWAI Driver The deprecated `CAN` peripheral driver is removed. Please use `TWAI` driver instead (i.e., include `driver/twai.h` in your application).

Register Access Macros Previously, all register access macros could be used as expressions, so the following was allowed:

```
uint32_t val = REG_SET_BITS(reg, bits, mask);
```

In ESP-IDF v5.0, register access macros which write or read-modify-write the register can no longer be used as expressions, and can only be used as statements. This applies to the following macros: `REG_WRITE`, `REG_SET_BIT`, `REG_CLR_BIT`, `REG_SET_BITS`, `REG_SET_FIELD`, `WRITE_PERI_REG`, `CLEAR_PERI_REG_MASK`, `SET_PERI_REG_MASK`, `SET_PERI_REG_BITS`.

To store the value which would have been written into the register, split the operation as follows:

```
uint32_t new_val = REG_READ(reg) | mask;
REG_WRITE(reg, new_val);
```

To get the value of the register after modification (which may be different from the value written), add an explicit read:

```
REG_SET_BITS(reg, bits, mask);
uint32_t new_val = REG_READ(reg);
```

Protocols

Mbed TLS For ESP-IDF v5.0, Mbed TLS has been updated from v2.x to v3.1.0.

For more details about Mbed TLS's migration from version 2.x to version 3.0 or greater, please refer to the official guide.

Breaking Changes (Summary)

Most Structure Fields Are Now Private

- Direct access to fields of structures (`struct` types) declared in public headers is no longer supported.
- Appropriate accessor functions (getter/setter) must be used for the same. A temporary workaround would be to use `MBEDTLS_PRIVATE` macro (**not recommended**).
- For more details, refer to the official guide.

SSL

- Removed support for TLS 1.0, 1.1, and DTLS 1.0
- Removed support for SSL 3.0

Deprecated Functions Were Removed from Cryptography Modules

- The functions `mbedtls_*_ret()` (related to MD, SHA, RIPEMD, RNG, HMAC modules) was renamed to replace the corresponding functions without `_ret` appended and updated return value.
- For more details, refer to the official guide.

Deprecated Config Options Following are some of the important config options deprecated by this update. The configs related to and/or dependent on these have also been deprecated.

- `MBEDTLS_SSL_PROTO_SSL3` : Support for SSL 3.0
- `MBEDTLS_SSL_PROTO_TLS1` : Support for TLS 1.0
- `MBEDTLS_SSL_PROTO_TLS1_1`: Support for TLS 1.1
- `MBEDTLS_SSL_PROTO_DTLS` : Support for DTLS 1.1 (Only DTLS 1.2 is supported now)
- `MBEDTLS_DES_C` : Support for 3DES ciphersuites
- `MBEDTLS_RC4_MODE` : Support for RC4-based ciphersuites

Note: This list includes only major options configurable through `idf.py menuconfig`. For more details on deprecated options, refer to the official guide.

Miscellaneous

Disabled Diffie-Hellman Key Exchange Modes The Diffie-Hellman Key Exchange modes have now been disabled by default due to security risks (see warning text here). Related configs are given below:

- `MBEDTLS_DHM_C` : Support for the Diffie-Hellman-Merkle module
- `MBEDTLS_KEY_EXCHANGE_DHE_PSK` : Support for Diffie-Hellman PSK (pre-shared-key) TLS authentication modes
- `MBEDTLS_KEY_EXCHANGE_DHE_RSA` : Support for cipher suites with the prefix `TLS-DHE-RSA-WITH-`

Note: During the initial step of the handshake (i.e., `client_hello`), the server selects a cipher from the list that the client publishes. As the DHE_PSK/DHE_RSA ciphers have now been disabled by the above change, the server would fall back to an alternative cipher; if in a rare case, it does not support any other cipher, the handshake would fail. To retrieve the list of ciphers supported by the server, one must attempt to connect with the server with a specific cipher from the client-side. Few utilities can help do this, e.g., `sslscan`.

Remove `certs` Module from X509 Library

- The `mbedtls/certs.h` header is no longer available in mbedtls 3.1. Most applications can safely remove it from the list of includes.

Breaking Change for `esp_crt_bundle_set` API

- The *`esp_crt_bundle_set()`* API now requires one additional argument named `bundle_size`. The return type of the API has also been changed to *`esp_err_t`* from `void`.

Breaking Change for `esp_ds_rsa_sign` API

- The `esp_ds_rsa_sign()` API now requires one less argument. The argument `mode` is no longer required.

HTTPS Server

Breaking Changes (Summary) Names of variables holding different certs in *`httpd_ssl_config_t`* structure have been updated.

- *`httpd_ssl_config::servercert`* variable inherits role of `cacert_pem` variable.
- *`httpd_ssl_config::servercert_len`* variable inherits role of `cacert_len` variable
- *`httpd_ssl_config::cacert_pem`* variable inherits role of `client_verify_cert_pem` variable

- *httpd_ssl_config::cacert_len* variable inherits role of client_verify_cert_len variable

The return type of the *httpd_ssl_stop()* API has been changed to *esp_err_t* from void.

ESP HTTPS OTA

Breaking Changes (Summary)

- The function *esp_https_ota()* now requires pointer to *esp_https_ota_config_t* as argument instead of pointer to *esp_http_client_config_t*.

ESP-TLS

Breaking Changes (Summary)

esp_tls_t Structure Is Now Private The *esp_tls_t* has now been made completely private. You cannot access its internal structures directly. Any necessary data that needs to be obtained from the ESP-TLS handle can be done through respective getter/setter functions. If there is a requirement of a specific getter/setter function, please raise an issue on ESP-IDF.

The list of newly added getter/setter function is as as follows:

- *esp_tls_get_ssl_context()* - Obtain the ssl context of the underlying ssl stack from the ESP-TLS handle.

Function Deprecations And Recommended Alternatives Following table summarizes the deprecated functions removed and their alternatives to be used from ESP-IDF v5.0 onwards.

Deprecated Function	Alternative
esp_tls_conn_new()	*esp_tls_conn_new_sync()*
esp_tls_conn_delete()	*esp_tls_conn_destroy()*

- The function *esp_tls_conn_http_new()* has now been termed as deprecated. Please use the alternative function *esp_tls_conn_http_new_sync()* (or its asynchronous *esp_tls_conn_http_new_async()*). Note that the alternatives need an additional parameter *esp_tls_t*, which has to be initialized using the *esp_tls_init()* function.

HTTP Server

Breaking Changes (Summary)

- http_server.h header is no longer available in esp_http_server. Please use esp_http_server.h instead.

ESP HTTP Client

Breaking Changes (Summary)

- The functions *esp_http_client_read()* and *esp_http_client_fetch_headers()* now return an additional return value -ESP_ERR_HTTP_EAGAIN for timeout errors - call timed-out before any data was ready.

TCP Transport

Breaking Changes (Summary)

- The function `esp_transport_read()` now returns `0` for a connection timeout and `< 0` for other errors. Please refer `esp_tcp_transport_err_t` for all possible return values.

MQTT Client

Breaking Changes (Summary)

- *`esp_mqtt_client_config_t`* have all fields grouped in sub structs.

Most common configurations are listed below:

- Broker address now is set in `esp_mqtt_client_config_t::broker::address::uri`
- Security related to broker verification in `esp_mqtt_client_config_t::broker::verification`
- Client username is set in `esp_mqtt_client_config_t::credentials::username`
- *`esp_mqtt_client_config_t`* no longer supports the `user_context` field. Please use *`esp_mqtt_client_register_event()`* instead for registering an event handler; the last argument `event_handler_arg` can be used to pass user context to the handler.

ESP-Modbus

Breaking Changes (Summary) The ESP-IDF component `freemodbus` has been removed from ESP-IDF and is supported as a separate component. Additional information for the `ESP-Modbus` component can be found in the separate repository:

- ESP-Modbus component on GitHub

The `main` component folder of the new application shall include the component manager manifest file `idf_component.yml` as in the example below:

```
dependencies:
  espressif/esp-modbus:
    version: "^1.0"
```

The `esp-modbus` component can be found in component manager registry. Refer to component manager documentation for more information on how to set up the component manager.

For applications targeting v4.x releases of ESP-IDF that need to use new `esp-modbus` component, adding the component manager manifest file `idf_component.yml` will be sufficient to pull in the new component. However, users should also exclude the legacy `freemodbus` component from the build. This can be achieved using the statement below in the project's `CMakeLists.txt`:

```
set(EXCLUDE_COMPONENTS freemodbus)
```

Provisioning

Protocomm The `pop` field in the *`protocomm_set_security()`* API is now deprecated. Please use the `sec_params` field instead of `pop`. This parameter should contain the structure (including the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` parameter should contain the pointer to the structure of type *`protocomm_security2_params_t`*.

Wi-Fi Provisioning

- The `pop` field in the *`wifi_prov_mgr_start_provisioning()`* API is now deprecated. For backward compatibility, `pop` can be still passed as a string for security version 1. However, for security version 2, the `wifi_prov_sec_params` argument needs to be passed instead of `pop`. This parameter should contain the structure (containing the security parameters) as required by the protocol version used. For example, when using security version 2, the `wifi_prov_sec_params` parameter should contain the pointer to the structure of type *`wifi_prov_security2_params_t`*. For security 1, the behaviour and the usage of the API remain the same.
- The API *`wifi_prov_mgr_is_provisioned()`* does not return *`ESP_ERR_INVALID_STATE`* error any more. This API now works without any dependency on provisioning manager initialization state.

ESP Local Control The `pop` field in the *`esp_local_ctrl_proto_sec_cfg_t`* API is now deprecated. Please use the `sec_params` field instead of `pop`. This field should contain the structure (containing the security parameters) as required by the protocol version used.

For example, when using security version 2, the `sec_params` field should contain pointer to the structure of type *`esp_local_ctrl_security2_params_t`*.

Removed or Deprecated Components

Components Moved to ESP-IDF Component Registry Following components are removed from ESP-IDF and moved to ESP-IDF Component Registry:

- libsodium
- cbor
- jsmn
- esp_modem
- nghttp
- mdns
- esp_websocket_client
- asio
- freemodbus
- sh2lib
- expat
- coap
- esp-cryptoauthlib
- qrcode
- tjpgd
- esp_serial_slave_link
- tinyusb

Note: Please note that http parser functionality which was previously part of `nghttp` component is now part of http_parser component.

These components can be installed using `idf.py add-dependency` command.

For example, to install libsodium component with the exact version X.Y, run `idf.py add-dependency libsodium==X.Y`.

To install libsodium component with the latest version compatible to X.Y according to semver rules, run `idf.py add-dependency libsodium~X.Y`.

To find out which versions of each component are available, open https://components.espressif.com, search for the component by its name and check the versions listed on the component page.

Deprecated Components The following components are removed since they were deprecated in ESP-IDF v4.x:

- `tcpip_adapter`. Please use the *ESP-NETIF* component instead; you can follow the *TCP/IP Adapter*.

Note: OpenSSL-API component is no longer supported. It is not available in the IDF Component Registry, either. Please use *ESP-TLS* or mbedtls API directly.

Note: `esp_adc_cal` component is no longer supported. New adc calibration driver is in `esp_adc` component. Legacy adc calibration driver has been moved into `esp_adc` component. To use legacy `esp_adc_cal` driver APIs, you should add `esp_adc` component to the list of component requirements in CMakeLists.txt. Also check *Peripherals Migration Guide* for more details.

The targets components are no longer necessary after refactoring and have been removed:

- `esp32`
- `esp32s2`
- `esp32s3`
- `esp32c2`
- `esp32c3`
- `esp32h2`

Storage

New Component for the Partition APIs Breaking change: all the Partition API code has been moved to a new component esp_partition. For the complete list of affected functions and data-types, see header file esp_partition.h .

These API functions and data-types were previously a part of the spi_flash component, and thus possible dependencies on the `spi_flash` in existing applications may cause the build failure, in case of direct esp_partition_* APIs/data-types use (for instance, `fatal error: esp_partition.h: No such file or directory` at lines with `#include "esp_partition.h"`). If you encounter such an issue, please update your project's CMakeLists.txt file as follows:

Original dependency setup:

```
idf_component_register(...
                       REQUIRES spi_flash)
```

Updated dependency setup:

```
idf_component_register(...
                       REQUIRES spi_flash esp_partition)
```

Note: Please update relevant `REQUIRES` or `PRIV_REQUIRES` section according to your project. The above-presented code snippet is just an example.

If the issue persists, please let us know and we will assist you with your code migration.

SDMMC/SDSPI SD card frequency on SDMMC/SDSPI interface can be now configured through `sdmmc_host_t.max_freq_khz` to a specific value, not only `SDMMC_FREQ_PROBING` (400 kHz), `SDMMC_FREQ_DEFAULT` (20 MHz), or `SDMMC_FREQ_HIGHSPEED` (40 MHz). Previously, in case you have specified a custom frequency other than any of the above-mentioned values, the closest lower-or-equal one was selected anyway.

Now, the underlaying drivers calculate the nearest fitting value, given by available frequency dividers instead of an enumeration item selection. This could cause troubles in communication with your SD card without a change of the existing application code.If you encounter such an issue, please, keep trying different frequencies around your desired

value unless you find the one working well. To check the frequency value calculated and actually applied, use `void sdmmc_card_print_info(FILE* stream, const sdmmc_card_t* card)` function.

FatFs FatFs is now updated to v0.14. As a result, the function signature of `f_mkfs()` has changed. The new signature is `FRESULT f_mkfs (const TCHAR* path, const MKFS_PARM* opt, void* work, UINT len);` which uses `MKFS_PARM` struct as a second argument.

Partition Table The partition table generator no longer supports misaligned partitions. When generating a partition table, `ESP-IDF` only accepts partitions with offsets that align to 4 KB. This change only affects generating new partition tables. Reading and writing to already existing partitions remains unchanged.

VFS The `esp_vfs_semihost_register()` function signature is changed as follows:

- The new signature is `esp_err_t esp_vfs_semihost_register(const char* base_path);`
- The `host_path` parameter of the old signature no longer exists. Instead, the OpenOCD command `ESP_SEMIHOST_BASEDIR` should be used to set the full path on the host.

Function Signature Changes The following functions now return `esp_err_t` instead of `void` or `nvs_iterator_t`. Previously, when parameters were invalid or when something goes wrong internally, these functions would `assert()` or return a `nullptr`. With an `esp_err_t` returned, you can get better error reporting.

- *nvs_entry_find()*
- *nvs_entry_next()*
- *nvs_entry_info()*

Because the `esp_err_t` return type changes, the usage patterns of `nvs_entry_find()` and `nvs_entry_next()` become different. Both functions now modify iterators via parameters instead of returning an iterator.

The old programming pattern to iterate over an NVS partition was as follows:

```
nvs_iterator_t it = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_
↪ANY);
while (it != NULL) {
        nvs_entry_info_t info;
        nvs_entry_info(it, &info);
        it = nvs_entry_next(it);
        printf("key '%s', type '%d'", info.key, info.type);
};
```

The new programming pattern to iterate over an NVS partition is now:

```
nvs_iterator_t it = nullptr;
esp_err_t res = nvs_entry_find(<nvs_partition_name>, <namespace>, NVS_TYPE_ANY, &
↪it);
while(res == ESP_OK) {
    nvs_entry_info_t info;
    nvs_entry_info(it, &info); // Can omit error check if parameters are␣
↪guaranteed to be non-NULL
    printf("key '%s', type '%d'", info.key, info.type);
    res = nvs_entry_next(&it);
}
nvs_release_iterator(it);
```

Iterator Validity Note that because the function signature changes, if there is a parameter error, you may get an invalid iterator from `nvs_entry_find()`. Hence, it is important to initialize the iterator

to NULL before using nvs_entry_find(), so that you can avoid complex error checking before calling nvs_release_iterator(). A good example is the programming pattern above.

Removed SDSPI Deprecated API Structure sdspi_slot_config_t and function sdspi_host_init_slot() are removed, and replaced by structure sdspi_device_config_t and function sdspi_host_init_device() respectively.

ROM SPI Flash In versions before v5.0, ROM SPI flash functions were included via esp32**/rom/spi_flash.h. Thus, code written to support different ESP chips might be filled with ROM headers of different targets. Furthermore, not all of the APIs could be used on all ESP chips.

Now, the common APIs are extracted to esp_rom_spiflash.h. Although it is not a breaking change, you are strongly recommended to only use the functions from this header (i.e., prefixed with esp_rom_spiflash and included by esp_rom_spiflash.h) for better cross-compatibility between ESP chips.

To make ROM SPI flash APIs clearer, the following functions are also renamed:

- esp_rom_spiflash_lock() to esp_rom_spiflash_set_bp()
- esp_rom_spiflash_unlock() to esp_rom_spiflash_clear_bp()

SPI Flash Driver The esp_flash_speed_t enum type is now deprecated. Instead, you may now directly pass the real clock frequency value to the flash configuration structure. The following example demonstrates how to configure a flash frequency of 80MHz:

```
esp_flash_spi_device_config_t dev_cfg = {
    // Other members
    .freq_mhz = 80,
    // Other members
};
```

Legacy SPI Flash Driver To make SPI flash drivers more stable, the legacy SPI flash driver is removed from v5.0. The legacy SPI flash driver refers to default spi_flash driver since v3.0, and the SPI flash driver with configuration option CONFIG_SPI_FLASH_USE_LEGACY_IMPL enabled since v4.0. The major breaking change here is that the legacy spi_flash driver is no longer supported from v5.0. Therefore, the legacy driver APIs and the CONFIG_SPI_FLASH_USE_LEGACY_IMPL configuration option are both removed. Please use the new spi_flash driver's APIs instead.

Removed items	Replacement
spi_flash_erase_sector()	esp_flash_erase_region()
spi_flash_erase_range()	esp_flash_erase_region()
spi_flash_write()	esp_flash_write()
spi_flash_read()	esp_flash_read()
spi_flash_write_encrypted()	esp_flash_write_encrypted()
spi_flash_read_encrypted()	esp_flash_read_encrypted()

Note: New functions with prefix esp_flash accept an additional esp_flash_t* parameter. You can simply set it to NULL. This will make the function to run the main flash (esp_flash_default_chip).

The esp_spi_flash.h header is deprecated as system functions are no longer public. To use flash memory mapping APIs, you may include spi_flash_mmap.h instead.

System

Inter-Processor Call IPC (Inter-Processor Call) feature is no longer a stand-alone component and has been integrated into the `esp_system` component.

Thus, any project presenting a `CMakeLists.txt` file with the parameters `PRIV_REQUIRES esp_ipc` or `REQUIRES esp_ipc` should be modified to simply remove these options as the `esp_system` component is included by default.

ESP Clock The ESP Clock API (functions/types/macros prefixed with `esp_clk`) has been made into a private API. Thus, the previous include paths `#include "ESP32-S3/clk.h"` and `#include "esp_clk.h"` have been removed. If users still require usage of the ESP Clock API (though this is not recommended), it can be included via `#include "esp_private/esp_clk.h"`.

Note: Private APIs are not stable and no are longer subject to the ESP-IDF versioning scheme's breaking change rules. Thus, it is not recommended for users to continue calling private APIs in their applications.

Cache Error Interrupt The Cache Error Interrupt API (functions/types/macros prefixed with `esp_cache_err`) has been made into a private API. Thus, the previous include path `#include "ESP32-S3/cache_err_int.h"` has been removed. If users still require usage of the Cache Error Interrupt API (though this is not recommended), it can be included via `#include "esp_private/cache_err_int.h"`.

bootloader_support

- The function `bootloader_common_get_reset_reason()` has been removed. Please use the function `esp_rom_get_reset_reason()` in the ROM component.
- The functions `esp_secure_boot_verify_sbv2_signature_block()` and `esp_secure_boot_verify_rsa_signature_block()` have been removed without replacement. We do not expect users to use these directly. If they are indeed still neccessary, please open a feature request on GitHub explaining why these functions are necessary to you.

Brownout The Brownout API (functions/types/macros prefixed with `esp_brownout`) has been made into a private API. Thus, the previous include path `#include "brownout.h"` has been removed. If users still require usage of the Brownout API (though this is not recommended), it can be included via `#include "esp_private/brownout.h"`.

Trax The Trax API (functions/types/macros prefixed with `trax_`) has been made into a private API. Thus, the previous include path `#include "trax.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/trax.h"`.

ROM The previously deprecated ROM-related header files located in `components/esp32/rom/` (old include path: `rom/*.h`) have been moved. Please use the new target-specific path from `components/esp_rom/include/ESP32-S3/` (new include path: `ESP32-S3/rom/*.h`).

esp_hw_support

- The header files `soc/cpu.h` have been deleted and deprecated CPU util functions have been removed. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header files `hal/cpu_ll.h`, `hal/cpu_hal.h`, `hal/soc_ll.h`, `hal/soc_hal.h` and `interrupt_controller_hal.h` CPU API functions have been deprecated. ESP-IDF developers should include `esp_cpu.h` instead for equivalent functions.
- The header file `compare_set.h` have been deleted. ESP-IDF developers should use `esp_cpu_compare_and_set()` function provided in `esp_cpu.h` instead.

- `esp_cpu_get_ccount()`, `esp_cpu_set_ccount()` and `esp_cpu_in_ocd_debug_mode()` were removed from `esp_cpu.h`. ESP-IDF developers should use respectively `esp_cpu_get_cycle_count()`, `esp_cpu_set_cycle_count()` and `esp_cpu_dbgr_is_attached()` instead.
- The header file `esp_intr.h` has been deleted. Please include `esp_intr_alloc.h` to allocate and manipulate interrupts.
- The Panic API (functions/types/macros prefixed with `esp_panic`) has been made into a private API. Thus, the previous include path `#include "esp_panic.h"` has been removed. If users still require usage of the Trax API (though this is not recommended), it can be included via `#include "esp_private/panic_reason.h"`. Besides, developers should include `esp_debug_helpers.h` instead to use any debug-related helper functions, e.g., print backtrace.
- The header file `soc_log.h` is now renamed to `esp_hw_log.h` and has been made private. Users are encouraged to use logging APIs provided under `esp_log.h` instead.
- The header files `spinlock.h`, `clk_ctrl_os.h`, and `rtc_wdt.h` must now be included without the `soc` prefix. For example, `#include "spinlock.h"`.
- `esp_chip_info()` returns the chip version in the format = 100 * `major eFuse version` + `minor eFuse version`. Thus, the `revision` in the `esp_chip_info_t` structure is expanded to `uint16_t` to fit the new format.

PSRAM

- The target-specific header file `spiram.h` and the header file `esp_spiram.h` have been removed. A new component `esp_psram` is created instead. For PSRAM/SPIRAM-related functions, users now include `esp_psram.h` and set the `esp_psram` component as a component requirement in their `CMakeLists.txt` project files.
- `esp_spiram_get_chip_size` and `esp_spiram_get_size` have been deleted. You should use `esp_psram_get_size` instead.

eFuse

- The parameter type of function `esp_secure_boot_read_key_digests()` changed from `ets_secure_boot_key_digests_t*` to `esp_secure_boot_key_digests_t*`. The new type is the same as the old one, except that the `allow_key_revoke` flag has been removed. The latter was always set to `true` in current code, not providing additional information.
- Added eFuse wafer revisions: major and minor. The `esp_efuse_get_chip_ver()` API is not compatible with these changes, so it was removed. Instead, please use the following APIs: `efuse_hal_get_major_chip_version()`, `efuse_hal_get_minor_chip_version()` or `efuse_hal_chip_revision()`.

esp_common `EXT_RAM_ATTR` is deprecated. Use the new macro `EXT_RAM_BSS_ATTR` to put `.bss` on PSRAM.

esp_system

- The header files `esp_random.h`, `esp_mac.h`, and `esp_chip_info.h`, which were all previously indirectly included via the header file `esp_system.h`, must now be included directly. These indirect inclusions from `esp_system.h` have been removed.
- The Backtrace Parser API (functions/types/macros prefixed with `esp_eh_frame_`) has been made into a private API. Thus, the previous include path `#include "eh_frame_parser.h"` has been removed. If users still require usage of the Backtrace Parser API (though this is not recommended), it can be included via `#include "esp_private/eh_frame_parser.h"`.
- The Interrupt Watchdog API (functions/types/macros prefixed with `esp_int_wdt_`) has been made into a private API. Thus, the previous include path `#include "esp_int_wdt.h"` has been removed. If users still require usage of the Interrupt Watchdog API (though this is not recommended), it can be included via `#include "esp_private/esp_int_wdt.h"`.

SoC Dependency

- Public API headers listed in the Doxyfiles will not expose unstable and unnecessary SoC header files, such as `soc/soc.h` and `soc/rtc.h`. That means the user has to explicitly include them in their code if these "missing" header files are still wanted.
- Kconfig option `LEGACY_INCLUDE_COMMON_HEADERS` is also removed.
- The header file `soc/soc_memory_types.h` has been deprecated. Users should use the `esp_memory_utils.h` instead. Including `soc/soc_memory_types.h` will bring a build warning like `soc_memory_types.h is deprecated, please migrate to esp_memory_utils.h`

APP Trace One of the timestamp sources has changed from the legacy timer group driver to the new *GPTimer*. Kconfig choices like `APPTRACE_SV_TS_SOURCE_TIMER00` has been changed to `APPTRACE_SV_TS_SOURCE_GPTIMER`. User no longer need to choose the group and timer ID.

`esp_timer` The FRC2-based legacy implementation of `esp_timer` available on ESP32 has been removed. The simpler and more efficient implementation based on the LAC timer is now the only option.

ESP Image The image SPI speed enum definitions have been renamed.

- Enum `ESP_IMAGE_SPI_SPEED_80M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_1`.
- Enum `ESP_IMAGE_SPI_SPEED_40M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_2`.
- Enum `ESP_IMAGE_SPI_SPEED_26M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_3`.
- Enum `ESP_IMAGE_SPI_SPEED_20M` has been renamed to `ESP_IMAGE_SPI_SPEED_DIV_4`.

Task Watchdog Timers

- The API for `esp_task_wdt_init()` has changed as follows:
  - Configuration is now passed as a configuration structure.
  - The function will now handle subscribing of the idle tasks if configured to do so.
- The former `CONFIG_ESP_TASK_WDT` configuration option has been renamed to *CONFIG_ESP_TASK_WDT_INIT* and a new *CONFIG_ESP_TASK_WDT_EN* option has been introduced.

FreeRTOS

Legacy API and Data Types Previously, the `configENABLE_BACKWARD_COMPATIBILITY` option was set by default, thus allowing pre FreeRTOS v8.0.0 function names and data types to be used. The `configENABLE_BACKWARD_COMPATIBILITY` is now disabled by default, thus legacy FreeRTOS names/types are no longer supportd by default. Users should do one of the followings:

- Update their code to remove usage of legacy FreeRTOS names/types.
- Enable the *CONFIG_FREERTOS_ENABLE_BACKWARD_COMPATIBILITY* to explicitly allow the usage of legacy names/types.

Tasks Snapshot The header `task_snapshot.h` has been removed from `freertos/task.h`. ESP-IDF developers should include `freertos/task_snapshot.h` if they need tasks snapshot API.

The function `vTaskGetSnapshot()` now returns `BaseType_t`. Return value shall be `pdTRUE` on success and `pdFALSE` otherwise.

FreeRTOS Asserts Previously, FreeRTOS asserts were configured separately from the rest of the system using the `FREERTOS_ASSERT` kconfig option. This option has now been removed and the configuration is now done through `COMPILER_OPTIMIZATION_ASSERTION_LEVEL`.

Port Macro API The file `portmacro_deprecated.h` which was added to maintain backward compatibility for deprecated APIs is removed. Users are advised to use the alternate functions for the deprecated APIs as listed below:

- `portENTER_CRITICAL_NESTED()` is removed. Users should use the `portSET_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `portEXIT_CRITICAL_NESTED()` is removed. Users should use the `portCLEAR_INTERRUPT_MASK_FROM_ISR()` macro instead.
- `vPortCPUInitializeMutex()` is removed. Users should use the `spinlock_initialize()` function instead.
- `vPortCPUAcquireMutex()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUAcquireMutexTimeout()` is removed. Users should use the `spinlock_acquire()` function instead.
- `vPortCPUReleaseMutex()` is removed. Users should use the `spinlock_release()` function instead.

App Update

- The functions *`esp_ota_get_app_description()`* and *`esp_ota_get_app_elf_sha256()`* have been termed as deprecated. Please use the alternative functions *`esp_app_get_description()`* and *`esp_app_get_elf_sha256()`* respectively. These functions have now been moved to a new component esp_app_format. Please refer to the header file esp_app_desc.h .

Bootloader Support

- The *`esp_app_desc_t`* structure, which used to be declared in esp_app_format.h , is now declared in esp_app_desc.h .
- The function `bootloader_common_get_partition_description()` has now been made private. Please use the alternative function *`esp_ota_get_partition_description()`*. Note that this function takes *`esp_partition_t`* as its first argument instead of `esp_partition_pos_t`.

Chip Revision The bootloader checks the chip revision at the beginning of the application loading. The application can only be loaded if the version is `>=` *CONFIG_ESP32S3_REV_MIN* and `<` `CONFIG_ESP32S3_REV_MAX_FULL`.

During the OTA upgrade, the version requirements and chip revision in the application header are checked for compatibility. The application can only be updated if the version is `>=` *CONFIG_ESP32S3_REV_MIN* and `<` `CONFIG_ESP32S3_REV_MAX_FULL`.

Tools

ESP-IDF Monitor ESP-IDF Monitor makes the following changes regarding baud-rate:

- ESP-IDF monitor now uses the custom console baud-rate (*CONFIG_ESP_CONSOLE_UART_BAUDRATE*) by default instead of 115200.
- Setting a custom baud from menuconfig is no longer supported.
- A custom baud-rate can be specified from command line with the `idf.py monitor -b <baud>` command or through setting environment variables.
- Please note that the baud-rate argument has been renamed from `-B` to `-b` in order to be consistent with the global baud-rate `idf.py -b <baud>`. Run `idf.py monitor --help` for more information.

Deprecated Commands `idf.py` sub-commands and `cmake` target names have been unified to use hyphens (-) instead of underscores (_). Using a deprecated sub-command or target name will produce a warning. Users are advised to migrate to using the new sub-commands and target names. The following changes have been made:

Table 1: Deprecated Sub-command and Target Names

Old Name	New Name
efuse_common_table	efuse-common-table
efuse_custom_table	efuse-custom-table
erase_flash	erase-flash
partition_table	partition-table
partition_table-flash	partition-table-flash
post_debug	post-debug
show_efuse_table	show-efuse-table
erase_otadata	erase-otadata
read_otadata	read-otadata

Esptool The `CONFIG_ESPTOOLPY_FLASHSIZE_DETECT` option has been renamed to *CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE* and has been disabled by default. New and existing projects migrated to ESP-IDF v5.0 have to set *CONFIG_ESPTOOLPY_FLASHSIZE*. If this is not possible due to an unknown flash size at build time, then *CONFIG_ESPTOOLPY_HEADER_FLASHSIZE_UPDATE* can be enabled. However, once enabled, to keep the digest valid, an SHA256 digest is no longer appended to the image when updating the binary header with the flash size during flashing.

Windows Environment The Msys/Mingw-based Windows environment support got deprecated in ESP-IDF v4.0 and was entirely removed in v5.0. Please use *ESP-IDF Tools Installer* to set up a compatible environment. The options include Windows Command Line, Power Shell and the graphical user interface based on Eclipse IDE. In addition, a VS Code-based environment can be set up with the supported plugin: https://github.com/espressif/vscode-esp-idf-extension.

6.1.2 Migration from 5.0 to 5.1

GCC

GCC Version The previous GCC version was GCC 11.2.0. This has now been upgraded to GCC 12.2.0 on all targets. Users that need to port their code from GCC 11.2.0 to 12.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 12

Warnings The upgrade to GCC 12.2.0 has resulted in the addition of new warnings, or enhancements to existing warnings. The full details of all GCC warnings can be found in GCC Warning Options. Users are advised to double-check their code, then fix the warnings if possible. Unfortunately, depending on the warning and the complexity of the user's code, some warnings will be false positives that require non-trivial fixes. In such cases, users can choose to suppress the warning in multiple ways. This section outlines some common warnings that users are likely to encounter and ways to fix them.

-Wuse-after-free Typically, this warning should not produce false-positives for release-level code. But this may appear in test cases. There is an example of how it was fixed in ESP-IDF's `test_realloc.c`.

```
void *x = malloc(64);
void *y = realloc(x, 48);
TEST_ASSERT_EQUAL_PTR(x, y);
```

Pointers may be converted to int to avoid warning `-Wuse-after-free`.

```
int x = (int) malloc(64);
int y = (int) realloc((void *) x, 48);
TEST_ASSERT_EQUAL_UINT32((uint32_t) x, (uint32_t) y);
```

-Waddress GCC 12.2.0 introduces an enhanced version of the `-Waddress` warning option, which is now more eager in detecting the checking of pointers to an array in if-statements.

The following code triggers the warning:

```
char array[8];
...
if (array)
    memset(array, 0xff, sizeof(array));
```

Eliminating unnecessary checks resolves the warning.

```
char array[8];
...
memset(array, 0xff, sizeof(array));
```

RISC-V Builds Outside of ESP-IDF The RISC-V extensions `zicsr` and `zifencei` have been separated from the `I` extension. GCC 12 reflects this change, and as a result, when building for RISC-V ESP32 chips outside of the ESP-IDF framework, you must include the `_zicsr_zifencei` postfix when specifying the -march option in your build system.

Example:

```
riscv32-esp-elf-gcc main.c -march=rv32imac
```

Now is replaced with:

```
riscv32-esp-elf-gcc main.c -march=rv32imac_zicsr_zifencei
```

Peripherals

GPSPI Following items are deprecated. Since ESP-IDF v5.1, GPSPI clock source is configurable.

- `spi_get_actual_clock` is deprecated, you should use *spi_device_get_actual_freq()* instead.

LEDC

- *soc_periph_ledc_clk_src_legacy_t::LEDC_USE_RTC8M_CLK* is deprecated. Please use `LEDC_USE_RC_FAST_CLK` instead.

Storage

FatFs `esp_vfs_fat_sdmmc_unmount()` is now deprecated, and you can use *`esp_vfs_fat_sdcard_unmount()`* instead. This API is deprecated in previous ESP-IDF versions, but without a deprecation warning or migration guide. Since ESP-IDF v5.1, calling this `esp_vfs_fat_sdmmc_unmount()` API will generate a deprecation warning.

SPI_FLASH

- *`spi_flash_get_counters()`* is deprecated, please use *`esp_flash_get_counters()`* instead.
- *`spi_flash_dump_counters()`* is deprecated, please use *`esp_flash_dump_counters()`* instead.
- *`spi_flash_reset_counters()`* is deprecated, please use *`esp_flash_reset_counters()`* instead.

Networking

SNTP SNTP module now provides thread safe APIs to access lwIP functionality. It is recommended to use *ESP_NETIF* API. Please refer to the chapter *SNTP API* for more details.

System

FreeRTOS

Dynamic Memory Allocation

In the past, FreeRTOS commonly utilized the function `malloc()` to allocate dynamic memory. As a result, if an application allowed `malloc()` to allocate memory from external RAM (by configuring the *CONFIG_SPIRAM_USE* option as `CONFIG_SPIRAM_USE_MALLOC`), FreeRTOS had the potential to allocate dynamic memory from external RAM, and the specific location was determined by the heap allocator.

Note: Dynamic memory allocation for tasks (which are likely to consume the most memory) were an exception to the scenario above. FreeRTOS would use a separate memory allocation function to guarantee that dynamic memory allocate for a task was always placed in internal RAM.

Allowing FreeRTOS objects (such as queues and semaphores) to be placed in external RAM becomes an issue if those objects are accessed while the cache is disabled (such as during SPI flash write operations) and would lead to a cache access errors (see *Fatal Errors* for more details).

Therefore, FreeRTOS has been updated to always use internal memory (i.e., DRAM) for dynamic memory allocation. Calling FreeRTOS creation functions (e.g., *`xTaskCreate()`*, `xQueueCreate()`) guarantees that the memory allocated for those tasks/objects is from internal memory (see *FreeRTOS Heap* for more details).

Warning: If you previously relied on *CONFIG_SPIRAM_USE* to place FreeRTOS objects into external memory, this change will lead to increased usage of internal memory due the FreeRTOS objects now being allocated there.

To place a FreeRTOS task/object into external memory, it is now necessary to do so explicitly. The following methods can be employed:

- Allocate the task/object using one of the `...CreateWithCaps()` API such as *`xTaskCreateWithCaps()`* and *`xQueueCreateWithCaps()`* (see *IDF Additional API* for more details).
- Manually allocate external memory for those objects using *`heap_caps_malloc()`*, then create the objects from the allocated memory using one of the `...CreateStatic()` FreeRTOS functions.

Power Management

- `esp_pm_config_esp32xx_t` is deprecated, use `esp_pm_config_t` instead.
- `esp32xx/pm.h` is deprecated, use `esp_pm.h` instead.

6.1.3 Migration from 5.1 to 5.2

GCC

GCC Version The previous GCC version was GCC 12.2.0. This has now been upgraded to GCC 13.2.0 on all targets. Users that need to port their code from GCC 12.2.0 to 13.2.0 should refer to the series of official GCC porting guides listed below:

- Porting to GCC 13

Common Porting Problems and Fixes

`stdio.h` No Longer Includes `sys/types.h`

Issue Compilation errors may occur in code that previously worked with the old toolchain. For example:

```
#include <stdio.h>
clock_t var; // error: expected specifier-qualifier-list before 'clock_t'
```

Solution To resolve this issue, the correct header must be included. Refactor the code like this:

```
#include <time.h>
clock_t var;
```

Peripherals

UART

- *`UART_FIFO_LEN`* is deprecated. Please use *`UART_HW_FIFO_LEN`* instead.

I2C I2C driver has been redesigned (see *I2C API Reference*), which aims to unify the interface and extend the usage of I2C peripheral. Although it is recommended to use the new driver APIs, the legacy driver is still available in the previous include path `driver/i2c.h`.

The major breaking changes in concept and usage are listed as follows:

Major Changes in Concepts

- `i2c_config_t` which was used to configure the I2C bus, but it doesn't really tell whether to configure master or slave. So in the new design, master and slave initialization are separate, user can call `i2c_master_bus_config_t` or `i2c_slave_config_t`.
- `i2c_mode_t` which was used to tell whether I2C controller works in slave mode or master mode. This enumerator has been deprecated. In the new driver, users don'tneed to manually set the mode anymore since master and slave APIs are different.
- `i2c_rw_t` which was used to tell whether I2C master controller is performing a *write* or a *read* operation. This is now deprecated.
- `i2c_addr_mode_t` was renamed to `i2c_addr_bit_len_t`.
- In the legacy driver, operations needed to be chained with a command list (dynamically or statically created). The new driver now handles this internally, making the operations more size and space efficient.
- Capability flags like `I2C_SCLK_SRC_FLAG_FOR_NOMAL` are used to select clock source in the legacy driver. In the new driver, users can select clock source directly.

Major Changes in Usage

- I2C bus initialization is done in two parts: first, initialization of the bus with *`i2c_new_master_bus()`*, then, initialization of the I2C device with *`i2c_master_bus_add_device()`*.
- `i2c_reset_tx_fifo` and `i2c_reset_rx_fifo` have been removed, since it is never required to reset the fifo by users. Whole bus can still be reset by calling `i2c_master_bus_reset`.
- `i2c_cmd_link_xxx` functions have been removed, user doesn't need to use link to link commands on its own.
- `i2c_master_write_to_device` has been renamed to `i2c_master_transmit`.
- `i2c_master_read_from_device` has been renamed to `i2c_master_receive`.
- `i2c_master_write_read_device` has been renamed to `i2c_master_transmit_receive`
- `i2c_slave_write_buffer` has been renamed to `i2c_slave_transmit`
- `i2c_slave_read_buffer` has been renamed to `i2c_slave_receive`

Protocols

CoAP CoAP examples have been moved to idf-extra-components repository.

HTTP2 http2_request example has been moved to idf-extra-components repository.

Storage

NVS Encryption

- For SoCs with the HMAC peripheral (`SOC_HMAC_SUPPORTED`), turning on *Flash Encryption* will no longer automatically turn on *NVS Encryption*.
- You will need to explicitly turn on NVS encryption and select the required scheme (flash encryption-based or HMAC peripheral-based). You can select the HMAC peripheral-based scheme (*CONFIG_NVS_SEC_KEY_PROTECTION_SCHEME*), even if flash encryption is not enabled.

- SoCs without the HMAC peripheral will still automatically turn on NVS encryption when flash encryption is enabled.

SPI Flash Driver XMC-C series flash suspend support has been removed. According to feedback from the flash manufacturer, in some situations the XMC-C flash would require a 1ms interval between resume and next command. This is too long for a software request. Based on the above reason, in order to use suspend safely, we decide to remove flash suspend support from XMC-C series. But you can still force enable it via *CONFIG_SPI_FLASH_FORCE_ENABLE_XMC_C_SUSPEND*. If you have any questions, please contact espressif business support.

System

FreeRTOS

IDF FreeRTOS Upgrade The IDF FreeRTOS kernel (which is a dual-core SMP implementation of FreeRTOS) has been upgraded to be based on Vanilla FreeRTOS v10.5.1. With this upgrade, the design and implementation of IDF FreeRTOS has also been changed significantly. As a result, users should take not of the following changes to kernel behavior and API:

- When enabling single-core mode via the *CONFIG_FREERTOS_UNICORE* option, the kernel's behavior will now be identical to Vanilla FreeRTOS (see *Single-Core Mode* for more details).
- For SMP related APIs that were added by IDF FreeRTOS, checks on `xCoreID` arguments are now stricter. Providing out of range values for `xCoreID` arguments will now trigger an assert.
- The following SMP related APIs are now deprecated and replaced due to naming consistency reasons:
  - `xTaskGetAffinity()` is deprecated, call *`xTaskGetCoreID()`* instead.
  - `xTaskGetIdleTaskHandleForCPU()` is deprecated, call *`xTaskGetIdleTaskHandleForCore()`* instead.
  - `xTaskGetCurrentTaskHandleForCPU()` is deprecated, call *`xTaskGetCurrentTaskHandleForCore()`* instead.

Task Snapshot The Task Snapshot API has been made private due to a lack of a practical way for the API to be used from user code (the scheduler must be halted before the API can be called).

Xtensa A number of legacy include paths for Xtensa headers have been deprecated:

- `#include "freertos/xtensa_api.h"` is deprecated, please use `#include "xtensa_api.h"` instead.
- `#include "freertos/xtensa_context.h"` is deprecated, please use `#include "xtensa_context.h"` instead.
- `#include "freertos/xtensa_timer.h"` is deprecated, please use `#include "xtensa_timer.h"` instead.

Panic Handler Behavior The choice `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` in the configuration option *CONFIG_ESP_SYSTEM_PANIC* has been made dependent on whether the `esp_gdbstub` component is included in the build. When trimming the list of components in the build using `set(COMPONENTS main),esp_gdbstub` component has to be added to this list of components to make the `CONFIG_ESP_SYSTEM_PANIC_GDBSTUB` option available.

WiFi

WiFi Enterprise Security APIs defined in *esp_wpa2.h* have been deprecated. Please use newer APIs from *esp_eap_client.h*.

WiFi Disconnect Reason Codes For the event WIFI_EVENT_STA_DISCONNECTED, the original reason code WIFI_REASON_NO_AP_FOUND has been split as follows:

- REASON_NO_AP_FOUND(original and still used in some scenarios)
- REASON_NO_AP_FOUND_IN_RSSI_THRESHOLD
- REASON_NO_AP_FOUND_IN_AUTHMODE_THRESHOLD
- REASON_NO_AP_FOUND_W_COMPATIBLE_SECURITY

For details, please refer to *Wi-Fi Reason Code*.

Chapter 7

Libraries and Frameworks

7.1 Cloud Frameworks

ESP32-S3 supports multiple cloud frameworks using agents built on top of ESP-IDF. Here are the pointers to various supported cloud frameworks' agents and examples:

7.1.1 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. ESP RainMaker on GitHub.

7.1.2 AWS IoT

https://github.com/espressif/esp-aws-iot is an open source repository for ESP32-S3 based on Amazon Web Services' aws-iot-device-sdk-embedded-C.

7.1.3 Azure IoT

https://github.com/espressif/esp-azure is an open source repository for ESP32-S3 based on Microsoft Azure's azure-iot-sdk-c SDK.

7.1.4 Google IoT Core

https://github.com/espressif/esp-google-iot is an open source repository for ESP32-S3 based on Google's iot-device-sdk-embedded-c SDK.

7.1.5 Aliyun IoT

https://github.com/espressif/esp-aliyun is an open source repository for ESP32-S3 based on Aliyun's iotkit-embedded SDK.

7.1.6 Joylink IoT

https://github.com/espressif/esp-joylink is an open source repository for ESP32-S3 based on Joylink's joylink_dev_sdk SDK.

7.1.7 Tencent IoT

https://github.com/espressif/esp-welink is an open source repository for ESP32-S3 based on Tencent's welink SDK.

7.1.8 Tencentyun IoT

https://github.com/espressif/esp-qcloud is an open source repository for ESP32-S3 based on Tencentyun's qcloud-iot-sdk-embedded-c SDK.

7.1.9 Baidu IoT

https://github.com/espressif/esp-baidu-iot is an open source repository for ESP32-S3 based on Baidu's iot-sdk-c SDK.

7.2 Espressif's Frameworks

Here you will find a collection of the official Espressif libraries and frameworks.

7.2.1 Espressif Audio Development Framework

The ESP-ADF is a comprehensive framework for audio applications including:

- CODEC's HAL
- Music players and recorders
- Audio processing
- Bluetooth speakers
- Internet radios
- Hands-free devices
- Speech decognition

This framework is available on GitHub: ESP-ADF.

7.2.2 ESP-CSI

ESP-CSI is an experimental implementation that uses the Wi-Fi Channel State Information to detect the presence of a human body.

See the ESP-CSI project for more information.

7.2.3 Espressif DSP Library

The library provides algorithms optimized specifically for digital signal processing applications. This library supports:

- Matrix multiplication
- Dot product
- FFT (Fast Fourier Transform)
- IIR (Infinite Impulse Response)
- FIR (Finite Impulse Response)
- Vector math operations

This library is available on Github: ESP-DSP library.

7.2.4 ESP-WIFI-MESH Development Framework

This framework is based on the ESP-WIFI-MESH protocol with the following features:

- Fast network configuration
- Stable upgrade
- Efficient debugging
- LAN control
- Various application demos

This framework is available on Github: ESP-MDF.

7.2.5 ESP-WHO

The ESP-WHO is a face detection and recognition framework using the ESP32 and camera.

This framework is available on Github: ESP-WHO.

7.2.6 ESP RainMaker

ESP RainMaker is a complete solution for accelerated AIoT development. Using ESP RainMaker, you can create AIoT devices from the firmware to the integration with voice-assistant, phone apps and cloud backend.

This project is available on Github: ESP RainMaker on GitHub.

7.2.7 ESP-IoT-Solution

ESP-IoT-Solution contains commonly used device drivers and code frameworks when developing IoT systems. The device drivers and code frameworks within the ESP-IoT-Solution are organized as separate components, allowing them to be easily integrated into an ESP-IDF project.

ESP-IoT-Solution includes:

- Device drivers for sensors, display, audio, GUI, input, actuators, etc.
- Framework and documentation for low power, security, storage, etc.
- Guide for Espressif open source solutions from practical application point.

This solution is available on Github: ESP-IoT-Solution on GitHub.

7.2.8 ESP-Protocols

The ESP-Protocols repository contains a collection of protocol components for ESP-IDF. The code within ESP-Protocols is organized into separate components, allowing them to be easily integrated into an ESP-IDF project. Additionally, each component is available in IDF Component Registry.

ESP-Protocols components:

- esp_modem enables connectivity with GSM/LTE modems using AT commands or PPP protocol. See the esp_modem documentation.
- mdns (mDNS) is a multicast UDP service that is used to provide local network service and host discovery. See the mdns documentation.
- esp_websocket_client is a managed component for ESP-IDF that contains implementation of WebSocket protocol client for ESP32. See the esp_websocket_client documentation. For detailes of WebSocket protocol client, see WebSocket_protocol_client.
- asio is a cross-platform C++ library, see https://think-async.com/Asio/. It provides a consistent asynchronous model using a modern C++ approach. See the asio documentation.

7.2.9 ESP-BSP

The ESP-BSP repository contains Board Support Packages (BSPs) for various Espressif's and third-party development boards. BSPs help to quickly get started with a supported board. Usually they contain pinout definition and helper functions that will initialize peripherals for the specific board. Additionally, the BSPs contain drivers for external chips populated on the development board, such as sensors, displays, audio codecs, etc.

7.2.10 ESP-IDF-CXX

ESP-IDF-CXX contains C++ wrappers for part of ESP-IDF. The focuses are on ease of use, safety, automatic resource management. They also move error checking from runtime to compile time to prevent running failure. There are C++ classes for ESP-Timer, I2C, SPI, GPIO and other peripherals or features of ESP-IDF. ESP-IDF-CXX is available as a component from the component registry. Please check the project's README.md for more information.

Chapter 8

Contributions Guide

We welcome contributions to the ESP-IDF project!

8.1 How to Contribute

Contributions to ESP-IDF - fixing bugs, adding features, adding documentation - are welcome. We accept contributions via Github Pull Requests.

8.2 Before Contributing

Before sending us a Pull Request, please consider this list of points:

- Is the contribution entirely your own work, or already licensed under an Apache License 2.0 compatible Open Source License? If not then we unfortunately cannot accept it. Please check the *Copyright Header Guide* for additional information.
- Does any new code conform to the ESP-IDF *Style Guide*?
- Have you installed the *pre-commit hook* for ESP-IDF project?
- Does the code documentation follow requirements in *Documenting Code*?
- Is the code adequately commented for people to understand how it is structured?
- Is there documentation or examples that go with code contributions? There are additional suggestions for writing good examples in examples readme.
- Are comments and documentation written in clear English, with no spelling or grammar errors?
- Example contributions are also welcome. Please check the *Creating Examples* guide for these.
- If the contribution contains multiple commits, are they grouped together into logical changes (one major change per pull request)? Are any commits with names like "fixed typo" squashed into previous commits?
- If you are unsure about any of these points, please open the Pull Request anyhow and then ask us for feedback.

8.3 Pull Request Process

After you open the Pull Request, there will probably be some discussion in the comments field of the request itself.

Once the Pull Request is ready to merge, it will first be merged into our internal git system for in-house automated testing.

If this process passes, it will be merged into the public GitHub repository.

8.4 Legal Part

Before a contribution can be accepted, you will need to sign our *Contributor Agreement*. You will be prompted for this automatically as part of the Pull Request process.

8.5 Related Documents

8.5.1 Espressif IoT Development Framework Style Guide

About This Guide

Purpose of this style guide is to encourage use of common coding practices within the ESP-IDF.

Style guide is a set of rules which are aimed to help create readable, maintainable, and robust code. By writing code which looks the same way across the code base we help others read and comprehend the code. By using same conventions for spaces and newlines we reduce chances that future changes will produce huge unreadable diffs. By following common patterns for module structure and by using language features consistently we help others understand code behavior.

We try to keep rules simple enough, which means that they can not cover all potential cases. In some cases one has to bend these simple rules to achieve readability, maintainability, or robustness.

When doing modifications to third-party code used in ESP-IDF, follow the way that particular project is written. That will help propose useful changes for merging into upstream project.

C Code Formatting

Naming

- Any variable or function which is only used in a single source file should be declared `static`.
- Public names (non-static variables and functions) should be namespaced with a per-component or per-unit prefix, to avoid naming collisions. ie `esp_vfs_register()` or `esp_console_run()`. Starting the prefix with `esp_` for Espressif-specific names is optional, but should be consistent with any other names in the same component.
- Static variables should be prefixed with `s_` for easy identification. For example, `static bool s_invert`.
- Avoid unnecessary abbreviations (ie shortening `data` to `dat`), unless the resulting name would otherwise be very long.

Indentation Use 4 spaces for each indentation level. Do not use tabs for indentation. Configure the editor to emit 4 spaces each time you press tab key.

Vertical Space Place one empty line between functions. Do not begin or end a function with an empty line.

```
void function1()
{
    do_one_thing();
    do_another_thing();
                                    // INCORRECT, do not place empty line here
}
                                    // place empty line here
void function2()
{
                                    // INCORRECT, do not use an empty line here
    int var = 0;
    while (var < SOME_CONSTANT) {
        do_stuff(&var);
```

(continues on next page)

(continued from previous page)

```
    }
}
```

The maximum line length is 120 characters as long as it does not seriously affect the readability.

Horizontal Space Always add single space after conditional and loop keywords:

```
if (condition) {     // correct
    // ...
}

switch (n) {         // correct
    case 0:
        // ...
}

for(int i = 0; i < CONST; ++i) {     // INCORRECT
    // ...
}
```

Add single space around binary operators. No space is necessary for unary operators. It is okay to drop space around multiply and divide operators:

```
const int y = y0 + (x - x0) * (y1 - y0) / (x1 - x0);     // correct

const int y = y0 + (x - x0)*(y1 - y0)/(x1 - x0);         // also okay

int y_cur = -y;                                          // correct
++y_cur;

const int y = y0+(x-x0)*(y1-y0)/(x1-x0);                 // INCORRECT
```

No space is necessary around `.` and `->` operators.

Sometimes adding horizontal space within a line can help make code more readable. For example, you can add space to align function arguments:

```
esp_rom_gpio_connect_in_signal(PIN_CAM_D6,   I2S0I_DATA_IN14_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_D7,   I2S0I_DATA_IN15_IDX, false);
esp_rom_gpio_connect_in_signal(PIN_CAM_HREF, I2S0I_H_ENABLE_IDX,  false);
esp_rom_gpio_connect_in_signal(PIN_CAM_PCLK, I2S0I_DATA_IN15_IDX, false);
```

Note however that if someone goes to add new line with a longer identifier as first argument (e.g., `PIN_CAM_VSYNC`), it will not fit. So other lines would have to be realigned, adding meaningless changes to the commit.

Therefore, use horizontal alignment sparingly, especially if you expect new lines to be added to the list later.

Never use TAB characters for horizontal alignment.

Never add trailing whitespace at the end of the line.

Braces

- Function definition should have a brace on a separate line:

```
// This is correct:
void function(int arg)
{

}
```

(continues on next page)

(continued from previous page)

```
// NOT like this:
void function(int arg) {

}
```

- Within a function, place opening brace on the same line with conditional and loop statements:

```
if (condition) {
    do_one();
} else if (other_condition) {
    do_two();
}
```

Comments Use `//` for single line comments. For multi-line comments it is okay to use either `//` on each line or a `/* */` block.

Although not directly related to formatting, here are a few notes about using comments effectively.

- Do not use single comments to disable some functionality:

```
void init_something()
{
    setup_dma();
    // load_resources();                // WHY is this thing commented, asks␣
↪the reader?
    start_timer();
}
```

- If some code is no longer required, remove it completely. If you need it you can always look it up in git history of this file. If you disable some call because of temporary reasons, with an intention to restore it in the future, add explanation on the adjacent line:

```
void init_something()
{
    setup_dma();
    // TODO: we should load resources here, but loader is not fully integrated␣
↪yet.
    // load_resources();
    start_timer();
}
```

- Same goes for `#if 0 ... #endif` blocks. Remove code block completely if it is not used. Otherwise, add comment explaining why the block is disabled. Do not use `#if 0 ... #endif` or comments to store code snippets which you may need in the future.
- Do not add trivial comments about authorship and change date. You can always look up who modified any given line using git. E.g., this comment adds clutter to the code without adding any useful information:

```
void init_something()
{
    setup_dma();
    // XXX add 2016-09-01
    init_dma_list();
    fill_dma_item(0);
    // end XXX add
    start_timer();
}
```

Line Endings Commits should only contain files with LF (Unix style) endings.

Windows users can configure git to check out CRLF (Windows style) endings locally and commit LF endings by setting the `core.autocrlf` setting. *Github has a document about setting this option <github-line-endings>.*

If you accidentally have some commits in your branch that add LF endings, you can convert them to Unix by running this command in an MSYS2 or Unix terminal (change directory to the IDF working directory and check the correct branch is currently checked out, beforehand):

```
git rebase --exec 'git diff-tree --no-commit-id --name-only -r HEAD | xargs␣
↪dos2unix && git commit -a --amend --no-edit --allow-empty' master
```

(Note that this line rebases on master, change the branch name at the end to rebase on another branch.)

For updating a single commit, it is possible to run `dos2unix FILENAME` and then run `git commit --amend`

Formatting Your Code ESP-IDF uses Astyle to format source code. The configuration is stored in tools/ci/astyle-rules.yml file.

Initially, all components are excluded from formatting checks. You can enable formatting checks for the component by removing it from `components_not_formatted_temporary` list. Then run:

```
pre-commit run --files <path_to_files> astyle_py
```

Alternatively, you can run `astyle_py` manually. You can install it with `pip install astyle_py==VERSION`. Make sure you have the same version installed as the one specified in .pre-commit-config.yaml file. With `astyle_py` installed, run:

```
astyle_py --rules=$IDF_PATH/tools/ci/astyle-rules.yml <path-to-file>
```

Type Definitions Should be snake_case, ending with _t suffix:

```
typedef int signed_32_bit_t;
```

Enum Enums should be defined through the *typedef* and be namespaced:

```
typedef enum
{
    MODULE_FOO_ONE,
    MODULE_FOO_TWO,
    MODULE_FOO_THREE
} module_foo_t;
```

Assertions The standard C `assert()` function, defined in `assert.h` should be used to check conditions that should be true in source code. In the default configuration, an assert condition that returns `false` or 0 will call `abort()` and trigger a *Fatal Error*.

`assert()` should only be used to detect unrecoverable errors due to a serious internal logic bug or corruption, where it is not possible for the program to continue. For recoverable errors, including errors that are possible due to invalid external input, an *error value should be returned*.

Note: When asserting a value of type `esp_err_t``is equal to ``ESP_OK`, use the *ESP_ERROR_CHECK Macro* instead of an `assert()`.

It is possible to configure ESP-IDF projects with assertions disabled (see *CONFIG_COMPILER_OPTIMIZATION_ASSERTION_LEVEL*). Therefore, functions called in an `assert()` statement should not have side-effects.

It is also necessary to use particular techniques to avoid "variable set but not used" warnings when assertions are disabled, due to code patterns such as:

```
int res = do_something();
assert(res == 0);
```

Once the `assert` is optimized out, the `res` value is unused and the compiler will warn about this. However the function `do_something()` must still be called, even if assertions are disabled.

When the variable is declared and initialized in a single statement, a good strategy is to cast it to `void` on a new line. The compiler will not produce a warning, and the variable can still be optimized out of the final binary:

```
int res = do_something();
assert(res == 0);
(void)res;
```

If the variable is declared separately, for example if it is used for multiple assertions, then it can be declared with the GCC attribute `__attribute__((unused))`. The compiler will not produce any unused variable warnings, but the variable can still be optimized out:

```
int res __attribute__((unused));

res = do_something();
assert(res == 0);

res = do_something_else();
assert(res != 0);
```

Header File Guards

All public facing header files should have preprocessor guards. A pragma is preferred:

```
#pragma once
```

over the following pattern:

```
#ifndef FILE_NAME_H
#define FILE_NAME_H
...
#endif // FILE_NAME_H
```

In addition to guard macros, all C header files should have `extern "C"` guards to allow the header to be used from C++ code. Note that the following order should be used: `pragma once`, then any `#include` statements, then `extern "C"` guards:

```
#pragma once

#include <stdint.h>

#ifdef __cplusplus
extern "C" {
#endif

/* declarations go here */

#ifdef __cplusplus
}
#endif
```

Include Statements

When writing `#include` statements, try to maintain the following order:

- C standard library headers.
- Other POSIX standard headers and common extensions to them (such as `sys/queue.h`.)
- Common IDF headers (`esp_log.h`, `esp_system.h`, `esp_timer.h`, `esp_sleep.h`, etc.)
- Headers of other components, such as FreeRTOS.
- Public headers of the current component.
- Private headers.

Use angle brackets for C standard library headers and other POSIX headers (`#include <stdio.h>`).

Use double quotes for all other headers (`#include "esp_log.h"`).

C++ Code Formatting

The same rules as for C apply. Where they are not enough, apply the following rules.

File Naming C++ Header files have the extension `.hpp`. C++ source files have the extension `.cpp`. The latter is important for the compiler to distinguish them from normal C source files.

Naming

- **Class and struct** names shall be written in `CamelCase` with a capital letter as beginning. Member variables and methods shall be in `snake_case`. An exception from `CamelCase` is if the readability is severely decreased, e.g., in `GPIOOutput`, then an underscore _ is allowed to make it more readable: `GPIO_Output`.
- **Namespaces** shall be in lower `snake_case`.
- **Templates** are specified in the line above the function declaration.
- Interfaces in terms of Object-Oriented Programming shall be named without the suffix `...Interface`. Later, this makes it easier to extract interfaces from normal classes and vice versa without making a breaking change.

Member Order in Classes In order of precedence:

- First put the public members, then the protected, then private ones. Omit public, protected or private sections without any members.
- First put constructors/destructors, then member functions, then member variables.

For example:

```
class ForExample {
public:
    // first constructors, then default constructor, then destructor
    ForExample(double example_factor_arg);
    ForExample();
    ~ForExample();

    // then remaining pubic methods
    set_example_factor(double example_factor_arg);

    // then public member variables
    uint32_t public_data_member;

private:
    // first private methods
    void internal_method();

    // then private member variables
    double example_factor;
};
```

Spacing

- Do not indent inside namespaces.
- Put `public`, `protected` and `private` labels at the same indentation level as the corresponding `class` label.

Simple Example

```
// file spaceship.h
#ifndef SPACESHIP_H_
#define SPACESHIP_H_
#include <cstdlib>

namespace spaceships {

class SpaceShip {
public:
    SpaceShip(size_t crew);
    size_t get_crew_size() const;

private:
    const size_t crew;
};

class SpaceShuttle : public SpaceShip {
public:
    SpaceShuttle();
};

class Sojuz : public SpaceShip {
public:
    Sojuz();
};

template <typename T>
class CargoShip {
public:
    CargoShip(const T &cargo);

private:
    T cargo;
};

} // namespace spaceships

#endif // SPACESHIP_H_

// file spaceship.cpp
#include "spaceship.h"

namespace spaceships {

// Putting the curly braces in the same line for constructors is OK if it only␣
↪initializes
// values in the initializer list
SpaceShip::SpaceShip(size_t crew) : crew(crew) { }

size_t SpaceShip::get_crew_size() const
{
    return crew;
}
```

(continues on next page)

(continued from previous page)

```
SpaceShuttle::SpaceShuttle() : SpaceShip(7)
{
    // doing further initialization
}

Sojuz::Sojuz() : SpaceShip(3)
{
    // doing further initialization
}

template <typename T>
CargoShip<T>::CargoShip(const T &cargo) : cargo(cargo) { }

} // namespace spaceships
```

CMake Code Style

- Indent with four spaces.
- Maximum line length 120 characters. When splitting lines, try to focus on readability where possible (for example, by pairing up keyword/argument pairs on individual lines).
- Do not put anything in the optional parentheses after `endforeach()`, `endif()`, etc.
- Use lowercase (`with_underscores`) for command, function, and macro names.
- For locally scoped variables, use lowercase (`with_underscores`).
- For globally scoped variables, use uppercase (`WITH_UNDERSCORES`).
- Otherwise follow the defaults of the cmake-lint project.

Configuring the Code Style for a Project Using EditorConfig

EditorConfig helps developers define and maintain consistent coding styles between different editors and IDEs. The EditorConfig project consists of a file format for defining coding styles and a collection of text editor plugins that enable editors to read the file format and adhere to defined styles. EditorConfig files are easily readable and they work nicely with version control systems.

For more information, see EditorConfig Website.

Third Party Component Code Styles

ESP-IDF integrates a number of third party components where these components may have differing code styles.

FreeRTOS The code style adopted by FreeRTOS is described in the FreeRTOS style guide. Formatting of FreeRTOS source code is automated using Uncrustify, thus a copy of the FreeRTOS code style's Uncrustify configuration (`uncrustify.cfg`) is stored within ESP-IDF FreeRTOS component.

If a FreeRTOS source file is modified, the updated file can be formatted again by following the steps below:

1. Ensure that Uncrustify (v0.69.0) is installed on your system
2. Run the following command on the update FreeRTOS source file (where `source.c` is the path to the source file that requires formatting).

```
uncrustify -c $IDF_PATH/components/freertos/FreeRTOS-Kernel/uncrustify.cfg --
↪replace source.c --no-backup
```

Documenting Code

Please see the guide here: *Documenting Code*.

Structure

To be written.

Language Features

To be written.

8.5.2 Install Pre-commit Hook for ESP-IDF Project

Required Dependency

Python 3.8.* or above. This is our recommended Python version for ESP-IDF developers.

If you still have Python versions not compatible, update your Python versions before installing the pre-commit hook.

Install `pre-commit`

Run `pip install pre-commit`

Install `pre-commit` Hook

1. Go to the ESP-IDF project directory.
2. Run `pre-commit install --allow-missing-config -t pre-commit -t commit-msg`. Install hook by this approach will let you commit successfully even in branches without the `.pre-commit-config.yaml`
3. pre-commit hook will run automatically when you are running `git commit` command

Uninstall `pre-commit` Hook

Run `pre-commit uninstall`

What Is More?

For detailed usage, please refer to the documentation of pre-commit.

Common Problems For Windows Users

`/usr/bin/env: python: Permission denied.`

> If you are in Git Bash, please check the python executable location by run `which python`.
>
> If the executable is under `~/AppData/Local/Microsoft/WindowsApps/`, then it is a link to Windows AppStore, not a real one.
>
> Please install Python manually and update this in your `PATH` environment variable.

Your `USERPROFILE` contains non-ASCII characters

> `pre-commit` may fail when initializing an environment for a particular hook when the path of `pre-commit`'s cache contains non-ASCII characters. The solution is to set `PRE_COMMIT_HOME` to a path containing only standard characters before running pre-commit.

- CMD: `set PRE_COMMIT_HOME=C:\somepath\pre-commit`
- PowerShell: `$Env:PRE_COMMIT_HOME = "C:\somepath\pre-commit"`
- git bash: `export PRE_COMMIT_HOME="/c/somepath/pre-commit"`

8.5.3 Documenting Code

The purpose of this description is to provide a quick summary of the documentation style used in espressif/esp-idf repository and how to add new documentation.

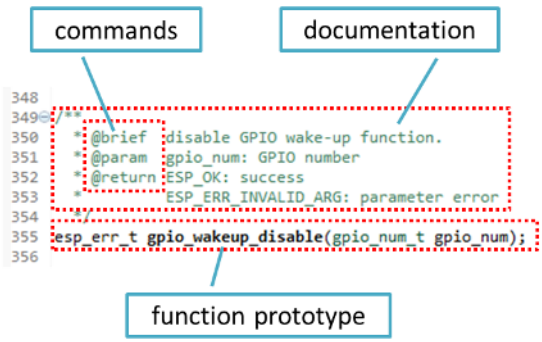
Introduction

When documenting code for this repository, please follow Doxygen style. You are doing it by inserting special commands, for instance `@param`, into standard comments blocks, for example:

```
/**
 * @param ratio this is oxygen to air ratio
 */
```

Doxygen can phrase the code, extract the commands together with subsequent text, and build documentation out of it.

Typical comment block, that contains documentation of a function, looks like below:

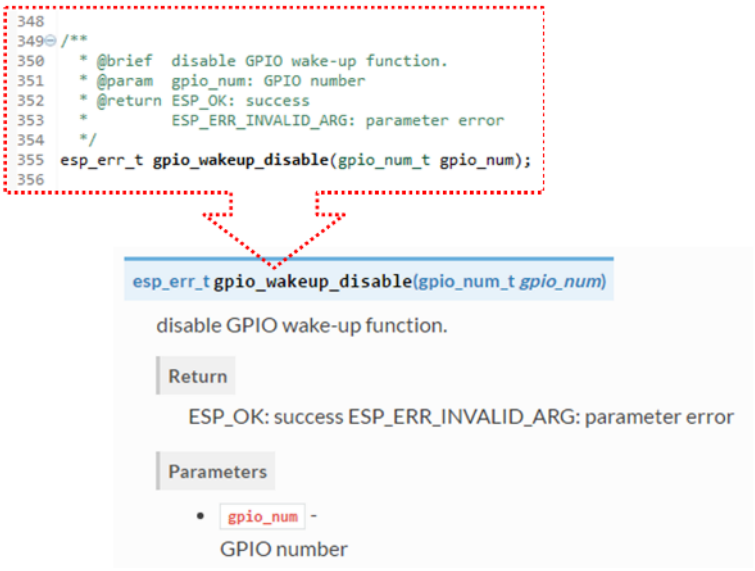


Doxygen supports a couple of formatting styles. It also gives you great flexibility on the level of details to include in documentation. To get familiar with available features, please check data-rich and very well-organized Doxygen Manual.

Why We Need Doxygen?

The ultimate goal is to ensure that all the code is consistently documented, so we can use tools like Sphinx and Breathe to aid preparation and automatic updates of API documentation when the code changes.

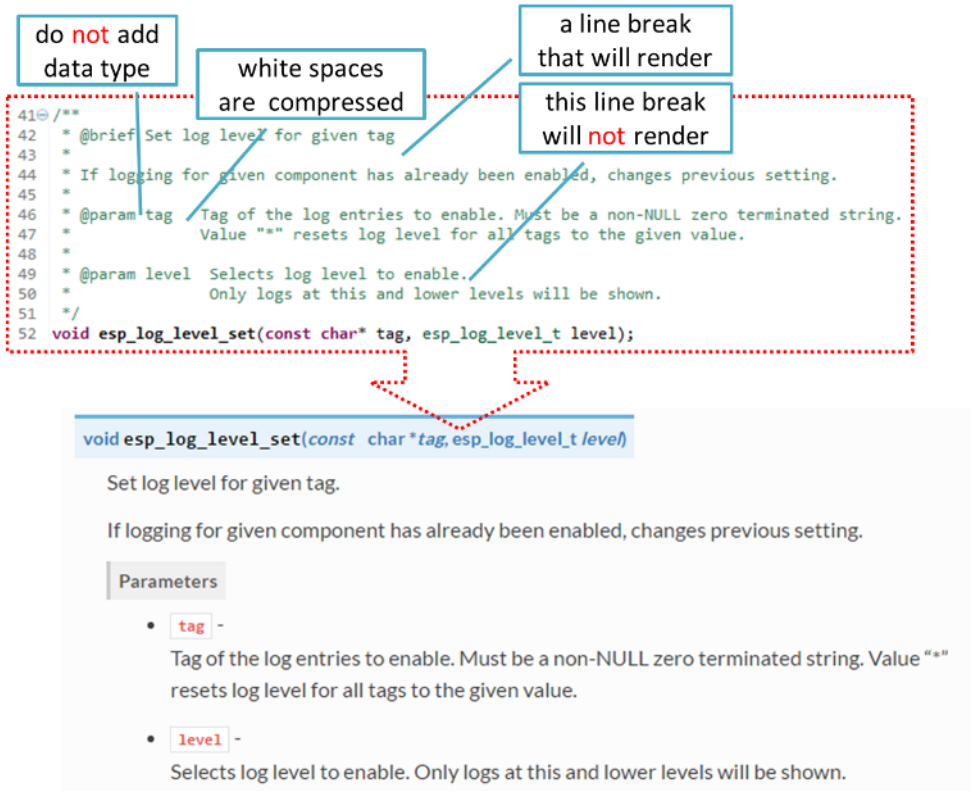
With these tools, the above piece of code renders like below:



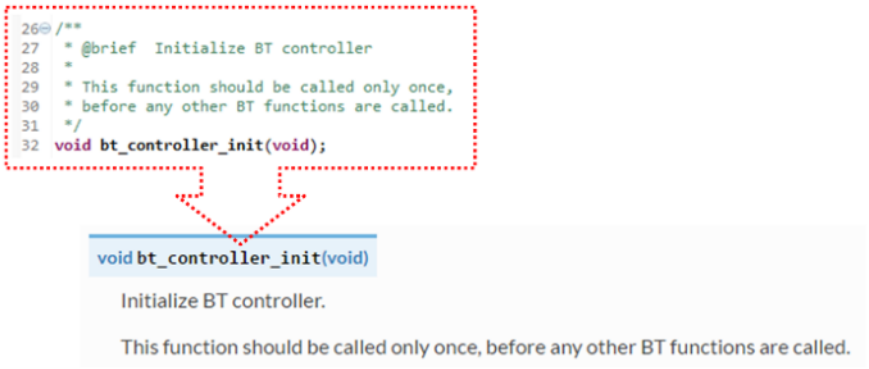
Go for It!

When writing code for this repository, please follow guidelines below:

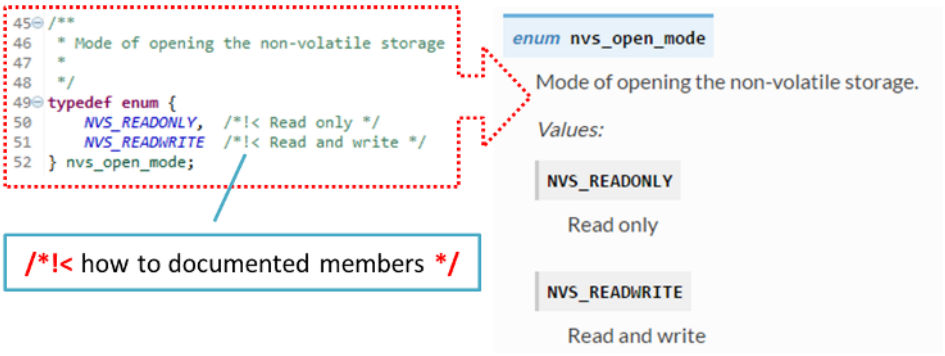
1. Document all building blocks of code, including functions, structs, typedefs, enums, macros, etc. Provide enough information about purpose, functionality, and limitations of documented items, as you would like to see them documented when reading the code by others.
2. Documentation of function should describe what this function does. If it accepts input parameters and returns some value, all of them should be explained.
3. Do not add a data type before parameter or any other characters besides spaces. All spaces and line breaks are compressed into a single space. If you like to break a line, then break it twice.



4. If function has void input or does not return any value, then skip `@param` or `@return`.



5. When documenting a `define` as well as members of a `struct` or `enum`, place specific comment like below after each member.



6. To provide well-formatted lists, break the line after command (like `@return` in the example below).

```
*
* @return
*     - ESP_OK if erase operation was successful
*     - ESP_ERR_NVS_INVALID_HANDLE if handle has been closed or is NULL
*     - ESP_ERR_NVS_READ_ONLY if handle was opened as read only
*     - ESP_ERR_NVS_NOT_FOUND if the requested key does not exist
*     - other error codes from the underlying storage driver
*
```

7. Overview of functionality of documented header file, or group of files that make a library, should be placed in a separate `README.rst` file of the same directory. If this directory contains header files for different APIs, then the file name should be `apiname-readme.rst`.

Go One Extra Mile

Here are a couple of tips on how you can make your documentation even better and more useful to the reader and writer.

When writing code, please follow the guidelines below:

1. Add code snippets to illustrate implementation. To do so, enclose snippet using `@code{c}` and `@endcode` commands.

```
*
* @code{c}
* // Example of using nvs_get_i32:
* int32_t max_buffer_size = 4096; // default value
* esp_err_t err = nvs_get_i32(my_handle, "max_buffer_size", &max_buffer_size);
* assert(err == ESP_OK || err == ESP_ERR_NVS_NOT_FOUND);
* // if ESP_ERR_NVS_NOT_FOUND was returned, max_buffer_size will still
* // have its default value.
```

(continues on next page)

(continued from previous page)

```
* @endcode
*
```

The code snippet should be enclosed in a comment block of the function that it illustrates.

2. To highlight some important information use command `@attention` or `@note`.

```
*
* @attention
*     1. This API only impact WIFI_MODE_STA or WIFI_MODE_APSTA mode
*     2. If the ESP32 is connected to an AP, call esp_wifi_disconnect to␣
↪disconnect.
*
```

Above example also shows how to use a numbered list.

3. To provide common description to a group of similar functions, enclose them using `/**@{*/` and `/**@}*/` markup commands.

```
/**@{*/
/**
 * @brief common description of similar functions
 *
 */
void  first_similar_function (void);
void second_similar_function (void);
/**@}*/
```

For practical example see nvs_flash/include/nvs.h.

4. You may want to go even further and skip some code like repetitive defines or enumerations. In such case, enclose the code within `/** @cond */` and `/** @endcond */` commands. Example of such implementation is provided in driver/gpio/include/driver/gpio.h.
5. Use markdown to make your documentation even more readable. You will add headers, links, tables and more.

```
*
* [ESP32-S3 Technical Reference Manual](https://www.espressif.com/sites/
↪default/files/documentation/esp32-s3_technical_reference_manual_en.pdf)
*
```

Note: Code snippets, notes, links, etc., will not make it to the documentation, if not enclosed in a comment block associated with one of the documented objects.

6. Prepare one or more complete code examples together with description. Place description to a separate file `README.md` in specific folder of examples directory.

Standardize Document Format

When it comes to text, please follow guidelines below to provide well-formatted Markdown (.md) or reST (.rst) documents.

1. Please ensure that one paragraph is written in one line. Do not break lines like below. Breaking lines to enhance readability is only suitable for writing code. To make the text easier to read, it is recommended to place an empty line to separate the paragraph.

2. Please make the line number of CN and EN documents consistent like below. The benefit of this approach is that it can save time for both writers and translators. When non-bilingual writers need to update text, they only need to update the same line in the corresponding CN or EN document. For translators, if documents are updated in English, then translators can quickly locate where to update in the corresponding CN document later. Besides, by comparing the total number of lines in EN and CN documents, you can quickly find out whether the CN version lags behind the EN version.

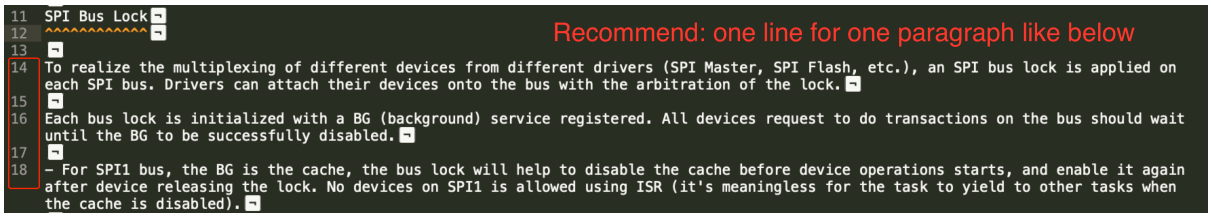


Fig. 1: One line for one paragraph (click to enlarge)

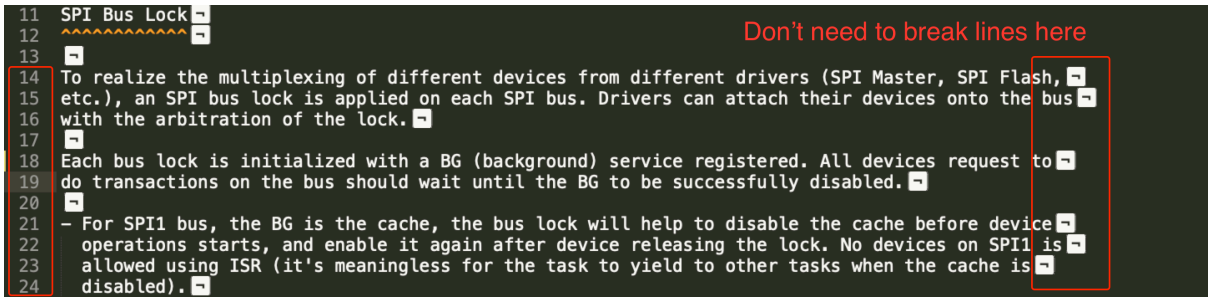

Fig. 2: No line breaks within the same paragraph (click to enlarge)

Fig. 3: Keep the line number for EN and CN documents consistent (click to enlarge)

Building Documentation

The documentation is built with the *esp-docs* Python package, which is a wrapper around Sphinx.

To install it simply do:

```
pip install esp-docs
```

After a successful install then the documentation can be built from the docs folder with:

```
build-docs build
```

or for specific target and language with:

```
build-docs -t esp32 -l en build
```

For more in-depth documentation about *esp-docs* features please see the documentation at esp-docs.

Wrap Up

We love good code that is doing cool things. We love it even better, if it is well-documented, so we can quickly make it run and also do the cool things.

Go ahead, contribute your code and documentation!

8.5.4 Creating Examples

Each ESP-IDF example is a complete project that someone else can copy and adapt the code to solve their own problem. Examples should demonstrate ESP-IDF functionality, while keeping this purpose in mind.

Structure

- The `main` directory should contain a source file named `(something)_example_main.c` with the main functionality.
- If the example has additional functionality, split it logically into separate C or C++ source files under `main` and place a corresponding header file in the same directory.
- If the example has a lot of additional functionality, consider adding a `components` directory to the example project and make some example-specific components with library functionality. Only do this if the components are specific to the example, if they are generic or common functionality then they should be added to ESP-IDF itself.
- The example should have a `README.md` file. Use the template example README and adapt it for your particular example.
- Examples should have a `pytest_<example name>.py` file for running an automated example test. If submitting a GitHub Pull Request which includes an example, it is OK not to include this file initially. The details can be discussed as part of the Pull Request. Please refer to *IDF Tests with Pytest Guide* for details.

General Guidelines

Example code should follow the *Espressif IoT Development Framework Style Guide*.

Checklist

Checklist before submitting a new example:

- Example project name (in `README.md`) uses the word "example". Use "example" instead of "demo", "test" or similar words.
- Example does one distinct thing. If the example does more than one thing at a time, split it into two or more examples.
- Example has a `README.md` file which is similar to the template example README .
- Functions and variables in the example are named according to *naming section of the style guide*. For non-static names which are only specific to the example's source files, you can use `example` or something similar as a prefix.
- All code in the example is well structured and commented.
- Any unnecessary code (old debugging logs, commented-out code, etc.) is removed from the example.
- Options in the example (like network names, addresses, etc) are not hard-coded. Use configuration items if possible, or otherwise declare macros or constants.
- Configuration items are provided in a `KConfig.projbuild` file with a menu named "Example Configuration". See existing example projects to see how this is done.
- All original example code has a license header saying it is "in the public domain / CC0", and a warranty disclaimer clause. Alternatively, the example is licensed under Apache License 2.0. See existing examples for headers to adapt from.
- Any adapted or third party example code has the original license header on it. This code must be licensed compatible with Apache License 2.0.

8.5.5 API Documentation Template

Note: *INSTRUCTIONS*

1. Use this file (docs/en/api-reference/template.rst) as a template to document API.
2. Change the file name to the name of the header file that represents the documented API.
3. Include respective files with descriptions from the API folder using `..include::`
   - README.rst
   - example.rst
   - ...
4. Optionally provide description right in this file.
5. Once done, remove all instructions like this one and any superfluous headers.

Overview

Note: *INSTRUCTIONS*

1. Provide overview where and how this API may be used.
2. Include code snippets to illustrate functionality of particular functions when applicable.
3. To distinguish between sections, use the following heading levels:
   - # with overline, for parts
   - * with overline, for chapters
   - = for sections
   - - for subsections
   - ^ for subsubsections
   - " for paragraphs

Application Example

Note: *INSTRUCTIONS*

1. Prepare one or more practical examples to demonstrate functionality of this API.
2. Each example should follow pattern of projects located in `esp-idf/examples/` folder.
3. Place example in this folder, and add `README.md` file.
4. Provide overview of demonstrated functionality in `README.md`.
5. With good overview readers should be able to understand what example does without opening the source code.
6. Depending on complexity of example, break down description of code into parts and provide overview of functionality of each part.
7. Include flow diagram and screenshots of application output if applicable.
8. Finally add in this section synopsis of each example together with link to respective folder in `esp-idf/examples/`.

API Reference

Note: *INSTRUCTIONS*

1. ESP-IDF repository provides automatic update of API reference documentation using *code markup retrieved by Doxygen from header files*.
2. Update is done on each documentation build by invoking Sphinx extension `esp_extensions/run_doxygen.py` for all header files listed in the `INPUT` statement of docs/doxygen/Doxyfile.
3. Each line of the `INPUT` statement (other than a comment that begins with `##`) contains a path to header file `*.h` that is used to generate corresponding `*.inc` files:

```
##
## Wi-Fi - API Reference
##
../components/esp32/include/esp_wifi.h \
../components/esp32/include/esp_smartconfig.h \
```

4. When the headers are expanded, any macros defined by default in `sdkconfig.h` as well as any macros defined in SOC-specific `include/soc/*_caps.h` headers will be expanded. This allows the headers to include or exclude material based on the `IDF_TARGET` value.
5. The `*.inc` files contain formatted reference of API members generated automatically on each documentation build. All `*.inc` files are placed in Sphinx `_build` directory. To see directives generated, e.g., `esp_wifi.h`, run `python gen-dxd.py esp32/include/esp_wifi.h`.
6. To show contents of `*.inc` file in documentation, include it as follows:

```
.. include-build-file:: inc/esp_wifi.inc
```

   For example see docs/en/api-reference/network/esp_wifi.rst
7. Optionally, rather that using `*.inc` files, you may want to describe API in you own way. See docs/en/api-reference/storage/fatfs.rst for example.
   Below is the list of common `.. doxygen...::` directives:
   - Functions - `.. doxygenfunction:: name_of_function`
   - Unions - `.. doxygenunion:: name_of_union`
   - Structures - `.. doxygenstruct:: name_of_structure` together with `:members:`
   - Macros - `.. doxygendefine:: name_of_define`
   - Type Definitions - `.. doxygentypedef:: name_of_type`
   - Enumerations - `.. doxygenenum:: name_of_enumeration`

   See Breathe documentation for additional information.
   To provide a link to header file, use the *link custom role* directive as follows:

```
* :component_file:`path_to/header_file.h`
```

8. In any case, to generate API reference, the file docs/doxygen/Doxyfile should be updated with paths to `*.h` headers that are being documented.
9. When changes are committed and documentation is built, check how this section has been rendered. *Correct annotations* in respective header files, if required.

8.5.6 Contributor Agreement

Individual Contributor Non-Exclusive License Agreement Including the Traditional Patent License OPTION

Thank you for your interest in contributing to this Espressif project hosted on GitHub ("We" or "Us").

The purpose of this contributor agreement ("Agreement") is to clarify and document the rights granted by contributors to Us. To make this document effective, please follow the instructions in the *Contributions Guide*.

1. DEFINITIONS **You** means the Individual Copyright owner who submits a Contribution to Us. If You are an employee and submit the Contribution as part of your employment, You must have had Your employer approve this Agreement or sign the Entity version of this Agreement.

Contribution means any original work of authorship (software and/or documentation) including any modifications or additions to an existing work, Submitted by You to Us, in which You own the Copyright. If You do not own the Copyright in the entire work of authorship, please contact Us by submitting a comment on GitHub.

Copyright means all rights protecting works of authorship owned or controlled by You, including copyright, moral and neighboring rights, as appropriate, for the full term of their existence including any extensions by You.

Material means the software or documentation made available by Us to third parties. When this Agreement covers more than one software project, the Material means the software or documentation to which the Contribution was Submitted. After You Submit the Contribution, it may be included in the Material.

Submit means any form of physical, electronic, or written communication sent to Us, including but not limited to electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, Us, but excluding communication that is conspicuously marked or otherwise designated in writing by You as "Not a Contribution."

Submission Date means the date You Submit a Contribution to Us.

Documentation means any non-software portion of a Contribution.

2. COPYRIGHT LICENSE 2.1 Grant of Copyright License to Us

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, NON-exclusive, perpetual and irrevocable license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, under the Copyright covering the Contribution to use the Contribution by all means, including, but not limited to:

- to publish the Contribution
- to modify the Contribution, to prepare derivative works based upon or containing the Contribution and to combine the Contribution with other software code
- to reproduce the Contribution in original or modified form
- to distribute, to make the Contribution available to the public, display and publicly perform the Contribution in original or modified form

2.2 Moral Rights remain unaffected to the extent they are recognized and not waivable by applicable law. Notwithstanding, You may add your name in the header of the source code files of Your Contribution and We will respect this attribution when using Your Contribution.

3. PATENT LICENSE 3.1 Grant of Patent License to US

Subject to the terms and conditions of this Agreement, You hereby grant to Us a worldwide, royalty-free, non-exclusive, perpetual and irrevocable (except as stated in Section 3.2) patent license, with the right to transfer an unlimited number of non-exclusive licenses or to grant sublicenses to third parties, to make, have made, use, sell, offer for sale, import and otherwise transfer the Contribution and the Contribution in combination with the Material (and portions of such combination). This license applies to all patents owned or controlled by You, whether already acquired or hereafter acquired, that would be infringed by making, having made, using, selling, offering for sale, importing or otherwise transferring of Your Contribution(s) alone or by combination of Your Contribution(s) with the Material.

3.2 Revocation of Patent License

You reserve the right to revoke the patent license stated in section 3.1 if We make any infringement claim that is targeted at your Contribution and not asserted for a Defensive Purpose. An assertion of claims of the Patents shall be considered for a "Defensive Purpose" if the claims are asserted against an entity that has filed, maintained, threatened, or voluntarily participated in a patent infringement lawsuit against Us or any of Our licensees.

4. DISCLAIMER THE CONTRIBUTION IS PROVIDED "AS IS". MORE PARTICULARLY, ALL EXPRESSED OR IMPLIED WARRANTIES INCLUDING, WITHOUT LIMITATION, ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT ARE EXPRESSLY DISCLAIMED BY YOU TO US AND BY US TO YOU. TO THE EXTENT THAT ANY SUCH WARRANTIES CANNOT BE DISCLAIMED, SUCH WARRANTY IS LIMITED IN DURATION TO THE MINIMUM PERIOD PERMITTED BY LAW.

5. Consequential Damage Waiver TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT WILL YOU OR US BE LIABLE FOR ANY LOSS OF PROFITS, LOSS OF ANTICIPATED SAVINGS, LOSS OF DATA, INDIRECT, SPECIAL, INCIDENTAL, CONSEQUENTIAL AND EXEMPLARY DAMAGES ARISING OUT OF THIS AGREEMENT REGARDLESS OF THE LEGAL OR EQUITABLE THEORY (CONTRACT, TORT OR OTHERWISE) UPON WHICH THE CLAIM IS BASED.

6. Approximation of Disclaimer and Damage Waiver IF THE DISCLAIMER AND DAMAGE WAIVER MENTIONED IN SECTION 4 AND SECTION 5 CANNOT BE GIVEN LEGAL EFFECT UNDER APPLICABLE LOCAL LAW, REVIEWING COURTS SHALL APPLY LOCAL LAW THAT MOST CLOSELY APPROXIMATES AN ABSOLUTE WAIVER OF ALL CIVIL LIABILITY IN CONNECTION WITH THE CONTRIBUTION.

7. Term 7.1 This Agreement shall come into effect upon Your acceptance of the terms and conditions.

7.2 In the event of a termination of this Agreement, sections 4, 5, 6, 7 and 8 shall survive such termination and shall remain in full force thereafter. For the avoidance of doubt, Contributions that are already licensed under a free and open source license at the date of the termination shall remain in full force after the termination of this Agreement.

8. Miscellaneous 8.1 This Agreement and all disputes, claims, actions, suits or other proceedings arising out of this agreement or relating in any way to it shall be governed by the laws of People's Republic of China excluding its private international law provisions.

8.2 This Agreement sets out the entire agreement between You and Us for Your Contributions to Us and overrides all other agreements or understandings.

8.3 If any provision of this Agreement is found void and unenforceable, such provision will be replaced to the extent possible with a provision that comes closest to the meaning of the original provision and that is enforceable. The terms and conditions set forth in this Agreement shall apply notwithstanding any failure of essential purpose of this Agreement or any limited remedy to the maximum extent possible under law.

8.4 You agree to notify Us of any facts or circumstances of which you become aware that would make this Agreement inaccurate in any respect.

8.5.7 Copyright Header Guide

ESP-IDF is released under the Apache License 2.0 with some additional third-party copyrighted code released under various licenses. For further information please refer to *the list of copyrights and licenses*.

This page explains how the source code should be properly marked with a copyright header. ESP-IDF uses the Software Package Data Exchange (SPDX) format which is short and can be easily read by humans or processed by automated tools for copyright checks.

How to Check the Copyright Headers

Please make sure you have installed the *pre-commit hooks* which contain a copyright header checker as well. The checker can suggest a header if it is not able to detect a properly formatted SPDX header.

What If the Checker's Suggestion Is Incorrect?

No automated checker (no matter how good is) can replace humans. So the developer's responsibility is to modify the offered header to be in line with the law and the license restrictions of the original code on which the work is based on. Certain licenses are not compatible between each other. Such corner cases will be covered by the following examples.

The checker can be configured with the `tools/ci/check_copyright_config.yaml` configuration file. Please check the options it offers and consider updating it in order to match the headers correctly.

Common Examples of Copyright Headers

The simplest case is when the code is not based on any licensed previous work, e.g., it was written completely from scratch. Such code can be decorated with the following copyright header and put under the license of ESP-IDF:

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Apache-2.0
 */
```

Less Restrictive Parts of ESP-IDF Some parts of ESP-IDF are deliberately under less restrictive licenses in order to ease their re-use in commercial closed source projects. This is the case for ESP-IDF examples which are in Public domain or under the Creative Commons Zero Universal (CC0) license. The following header can be used in such source files:

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: Unlicense OR CC0-1.0
 */
```

The option allowing multiple licenses joined with the `OR` keyword from the above example can be achieved with the definition of multiple allowed licenses in the `tools/ci/check_copyright_config.yaml` configuration file. Please use this option with care and only selectively for a limited part of ESP-IDF.

Third Party Licenses Code licensed under different licenses, modified by Espressif Systems and included in ESP-IDF cannot be licensed under Apache License 2.0 not even if the checker suggests it. It is advised to keep the original copyright header and add an SPDX before it.

The following example is a suitable header for a code licensed under the "GNU General Public License v2.0 or later" held by John Doe with some additional modifications done by Espressif Systems:

```
/*
 * SPDX-FileCopyrightText: 1991 John Doe
 *
 * SPDX-License-Identifier: GPL-2.0-or-later
 *
 * SPDX-FileContributor: 2019-2023 Espressif Systems (Shanghai) CO LTD
 */
```

The licenses can be identified and the short SPDX identifiers can be found in the official SPDX license list. Other very common licenses are the GPL-2.0-only, the BSD-3-Clause, and the BSD-2-Clause.

In exceptional case, when a license is not present on the SPDX license list, it can be expressed by using the LicenseRef-[idString] custom license identifier, for example `LicenseRef-Special-License`. The full license text must be added into the `LICENSES` directory under `Special-License` filename.

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: LicenseRef-Special-License
 */
```

Dedicated `LicenseRef-Included` custom license identifier can be used to express a situation when the custom license is included directly in the source file.

```
/*
 * SPDX-FileCopyrightText: 2015-2023 Espressif Systems (Shanghai) CO LTD
 *
 * SPDX-License-Identifier: LicenseRef-Included
 *
 * <Full custom license text>
 */
```

The configuration stored in `tools/ci/check_copyright_config.yaml` offers features useful for third party licenses:

- A different license can be defined for the files part of a third party library.
- The check for a selected set of files can be permanently disabled. Please use this option with care and only in cases when none of the other options are suitable.

8.5.8 pytest in ESP-IDF

ESP-IDF has numerous types of tests that are meant to be executed on an ESP chip (known as **on target testing**). Target tests are usually compiled as part of an IDF project used for testing (known as a **test app**), where test apps follows the same build, flash, and monitor process of any other standard IDF project.

Typically, on target testing will require a connected host (e.g., a PC) that is responsible for triggering a particular test case, providing test data, and inspecting test results.

ESP-IDF uses the pytest framework (and some pytest plugins) on the host side to automate on target testing. This guide introduces pytest in ESP-IDF and covers the following concepts:

1. The different types of test apps in ESP-IDF.
2. Using the pytest framework in Python scripts to automate target testing.
3. ESP-IDF Continuous Integration (CI) target testing process.
4. How to run target tests locally with pytest.
5. pytest tips and tricks.

Note: In ESP-IDF, we use the following pytest plugins by default:

- pytest-embedded with default services `esp,idf`
- pytest-rerunfailures

All the concepts and usages introduced in this guide are based on the default behavior of these plugins, thus may not be available in vanilla pytest.

Installation

All dependencies could be installed by running the install script with the `--enable-pytest` argument:

```
$ install.sh --enable-pytest
```

Common Issues During Installation

No Package 'dbus-1' Found

```
configure: error: Package requirements (dbus-1 >= 1.8) were not met:

No package 'dbus-1' found

Consider adjusting the PKG_CONFIG_PATH environment variable if you
installed software in a non-standard prefix.
```

If you encounter the error message above, you may need to install some missing packages.

If you are using Ubuntu, you may need to run:

```
sudo apt-get install libdbus-glib-1-dev
```

or

```
sudo apt-get install libdbus-1-dev
```

For other Linux distributions, please Google the error message above and find which missing packages need to be installed for your particular distribution.

Invalid Command 'bdist_wheel'

```
error: invalid command 'bdist_wheel'
```

If you encounter the error message above, you may need to install some missing Python packages such as:

```
python -m pip install -U pip
```

or

```
python -m pip install wheel
```

Note: Before running the pip commands, please make sure you are using the IDF Python virtual environment.

Test Apps

ESP-IDF contains different types of test apps that can be automated using pytest.

Component Tests ESP-IDF components typically contain component specific test apps that execute component specific unit tests. Component test apps are the recommended way to test components. All the test apps should be located under `${IDF_PATH}/components/<COMPONENT_NAME>/test_apps`, for example:

```
components/
└── my_component/
      ├── include/
      │   └── ...
      ├── test_apps/
      │   ├── test_app_1
      │   │   ├── main/
      │   │   │   └── ...
      │   │   ├── CMakeLists.txt
      │   │   └── pytest_my_component_app_1.py
      │   ├── test_app_2
      │   │   ├── ...
      │   │   └── pytest_my_component_app_2.py
      │   └── parent_folder
      │       ├── test_app_3
      │       │   ├── ...
      │       │   └── pytest_my_component_app_3.py
      │       └── ...
      ├── my_component.c
      └── CMakeLists.txt
```

Example Tests The purpose of ESP-IDF examples is to demonstrate parts of ESP-IDF functionality to users (refer to Examples Readme for more information).

However, to ensure that these examples operate correctly, examples can be treated as test apps and executed automatically by using pytest. All examples should be located under `${IDF_PATH}/examples`, with tested example including a Python test script, for example:

```
examples/
└── parent_folder/
    └── example_1/
        ├── main/
        │   └── ...
        ├── CMakeLists.txt
        └── pytest_example_1.py
```

Custom Tests Custom Tests are tests that aim to test some arbitrary functionality of ESP-IDF, thus are not intended to demonstrate IDF functionality to users in any way.

All custom test apps are located under `${IDF_PATH}/tools/test_apps`. For more information please refer to the Custom Test Readme .

pytest in ESP-IDF

pytest Execution Process

1. Bootstrapping Phase

   Create session-scoped caches:

   - port-target cache
   - port-app cache

2. Collection Phase

A. Gather all Python files with the prefix `pytest_`.
B. Gather all test functions with the prefix `test_`.
C. Apply the params, and duplicate the test functions.
D. Filter the test cases with CLI options. For the detailed usages, see *Filter the Test Cases*.

3. Execution Phase

   A. Construct the fixtures. In ESP-IDF, the common fixtures are initialized in this order:

      a. `pexpect_proc`: pexpect instance
      b. `app`: IdfApp instance

         The test app's information (e.g., sdkconfig, flash_files, partition_table, etc) would be parsed at this phase.

      c. `serial`: IdfSerial instance

         The port of the host to which the target is connected is auto-detected. In the case of multiple targets connected to the host, the test target's type is parsed from the app. The test app binary files are flashed to the test target automatically.

      d. `dut`: IdfDut instance

   B. Run the real test function.
   C. Deconstruct the fixtures in this order:

      a. `dut`

      i. close the `serial` port.
      ii. (Only for apps with Unity test framework) generate JUnit report of the Unity test cases.

      b. `serial`
      c. `app`
      d. `pexpect_proc`: Close the file descriptor

   D. (Only for apps with Unity test framework)

      If `dut.expect_from_unity_output()` is called, an `AssertionError` is raised upon detection of a Unity test failure.

4. Reporting Phase

A. Generate JUnit report of the test functions.
B. Modify the JUnit report test case name into ESP-IDF test case ID format: `<target>.<config>.<test function name>`.

5. Finalizatoin Phase (Only for apps with Unity test framework)

   Combine the JUnit reports if the JUnit reports of the Unity test cases are generated.

Basic Example This following Python test script example is taken from pytest_console_basic.py .

```
@pytest.mark.esp32
@pytest.mark.esp32c3
@pytest.mark.generic
@pytest.mark.parametrize('config', [
    'history',
    'nohistory',
], indirect=True)
def test_console_advanced(config: str, dut: IdfDut) -> None:
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```

To demonstrate how pytest is typically used in an ESP-IDF test script, let us go through this simple test script line by line in the following subsections.

Target Markers Pytest markers can be used to indicate which targets (i.e., which ESP chip) a particular test case should should run on. For example:

```
@pytest.mark.esp32      # <-- support esp32
@pytest.mark.esp32c3    # <-- support esp32c3
@pytest.mark.generic    # <-- test env "generic"
```

The example above indicates that a particular test case is supported on the ESP32 and ESP32-C3. Furthermore, the target's board type should be `generic`. For more details regarding the `generic` type, you may run `pytest --markers` to get detailed information regarding all markers.

Note: If the test case can be run on all targets officially supported by ESP-IDF (call `idf.py --list-targets` for more details), you can use a special marker `supported_targets` to apply all of them in one line.

Parameterized Markers You can use `pytest.mark.parametrize` with `config` to apply the same test to different apps with different sdkconfig files. For more information about `sdkconfig.ci.xxx` files, please refer to the Configuration Files section under this readme .

```
@pytest.mark.parametrize('config', [
    'history',      # <-- run with app built by sdkconfig.ci.history
    'nohistory',    # <-- run with app built by sdkconfig.ci.nohistory
], indirect=True)   # <-- `indirect=True` is required
```

Overall, this test function would be replicated to 4 test cases:

- `esp32.history.test_console_advanced`
- `esp32.nohistory.test_console_advanced`
- `esp32c3.history.test_console_advanced`
- `esp32c3.nohistory.test_console_advanced`

Testing Serial Output To ensure that test has executed successfully on target, the test script can test that serial output of the target using the `dut.expect()` function, for example:

```
def test_console_advanced(config: str, dut: IdfDut) -> None:  # The value of␣
↪argument ``config`` is assigned by the parameterization.
    if config == 'history':
        dut.expect('Command history enabled')
    elif config == 'nohistory':
        dut.expect('Command history disabled')
```

The `dut.expect(...)` will first compile the expected string into regex, which in turn is then used to seek through the serial output until the compiled regex is matched, or until a timeout occurs.

Please pay extra attention to the expected string when it contains regex keyword characters (e.g., parentheses, square brackets). Alternatively, you may use `dut.expect_exact(...)` that will attempt to match the string without converting it into regex.

For more information regarding the different types of `expect` functions, please refer to the pytest-embedded Expecting documentation.

Advanced Examples

Multi-Target Tests with the Same App In some cases a test may involve multiple targets running the same test app. In this case, multiple DUTs can be instantiated using `parameterize`, for example:

```
@pytest.mark.esp32s2
@pytest.mark.esp32s3
@pytest.mark.usb_host
@pytest.mark.parametrize('count', [
    2,
], indirect=True)
def test_usb_host(dut: Tuple[IdfDut, IdfDut]) -> None:
    device = dut[0]  # <-- assume the first dut is the device
    host = dut[1]    # <-- and the second dut is the host
    ...
```

After setting the param `count` to 2, all these fixtures are changed into tuples.

Multi-Target Tests with Different Apps In some cases (in particular protocol tests), a test may involve multiple targets running different test apps (e.g., separate targets to act as master and slave). In this case, multiple DUTs with different test apps can be instantiated using `parameterize`.

This code example is taken from pytest_wifi_getting_started.py .

```
@pytest.mark.esp32
@pytest.mark.multi_dut_generic
@pytest.mark.parametrize(
    'count, app_path', [
        (2,
         f'{os.path.join(os.path.dirname(__file__), "softAP")}|{os.path.join(os.
↪path.dirname(__file__), "station")}'),
    ], indirect=True
)
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]
    ...
```

Here the first DUT was flashed with the app softAP , and the second DUT was flashed with the app station .

Note: Here the `app_path` should be set with absolute path. The `__file__` macro in Python would return the absolute path of the test script itself.

Multi-Target Tests with Different Apps and Targets This code example is taken from pytest_wifi_getting_started.py . As the comment says, for now it is not running in the ESP-IDF CI.

```
@pytest.mark.parametrize(
    'count, app_path, target', [
        (2,
         f'{os.path.join(os.path.dirname(__file__), "softAP")}|{os.path.join(os.
↪path.dirname(__file__), "station")}',
         'esp32|esp32s2'),
        (2,
         f'{os.path.join(os.path.dirname(__file__), "softAP")}|{os.path.join(os.
↪path.dirname(__file__), "station")}',
         'esp32s2|esp32'),
    ],
    indirect=True,
)
def test_wifi_getting_started(dut: Tuple[IdfDut, IdfDut]) -> None:
    softap = dut[0]
    station = dut[1]
    ...
```

Overall, this test function would be replicated to 2 test cases:

- softAP with ESP32 target, and station with ESP32-S2 target
- softAP with ESP32-S2 target, and station with ESP32 target

Support Different Targets with Different sdkconfig Files This code example is taken from pytest_panic.py as an advanced example.

```
CONFIGS = [
    pytest.param('coredump_flash_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
↪esp32s2]),
    pytest.param('coredump_flash_elf_sha', marks=[pytest.mark.esp32]),  # sha256␣
↪only supported on esp32
    pytest.param('coredump_uart_bin_crc', marks=[pytest.mark.esp32, pytest.mark.
↪esp32s2]),
    pytest.param('coredump_uart_elf_crc', marks=[pytest.mark.esp32, pytest.mark.
↪esp32s2]),
    pytest.param('gdbstub', marks=[pytest.mark.esp32, pytest.mark.esp32s2]),
    pytest.param('panic', marks=[pytest.mark.esp32, pytest.mark.esp32s2]),
]

@pytest.mark.parametrize('config', CONFIGS, indirect=True)
...
```

Custom Classes Usually, you may want to write a custom class under these conditions:

1. Add more reusable functions for a certain number of DUTs.
2. Add custom setup and teardown functions in different phases described in Section *pytest Execution Process*.

This code example is taken from panic/conftest.py .

```
class PanicTestDut(IdfDut):
    ...

@pytest.fixture(scope='module')
def monkeypatch_module(request: FixtureRequest) -> MonkeyPatch:
    mp = MonkeyPatch()
    request.addfinalizer(mp.undo)
    return mp

@pytest.fixture(scope='module', autouse=True)
```

(continues on next page)

(continued from previous page)

```
def replace_dut_class(monkeypatch_module: MonkeyPatch) -> None:
    monkeypatch_module.setattr('pytest_embedded_idf.dut.IdfDut', PanicTestDut)
```

`monkeypatch_module` provides a module-scoped monkeypatch fixture.

`replace_dut_class` is a module-scoped autouse fixture. This function replaces the `IdfDut` class with your custom class.

Mark Flaky Tests Certain test cases are based on Ethernet or Wi-Fi. However, the test may be flaky due to networking issues. Thus, it is possible to mark a particular test case as flaky.

This code example is taken from pytest_esp_eth.py .

```
@pytest.mark.flaky(reruns=3, reruns_delay=5)
def test_esp_eth_ip101(dut: IdfDut) -> None:
    ...
```

This flaky marker means that if the test function failed, the test case would rerun for a maximum of 3 times with 5 seconds delay.

Mark Known Failures Sometimes, a test can consistently fail for the following reasons:

- The feature under test (or the test itself) has a bug.
- The test environment is unstable (e.g., due to network issues) leading to a high failure ratio.

Now you may mark this test case with marker xfail with a user-friendly readable reason.

This code example is taken from pytest_panic.py

```
@pytest.mark.xfail('config.getvalue("target") == "esp32s2"', reason='raised␣
↪IllegalInstruction instead')
def test_cache_error(dut: PanicTestDut, config: str, test_func_name: str) -> None:
```

This marker means that test is a known failure on the ESP32-S2.

Mark Nightly Run Test Cases Some test cases are only triggered in nightly run pipelines due to a lack of runners.

```
@pytest.mark.nightly_run
```

This marker means that the test case would only be run with env var `NIGHTLY_RUN` or `INCLUDE_NIGHTLY_RUN`.

Mark Temporarily Disabled in CI Some test cases which can pass locally may need to be temporarily disabled in CI due to a lack of runners.

```
@pytest.mark.temp_skip_ci(targets=['esp32', 'esp32s2'], reason='lack of runners')
```

This marker means that the test case could still be run locally with `pytest --target esp32`, but will not run in CI.

Run Unity Test Cases For component-based unit test apps, all single-board test cases (including normal test cases and multi-stage test cases) can be run using the following command:

```
def test_component_ut(dut: IdfDut):
    dut.run_all_single_board_cases()
```

Using this command will skip all the test cases containing the `[ignore]` tag.

If you need to run a group of test cases, you may run:

```
def test_component_ut(dut: IdfDut):
    dut.run_all_single_board_cases(group='psram')
```

It would trigger all test cases with the `[psram]` tag.

You may also see that there are some test scripts with the following statements, which are deprecated. Please use the suggested one as above.

```
def test_component_ut(dut: IdfDut):
    dut.expect_exact('Press ENTER to see the list of tests')
    dut.write('*')
    dut.expect_unity_test_output()
```

For further reading about our unit testing in ESP-IDF, please refer to *our unit testing guide*.

Running Tests in CI

The workflow in CI is simple, build jobs > target test jobs.

Build Jobs

Build Job Names

- Component-based Unit Tests: `build_pytest_components_<target>`
- Example Tests: `build_pytest_examples_<target>`
- Custom Tests: `build_pytest_test_apps_<target>`

Build Job Commands The command used by CI to build all the relevant tests is: `python $IDF_PATH/tools/ci/ci_build_apps.py <parent_dir> --target <target> -vv --pytest-apps`

All apps which supported the specified target would be built with all supported sdkconfig files under `build_<target>_<config>`.

For example, If you run `python $IDF_PATH/tools/ci/ci_build_apps.py $IDF_PATH/examples/system/console/basic --target esp32 --pytest-apps`, the folder structure would be like this:

```
basic
├── build_esp32_history/
│   └── ...
├── build_esp32_nohistory/
│   └── ...
├── main/
├── CMakeLists.txt
├── pytest_console_basic.py
└── ...
```

All the build folders would be uploaded as artifacts under the same directories.

Target Test Jobs

Target Test Job Names

- Component-based Unit Tests: `component_ut_pytest_<target>_<test_env>`
- Example Tests: `example_test_pytest_<target>_<test_env>`
- Custom Tests: `test_app_test_pytest_<target>_<test_env>`

Target Test Job Commands The command used by CI to run all the relevant tests is: `pytest <parent_dir> --target <target> -m <test_env_marker>`

All test cases with the specified target marker and the test env marker under the parent folder would be executed.

The binaries in the target test jobs are downloaded from build jobs. the artifacts would be placed under the same directories.

Running Tests Locally

First you need to install ESP-IDF with additional Python requirements:

```
$ cd $IDF_PATH
$ bash install.sh --enable-pytest
$ . ./export.sh
```

By default, the pytest script will look for the build directory in this order:

- `build_<target>_<sdkconfig>`
- `build_<target>`
- `build_<sdkconfig>`
- `build`

Which means, the simplest way to run pytest is calling `idf.py build`.

For example, if you want to run all the esp32 tests under the `$IDF_PATH/examples/get-started/hello_world` folder, you should run:

```
$ cd examples/get-started/hello_world
$ idf.py build
$ pytest --target esp32
```

If you have multiple sdkconfig files in your test app, like those `sdkconfig.ci.*` files, the simple `idf.py build` won't apply the extra sdkconfig files. Let us take `$IDF_PATH/examples/system/console/basic` as an example.

If you want to test this app with config `history`, and build with `idf.py build`, you should run

```
$ cd examples/system/console/basic
$ idf.py -DSDKCONFIG_DEFAULTS="sdkconfig.defaults;sdkconfig.ci.history" build
$ pytest --target esp32 --sdkconfig history
```

If you want to build and test with all sdkconfig files at the same time, you should use our CI script as an helper script:

```
$ cd examples/system/console/basic
$ python $IDF_PATH/tools/ci/ci_build_apps.py . --target esp32 -vv --pytest-apps
$ pytest --target esp32
```

The app with `sdkconfig.ci.history` will be built in `build_esp32_history`, and the app with `sdkconfig.ci.nohistory` will be built in `build_esp32_nohistory`. `pytest --target esp32` will run tests on both apps.

Tips and Tricks

Filter the Test Cases

- Filter by target with `pytest --target <target>`
  pytest would run all the test cases that support specified target.
- Filter by sdkconfig file with `pytest --sdkconfig <sdkconfig>`
  If `<sdkconfig>` is `default`, pytest would run all the test cases with the sdkconfig file `sdkconfig.defaults`.
  In other cases, pytest would run all the test cases with sdkconfig file `sdkconfig.ci.<sdkconfig>`.

Add New Markers We are using two types of custom markers, target markers which indicate that the test cases should support this target, and env markers which indicate that the test cases should be assigned to runners with these tags in CI.

You can add new markers by adding one line under the `${IDF_PATH}/conftest.py`. If it is a target marker, it should be added into `TARGET_MARKERS`. If it is a marker that specifies a type of test environment, it should be added into `ENV_MARKERS`. The syntax should be: `<marker_name>: <marker_description>`.

Generate JUnit Report You can call pytest with `--junitxml <filepath>` to generate the JUnit report. In ESP-IDF, the test case name would be unified as `<target>.<config>.<function_name>`.

Skip Auto Flash Binary Skipping auto-flash binary every time would be useful when you are debugging your test script.

You can call pytest with `--skip-autoflash y` to achieve it.

Record Statistics Sometimes you may need to record some statistics while running the tests, like the performance test statistics.

You can use record_xml_attribute fixture in your test script, and the statistics would be recorded as attributes in the JUnit report.

Logging System Sometimes you may need to add some extra logging lines while running the test cases.

You can use Python logging module to achieve this.

Useful Logging Functions (as Fixture)

`log_performance`

```
def test_hello_world(
    dut: IdfDut,
    log_performance: Callable[[str, object], None],
) -> None:
    log_performance('test', 1)
```

The above example would log the performance item with pre-defined format: `[performance][test]: 1` and record it under the `properties` tag in the JUnit report if `--junitxml <filepath>` is specified. The JUnit test case node would look like:

```
<testcase classname="examples.get-started.hello_world.pytest_hello_world" file=
↪"examples/get-started/hello_world/pytest_hello_world.py" line="13" name="esp32.
↪default.test_hello_world" time="8.389">
    <properties>
        <property name="test" value="1"/>
    </properties>
</testcase>
```

`check_performance` We provide C macros `TEST_PERFORMANCE_LESS_THAN` and `TEST_PERFORMANCE_GREATER_THAN` to log the performance item and check if the value is in the valid range. Sometimes the performance item value could not be measured in C code, so we also provide a Python function for the same purpose. Please note that using C macros is the preferred approach, since the Python function could not recognize the threshold values of the same performance item under different ifdef blocks well.

```
def test_hello_world(
    dut: IdfDut,
    check_performance: Callable[[str, float, str], None],
) -> None:
    check_performance('RSA_2048KEY_PUBLIC_OP', 123, 'esp32')
    check_performance('RSA_2048KEY_PUBLIC_OP', 19001, 'esp32')
```

The above example would first get the threshold values of the performance item `RSA_2048KEY_PUBLIC_OP` from components/idf_test/include/idf_performance.h and the target-specific one components/idf_test/include/esp32/idf_performance_target.h, then check if the value reached the minimum limit or exceeded the maximum limit.

Let us assume the value of `IDF_PERFORMANCE_MAX_RSA_2048KEY_PUBLIC_OP` is 19000. so the first `check_performance` line would pass and the second one would fail with warning: `[Performance] RSA_2048KEY_PUBLIC_OP value is 19001, doesn\'t meet pass standard 19000.0`.

Chapter 9

ESP-IDF Versions

The ESP-IDF GitHub repository is updated regularly, especially the master branch where new development takes place.

For production use, there are also stable releases available.

9.1 Releases

The documentation for the current stable release version can always be found at this URL:

https://docs.espressif.com/projects/esp-idf/en/stable/

Documentation for the latest version (master branch) can always be found at this URL:

https://docs.espressif.com/projects/esp-idf/en/latest/

The full history of releases can be found on the GitHub repository Releases page. There you can find release notes, links to each version of the documentation, and instructions for obtaining each version.

9.2 Which Version Should I Start With?

- For production purposes, use the current stable version. Stable versions have been manually tested, and are updated with "bugfix releases" which fix bugs without changing other functionality (see *Versioning Scheme* for more details). Every stable release version can be found on the Releases page. Also refer to Compatibility Between ESP-IDF Releases and Revisions of Espressif SoCs to make sure the ESP-IDF version you selected is compatible with the chip revision you are going to produce with.
- For prototyping, experimentation or for developing new ESP-IDF features, use the latest version (master branch in Git). The latest version in the master branch has all the latest features and has passed automated testing, but has not been completely manually tested ("bleeding edge").
- If a required feature is not yet available in a stable release, but you do not want to use the master branch, it is possible to check out a pre-release version or a release branch. It is recommended to start from a stable version and then follow the instructions for *Updating to a Pre-Release Version* or *Updating to a Release Branch*.
- If you plan to use another project which is based on ESP-IDF, please check the documentation of that project to determine the version(s) of ESP-IDF it is compatible with.

See *Updating ESP-IDF* if you already have a local copy of ESP-IDF and wish to update it.

9.3 Versioning Scheme

ESP-IDF uses Semantic Versioning. This means that:

- Major Releases, like `v3.0`, add new functionality and may change functionality. This includes removing deprecated functionality.
  If updating to a new major release (for example, from `v2.1` to `v3.0`), some of your project's code may need updating and functionality may need to be re-tested. The release notes on the Releases page include lists of Breaking Changes to refer to.
- Minor Releases like `v3.1` add new functionality and fix bugs but will not change or remove documented functionality, or make incompatible changes to public APIs.
  If updating to a new minor release (for example, from `v3.0` to `v3.1`), your project's code does not require updating, but you should re-test your project. Pay particular attention to the items mentioned in the release notes on the Releases page.
- Bugfix Releases like `v3.0.1` only fix bugs and do not add new functionality.
  If updating to a new bugfix release (for example, from `v3.0` to `v3.0.1`), you do not need to change any code in your project, and you only need to re-test the functionality directly related to bugs listed in the release notes on the Releases page.

9.4 Support Periods

Each ESP-IDF major and minor release version has an associated support period. After this period, the release is End of Life and no longer supported.

The ESP-IDF Support Period Policy explains this in detail, and describes how the support periods for each release are determined.

Each release on the Releases page includes information about the support period for that particular release.

As a general guideline:

- If starting a new project, use the latest stable release.
- If you have a GitHub account, click the "Watch" button in the top-right of the Releases page and choose "Releases only". GitHub will notify you whenever a new release is available. Whenever a bug fix release is available for the version you are using, plan to update to it.
- If possible, periodically update the project to a new major or minor ESP-IDF version (for example, once a year.) The update process should be straightforward for Minor updates, but may require some planning and checking of the release notes for Major updates.
- Always plan to update to a newer release before the release you are using becomes End of Life.

Each ESP-IDF major and minor release (V4.1, V4.2, etc) is supported for 30 months after the initial stable release date.

Supported means that the ESP-IDF team will continue to apply bug fixes, security fixes, etc to the release branch on GitHub, and periodically make new bugfix releases as needed.

Support period is divided into "Service" and "Maintenance" period:

Period	Duration	Recommended for new projects?
Service	12 months	Yes
Maintenance	18 months	No

During the Service period, bugfixes releases are more frequent. In some cases, support for new features may be added during the Service period (this is reserved for features which are needed to meet particular regulatory requirements or standards for new products, and which carry a very low risk of introducing regressions.)

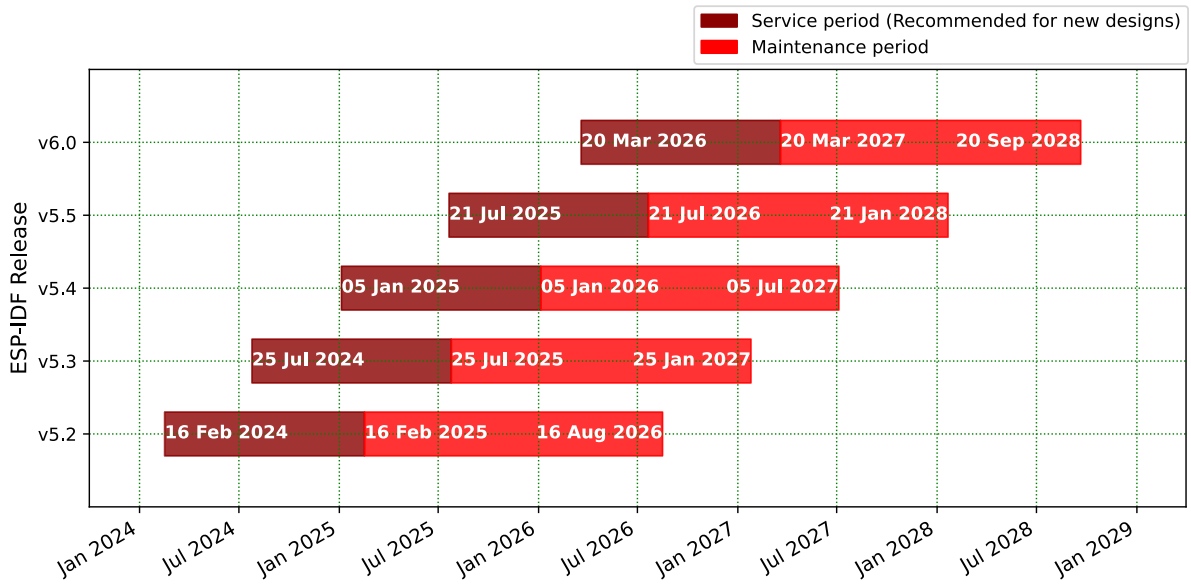
During the Maintenance period, the version is still supported but only bugfixes for high severity issues or security issues will be applied.

Using an "In Service" version is recommended when starting a new project.

Users are encouraged to upgrade all projects to a newer ESP-IDF release before the support period finishes and the release becomes End of Life (EOL). It is our policy to not continue fixing bugs in End of Life releases.

Pre-release versions (betas, previews, `-rc` and `-dev` versions, etc) are not covered by any support period. Sometimes a particular feature is marked as "Preview" in a release, which means it is also not covered by the support period.

The ESP-IDF Programming Guide has information about the different versions of ESP-IDF (major, minor, bugfix, etc).



9.5 Checking the Current Version

The local ESP-IDF version can be checked by using idf.py:

```
idf.py --version
```

The ESP-IDF version is also compiled into the firmware and can be accessed (as a string) via the macro `IDF_VER`. The default ESP-IDF bootloader will print the version on boot (the version information is not always updated if the code in the GitHub repo is updated, it only changes if there is a clean build or if that particular source file is recompiled).

If writing code that needs to support multiple ESP-IDF versions, the version can be checked at compile time using *compile-time macros*.

Examples of ESP-IDF versions:

Version String	Meaning
`v3.2-dev-306-gbeb3611ca`	Master branch pre-release. - `v3.2-dev` - in development for version 3.2. - `306` - number of commits after v3.2 development started. - `beb3611ca` - commit identifier.
`v3.0.2`	Stable release, tagged `v3.0.2`.
`v3.1-beta1-75-g346d6b0ea`	Beta version in development (on a *release branch*). - `v3.1-beta1` - pre-release tag. - `75` - number of commits after the pre-release beta tag was assigned. - `346d6b0ea` - commit identifier.
`v3.0.1-dirty`	Stable release, tagged `v3.0.1`. - `dirty` means that there are modifications in the local ESP-IDF directory.

9.6 Git Workflow

The development (Git) workflow of the Espressif ESP-IDF team is as follows:

- New work is always added on the master branch (latest version) first. The ESP-IDF version on `master` is always tagged with `-dev` (for "in development"), for example `v3.1-dev`.
- Changes are first added to an internal Git repository for code review and testing but are pushed to GitHub after automated testing passes.
- When a new version (developed on `master`) becomes feature complete and "beta" quality, a new branch is made for the release, for example `release/v3.1`. A pre-release tag is also created, for example `v3.1-beta1`. You can see a full list of branches and a list of tags on GitHub. Beta pre-releases have release notes which may include a significant number of Known Issues.
- As testing of the beta version progresses, bug fixes will be added to both the `master` branch and the release branch. New features for the next release may start being added to `master` at the same time.
- Once testing is nearly complete a new release candidate is tagged on the release branch, for example `v3.1-rc1`. This is still a pre-release version.
- If no more significant bugs are found or reported, then the final Major or Minor Version is tagged, for example `v3.1`. This version appears on the Releases page.
- As bugs are reported in released versions, the fixes will continue to be committed to the same release branch.
- Regular bugfix releases are made from the same release branch. After manual testing is complete, a bugfix release is tagged (i.e., `v3.1.1`) and appears on the Releases page.

9.7 Updating ESP-IDF

Updating ESP-IDF depends on which version(s) you wish to follow:

- *Updating to Stable Release* is recommended for production use.

- *Updating to Master Branch* is recommended for the latest features, development use, and testing.
- *Updating to a Release Branch* is a compromise between the first two.

Note: These guides assume that you already have a local copy of ESP-IDF cloned. To get one, check Step 2 in the *Getting Started* guide for any ESP-IDF version.

9.7.1 Updating to Stable Release

To update to a new ESP-IDF release (recommended for production use), this is the process to follow:

- Check the Releases page regularly for new releases.
- When a bugfix release for the version you are using is released (for example, if using `v3.0.1` and `v3.0.2` is released), check out the new bugfix version into the existing ESP-IDF directory.
- In Linux or macOS system, please run the following commands to update the local branch to vX.Y.Z:

```
cd $IDF_PATH
git fetch
git checkout vX.Y.Z
git submodule update --init --recursive
```

- In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.
- When major or minor updates are released, check the Release Notes on the releases page and decide if you want to update or to stay with your current release. Updating is via the same Git commands shown above.

Note: If you installed the stable release via zip file instead of using git, it might not be possible to update versions using the commands. In this case, update by downloading a new zip file and replacing the entire `IDF_PATH` directory with its contents.

9.7.2 Updating to a Pre-Release Version

It is also possible to `git checkout` a tag corresponding to a pre-release version or release candidate, the process is the same as *Updating to Stable Release*.

Pre-release tags are not always found on the Releases page. Consult the list of tags on GitHub for a full list. Caveats for using a pre-release are similar to *Updating to a Release Branch*.

9.7.3 Updating to Master Branch

Note: Using Master branch means living "on the bleeding edge" with the latest ESP-IDF code.

To use the latest version on the ESP-IDF master branch, this is the process to follow:

- In Linux or macOS system, please run the following commands to check out to the master branch locally:

```
cd $IDF_PATH
git checkout master
git pull
git submodule update --init --recursive
```

- In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.
- Periodically, re-run `git pull` to pull the latest version of master. Note that you may need to change your project or report bugs after updating your master branch.

- To switch from master to a release branch or stable version, run `git checkout` as shown in the other sections.

Important: It is strongly recommended to regularly run `git pull` and then `git submodule update --init --recursive` so a local copy of master does not get too old. Arbitrary old master branch revisions are effectively unsupportable "snapshots" that may have undocumented bugs. For a semi-stable version, try *Updating to a Release Branch* instead.

9.7.4 Updating to a Release Branch

In terms of stability, using a release branch is part-way between using the master branch and only using stable releases. A release branch is always beta quality or better, and receives bug fixes before they appear in each stable release.

You can find a list of branches on GitHub.

For example, in Linux or macOS system, you can execute the following commands to follow the branch for ESP-IDF v3.1, including any bugfixes for future releases like `v3.1.1`, etc:

```
cd $IDF_PATH
git fetch
git checkout release/v3.1
git pull
git submodule update --init --recursive
```

In the Windows system, please replace `cd $IDF_PATH` with `cd %IDF_PATH%`.

Each time you `git pull` this branch, ESP-IDF will be updated with fixes for this release.

Note: There is no dedicated documentation for release branches. It is recommended to use the documentation for the closest version to the branch which is currently checked out.

Chapter 10

Resources

10.1 PlatformIO

- *What Is PlatformIO?*
- *Installation*
- *Configuration*
- *Tutorials*
- *Project Examples*
- *Next Steps*

10.1.1 What Is PlatformIO?

PlatformIO is a cross-platform embedded development environment with out-of-the-box support for ESP-IDF.

Since ESP-IDF support within PlatformIO is not maintained by the Espressif team, please report any issues with PlatformIO directly to its developers in the official PlatformIO repositories.

A detailed overview of the PlatformIO ecosystem and its philosophy can be found in the official PlatformIO documentation.

10.1.2 Installation

- PlatformIO IDE is a toolset for embedded C/C++ development available on Windows, macOS and Linux platforms.
- PlatformIO Core (CLI) is a command-line tool that consists of multi-platform build system, platform and library managers and other integration components. It can be used with a variety of code development environments and allows integration with cloud platforms and web services

10.1.3 Configuration

Please go through the official PlatformIO configuration guide for ESP-IDF.

10.1.4 Tutorials

- ESP-IDF and ESP32-DevKitC: debugging, unit testing, project analysis

10.1.5 Project Examples

Please check ESP-IDF page in the official PlatformIO documentation

10.1.6 Next Steps

Here are some useful links for exploring the PlatformIO ecosystem:

- Learn more about integrations with other IDEs or Text Editors
- Get help from PlatformIO community

10.2 CLion

10.2.1 What Is CLion?

CLion is a cross-platform integrated Development Environment (IDE) for C and C++ programming. CLion also provides dedicated support for ESP-IDF, allowing developers to seamlessly work with the ESP-IDF framework.

10.2.2 Installation

To install CLion, please follow the instructions provided in Install CLion for your operating system (Windows, macOS, or Linux).

10.2.3 Configuration

To configure an ESP-IDF project in CLion, please refer to the guide on Configure an ESP CMake project in CLion. This guide will walk you through the necessary steps to set up your project properly.

10.2.4 Resources

For more information about CLion and ESP-IDF integration, please refer to the following resource:

- CLion Documentation: The official documentation for CLion provides detailed information on various aspects of the IDE, including ESP-IDF integration.

10.3 VisualGDB

10.3.1 What Is VisualGDB?

VisualGDB is a powerful extension for Microsoft Visual Studio that provides advanced development tools and features for embedded systems, including support for the ESP-IDF framework. VisualGDB allows you to leverage the familiar

and feature-rich Visual Studio environment for your ESP-IDF projects, enabling efficient coding, debugging, and deployment.

10.3.2 Installation

Please download and install VisualGDB by following the steps stated in VisualGDB download and installation.

10.3.3 Configuration

Creating Advanced ESP32 Projects with ESP-IDF provide basic steps about how to configure an ESP-IDF project in VisualGDB.

You can also refer to Advanced ESP-IDF Project Structure to get a more comprehensive impression for developing ESP-IDF projects using VisualGDB.

10.3.4 Resources

For more information about VisualGDB and ESP-IDF integration, refer to the following resources:

- VisualGDB Documentation: The official documentation for VisualGDB provides comprehensive guides and tutorials on using VisualGDB with ESP-IDF.

For inquiries related to these third-party tools, we recommend seeking assistance from the respective tool's support channels or user communities.

10.4 Useful Links

- The esp32.com forum is a place to ask questions and find community resources.
- Check the Issues section on GitHub if you find a bug or have a feature request. Please check existing Issues before opening a new one.
- A comprehensive collection of solutions, practical applications, components and drivers based on ESP-IDF is available in ESP IoT Solution repository. In most of cases descriptions are provided both in English and in 中文.
- To develop applications using Arduino platform, refer to Arduino core for the ESP32, ESP32-S2 and ESP32-C3.
- Several books have been written about ESP32 and they are listed on Espressif web site.
- If you're interested in contributing to ESP-IDF, please check the *Contributions Guide*.
- For additional ESP32-S3 product related information, please refer to documentation section of Espressif site.
- Download latest and previous versions of this documentation in PDF and HTML format.

Chapter 11

Copyrights and Licenses

11.1 Software Copyrights

All original source code in this repository is Copyright (C) 2015-2023 Espressif Systems. This source code is licensed under the Apache License 2.0 as described in the file LICENSE.

Additional third party copyrighted code is included under the following licenses.

Where source code headers specify Copyright & License information, this information takes precedence over the summaries made here.

Some examples use external components which are not Apache licensed, please check the copyright description in each example source code.

11.1.1 Firmware Components

These third party libraries can be included into the application (firmware) produced by ESP-IDF.

- Newlib is licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB .
- Xtensa header files are Copyright (C) 2013 Tensilica Inc and are licensed under the MIT License as reproduced in the individual header files.
- Original parts of FreeRTOS (components/freertos) are Copyright (C) 2017 Amazon.com, Inc. or its affiliates are licensed under the MIT License, as described in license.txt .
- Original parts of LWIP (components/lwip) are Copyright (C) 2001, 2002 Swedish Institute of Computer Science and are licensed under the BSD License as described in COPYING file .
- wpa_supplicant Copyright (c) 2003-2022 Jouni Malinen <j@w1.fi> and contributors and licensed under the BSD license.
- Fast PBKDF2 Copyright (c) 2015 Joseph Birr-Pixton and licensed under CC0 Public Domain Dedication license.
- FreeBSD net80211 Copyright (c) 2004-2008 Sam Leffler, Errno Consulting and licensed under the BSD license.
- argtable3 argument parsing library Copyright (C) 1998-2001,2003-2011,2013 Stewart Heitmann and licensed under 3-clause BSD license. argtable3 also includes the following software components. For details, please see argtable3 LICENSE file .
  - C Hash Table library, Copyright (c) 2002, Christopher Clark and licensed under 3-clause BSD license.
  - The Better String library, Copyright (c) 2014, Paul Hsieh and licensed under 3-clause BSD license.
  - TCL library, Copyright the Regents of the University of California, Sun Microsystems, Inc., Scriptics Corporation, ActiveState Corporation and other parties, and licensed under TCL/TK License.
- linenoise line editing library Copyright (c) 2010-2014 Salvatore Sanfilippo, Copyright (c) 2010-2013 Pieter Noordhuis, licensed under 2-clause BSD license.
- FatFS library, Copyright (C) 2017 ChaN, is licensed under a BSD-style license .

- cJSON library, Copyright (c) 2009-2017 Dave Gamble and cJSON contributors, is licensed under MIT license as described in LICENSE file .
- micro-ecc library, Copyright (c) 2014 Kenneth MacKay, is licensed under 2-clause BSD license.
- Mbed TLS library, Copyright (C) 2006-2018 ARM Limited, is licensed under Apache License 2.0 as described in LICENSE file .
- SPIFFS library, Copyright (c) 2013-2017 Peter Andersson, is licensed under MIT license as described in LICENSE file .
- SD/MMC driver is derived from OpenBSD SD/MMC driver, Copyright (c) 2006 Uwe Stuehler, and is licensed under BSD license.
- ESP-MQTT MQTT Package (contiki-mqtt) - Copyright (c) 2014, Stephen Robinson, MQTT-ESP - Tuan PM <tuanpm at live dot com> is licensed under Apache License 2.0 as described in LICENSE file .
- BLE Mesh is adapted from Zephyr Project, Copyright (c) 2017-2018 Intel Corporation and licensed under Apache License 2.0.
- mynewt-nimble Apache Mynewt NimBLE, Copyright 2015-2018, The Apache Software Foundation, is licensed under Apache License 2.0 as described in LICENSE file .
- TLSF allocator Two Level Segregated Fit memory allocator, Copyright (c) 2006-2016, Matthew Conte, and licensed under the BSD 3-clause license.
- openthread, Copyright (c) The OpenThread Authors, is licensed under BSD License as described in LICENSE file .
- UBSAN runtime —Copyright (c) 2016, Linaro Limited and Jiří Zárevúcky, licensed under the BSD 2-clause license.
- HTTP Parser Based on src/http/ngx_http_parse.c from NGINX copyright Igor Sysoev. Additional changes are licensed under the same terms as NGINX and Joyent, Inc. and other Node contributors. For details please check LICENSE file .
- SEGGER SystemView target-side library, Copyright (c) 1995-2021 SEGGER Microcontroller GmbH, is licensed under BSD 1-clause license.

11.1.2 Documentation

- HTML version of the ESP-IDF Programming Guide uses the Sphinx theme sphinx_idf_theme, which is Copyright (c) 2013-2020 Dave Snider, Read the Docs, Inc. & contributors, and Espressif Systems (Shanghai) CO., LTD. It is based on sphinx_rtd_theme. Both are licensed under MIT license.

11.2 ROM Source Code Copyrights

Espressif SoCs mask ROM hardware includes binaries compiled from portions of the following third party software:

- Newlib , licensed under the BSD License and is Copyright of various parties, as described in COPYING.NEWLIB .
- Xtensa libhal, Copyright (c) Tensilica Inc and licensed under the MIT license (see below).
- TinyBasic Plus, Copyright Mike Field & Scott Lawrence and licensed under the MIT license (see below).
- miniz, by Rich Geldreich - placed into the public domain.
- TJpgDec Copyright (C) 2011, ChaN, all right reserved. See below for license.
- **Parts of Zephyr RTOS USB stack:**
  - DesignWare USB device driver Copyright (c) 2016 Intel Corporation and licensed under Apache 2.0 license.
  - Generic USB device driver Copyright (c) 2006 Bertrik Sikken (bertrik@sikken.nl), 2016 Intel Corporation and licensed under BSD 3-clause license.
  - USB descriptors functionality Copyright (c) 2017 PHYTEC Messtechnik GmbH, 2017-2018 Intel Corporation and licensed under Apache 2.0 license.
  - USB DFU class driver Copyright (c) 2015-2016 Intel Corporation, 2017 PHYTEC Messtechnik GmbH and licensed under BSD 3-clause license.
  - USB CDC ACM class driver Copyright (c) 2015-2016 Intel Corporation and licensed under Apache 2.0 license.

11.3 Xtensa libhal MIT License

Copyright (c) 2003, 2006, 2010 Tensilica Inc.

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

11.4 TinyBasic Plus MIT License

Copyright (c) 2012-2013

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and associated documentation files (the "Software"), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

THE SOFTWARE IS PROVIDED "AS IS", WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT. IN NO EVENT SHALL THE AUTHORS OR COPYRIGHT HOLDERS BE LIABLE FOR ANY CLAIM, DAMAGES OR OTHER LIABILITY, WHETHER IN AN ACTION OF CONTRACT, TORT OR OTHERWISE, ARISING FROM, OUT OF OR IN CONNECTION WITH THE SOFTWARE OR THE USE OR OTHER DEALINGS IN THE SOFTWARE.

11.5 TJpgDec License

TJpgDec - Tiny JPEG Decompressor R0.01 (C) ChaN, 2011 The TJpgDec is a generic JPEG decompressor module for tiny embedded systems. This is a free software that opened for education, research and commercial developments under license policy of following terms.

Copyright (C) 2011, ChaN, all right reserved.

- The TJpgDec module is a free software and there is NO WARRANTY.
- No restriction on use. You can use, modify and redistribute it for personal, non-profit or commercial products UNDER YOUR RESPONSIBILITY.
- Redistributions of source code must retain the above copyright notice.

Chapter 12

About

This is documentation of ESP-IDF, the framework to develop applications for ESP32-S3.

The ESP32-S3 is a 2.4 GHz Wi-Fi Bluetooth Low Energy combo SoC, which integrates a Xtensa® 32-bit LX7 CPU.

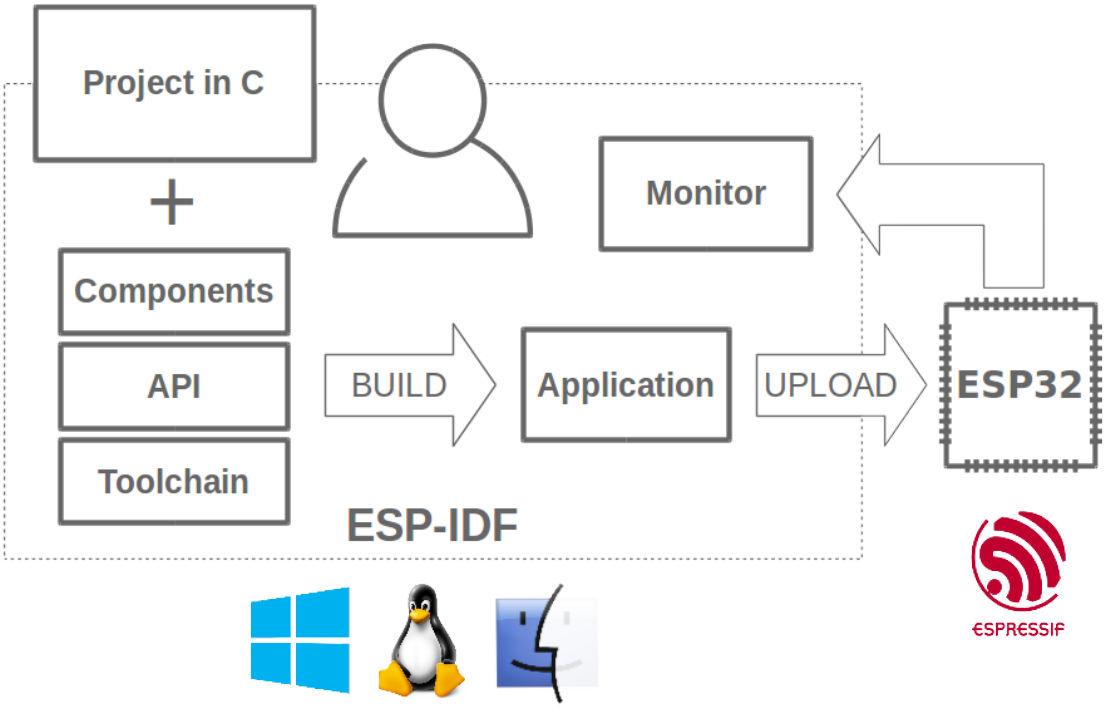


Fig. 1: Espressif IoT Integrated Development Framework

The ESP-IDF, Espressif IoT Development Framework, provides toolchain, API, components and workflows to develop applications for ESP32-S3 using Windows, Linux and macOS operating systems.

Chapter 13

Switch Between Languages

The ESP-IDF Programming Guide is now available in two languages. Please refer to the English version if there is any discrepancy.

- English
- Chinese

You can easily change from one language to another by clicking the language link you can find at the top of every document that has a translation.
